THE

VOYAGE OF H.M.S. CHALLENGER.

ZOOLOGY—VOL. XXIX.

TEXT—FIRST HALF.
REPORT
ON THE
SCIENTIFIC RESULTS
OF THE
VOYAGE OF H.M.S. CHALLENGER
DURING THE YEARS 1873-76

UNDER THE COMMAND OF
Captain GEORGE S. NARES, R.N., F.R.S.
AND THE LATE
Captain FRANK TOURLE THOMSON, R.N.

PREPARED UNDER THE SUPERINTENDENCE OF
THE LATE
Sir C. WYVILLE THOMSON, Knt., F.R.S., &c.
REGIUS PROFESSOR OF NATURAL HISTORY IN THE UNIVERSITY OF EDINBURGH
DIRECTOR OF THE CIVILIAN SCIENTIFIC STAFF ON BOARD
AND NOW OF
JOHN MURRAY, LL.D., Ph.D., &c.
ONE OF THE NATURALISTS OF THE EXPEDITION

ZOONOLOGY—Vol. XXIX.

Price (Two Volumes of Text and Volume of Plates) £4, 10s.
CONTENTS.

Report on the Amphipoda collected by H.M.S. Challenger during the years 1873-1876.

By Rev. Thomas R. R. Stebbing, M.A.

FIRST HALF.

79101
EDITORIAL NOTE.

The collections of Amphipoda procured in the trawls, dredges, and tow-nets during the voyage of H.M.S. Challenger were placed in the hands of the Rev. Thomas R. R. Stebbing for examination and description in the summer of 1882. From not long after that date up to the present time Mr. Stebbing has been almost exclusively occupied in the work connected with the preparation of this extensive and valuable Report, which will be welcomed by all students of the Crustacea.

There is the same uncertainty connected with the Amphipoda as with several other groups of animals taken in the trawls and tow-nets, as to the depths at which the specimens were captured. Some were undoubtedly taken at or near the bottom, while others were as certainly taken in the surface and subsurface waters, but with others again there is a great deal of doubt. Although a record of the depths to which the nets were let down was attached to the specimens, the naturalists of the Expedition did not intend to convey the impression that the specimens necessarily came from the depths indicated.

This Report, which forms Part LXVII. and Volume XXIX. of the Zoological Series of Reports, consists of 1774 pages of letterpress, with 212 Plates and a Map. The whole is bound up in three separate portions, two of letterpress and one of Plates.

The first Instalment of the Manuscript was received by me on the 5th December 1885, and the last on the 30th November 1888.

John Murray.

VOYAGE OF H.M.S. CHALLENGER.

ZOOLOGY.

REPORT on the Amphipoda collected by H.M.S. Challenger during the Years 1873–76. By the Rev. Thomas R. R. Stebbing, M.A.

PREFACE.

It will easily be understood that the various portions of this Report have not been prepared without a considerable amount of laborious perseverance. Even points of slight importance, such as the derivations of generic names, have involved no little expenditure of time and toil, and (as with those names for which no derivation has been found) sometimes most trouble has been taken where the result is least satisfactory. Considering that the earlier pages were printed off before the work represented by the later pages had shed its light upon them, the Report is unlikely to be wholly free from deficiencies, inconsistencies, and other faults and mischances. In the completed volume it may well happen that many of these will be far easier to detect than they were to avoid. But, whatever the defects that may actually exist, either in the descriptive part of the Report or in that which deals with the literature of the subject, I venture to suppose that they might have been fewer had all the writings taken into account been always at hand to be referred to, compared, and pondered over whenever occasion required, while I am sure that they must have been far more numerous, had I not fortunately met with the different forms of assistance which I now desire most gratefully to acknowledge.

The ready and courteous liberality with which the Royal, the Linnean, and the Zoological Societies of London, the Royal Society of Edinburgh, and the Advocates’ Library, place their rich stores of literature at the service of the student, has laid me, (Zool. Chall. Exp.—Part LXVII.—1888.)
no doubt in common with many others, under a deep obligation. My earnest thanks are also due to my personal friends, Mr. Spence Bate, the Rev. Canon Norman, and Dr. Murray, the Editor of the Challenger Reports, for the uncommon generosity with which they have allowed me to borrow from their libraries, and retain, not for weeks only, but in some instances for years together, rare and costly books and pamphlets. For the loan of valuable books or papers I am indebted likewise to Professor Alphonse Milne-Edwards, to Mr. W. E. Hoyle, of the Challenger Office, to Mr. Edward Saunders, of Lloyds, and to one or two other friends. Nor must I forget the friendly and unsparing zeal with which both Mr. Hoyle and Mr. James Chunley, of the Challenger Office, have assisted me in my book-borrowing career.

For favouring me with one or several or all of their contributions to the literature of the Amphipoda I have to thank a large number of gentlemen: in Great Britain, C. Spence Bate, G. Herbert Fowler, E. J. Miers, A. M. Norman, David Robertson, W. Baldwin Spencer, and A. O. Walker; on the Continent of Europe, Carl W. S. Aurivillius, Th. Barrois, Jules Bonnier, Carl BojANJIUS, Edouard Chevreux, A. Della Valle, Adrien Dollfus, Henri Gadeau de Kerville, Jules de Guerne, H. J. Hansen, R. Koehler, W. Lilljeborg, G. Pfeffer, G. O. Sars, J. Sparre Schneider, and August Wrześniowski; in the United States of America, Walter Faxon and S. I. Smith; in Australia, W. A. Haswell; in New Zealand, Charles Chilton, T. W. Kirke, and G. M. Thomson. To the kindness of Professor S. I. Smith and Mr. E. J. Miers I am under a special obligation, since, when the first sets which they had sent me of their valuable papers had been destroyed by an accident, they generously and to my great convenience repeated their gifts.

In obtaining the biographical notes, given where possible in connection with the notice of each author's earliest work on the Amphipoda, I have received much kind assistance from Professor G. O. Sars, Professor S. I. Smith, and Mr. W. E. Hoyle.

For various specimens of Amphipoda I wish cordially to thank Dr. Bruce, of the Military Hospital, Malta, Mr. Charles Chilton, of Dunedin, New Zealand, Mr. W. A. Haswell, of the University of Sydney, Australia, Canon Norman, of Burnmoor Rectory, Fence Houses, Mr. David Robertson, of Cumbrae, Scotland, Herr Conservator J. Sparre Schneider, of Tromsö, Norway, Professor S. I. Smith, of New Haven, Connecticut, U.S.A., Mr. G. M. Thomson, Rector of the High School, Dunedin, New Zealand, and Mr. A. O. Walker, of Chester. For purposes of comparison with the Challenger collection, as well as for throwing light upon frequent doubts which the literature of the subject suggested, many of these specimens were of great importance. Some proved in actual fact extremely useful, and almost all might have been of the highest service had not the pressure imposed by the limits of time forced me too much to neglect them.

GLOSSARY AND GENERAL INDEX, 1727
INTRODUCTION.

Bibliography.—In literature the age of the Amphipoda scarcely reaches back beyond a century and a quarter. Linnaeus knew almost nothing about them. At least, in one of his descriptions he is shrewdly suspected of having mistaken the head of the animal for its tail. Of particular species, it is true, earlier writers, such as Friderich Martens the ship’s barber of Hamburg, had formed fairly accurate conceptions. In the middle of the sixteenth century Rondelet figured a specimen, but perhaps, like Linnaeus two centuries later, without clearly knowing at which end of the creature to look for its head. Nearly two thousand years before Rondelet it is surmised that the keen glance of Aristotle had noted the existence of this tribe of diminutive shrimps, but his observation, though it throws a venerable prestige over their scientific record, did nothing to awaken any fruitful interest in their character and distribution. The institution of the genus Gammarus by J. C. Fabricius in 1775 presently brought the Amphipoda together as a group, although naturally it was due to earlier labours that any necessity for grouping was perceived. During the next forty years these Crustaceans no longer suffered from the neglect which had previously left them obscure. When Latreille, in 1816, gave them the name Amphipoda, an important stage was marked in the growing knowledge and interest about them. Since then they have received a very ample measure of attention, and at the present day they are studied in many parts of the world with great skill and evident enthusiasm. Of the literature of the subject numerous lists have been published, among which that by the late Axel Boeck in 1872 is the most important. He arranges in alphabetical order the names of one hundred and fifty authors, giving the titles of their contributions to the number in all of two hundred and seventy-three. This catalogue extends to the year 1871. A separate chronological review of the literature is carried down only to the year 1855. This part of Boeck’s work is especially valuable for the comments which his large knowledge of the subject enabled him to supply. He intimates, however, that his comments are chiefly concerned with northern species. For dealing properly with the almost cosmopolitan Challenger collection it seemed indispensable to verify, and as far as possible to complete, the review which Boeck had so admirably begun. Neither the difficulty of the task nor the prodigious bulk of the material result was at first foreseen. From folio to pamphlet a vast mass of literature had to be consulted. How much borrowing of

(zool. chall. exp.—part lxvii.—1888.)

Xxx b
books and buying of books, how many journeyings to and fro, how many researches ending in nothing, are necessarily involved in such consultation, those who have had a similar experience will well know, and those who have not had it can scarcely be made to understand. Without therefore expatiating on the difficulties which I suppose myself to have conquered or on the difficulties which conquered me, it may suffice to mention that, as the record proceeded, the plan of it was more than once changed, the earlier notices being rewritten and expanded, under the influence of a growing desire that as much of the task as possible should be done once for all and need no second doing. In the form actually adopted, the titles of works are given in chronological order, so far as the year of publication is concerned, but within that year they for the most part follow the alphabetical order of the authors' names.\(^1\) Accuracy in the dates given has been anxiously aimed at, seeing that without this accuracy it is sometimes impossible to determine those questions of priority on which scientific nomenclature so much depends. But precision is very difficult to arrive at, when the only available copy of a work is an undated extract from a foreign magazine, or from the proceedings of a learned society, read in one year and published in the next or the next but one. It is greatly to be wished that "separate copies" should not only have the true paging, as Darwin\(^2\) urges, but that they should also have that date of publication from which the new genera and species contained in them have a claim to reckon their priority.

The title of each work mentioned in the Bibliography is accompanied, it will be seen, as a rule by some notice of its contents. There are a few exceptions, where papers, of which the titles could be cited on adequate authority, have remained inaccessible, or where the titles themselves seemed sufficiently suggestive without further comment. Here and there, like a sign-post with the legend "No Road" upon it, the title of a book has been given for the sake of saying that it contains nothing about the Amphipoda. On the other hand some obscure works, perhaps really bearing on the subject, are omitted from the general list and only incidentally referred to as occasion offered. In the notices taken collectively two special objects have been aimed at:

1. To quote the original definition of every genus of the Amphipoda.
2. To give under its proper date the name of every new species.

Two objects of a more general character have also been kept in view, namely, first, to give some idea of the character of the information which the various writings supply, and secondly, in so doing to produce a record, after the annalistic method, of the progress of knowledge in this branch of natural history.

It will be readily understood that a generic definition as at first framed is often little

---

\(^1\) The following names are exceptions to the alphabetical order on the pages mentioned:—Sela, Linnaeus, p. 18; Linnaeus, p. 20; Stren, p. 28; Olausen, p. 36; Gimiani, Hammer, p. 38; Fabricius, p. 40; Foreski, p. 43; de Quercio, p. 47; Linnaeus, p. 53; Roemer, p. 55; Pallas, p. 65; Lairelle, p. 71; Lafinesque, p. 87; Leach, p. 89; Pollini, de Blainville, p. 93; Leach, p. 107; Costa, Krayser, p. 177; Kraus, p. 205; Bate and Westwood, p. 340; Gerstaecker, p. 342; Cunningham, p. 404.

REPORT ON THE AMPHIPODA.

suited for the purposes of later classifications, yet each remodelling requires to be tested by that earliest form which is here reproduced. While every definition has been given which claimed to refer to a new genus, references have also been made, wherever available, to authorities who have disputed the claim of novelty, or to other reasonable grounds for rejecting the defined name. When the type-species is well known, and specimens of it have been examined by more than one competent observer, the true position of a genus is comparatively easy to determine. But sometimes the solitary specimen on which a genus was founded has since been lost or destroyed or damaged past recognition. In some of these cases the genus remains either absolutely obscure or only the sport of ingenious guesses. It would be convenient if some limit of time could be established, so that after fifty or a hundred years the names which no one had been able to identify throughout such a period should lose their right of priority.

With species, as with genera, all that have ever been published as new ones are admitted to the record. So far the task is simple. But here too an attempt has been made, by references and suggestions, to guide the reader through the labyrinth of synonyms. This part of the work is full of perplexity and complication, and the labour here bestowed upon it can pretend to little more success than that of having drawn into one view a large number of problems still requiring solution. Conjectural determinations for or against the validity of a species, apart from observation of the actual specimens described, must be accepted with much reserve even from the most experienced writers; for example, a consensus of important authorities had long referred Kroyer's Stegocephalus inflatus to Phipp's earlier Cancer ampulla, yet in 1887 Hansen decides that Kroyer's species is after all distinct. But the very fact that mistakes are so often made in the attempt to regulate synonymy should at least have the useful result of awakening attention to the extraordinary amount of trouble caused by vague and inadequate descriptions, especially when these are given without explanatory figures of the object described.

In the general treatment of the large mass of literature here brought under review I have desired as much as possible to save trouble to any naturalist who might in the future have to deal with a collection similar to that which is the subject of this Report. Hence brief notices of the Amphipoda and descriptions of single species embalmed in large works have been quoted in full, and occasionally for the same reason short separate treatises have received a longer notice than their intrinsic importance, apart from their rarity, would have demanded. On the other hand, some works, such as the British Sessile-Eyed Crustacea by Bate and Westwood, and Boeck's great work on the Arctic and Scandinavian Amphipoda, have been only briefly noticed, since they are already widely known and of necessity in general use, so that the enormous space required for an exhaustive discussion of their contents would have been to a great extent needlessly absorbed. Among the writings of the last century, attention should, I think,
be called to the superiority which Pallas displays in his descriptions of Amphipoda. In
the present century Kroyer can have but few rivals for combined fulness and accuracy of
detail. In the whole multitude of contributions to the voluminous literature here con-
sidered, it is obvious that some writers have done more harm than good, or that, to speak
in the most lenient terms, their productions are of no value whatever; but while this can be
fairly said only in rare cases, the examples are very numerous of fruitful industry and
high scientific excellence. Without, however, any attempt to appraise seriatim the
merits and services of this host of writers, it may be convenient to mention a few works
which the student will find, if not indispensable, at least of foremost value, for particular
branches of the subject. Thus, for the general structure of an Amphipod, he should
certainly consult the Histoire Naturelle des Crustacés d'eau douce de Norvège, by
G. O. Sars, 1867; for embryogeny, the Mémoire sur la formation du Blastoderme chez
les Amphipodes, les Lernéens et les Copépodes, by E. van Beneden and E. Besselis,
1869, and Uljanin's Essay, 1881; for the circulation of the blood, the papers by
Wrzesińskiowski, 1879, and Delage, 1881; for the family of the Cyamidae, the contrib-
utions of Lütken, 1873 and 1887; for the Caprellidae, Mayer's Die Caprelliden,
1882, to which an Appendix is to be presently published; for the Phronimidae, Claus'
Essay, 1879, and for the Platyscelidae, the same writer's work of 1887; and to this
list the treatise by Bovallius on the Amphipoda Hyperina, and that by Wrzesiński
on the subterranean Amphipods, when completed, will doubtless need to be added. For
the study of the Amphipoda Gammarina the works of importance are so numerous that it
might be misleading to point out a few as more prominently essential than the rest,
yet on the difficult subject of the Ediceridae the paper by J. Sparre Schneider in 1883
ought not to be overlooked.

Classification.—The division of the Amphipoda into three groups, the Gammarina,
Caprellina, and Hyperina, has been long and widely accepted, and is followed in this
Report as of practical utility and based on reasonable grounds. Geology is unfortunately
almost silent about these Crustacea. To all intents and purposes there have been as yet
no fossil Amphipods discovered.1 If, nevertheless, we may assume the three groups to
have been all derived from a common ancestral form, then the evidence of the groups
themselves may be taken to show that the Gammarina and Caprellina, by their similar
mouth organs, are more nearly connected with one another than either with the
Hyperina, and that the Hyperina, in respect of their mouth organs, are furthest removed
from the primitive form, inasmuch as their maxillipeds have lost that resemblance to
modified legs which is so striking in the other two groups. From both the Gammarina
and the Hyperina the Caprellina are separated by the slight development of the pleon.
This character can readily be explained as an acquired adaptation to their habits of life.
If the suggestion be made that the ample pleon might as well have been developed from

1 See pp. 111, 118, 276, 300, 353, 409, 471, 486.
the feeblest form as the feeblest have been degraded or reduced from the more ample, the answer is this, that the impoverished condition attributed to the pleon in the Caprellina is correlated to other appearances of degradation in the same group, that no Caprelline stage has ever been observed in the embryos of the other two groups, and that the strongly developed pleon would scarcely have been so general, not only among Amphipods, but also in the neighbouring orders of Crustacea, had the ancestral form been nearest to the rudimentary one. Hence it appears to be a natural arrangement to place the Caprellina after, though next to, the Gammarina, and to let the Hyperina come last.

To any one glancing over the great variety of forms presented by different species of Amphipoda, and comparing an Orchestia with a Cystisoma, a Rhabdosoma with an Anonyx, a Pariambus with a Gammaracanthus, it might seem extremely rash to assume that all the Amphipoda could possibly have a lineage in common. But after prolonged examination of homologous parts the observer would not be so much impressed with the difficulty of a common descent as with the intrinsic simplicity of the processes by which these wonderful differences of structure might have been produced. For if a son may be taller than his father, a daughter stouter than her mother, in the same family one child have straight hair and another curls, one brother be smooth and the other a hairy man, variations of a corresponding kind suffice to explain the most striking dissimilarities that the Amphipoda can furnish. Lengthen or contract a limb, make a joint tumid or flatten it out, multiply the spines or prickles, narrow or expand the body, or so treat one part of it at the expense of another, let it be cylindrical or depressed or laterally pinched, stiffly outstretched or coiled into a ball,—by such differences as these, in regard to which many species present the most minute transitions, it will be found that genera and families are separated, without the least necessity or reasonableness of attributing to them other than a common origin.

In the hinder part of the pleon the Hyperina show a general but very variable agreement with the Gammarina, but in the front part of the pleon, and especially in the appendages of that part, the agreement is great and very constant. These appendages, commonly called pleopods, are perhaps less subject to variation throughout the two groups than any other part of the organism. Each of the first three segments of the pleon has a pair of these swimming-feet, the three pairs usually differing only a little one from the other; each member of a pair consists of a stem or peduncle supporting two branches; the branches as a rule differ only slightly from one another, each being of tapering form, composed of several joints, of which the first is invariably the largest; of these joints every one has an apical pair of long feathered setae, which on the small terminal joint are close together. No joint except the first is ever privileged to have more than one pair of these plumes, and no joint is ever normally without its pair.

On the peduncles of these swimming-feet, near the lower angle on the inner side, there
is the curious apparatus spoken of in this Report as the coupling-spines. Among the Gammarina occasionally these spines are numerous; among the Hyperina there are rarely, normally perhaps never, more than two to each peduncle. In both groups they are clearly spines that have been modified to serve one and the same purpose, namely, to hold the peduncles together for the swimming-stroke. For this purpose the apex of each spine is blunted and has backward directed teeth, the edges also often having a retroverted serrature, so that the spines of each pair of peduncles can be interlocked. That both groups, notwithstanding their otherwise extremely divergent forms, should so universally possess these coupling-spines, is surely a note of common ancestry. It is also easy to see that two quite simple spines in this position might be of some service for the object in view by the effect of mere friction, while natural selection would be ready to avail itself of any variation in the direction of the roughening of the spine, until the strongly serrate edges and dentate apices had been at length evolved. In the branches of the pleopods we find another note of community of origin for the two groups above mentioned. Besides the obvious similarity which these branches display in almost all the genera and species, they have in common the less easily noticed feature of carrying one or more cleft spines on the inner margin of the first joint of the inner branch. To this there are only rare exceptions, and those, perhaps, not difficult to explain. Throughout the Hyperina it appears that the joint in question never has more than one such spine, while in the Gammarina the number varies. The object served by these spines is no doubt similar to that of the coupling-spines. One arm of the cleft apex has a subterminal expansion, and the other arm is internally roughened or serrulate. By these contrivances a pair of the spines lying crosswise helps to keep together the branches of the pair of pleopods, and so to add force to the swimming-stroke. But these spines with cleft terminations have plumose shafts, and are evidently plumose setae modified for a special purpose. Indeed, in some species, in which the pairs of cleft spines are numerous, some of them show a gradational form combining the flexibility of the seta with the cleft termination of the spine.

Another example of gradational forms is exhibited by the maxillipeds of the Gammarina. The outer plates of these organs are commonly fringed with an apparatus, parts of which may be distinguished as respectively, teeth, spines, and setae, yet the teeth pass into spines, and the spines into setae by gradations so minute, that the practical difficulty arises in description of determining how many of these little appendages ought to be grouped under one name, and how many under another, yet no one would dream of interchanging the names of the two extremes of the series, the tooth and the seta.

In classifying the families of the Amphipoda within the principal divisions, not a few difficulties are encountered. We may attempt to place side by side those which in the

2 "Soie particuliere à bout bifurqué," Sars, loc. cit., fig. 8.
REPORT ON THE AMPHIPODA.

present state of knowledge appear to have the largest number of important affinities. But what affinities should be considered important for classification it is by no means easy to determine. Animals genealogically very wide apart may have adopted similar modes of life, and in so doing have become modified on parallel lines, while on the other hand, in species nearly related by descent, great divergence of character may have resulted from difference of habits, such as the assumption of a parasitic life by one branch of a family, when the other branches have remained independent. In classifying the Gammarina authors have usually placed the Orchestidae first. In the order of evolution they might rather be placed last. Among these alone of the Amphipoda has a capacity for terrestrial existence been acquired; some of them are gradually adding the faculty of walking upon dry land to the ordinary movements of slithering and leaping; all of them have lost the mandibular palp. Delage, founding his view upon the circulatory apparatus, suggests that the Corophidae are the ancestors in common of the other Gammarina and the Caprellidae. But Corophium volutator (Pallas), the subject of Delage's investigation, is far removed from a typical Amphipod. Though it has not the variety of movement found among the Orchestidae, yet, by having a body flattened instead of laterally compressed, it is perfectly capable of walking. It cannot perhaps, strictly speaking, be said to walk upon dry land, but it walks freely over moist mud in the open air. Of the three pairs of lateral orifices to the heart, so generally found among the Amphipoda, Delage has observed that the first two pairs are wanting in Corophium volutator, and that they are small and inactive in the Caprellide. But it may safely be said that if the Gammarina and Caprellidae were descended in separate lines from the Corophium, the degraded and inert Caprellidae would never have acquired the two additional pairs of orifices for which they have, it seems, no urgent need, and which their supposed ancestor of a higher type and more active habits is able to dispense with. Thus, while the character of the heart makes it very improbable that Corophium should have been an ancestor of the Caprellide, its shape and habits make it quite as unlikely that it should have been an ancestor of the Gammarina, so few of which have any activity out of water, and so many of which, the Orchestidae included, have the body laterally compressed.

On the supposition of a common origin of all the Amphipoda, it is obvious that families will have been gradually separated by the successive acquisition of distinctive characters. The supposition itself is based upon the fact that some characters are common to many families, since that fact is explained most simply on the principle of inheritance from a common ancestor. In the search, then, for ancestral characters, we must look away from what is rare and exceptional to what is commonplace and unattractive. When any single character is investigated in all the known species, some form will often be found of marked simplicity and completeness, round which the rest

1 See p. 526.
will be grouped at greater or less distances. These two attributes, simplicity and completeness, are evidently appropriate to an ancestral form. To begin with, each part of an organism will, by inheritance, resemble the part from which it has budded out. Successive variations introduce distinctions between the parts of an organism, just as they introduce distinctions between one organism and another. At the same time the simplicity sought for must be limited by some standard of completeness, otherwise we should be looking for the origin of things in general, not the ancestry of a particular group. In the structure of an Amphipod we may recognize simplicity in the segments of the pereon, where, as a rule, each segment is to a certain extent free from its neighbour and closely resembles it, and we may recognize it also in the flagella of the antennæ and branches of the pleopods, in which, commonly, numerous joints exhibit one and the same pattern. The theoretical completeness of the appendages rests to some extent on a comparison with other groups of Crustacea, but the limits either of completeness or simplicity which are to be expected in the special group are soon arrived at. If, then, by comparing not only one but every available character in all the families, we at length make some approach to a complete set of ancestral characteristics, we shall be able to construct an ideal Amphipod, with no parts degraded and none exaggerated. And if further, by comparing this ideal with existing species, we find one among them bearing an exceptionally close resemblance to it, such a species will have some claim to stand, not perhaps at the head, but in the centre of our classification, as most directly representing the type or original from which the other Amphipoda have in various degrees more widely diverged. As a matter of fact, in the genus Gammarus the well known species Gammarus pulex and Gammarus locusta are very much of the commonplace facies desired. They are naturally chosen for explanatory purposes and as representative species. They have the requisite completeness; the secondary flagellum of the upper antennæ is not wanting as in Amphithoe, nor the mandibular palp as in Dexamine and the Orchestidae; the palp of the first maxille is not degraded as in Orchestia, nor the maxilliped palp curtailed as in Lafystius; no segments of the pereon are coalesced as in Dulichia, nor of the pleon as in Atylus and Goplana; the third uropods are not uniramous as in Metopa, nor the second as in Cerapus. They have also the requisite simplicity, as could easily be shown by a detailed comparison with other species. The distribution of these two species lends an additional probability to the view that they represent an ancestral form. Far more than any other Amphipod Gammarus pulex appears to have spread itself over the fresh-water streams of the world, and Gammarus pulex is connected by the very closest ties with Gammarus locusta. It is clear from the general distribution of the Gammarina that the chief nurseries whence they issue are the weeds of the coast. From these the rivers are accessible as well as the ocean, yet in the rivers the species of Amphipoda are few, while in the ocean they are multitudinous. This admits of a simple explanation, if we accept Gammarus locusta as representing the ancestral form which at one time occupied the
world without the competition of other species of Amphipods. In order to enable the family to extend its range over the fresh-waters of the world, no further change was needed than such as would enable some of the progeny to pass from salt-water to brackish, and from brackish to fresh. But the sections of this genus having once obtained command of the rivers, by the capacity of living vigorously in the river-water, would have an immense advantage over all rivals attempting in the future to make a lodgment in the streams, while their capacity for life therein was in its initial stages and only feebly developed.

In the arrangement around and near to *Gammarus* of such genera as *Niphargus* and *Gammarocanthus* and *Maira*, there is in point of fact a very general agreement, so that we shall not be very rash in regarding the Gammaridae as a natural family. If from the considerations already mentioned we may regard it also as the typical family of the Amphipoda, the next point of interest will be to determine whether the other families can only be grouped confusedly around it, or whether any lines of succession can be suggested. It is evident that if the *Gammarus*-form had at any time such possession of the ocean-world that it was able to stock the majority of the fresh-water streams with genera and species which can be traced back to it in a direct line, the more or less amphibious Orchestidae ought to be traceable to the same source. Between *Gammarus* and *Talitrus* there are, it is true, important distinctions, but they are in part bridged over by the genera *Hyale* and *Hyalella*, and to a very considerable extent they show adaptation on the part of the Orchestidae in general to altered conditions of life.

The next family which seems easily derivable from *Gammarus* is that represented by the genus *Amphithoe*. It will be noticed in the history of the subject, that, before the minute subdivision of genera, the discoverer of a new species, if he did not assign it to *Gammarus*, was very apt to call it an *Amphithoe*. *Amphithoe* indeed has before now been chosen for description as a typical genus of the Amphipoda. The genus, in its present acceptation, has an extremely extensive distribution, and by the simplicity of structure which it exhibits, and its general approximation to *Gammarus*, it is well fitted to be the link between that genus and the nest-forming Podoceridae in general. Near to, yet not to be derived from, the Podoceridae, and by their somewhat more erratic characters placed at a greater distance from *Gammarus*, come the Photidae. Again, at various distances beyond the Podoceridae, we may imagine positions for the Corophidae, Cheluridae, Dulichidae, and Icelidae. The Dulichidae seem to lead on by a very natural sequence to the Caprellidae, with which Bate and Westwood have gone to the extreme length of actually classing them, in their group Aberrantia.

Returning to the family of the Gammaridae, we find in close alliance with it two other families, the Atylidae and Ensiridae; nor are these remote from the Pleustidae and Epimeridae. The remainder are by no means easy to group in any plausible order of relationship to the ancestral form. The eyes of the Ampeliscidae give them a position
apart from all the rest. The Lysianassidae are set apart in another direction by the peculiarities of the upper antennæ, the second gnathopods, and especially that character of the mandibles, on account of which Schiodte has named them the Trochalognatha. As far, however, as the antennæ are concerned, they are united to Schiodte's other group, the Eleutherognatha, by the new family Valettidae. The Stegocephalidae, while agreeing with the Lysianassidae in the upper antennæ, are less remote from Gammarus in the form of the second gnathopods. On the other hand, the character of the mandibles shows a further departure from the common type than is found anywhere else among the Gammarina. Hence a common ancestry may be supposed for these three families, branching off from Gammarus at a remote period.

In the Stenothoidae the genus Steno'ortho itself, being without the mandibular palp, may be regarded as a later form than the companion genus Metopa, in which that palp is retained. In the Leu'cothoe, by the characters of its mandibles and maxillipeds, seems to lead up to the Stenothoidae.

The Syrrho'idae and Synopidae on several accounts may plausibly be placed side by side. In one particular, the very short terminal joint of the mandibular palp, these families show an affinity to the Stenothoidæ; but apart from this point their affinities are with the Pontoporeidæ. Nearer than any of these to Gammarus stand the Odieeridæ.

The Iphimedidæ, Pardalisidæ, and Amphilochedidæ remain, with peculiarities that make every suggestion for their classification hazardous. At a venture the Pardalisidæ may be grouped with the Syrrho'idae, Synopidæ, and Pontoporeidæ; the Iphimedidæ with the Pleustidæ and Epi'meridæ; and lastly, the Amphilochedidæ left, where they are usually placed, in a somewhat dubious proximity to the Stenothoidæ.

Between the Gammarina and Hyperina there is a wide gap, over which at one point no bridge has yet been found, for, while in the Gammarina the maxillipeds always have a palp, they never have one in the Hyperina. In the Gammarina the mandibular palp has, with the rarest exceptions, a short first joint, whereas in the Hyperina this joint is frequently of great length, but here there are all sorts of connecting links, the mandibular palp in Cylo'pus being quite of the pattern common among the Gammarina. Milne-Edwards, in 1840, when establishing the Tribu des Hy'périnea Gammaroides, went so far as to say that the single genus, Vibilia, which he placed in it as a link between the Gammarina and the ordinary Hyperina, might almost as well stand in one division as the other. To this overstatement of the closeness of the tie between the two groups he was no doubt led by wrongly supposing that Vibilia had rudimentary palps to the maxillipeds.

Within the Hyperina, although marvellous diversity of form has been arrived at, there is comparatively little difficulty in tracing a family resemblance between the different sections. Naturally the Platyscelidæ or Hy'pérines anormales, with their strange zigzag
folding antennæ, may be regarded as the latest development, but the whole group of Hyperina must be supposed to be interconnected, not to be derived partly from one branch and partly from another branch of the existing Gammarina. It may be noticed, indeed, that though the Gammarina by their maxillipeds testify to an older type than is seen in the Hyperina, yet the latter in some genera retain in their turn a mark of antiquity which the Gammarina have lost, in the simplicity of the gnathopods, for these in \textit{Dairella} and \textit{Lycowopsis} are like ordinary pereopods. The general structure of the upper antennæ in the Hyperina calls to mind the family Lysianassidae, but there is the marked distinction that in none of the Hyperina is there a secondary flagellum to these antennæ; yet here the recently discovered \textit{Hyperiopsis voringii}, Sars, may supply a link, since with the antennæ of the Lysianassidae this curious species combines the eyes of a Hyperid. A connection between the Hyperina and the Lysianassidae has already been indicated by Boeck, who placed the family Prostomatidae at the head of the Gammarina, in immediate sequence to the Hyperina, because of the agreement which he considered to exist between that family and the Hyperidae and Orchestidae. The Prostomatidae are in close relationship with the Lysianassidae, and might, in my view, well be included in the older family. But if the Hyperina make any real approach to the Lysianassidae, it must not be supposed that they are derived from them, for the mandibles of the Gammaroid Hyperina point more directly to the \textit{Gammarus}-form than to that found in the Trochalognatha.

In offering these contributory suggestions towards a classification of the Amphipoda, my hope is that either by occasionally hitting the mark they may be of service, or that where they have missed it they may provoke a fruitful criticism, and either way that they may excite the ambition of the discerning and ingenuous to throw light upon the many problems which are still obscure.

\textit{Nomenclature.}—Most naturalists will sympathise with the lady who thought that, of all the discoveries astronomers had made about the stars, the finding out their names was the most wonderful. In zoology the new discoveries are generally far more troublesome to name than they would be if they were only stars or planets. A genus of sharks is bound to give way, if it turns out that a genus of animalcules has received the same appellation a month earlier, and the genus of animalcules, however laboriously and scientifically described, must give way in its turn, if it should prove that the same group of creatures has been obscured rather than explained fifty years before under a different name. But apart from these casualties, there is the enormous and increasing difficulty which arises from the multitude of workers in every field of natural history, who, in the absence of any rule or convention to the contrary, publish new genera and species in any literary vehicle that is for the moment handiest. One isolated description may have to be sought for in a costly volume of travels, and another in the local journal of Timbuctoo. It is rather to be wished than expected that an international law in science should intervene, and allow validity and priority only to names adequately published in
definite periodicals, of which one or more might be assigned to each large division of the animal and vegetable kingdoms. Even under this utopian arrangement the requirements of adequate publication would be very much at the mercy of different contributors.

Looking only to the Amphipoda, one sees and feels the natural tendency in those who describe actual specimens to multiply genera and species, while in those who classify the results obtained by others, the tendency is to be impatient of minute distinctions, to rejoice at being able to unite two species into one, and to ignore one genus in favour of another which they regard as embracing it. Nothing but good is done by those who pare away the superfluities of nomenclature by discovering that the same genus or species has been described under more than one name, but it is a question whether much profit has resulted from attempts to discard small genera in favour of a large comprehensive genus. In the history of the subject we see that the names of the rejected genera almost invariably obtain eventual acceptance, so that the attempts at suppression only result in a confused synonymy. Few authors, for instance, would now dispense with Melita and Miera of Leach, which to Milne-Edwards appeared useless and even injurious sub-divisions of Gammarus. Those who take the lead in introducing minute subdivisions do, indeed, force the hand of their successors, since differences which might well have been regarded as specific under a moderately wide genus, have to be accounted generic when the already existing genera of a family are separated by very small distinctions. But premature interference rather increases than remedies the confusion, although, when knowledge of the subject has largely advanced, the time and opportunity for a general revision may arrive and be thoroughly welcome.

As far as the form of a name is concerned, it has seemed to me beyond all question best to adopt that which the author of the name himself gave to it. This was far from being my original opinion. It is, of course, a delightful effort of criticism, and a token of one's own intrinsic superiority, to be able to correct the spelling of some eminent man of science. But in actual practice each correction makes a new name, adding therefore to the synonymy, and often making necessary the citation of two authorities instead of one. Sometimes the corrected form of a name comes into collision with a genus established before or since in some other branch of zoology. Sometimes a name is inconveniently lengthened in the effort to make it conform to the laws of philology, and a syllable is inserted which the originator of the name perhaps intentionally left out. As Leach has shown, it is not necessary for a scientific name to have a derivation at all, so that in the last resort the names which do not satisfy the laws of classical formation may be defended on the ground that one congeries of letters is as good as another. At any rate, for the purposes of natural history, the fixity of a name is of far more importance than any indirect lesson in scholarship of which it may be made the text. I may as well, however, confess that in respect to the genus Amphithoë I have not had courage to

1 Hist. Nat. des Crust., t. iii. p. 54.
revive Leach's original *Ampithoe*, and that in pedantically printing *Caprella equilibra*, Say, instead of Spencer Bate's *Caprella equilibra*, my object has been much more to emphasize the general view here advocated than to make converts to the use of that particular illustration of it. The custom of changing the gender of specific names, when species are transferred from genus to genus, seems to me inconvenient and unnatural. In every species of the Amphipoda there are males and females, and since the ungallant Romans imagined the masculine to be the worthier gender, it would tend to simplicity if that gender were preferred in the formation of all specific names. Changing the masculine ending into a feminine, to match the nominal sex of the genus, is much like saying that a man must be a woman if his parents have happened to christen him Maria.

The pronunciation of the names used in natural history is of comparatively little importance, since they are so much more frequently read by the eye than pronounced by the tongue. Nevertheless, it would be an advantageous custom if authors, when introducing a new name, would supply their readers with some means of determining the quantity of a doubtful syllable. In pronouncing long-established names, such as Gammarina, Caprellina, Hyperina, where the derivation will not help us, we must be guided either by usage which may fluctuate, or by euphony in respect of which tastes may differ, or by the genius of our own language which is pretty sure to prevail in the end. In the three examples cited, my own opinion is, that the penultimate syllable ought to be pronounced short, the accent being in each case laid upon the ante-penultimate. Although the Greek word ἰσπίνως, so accented and having a short penultimate syllable, has nothing to do with our Hyperina, yet the mere existence of such a word proves that there is nothing monstrous in the pronunciation now recommended.

*Distribution.*—How very extensive is the range of the Amphipoda may partly be seen by a glance at the map accompanying this Report. Northward, Amphipoda have been taken within 400 miles of the pole; in the opposite direction as far down as lat. 68° S. Of the great depths from which some of the Challenger Amphipoda are reported I do not like to speak with too much certainty, but there is no special reason for doubting that *Lanceola pacifica*, for instance, came actually from the depth assigned it of 2300 fathoms. It does not seem unnatural that some of the group should have been able to penetrate even to so great a depth as 13,500 feet beneath the surface of the sea, since on the continent of South America Mr. Whymper has found them at 13,500 feet above it. All the waters of the world, arctic and tropical, salt, brackish and fresh, oceans, lakes, rivers and wells, are tenanted by Amphipoda. From the rocks and sands and muddy fringes of coast and shore they are pushing out advanced guards in a sort of tentative manner on to the land, where, for ought we know, they may yet have a great future before them. That they have thriven so well hitherto may be attributed to various advantages, chiefly perhaps to their ready adaptability to so many varying circumstances. Diminutive size and mimetic colouring will often have helped to protect
them. An appetite, voracious, indeed, but not over fastidious, will seldom have allowed them, like more scrupulous feeders, to starve in the midst of plenty, while the prodigious swarms they bring forth have enabled them to offer a wholesome banquet to the monsters of the deep without any injurious diminution of their own numbers. The following list exhibits the species which have a more or less doubtful claim to have come from a depth greater than 300 fathoms. It is interesting to notice, that in the thirty-one specimens of Gammarina reported from these vast depths, twenty-five genera are represented, of which ten are new, and twenty-eight species, of which twenty-six are new.

1 1800 fathoms was the depth at the station at which this species of Phronima was taken, but in all probability the Phronima was taken at the surface.

² The depth at Station 243 at which this species was taken is 2800 fathoms.
REPORT ON THE AMPHIPODA.

Almost all the Hyperina, except in the genera Lanceola, Cystisoma, and Phronima, were expressly labelled as having been taken at or near the surface. In regard to the specimens of Phronima, it was probably considered that their capture at the surface would be taken for granted, their floating habitations having been frequently obtained.

How incomplete is our present knowledge of the whole group may be inferred, as well from the numerous additions which almost every voyage of scientific exploration makes to it, as in especial from those additions which the Challenger made by a few weeks stay in the Southern Ocean at Kerguelen Island and Heard Island. For, by the exertions of the Challenger Naturalists, from this small region, previously supposed to be very barren in Amphipods, the following list of species was obtained:—

Among the Gammarina:—

Anonyx cicadoides, n. sp., K. | Acanthochinus tricarinatus, n. sp., H.
Tryphosa antemipotens, n. sp., H. | Iphimedia pacifica, n. sp., K.
Tryphosa barbatipes, n. sp., K. | Iphimedia pulchridentata, n. sp., H.
Hippomedon kergueleni (Miers), K. | Atyloides australis (Miers), K.
Hippomedon trigonius, n. sp., K. | Harpinioides drepanocheir, n. sp., K.
Cheirimenedon crenatipalmatus, n. sp., K. | Triteta kergueleni, n. sp., K.
Sophrospic murrayi, n. sp., K. | Rhachotropis kergueleni, n. sp., K.
Orthomenc caucanus, n. sp., K. | Eusirus longipes, Boeck, K. and H.
Lepidepecreum foruminiferum, n. sp., K. | Eusiroides pompeii, n. sp., H.
Socarnoides kergueleni, n. sp., K. | Liljeborgia consanguinea, n. sp., K. and H.
Amphasia integricauda, n. sp., K. | Pholis macrocarpus, n. sp., K.
Acontistoma pepini, n. sp., K. | Aora kergueleni, n. sp., K.
Acontistoma kergueleni, n. sp., K. | Aora trichobostrichus, n. sp., K.
Kerygelenia compacta, n. sp., K. | Autonoe kergueleni, n. sp., K.
Metopa nasutigenes, n. sp., K. | Gammaropsis exsertipes, n. sp., K.
Cardenio pseudodactylus, n. sp., K. | Amphithoe kergueleni, n. sp., K.
Phoxocephalus kergueleni, n. sp., K. | Podocerus fideatus (Montagu), K.
Harpinia obtusifrons, n. sp., K. | Cerapus sismithi, n. sp., K.
Urothoe luchneassa, n. sp., K. | Haplocheira planosa, n. sp., K.
Holmedon schneideri, n. sp., K. | Platophium danae, n. sp., K.
Eeliceroides rostrata, n. sp., K. and H. | Neohela serrata, n. sp., K.
Zaramilla kergueleni, n. sp., K. | Protelopsis kergueleni, n. sp., K.

Among the Caprellina:—

Dodecas elongata, n. sp., K. | Euthemisto gaudichaudii (Guérin), K.

Among the Hyperina:—

Vibilia sp., between K. and H. | Primno sp., K.

1 K. stand for Kerguelen, H. for Heard Island.
Of the forty-eight species here enumerated, all but about half a dozen have been brought to light by the Challenger researches, and of the genera over which these species are distributed thirteen out of forty-three are new.

It may be convenient here to group together the names of the thirty-one new genera established in this Report:

Streetsia.

The new generic names proposed in the Report in exchange for older but preoccupied names of valid genera are as follows:—Caprellinopsis for Caprellina, G. M. Thomson; Euseciotes for Euseclus, Claus; Lysianax for Lysianassa, Milne-Edwards; Pariambus for Podalirius, Kroyer; Phorcorrhaphis for Phoracus, Milne-Edwards; Phoxocephalus for Phoxus, Kroyer; Priscillina for Priscilla, Bocck. Haustorius, Müller, is reinstated in place of Lepidactylis, Say, Phtisica, Slabber, in place of Proto, Leach, and Seina, Prestandres, in place of Tyro, Milne-Edwards, and Clydonia, Dana. Eginella, Bocck, is taken to include the preoccupied Eginia, Kroyer. For Constantia, Dybowski, Costantia, a form accidentally occurring in Dybowski’s own work, is adopted. For Eurytene, Liljeborg, Eurythenes is accepted from the pen of Professor S. I. Smith. For Dryope, Sp. Rate, although preoccupied, no alternative name is for the present offered, its relationship to the new genus Dryopoides requiring further consideration.

Of the hundred and eighty species which the Report describes as new, it is possible that a few come too near to older species to deserve specific distinction. Especially in the genera Hippomedon, Leneothœ, and Aora my suspicions are aroused that I may have introduced some unnecessary names; but such errors of judgment, if found to exist, will also, I hope, be found to be few.

1 This genus was first published in a preliminary notice in 1853.
BIBLIOGRAPHY.

B.C. ARISTOTELES, born about 385, died 322 B.C.

Cent. IV. De Animalibus Historiae. Libri x. (Jo. Gottlob Schneider, Lipsie, 1811). These ἱστορίαι περὶ τὰ ζῷα were probably published within the last thirteen years of their author's life. After his writings had met with sundry changes and chances, there is reason to believe "that about 50 years B.C. Andronieus produced the first edition of the collective works of Aristotle." See The Ethics of Aristotle, by Sir Alexander Grant, 1874, p. 9.

The passages in Aristotle which probably refer to the Amphipoda are the following — Book iv. ch. 2. Ἄν ὃῖ μαλακοστράκῳ ὕπε ἰτή το τέγο τοῦ καράβων καὶ τοῦτο παρεστίλησεν ἐπὶ τοῦ καλώς τοις ψύλλοις. Ὅτι δὲ διαφέροντα τῶν καράβων τῷ ἰχθὺς χρόνος καὶ ἄλλοι τινάς ὑπάρχειν οὐ πολλάς. "Εν δὲ τῶν καράβων, καὶ ἄλλο τῶς καρακίους. Γίνη δὲ πλάσω τῶν καράβων ἵνα καὶ τῶν καρακίων τῶν μὲν ἱρά καράβων ἅτι το κυψεῖ, καὶ δειγμάτα καὶ τὸ μικρὸν γένος ἅτι το γένος μέζων. Of the Malacostraca one genus is that of the carabid, and near to this a second of those called astraed. These differ from the carabid in not having chelas, and in a few other points. One genus is that of the carabides, and another that of the carabini. There are several genera of the carabides and the carabini; for to the carabides belong the gibbsae and the crangons, and the little genus; for these grow no bigger. Book iv. ch. 10, a passage, unfortunately incomplete, relating to the sleep of fishes and other water animals that have no eyelids: Αλλάκω ταῖς ἱερὸς οὐ ἱερὸς, εἶ μὴ διὰ τοῖς φθείραις καὶ τοῖς καλόμοιοις ψύλλοις . . . [αὐτὸς ἀπεμένεις] ὡστε κἂν τῆς χειρὸς λαμβάνοις μέλιον· ὥν τὸν χρόνον εἶσαι τὰς νυκτός, καταστάθησον προσπίπτομεν πολλά τὸ πλάζον όντε. Γίνονται δὲ ἐν τῷ βαθὺ τῆς δαλατής καὶ τοοῦτα τὸ πλάζον, ὡστε καὶ τὸ δέλαρ δὲ τὰν ἱερὸς γῆ, ἄν χρονία ἵπτη τῇ γῆς, καταστάθησον καὶ ἀνέκουσας πολλάκες οἱ ἄλλος περὶ τὸ δέλαρ ωστερ σφάγαις αὐξημένων αὐτῶν. For fish, unless [they are disturbed] by the lice and so-called fleas, are surprised in so tranquil a condition as to be easily taken even in the hand. But now if these are left [in the nets] during the night, they (the fleas) being many in number fall upon and devour them. In the deep of the sea they grow in such multitudes that any piece of fish for bait, if left long on the ground, they devour. And often the fishermen draw up round the bait as it were a globe of them clinging to it.

Gerstaeker thinks that the little genus of the first passage may well refer to such an Amphipod as Carinaria locata. Beock considers that the ὑπάλλον of the second passage, which eat the fish in the nets, are also likely to be Amphipods, since in the northern seas these act exactly in the way described. The statements of Klein and Holboll confirm this. As Aristotle apparently speaks of the bait on land, "ἐπὶ τὰς γῆς," being eaten by these creatures, it is likely enough that he alludes to more than one species; unless, as Bellon evidently supposed, the land intended be not dry land or shore, but the ground at the bottom of the sea.

(2001. CHALL. EXP.—PART LVIII.—1887.)
A.D. CAIUS PLINIUS SECUNDUS, born A.D. 23, died A.D. 79.

Historia naturalis. Libri xxxvii. (Gabriel Brotier, Tomus ii., Parisisiis, 1779).

In book xi. sect. lxxii., Pliny speaks of Crustata among marine animals. No earlier use of the word in this application seems to be known. In book ix. sect. xxi. he says, "Animal est parvum, scorpionis effigie, aranei magnitudine. Hoc se, et thymo, et ei qui gladiis vocantur, crebro delphini magnitudinem excedentis, sub pinnâ adigit aculeo: tantoque infestat dolore, ut in naves sequunmuro exililnat." This passage is only worth noting in comparison with Risso's statement that a species of Cyamus sometimes so irritates the thunmies in the Mediterranean that they jump out of water. Lätkén supposes that Risso has assigned to Cyamus an effect produced really by Brachiotta thymii. In book ix. sect. lxxii., Pliny appears to confuse, in a rather ludicrous passage, the Ædipere and Ædela mentioned in book iv. ch. 10, of Aristotle's History of Animals. In book ix. sect. li. he gives "Cancerorum generis, carabi, astaci, maie, paguri, herculeici, leones, et alia ignobiliora," among which the ignobilium may be supposed to correspond to the μερόν γένεσ of Aristotle, and to include some at least of the Amphipoda.

Petri Bellonii Cenomani De aquatilibus, Libri duo Cum iconibus ad viuum iporum effigiem, quoad ejus fieri potuit, expressis. Parisisiis, m.d.liii.

The second book, pages 318–348, is de aquatilibus exanguiibus. Of these "quæ Graecis Æmav, nobis exangua dicuntur," he says, "alia dum quidquid testa operuntur, quæ illi Ætrumeturma, alia verò mollis: quæ etiam molakótrpaca vocit, atque alia rursus iuxtea, sub quibus magna marinorum ac fluvialium phalanx contuitur. Exanguii igitur molles à nobis describentur ac depingûetur primum locutum, cancri et id genus ceteri. . . . Ultimo loco dejectamenta maris, nominibus etiam insignibus prædicta explicantur, quibus non-nunquam etiam vesci solemus."

Among the Crustata he considers that the Squilla fluvialitis parva, the Gambarella of the Romans, is intended by Aristotle's "parva quæ majores nunquâ effici possunt." In this Bellon is evidently not thinking of any Amphipod. The only allusion that he makes to Amphipods is to be found, if anywhere, in his cap. xii. p. 436, "De dejectamentis marinis," in the section headed "Asilus sive Estrum." This Isopod he figures with eight thoracic feet on each side, and concludes his account of it as follows:—"Aristotles octauo de historia animalium: Thunni (inquit) et Glaedii agitantur estrum, canis exortu, habent enim tuctque per id temus sub pinna seu vermiculum quern Assilum vocant. Iadem anhon videtar estrum seu Asilum disserum a pediculo et pulice constituebatur, quum eis etiam nomina propria φώκων θαλαταων; id est, pediculum marinum, et ψάλλες θαλαταων, id est pulcere marinum, imponat. Vocet et in mari pedicules (inquit Plinius) casco tritos in superficie ex acecto arribat jubent. Pisces vel manu caperentur, dum dormiunt (inquit Aristoteles) nisi pediculas et pulcibus sollicitarentur. Gignuntur in profundo mari tanta fossuditate, ut escan de pisco omollitam, si diu in imo manserit, totam corrodunt atque absuant. Et quidem sequamnimo piscator escan demissum, glomeratm vidiqne his bestiolis, perinde ut pilam affolit. Aristotles's "éti τετε μεγα," is here represented by "in imo," meaning "at the bottom of the sea," which is perhaps an attempt to correct the unmeaning words "in uno" in Gaza's translation, for which Aubert and Wimmer (1868) suggest "in humo."
1554. RONDELET, GUILLAUME, born 1507, died 1566 (Biographie Universelle).

Libri de piscibus marinis in quibus vero piscium officios expressae sunt. Lugduni, M.D.LIII. pp. 534-577.

Liber xvii., De Piscibus, que discantur Crustacea, contains chapters on Stalk-eyed and Sessile-eyed Crustacea and on Echinoderma. Chapter xxvii., De Pulice marino, begins: "Cum Maris purgamentis aliquoties repertae carnea crusta institat, quam hic depinximus, quam facile homunciones ridiculé pictae vel similias representat alius partibus locusta similis est, in cauda appendiculas habet locustae et similique modo, tam exigua est ut particulis corporis nisi ab oculo oculat possint, ob parvitasem nequitatur. Hanc puto esse φιχλον θαλαττων, id est, puicem marimum, de quo Aristoteles, quam de piscium sonno agit." He then proceeds with a translation of the passage from Aristotle, lib. iv. ch. 10. Boeck thinks he means some species of 

![Amphipod](https://via.placeholder.com/150)

Gammarus. The accompanying woodcut will give a fair idea of Rondelet's drawing, which has the special interest of being, I believe, the earliest known figure of an Amphipod, whether the original were a Gammarus, or, as seems equally possible, an Orchestia. In saying that its facies "represents a human being caricatured or a monkey," Rondelet has probably mistaken the tail for the head.

In ch. xxviii., De Pediculo Marino, he gives the figure of an Isopod, but explains that the φθερ ϑαλαττως of Aristotle applies not only to this, but also to a species, "qui in mari, quod est a Cyrena ad Egyptium circa delphinum est, qui omnium pinguisissimus fit paulbi copia, que delphini opera suppeditatur." The οὐρας of Aristotle, from the fins of the thunny, like a scorpion, and of the size of a spider, is not to be confused, he says, with these φθερα.

1558. GESNER, CONRAD (or GESSNER, KONRAD), born 1516, died 1565 (Encycl. Brit., 9th Ed.)

Conr. Gesner, medici Tigurini : Historiae animalium Liber IV, qui est de piscium et aquatilium animalium natura cum iconibus singularum ad vivum expressis vero omnibus. DCCVI. Continentur in hoc volumine Gulielmi Rodeletii quoque medicinæ professoris Regii in Schola Montpelhiensi & Petri Belloni Cenomani, medici hoc tempore Lutetiae eximii, de aquatilium singulis scripta. Tiguri, MDLVIII.

Boeck, De Skand. og Arkt. Amph., p. 19, gives the date of this work as 1548, and he says, p. 32, that it repeats on p. 994 Rondelet's text without any addition of importance, under the heading De pulice marino Rondeletii. Since the date 1548 was inconsistent with the reference to Rondelet, and the first edition of Gesner's work was not to be met with in England, I sought information from Copenhagen, and Mr. G. E. C. Gad has had the kindness to send me the full title and the date as above given of the first edition in question, from the Royal Library in Copenhagen. The first volume, he tells me, is dated 1551, the fourth volume 1558, and in this latter the heading "De pulice [pulice] marino Rondeletii" occurs not on page 994, but on page 894. In the 2nd Edition, 1620, the notice occurs on pp. 759-760. To Rondelet's account is added "Gignatur et in stagnis marinis similis," and a "Corollarium" about the uses of the psyllus marinus which laps upon the shore. The references in the Index to the account of the Puliculus marinus of Rondelet is given wrongly as p. 649 instead of 604.
Nomenclator aquatilium animantium. Icones animalium aquatilium in mari et dulceibus aquis degentium, plus quam d.m. cum nomenclaturis singulorum Latinis, Græcis, Italicis, Hispanicis, Gallicis, Germanicis, Anglicis, aliiq; interdum, per certos ordines digestae. Tiguri, Anno m.d.l.x.

In Tomus I he includes seventeen orders of marine animals, the Crustata forming the fourteenth. The fifteenth embraces the Testacea, a large portion of which is headed De Crustatis, apparently by a printer’s error. The sixteenth order is formed of the Insecta Marina, “ut sunt, Hippocampus, Eruca, Pediculus, Pulex, Askus, Hirudo mar. Vermes et Luminum quidam, Scolopendra.” On p. 267 he remarks, “Pulicem et Pediculum marinum, quam teun crusta integratur, Insectis potius quam ut Rondeletius Crustaceis, adiumxinus, quod forma eorum tota à Crustatis plurimum differe uelatur, majisq; ad Insecta accedere.”

Among the fresh water animals of Tomus II. he gives Astaeus fluvialiis and Cancer fluvialiis but no Amphipoda. His brief remarks on Pulex marinus are perhaps generalised from what he has read, heard, or seen animals belonging to the Orchestidea, Gammarides, and Cymidæ.

Matthiolum (Mattioni), Petrus Andreas, born 1500, died 1577 (Biographie Universelle).

Commentarii in vi libros Pedacii Dioscoridis Anazarbei de Medica materia, ab ipso autore recogniti, et locis plus mille aucti, m.d.lxxxiii Venetis. (Epistola nuncupatoria, dated m.d.l.xv.)

Pages 278–284 discuss various Crustacea or Crustata, including Cancer, Astaeus, Gammarus, Squillarum, Muta, Pagurus, Cancerul; none of them Amphipoda. He refers to Aristotle’s book iv. ch. 2, discussing the often quoted words “Squillarum enim genere continentur gibbes, crangones, et parve, quae majores quoniam effici possunt,” with the remark, “Quibus liquidus constat, vulgare gammarulos Aristotelis parvas facile esse Squillas, cum ii majores quoniam evandat, quam qui semper parvi in piscarum habentur venales.”

Aldrovandi, Ulisse, born 1522, died 1605 (Biographie Universelle). (The date 1607, given in the Encycl. Brit., 9th Ed., is inconsistent with the title page here quoted).

The second book is De Crustatis, and contains the wisdom of the ancients concerning these animals. In regard to the name he says, “Quae Græci et presertim Aristoteliae μαλακόπρακες, Latini hoc tempore Crustacea vocant : Pilius Crustata, cum inquit, In marinis
REPORT ON THE AMPHIPODA.

Crustata et Cartilaginea priores dentes habent." Nothing certain about Amphipods can be derived from Aldrovandi, though some of his allusions to the small kinds of Crustacea may have them in view. The remark attributed to Pliny is not that which he actually makes. On the contrary, as to these dentes he seems to express a doubt by the words, "At in marinis crustata et cartilaginea primores [sc. dentes] habere, itum echinis quinos esse, unde intelligi potuerit, miror." Aldrovandi's misquotation reappears in Facicoliati's great Latin Dictionary, except that "primores" is there correctly given instead of "priores."

1634. MOUFET, THOMAS, born about 1550, died 1604 (thirty years before his work was published).

On page 321 he says, "Pediculus marinus Insectum est Balneis [Balanis] ectorumque generi infestum, quos moriendo titilandoque in fuorum agit, ut se in arenam projicere aridumque petere coguntur. The figure at the side is not a Cyamus but one of the Cymothoidea. On page 322 he says, Pulex sive Asellus marinus equilium moliorem refert, nisi quod quatuor tantum pedibus (pacc Gesneri dixerim) donatur, et frequentibus longisque saltibus se liberat, a numero pedum. Asellus dictus a saltu, Aristoteles pulex: a dorso gibbosae, Scrofula nuncupatur; color illi lividae cum nigredine. Longitu dor fluvistium, digitum transversum; latitu dor, semidigitum non superat; marinaror major dimensio, qui litorre reflente, et in aquis dulcisbus sepe conspicitur. Venatoribus item spectatibusque mirum agilitatis prevem exemplum." There is a figure given, without name or reference, on the last plate but one, which is probably a generalised representation of this description. It is rather a satire on the expression "ad vivum expressis Iconibus" in the title. The animals referred to may include the sand-hoppers and shore-hoppers, Talitrus, Orchestia, Hyale, as well as the fresh-water Gammarus pulex and the salt-water Gammarus locusta, Gammarus marinus, et hoc genus omne.

1665. SACHS, PHILIPP JACOB, born 1627, died 1672 (Hagen).

The title of this curious and amusing book very fairly indicates its contents, only unfortunately at that time the Crustacea now known as Gammarids had excited little or no attention. On page 53 he mentions that the Squillae are divided into marinus and flustratiles. He then continues: "Marinus rarior secundum Arist. IV. II. 2, in Latas, spinosas, erongones, in Gibbas kőpes et in pareas que nunquam mai ores fluit dividuntur. The Squilla gibbe, he says, are divided by Schoenfeld into two species. With the smaller, which does not turn red when cooked, at the mouth of the Elbe and the Oder they feed pigs and ducks,
so numerous are these shrimps. This may refer to the common eatable shrimp, but what
follows appears to include species of Orchestidæ or other Amphipods, for he says: “In
Hobsatia vocantur Hurren / Dithmarasis Rant / Belgis Carnelen / Carnere / Carneten /
Galls Sauterde, Cheorette, Gneerette, ein Ereqgifte / Anergicæ Gen. f. 127. / Opringfretse.
In Sametorum litoore maxima carum copia est, et alibi quoque in littoribus Germania et
Belgii. Er parve Squilla gibbae avide expetuntur ab Harenghi.” He goes on to say that
many eminent naturalists had stated that the herring fed on nothing but sea-water, an
opinion which Bohn had satisfactorily refuted by finding in a herring’s stomach forty
Squilla gibba (Carnet), and Neueranzius by finding more than sixty, though smaller ones.
(These may have been Hypermna, see note on Thomas Edward, 1868.) On pages 95–97,
under the heading Squilla minima, he gives the following, § ix.: “Ex Squillis parvis et
nomine ferre carent. Germ, ein Zwergfretzein / ein feiner Ghernier quibusdam εἶλαρος
[read εὖλαρος] a colore subfulvo, cocta tamen rubescunt, λεοφόρον manque viridem, modo
luteum colorum Grecis Significat. Ob exiguitatem Vascones Circule quasi Avenam vocant,
quae e Garuma copiosa extrahunt, et pugilation devorant, sicut avenam veteriue. Coci
quidam vocant Brasse, que vox hodie Avenam significat, dicitur in illam, 1, que Romans
Gambarretta dicitur.

“2. Quae Gambaruqio, estque adeo exigua ut mille vic unam libram sequunt. Squillis affine Ani-
malecatum memorat Schonefelti, p. LXXXIII. piscatoribus infestum, quod ad mare Balticum
vulgaris nominat Esefjoc seu Esefuweren / squillis minimis figura respondens, crustaqua
instar iliarii contextum, vic transversum digitum longum retibus et tendiculis, quibus hami
atifuguntur, mire noxium, quae magno piscatorum detrimento arrodit.”

It may be noted that at this date the Crustacea are not included among the Insecta. For
Animal being divided into Perfectum, δεναιναι sanguine venilittum, and Imperfectum, ναιναι
crescunque, quod non habet sanguinem proprium dictum, sed humorem aliun proportionem
sanguinis respondentem, the subdivision of Imperfectum Animal seu crescunque is made as
follows:—
1. In Insectum δεναιναι, quod corpus incisuris distinctum habeat: 2. In molle,
quod molli crete contextum μακακόκεφυμα. 3. In crustaceum, quod tenue cruenta obtectum

1675. Martens, Friderich.

Friderich Martens vom Hamburg Spitzbergsiche oder Groenlandische Reise
Beschreibung gethan im Jahr 1671. Aus eignen Erfahrungen beschieden / die dazu
erfordernde Figuren nach dem Leben selbst abgerissen / (so hierbey in Kupffier zu
sehen) und jetzo durch den Druck mitgetheilet. Hamburg. Im Jahr 1675.

The fifth chapter, p. 83, is headed “Von etlichen Schilf geschlechtner / so auff Grön
landischen / oder Spitzbergen Reisen gefangen werden.” Among these he dis-
tinguishes Krabben and Sterbfische. Of the Krabben he had met with four kinds,
first, the Meersquine as the French call it, next, rothe Krabben oder Garnellen,
thirdly, kleine grate Krabben oder Grand, and fourthly, die so genannte Walfischs
Laarre. In describing the two last of these, Martens has the distinction of having been, so
far as is known, the first to give anything like a definite description of an Amphipod.
For this reason the accounts of his third and fourth species seem worth giving in full, as also
for other reasons the account of number two. They read as follows:—

2. Garnell. Unter den Garnellen die man hier sichtet und die man in Spitzbergen findet is
kein Unterschied. Spitzbergsiche aber seynd von Farben auch ungekocht roth / rother wie
die von Lübeck gekocht zu uns gebraucht werden. Der Kopf ist sonderlich / bestehet von

On page 58, in describing the "Lumbe," he says, "In ihren Magen habe ich gefunden kleine Fische und rothe Garnellen / und etliche Sandsteine. Wie ich dann solche vollkommenlich erkannt / nachdem eine Lumbe im fliegen eine grosse rothe Krabbe auf das Schiff fallen liess / welche ich auch an gemeldten Orthe abgerissen." The woodcuts are copied from the figures given by Martens in his Plates P. and Q.

It seems quite obvious that the Garnell, number 2, with the eyes raised out of the head like Krebs Augen, and with eighteen legs, and capable of being describend as a great red Krebbe, cannot have anything to do with a Caprella. On the other hand these rather curious circumstances are to be noticed: first, that while the description of "Garnell" refers to a life-size figure which is not to be found, the figure under Plate P. is left without any description; secondly, that a copy of this figure, with the word "Garnell" attached to it in a pecuilar manner, as if to avoid all possibility of mistake, is given by Adelung in 1768 to accompany his modernised version of Martens, and is definitely referred to the description of "Der Garnell," while, lastly, Herbst, Nat. der Krabben and Krebs, II. 142-144, under "Cancer (Gammarellus) linearis," refers to "Martin Spielberg, tab. B. fig. I p. 115, Granat," and winds up his account of this species with the words, "Die Vögel fressen diese Thiere als ihre liebste Speise, and halten sich häufig an denen Orten auf, wo man die findet. Man trifft sie aber vornehmlich in den Hüfen zwischen und unten den Steinen im Wasser, und auch in des Wallisches Saam en an, der auf dem Wasser treibt," thus adding to the perplexity by combining a reference to figure i with words obviously borrowed from the account that applies to figure e. Boeck is of opinion that the figure i represents Caprella septem-trionalis, Kröyer, on the ground that no other Caprella is found at Spitzbergen. Mayer, Caprelliden, p. 2, does not accept Boeck's argument, and considers that, as the species represented is undescribed, it would be undeserving of further notice, but for the reference to it in Lütken.

The Kleiner Garnell, number 3, being found among and under stones, may in Boeck's opinion be Gammarnus locuta, that being found in such situations at Spitzbergen. Since the Wallfisch of Martens is known to be the Greenland Whale, Ballena mysticus, Lütken
inverts that its parasite must be that which he has named *Cyamus mystici*, rejecting the name *Cyamus celii*, as having been applied confusedly to several species. Though Martens' drawing of this species, Plate Q, fig. d, is a very odd one, the description is vouched for by Lütken as being in many points correct, and in any case such as should have prevented later writers from confusing the species with the *Pygothidae*.

*Methodus Insectorum seu Insecta in Methodum aliqualem digesta*: a Joanne Rayo, Londini, eelorcv.

"Insecta," he says, "sunt vel *αμυγρόφωτα*, hoc est, que nullam subeunt formae mutationem; vel *μεταμορφοσκέφαλα*, hoc est, que formam mutant.

"Insecta *μεταμορφοσκέφαλα* sunt vel *Arsiδa seu Pedibus destituta*, vel *Pedata*. Ex his nonnulla pedem aliquoties mutant.

Under "Insecta *μεταμορφοσκέφαλα* Pedata," he says:

The third group he thus describes:

The *Holocerda* contain *Terrestria*, *Julus* and *Scolopendra*; *Aquatica*, the Cornish *Scalp*, with 38 feet, *Scolopendra marina*, and *Animalculum bicorpor se bicaudatum*.

The account of the *μεταμορφοσκέφαλα* he concludes with the words, "Hanc Methodum Insectorum intamameditabilium D. Francisci Wullaghby demum." This explains the initials F. W. in the following notice.

*Historia Insectorum*. Opus posthumum, jussu Regis Societatis Londinensis editum. Londini, m.dcc.x.

On pages 43, 44, the following notices are given:

THE VOYAGE OF H.M.S. CHALLENGER.

directe antorsum extendit; ad quorum radices alia duae, multo breviores. Corpus ferè pellucidum, celerrimè movetur saltando ut Pulex, sed praecipue extra aquam. Pedum secundum par chelarum instar lata. Inter pedes et caudam alia sunt sive Appendices, sive pedes, graciles et breves quibus eva adhurree probabile est ut in Locius. Cauda cirrorum fasciculo constat. In litoribus sub lapidibus innumerè inveniuntur.

"Pulex fluvialitis, q. An à marino differet. F. W. Pedum quinque paria posteriora longa et gracilia sunt, duo capiti proxima breviora, non chelis sed (ni fallor) hamulis donata, ut in Squillis. Juniores matribus adherrent, quae in circulum ferè se contorquent, et pullos amplexuntur. A capite duo precedent Antennarum paria. Quae in nostris rivulis sunt, non saltant ut marine, sed incurvans se et natans podiceo exercendo satis celeriter. Ha in aquis calidis in specie Custoxa prope Vincentiam in Italia inveniuntur, ubi nulla animalia vivunt."

Of these three notices the first probably refers, as pointed out by Pallas himself, to Oniscus volutator, Pallas, 1766; the second, to judge by the short upper antennas, the large-handed second feet, and the saltatory motion, especially out of water, no doubt principally refers to Oniscus gammarellus, Pallas, though the attendant query implies that species of Gammarus were also in view; the third notice evidently includes two species, that from the warm springs of Custoxa in Italy being, Boeck says, Gammarus pungens, while the other is obviously the common fresh-water Gammarus pulex.

1728. FRISCH, JOHANN LEONHARD, born 1666, died 1743 (Hagen).

In part vii., section xviii., page 26, is headed "Von Krebs-formigen Wasser-Wurm." Of this he says, "Der grüeste wird etwan Zoll-lang die Übereinkunft mit Krebsen, der Gestalt nach, leidet gar wohl, dass man ihm davon einen Namen giebt, weber noch keinen hat." With the longer upper antennas he thinks it feels what is in front of and beside it, with the smaller lower ones it feels what underneath might do it harm or supply it with food. He concludes that it cannot be one of the insects which undergo further transformation. Its fresh-water habitat, and the figures which Frisch gives, justify Boeck's opinion that Gammarus pulex is here in question. It is depicted on pl. xviii. figs. 1, 2, 3. The whole plate is reproduced in the accompanying woodcut.
1734. Seba, Albert, born 1665, died 1736 (Biographie Universelle).

Locupletissimi rerum naturalium Thesauri accurata descriptio, et iconibus artificioissimis expressio, per universam physices historiam. Opus cui, in hoc rerum genere, nullum par exstitit. Ex toto terrarum orbe collegit, digestit, descriptit, et depingendum curavit Albertus Seba. Tomus i. Amstelodami, MDCCXXXIV.

On page 142 he gives Pediculi ceti, Poux de Baleines, with a sailor's story that they slip into the ears of the whales and pierce them with their bite. Lütken says that the figures, pl. xc. fig. 5, E, F, G, H, may with tolerable certainty be referred to Cymamus mysticeti, i.e., to the Cymamus which infests the Nordhval (a whalebone Whale, known in English as the Right-whale, the Greenland Whale, or the Common Whale), Balena mysticetus, and that E, F represent a male, G a female, and H a young male. The “quatre pieds au milieu longs et menus” are drawn as if articulated.

1735. Linné, Carl (also Carolus Linnaeus, Carl von Linné, and, in Trupp’s translation of Stoever’s Life, Sir Charles Linnaeus), born 1707, died 1778.

Systema Naturae, systematice proposita per Classes, Ordines, Genera, et Species. Lugduni Batavorum, MDCCXXXV.

In the Regnum Animale, the fifth of the six classes is devoted to the Insecta, “Corpus crista ossa cutis loco tectum. Caput antennis instructum.” This class includes the Coleoptera, Angioptera, Hemiptera, and Aptera (“ala nullae”). The Aptera contain the divisions or genera, “Pediculus, Pulex, Monoculus, Acharus, Araneus, Cancer (“Podos 12, priores cheliformes”), Oniscus (“Podos 14”), Scolopendra.” Cancer contains the species “Cancer, Pagurus, Majas, Gammarus, Astacus, Squilla, Eremita.” Oniscus contains “Asellus Officin. Asellus aquat.”

1738. Linnaeus.

Animalia per Sveciam observata.

In this work the pages are headed Scient. Svec. A.MDCCXXXVI. Among the Aptera under Cancer are given, besides Cancer marinus, Majas, Astacus, Gammarus, four short descriptions of species of Cancer, and the name “Cancillus, Matth. Diosc., 230,” corresponding probably to what he elsewhere calls Eremita, Cancillus being Swammerdam’s name for Bernard l’Hermite, in 1681.

1740. Linnaeus.

The Regnum Animale has six classes: Insecta the fifth, “Corpus ossibus cutis loco tectum, Caput antennis instructum.” The Insecta include four orders, the Aptera, “ala nullae,” being the fourth. These comprise the genera, “Pediculus, Pulex, Pedura, Monoculus, Kermes, Acharus, Aranea, Scorpio, Cancer, Oniscus, Scolopendra.” Cancer (“Podos X; primores
THE VOYAGE OF H.M.S. CHALLENGER.

*Ovali duo. Cauda foliata*”) includes “Cancer, Pagurus, Majas, Gammarus Astacus, Squilla, Enemita.” *Oxyscus (Peleus XIV.)* includes “Milleps, Asellus aqu.”

With the above agree Editio quarta ab Auctore emendata et aucta, Parisiis MDCCLXXIV.

In a German edition, Halle, 1740, with a preface by Johann Joachim Lagen, *Cancer* is defined “Peleus 12, priores cheliforones. Mit 12 Füssen, da die vordersten Scheren sind.” The German explanation of *Gammarus* is “Der kleinste Krebs mit langen Schwanzen (Spring-Krebs”), as though *Gammarus* were an Amphipod, which in the intention of Linneus it clearly was not. According to Herbst, Krabben und Krebs, ii. pp. 42, 43, “Cancer (Astacus) gammarus” is the great common lobster, which from the Greek *kAmyapos*, through the Latin Gammarus, derived its name in Danish *Hammer*, in German *Hammer*, in French *Homar* (later *homard*).

1741. Egede, Hans, born 1686, died 1758 (Biographie Universelle).

Cap. vi. p. 36, is headed “Hvad Slags Diur Fiske og Fugle den Grønlandske, Sæ giver af sig etc.” The accompanying plate contains a figure of a Hvalfisk, with a minute reproduction having the words “pag. 39, i: 24” above it, and below it “Hvalf: luus” and a figure of that creature, which is obviously borrowed from Martens. On page 39, where the smallness of the creatures which form the food of the whale is contrasted with the size of the whale itself, the author says, “Nu skalde man fulde kokken ved et salt Krop maas nødvendig behøve mange andre Fiske og Sæ-Dyr til sin Føde; men hans spise er indt et uden noget som kaldes Hvalfiske Aas, af Skikkelser og Størrelse som i Figuren ses, det er brun af Farve haver 2. smaa Fløser hvormed det beveger sig i Vandet, dog saa langeomt, at man kanser dem op af Vandet med Hamden, som med et Øsse-Kar. Dette Slags Aas er veigt, Saa maas man rivet det i mellem Fingrene, er det som Flet eller Thran.” From which it may be supposed that Egede has confused the *Cymuna* which feeds on the whale with the Gammarides or other small fry on which the whale feeds.

1743. Klein, Jacob Theodor, born 1685, died 1759 (Biographie Universelle), died February 27, 1760 (Hagen).

In the “Preludium de Crustatis in specie de Squilla et Insectis Malacostracis Maris Balthici ubi et de Oniscis,” he says, p. 32, “Primi generis malacostracae sunt; Canceri, Gamari, Squillae. Secundi: Extoma sive Insecta Crustata.” On p. 34, the Squilla, which he identifies with *sapid* and *sapidus* of Aristotle, are thus defined:—“Squilla sunt malacostra, corpore prolongato, quadrumenius gibba; quintus caeruleus cheliformibus, d’erubetibus octo, in exitu acutatis, cauda tabellata.

“d/ Allucinatit sunt autores, qvi Squillarum brachia forcipibus sive chelis carentia scripserunt; confrrantur figura, quam ad vivum fieri fecimus. Error inde enatus, quod locustas, urae
1745. LINNAEUS.

He describes *Cancer pulex fluviatilis*, p. 96, which he found on the strand at Oeland. From the mention of oblong red blotches on the sides of the segments, Boeck conjectures that this may be *Gammarus marinus*. Bate and Westwood, it may be noticed, regard the red spots on the sides as a distinguishing mark of *Gammarus locusta*. Brit. Sess. Crust., vol. i. p. 380. The *Cancer macrourus coruleus thorace articulato*, p. 260, which Linnaeus found on the shore in Gottland, may in Boeck's opinion be *Gammarus locusta*. Hans Ström, in 1765, expresses the opinion that Linnaeus has here given two descriptions for one species. Bate and Westwood and Boeck alike refer to the *coruleus species* of p. 260 as a synonym of *Gammarus locusta*, while the species of p. 96, with the red blotches, is not given as a synonym of any species either by Boeck or the other authors. The observation of Bruzelius, that *Gammarus locusta* is the only species of *Gammarus* which occurs in Gottland, is a negative argument on which but little stress can be laid.

1746. LINNAEUS.

Fauna Suecica sistens Animalia Suecica Regni, &c. Lugduni Batavorum, 1746.

The two last species of the genus *Cancer* are thus given:—

"1233. Cancer macrourus rufescens; thorace articulato. Raf. ins. 44. Pulex fluviatilis.

Both of these, in Boeck's opinion, refer to *Gammarus locusta*, the references to Ray's and
Frisch's fresh-water forms being out of place. But, since under 1253 the reference to the Iter Od. and the word "rufescens" imply that the shrimp with the red blotches, of the Ölandska resa, p. 96, is in question, Boeck can hardly be right in calling it in one place marinus and in the other locusta.

1747. LINNÆUS.

For Cancer this fully agrees with the edition of 1740, and, as in the German edition of that date, against "Gamarus" is placed "kleinste Krebs mit langem Schwanz (Springkrebs)."

1748. LINNÆUS.

In this, as in previous editions, the Animale Regnum has six classes, the Insecta being the fifth, which is divided into seven orders, of which the Apera, "alae nulæ," are the last. This contains eleven genera, Pediculus, Pulex, Pedura, Monoculus, Acurus, Aranes, Scorpio, Cancer, Oncites, Scopodenra, Julne. "Cancer" contains eight species, Cancer, Pagurus, Magus, Gammarrus, Astacus, Squilla, Eremita, Pulex aquatus. "Oncites" has three, Entomon pyramidale, Milipes, Asellus aquaticus. Cancer is defined as having "Pedes X : primores cheliformes. Oculi II. Cauda foliosa."

A copy of this edition was published Lipsiae, 1748.

1749. KLEIN, J. T.

Jacobi Theodori Klein Historiae Piscium Naturalis promovendæ Missus quintus et ultimus de Piscibus per branchias apertas spirantibus. Gedani, 1749.

In the Fasciculus Septimus, on Callarias (Gadus, Moribus, the Cod), he says, page 9, "Delectantur Callarias squilla cinerea (preclud. de crustatis, p. 36) & pedibus marinis; Horum meliores figuras superaddimus Trib. IV. I. A. naturalis magnitudinis. C sub vitro aequus sed pedibus mutilus, B vero exacte animalculum representat." He then proceeds, with a reference to "Kilianus Stobæus (Act Suec. 1733. p. 79)," to retract the opinion expressed in his earlier Preludium, "quod nullem insectum crustaceum, nemum caprom Aristot. exuvias suas deponat, neque caneri neque astuci marii." His figures evidently refer to Gamarus locusta, although, as Boeck notices, the secondary flagellum is not given, nor the eye correctly drawn.

1751. LINNÆUS.

Skånska resa, på höga Överhetens befallning förrättad år 1749. Stockholm, 1751.

The Pulex fluviatilis which Linnaeus found skipping about on the strand like a grasshopper, is clearly, Boeck says, Orchestia littorea. It must therefore be distinguished from the Cancer.
pulex fluviatilis of the Ölandska resa, but there is always the possibility that Linnaeus may
have given the name fluviatilis from having observed a true Gammarus pulex, may have
described the red blotches from a Gammarus locusta, and in the statement, Fann. Sv.
1253, “Habitat ad littorium maris vulgatissimus,” as well as in this work, may have been
referring to the Orchestiidae.

1751-3. Steller, Georg Wilhelm, born 1709, died 1745 (Biographic Universelle),
died 1746 (Hagen).

Georg Wilhelm Stellers ausführliche Beschreibung von sonderbaren Meer-
thieren, mit Erläuterungen und nötigen Kupfern verschen. Halle, 1753.

The passages from the Latin account, 1751, are quoted by J. F. Brandt, 1840. They fully agree
with the German rendering, 1753, except that where the German says, “der Brustring
stehet eine halbe Linie vor;” the Latin says that this (which probably means the second
person) segment “dimidiam lament refert.”

At page 106 of the Beschreibung, Steller says, “Die Meerkuh wird von einem besondern Ungeziefer,
welches gleichsam eine Laus ist, geplaget. Dasselbe hält sich in den ranztühlen Füssn,
in den Brüsten, in der Warte an beflüllten Orten, im Hintern, und in chagrín—ähnlichen
Höhen der Oberhaut in grosser Menge auf. Indem sie auch die Oberhaut und Unterhaut
durchblieben, so entstehen von der auslaufenden wäßrigen Feuchtigkeit Wartzen, die
hin und wieder zu sehen sind. Allein diesen Insecten stellen hinwieder die Meermöwen
(Lar) nach,” which kindly pick them off the creature’s back.

“Dieses Ungeziefer ist mehrerehls einen halben Zoll lang, voll Ringe und sechsfüssig, weiss
oder gelblich und durchscheinend. Der Kopf ist lenglisch und spitzig, grösser als der
Saman von Hirsch. Vor den Stirn sind zeyw kurze knotige Fühlhörsner, welche eine
halbe Linie lang hervor gehen. Ausstatt des Unterkinnbackens hat es zeyw dünne Aarragen,
jedes mit zwey Gelencken, wie ein Meerkuhe, am Ende sehr spitzig und wie Nagel; das
Uebrige bestehet nach Anzahl der Füssse in sechs Ringen, die quer über gehen, auf dem
Rücken gewölbt, und eine dichtthil Linie breit sind. Der Ring oder Pantzer auf der
Brust ist Zwemal breiter, und die Rings werden immer enger, je näher es nach dem
Schwanze gehet. Der Brustring stehet eine halbe Linie vor; an diesen haften zur Seiten
ein paar dicke Scheren mit zwey Gelencken. Eine jede Schere ist mit einem biegamen
Stachel versehen, womit es in die Oberhaut des Manatli sehr feste fasset. Die übrigen
Füssse sind schlanck; alle endigen sich mit Stacheln, und werden allmählich kürzer.
Die zwey letzten, welche die kürzesten sind, laufen aus dem Ringe des Schwanzes; sie sind
das Ende vom Körper, und das Thier schiebet sich darauf fort.” There are other refer-
ences at pages 54 and 97 to this parasite upon the (now extinct) Sea-Cow, Rhynina localis.
Steller’s description, though for the time carefully detailed, is so perplexing that J. F.
Brandt proposed to place the creature in a new genus as Sirenocymus rhynitis. Lütken,
1873, gives a Danish translation of the passage above quoted. He provisionally accepts
the species as Cyamus rhynitis, J. F. Brandt, while agreeing with Brandt’s suggestions that
it may be some Proto-like form, or a link between the Cyamides and Caprellides, and that
there may still be a chance of finding some species of Sirenocymus on the still living Sea-
Cows, the Dugongs and Manatees.
1754. LINNÉUS.

The Oniscus ceti may be, Lütken thinks, the Cyamus which lives on Balana mysticetus. He quotes the description from p. 89, "Oniscus ovalis, segments excepto secundo in medio interruptis ('med afbratna leder'). Caput parvum. "Antennae 2, singulae articulis 4; corpus ovale, magnitudine Ricini, sectum segmentis 7, interruptis in medio, excepto solo secundo. Pedes paribus 7, quorum 1 minutum sub capite, 2 crassius ovatum, 3 & 4 mutica, 5, 6, 7 ovata, uncinata." Seba's figure is referred to. The statement that the segments, except the second, are interrupted in the middle, Lütken considers rather obscure. It seems to allude to their being articulated to one another only by the central portion, while between the first (cephalothoracic) segment and the second segment there are no such lateral interspaces.

1755. RÖSEL VON ROSENHOF, AUGUST JOHANN, born 1705, died 1759 (Biographie Universelle).

He accepts Linnæus's classification of the Crustacea with the Apterous Insects, for the additional reasons that, like insects, they have no bones, that their mouths open and shut not from above and below but from side to side, that they cannot shut their eyes, and that their breathing is not through mouth or nose but through lateral openings in the body (p. 306, mis-pagination for p. 308). Pages 351–357 describe "Die kleine Garneele unserer Flüsse. Tab. IXII." From its agreement with the marine Garneele, Rösel thinks that the little river shrimp would fitly be called die kleine Flusgarneele, and as the Garneele is called Squilla in Latin, he explains that the inscription Astacus fluviatilis on his plates lxii. and lxiii. ought to read Squilla fluviatilis for pl. lxii., and Squilla marina for pl. lxiii. He carefully observed the habits and structure of his specimen of the former, which cannot be confused with Gammarus pulex, if any trust is placed in Rösel's statement, "Vom Leib ist solche ziemlich schmal, und diesen bedecken vierzehn Schuppen, von welchen die sieben hintersten oder letzteren, mitten auf dem Rücken mit rothen scharfen Spitzen versehen sind, welche, wenn sich die Garneele krümnet in die Höfe gehen und hervorragen." Burgersdijk, who discusses the synonymy and characteristics of Gammarus pulex with great fulness, retains the name Gammarus roesletii, first given to Rösel's species by Gervais in 1835, but there seems no adequate reason for rejecting the specific name fluviatilis given by Rösel himself.
REPORT ON THE AMPHIPODA.

1756. Brisson, Mathurin-Jacques, born 1723, died 1806 (Biographie Universelle).

Regnum Animale in Classes IX distributum, etc. Parisiis, m.dcc.lvi.

These nine classes are Quadrupeda, Cetacea, Aves, Reptilia, Pisces cartilaginei, Pisces propriè dieti, Crustacea, Insecta, Vermes. As to Classis VII., he says, "Horum character est Caput antennis instructum: et pedes octo et ultra."

1756. Linneüs.

Systema Naturæ. Editio multo auctior et emendatior. Lugduni Batavorum. m.dcc.lvi.

The Aptera are the seventh order with the same genera as heretofore. Cancer is thus defined "Pèdes X. vel XX., quorum duo priores semper cheliferi. Oculi duo stiliformes. Cauda foliosa, quandoque longa, intemnum brevis." The species are as given in 1748.

1758. Linneüs.

Systema Naturæ. Stockholm, vol. i. 1758. (The eleventh, reckoned by Linnaeus the tenth, edition.)

On p. 636 Oniscus ceti is described as in 1754, but besides the reference to Mus. Ad. Fril. and to Seba, one is given to Martens. (Lütken.)

1758. Vandelli, Domenico, born about 1732, died a little before the end of the century (Biographie Universelle).

De Aponi Thermis. Patav., 1758.

See Note on Olivi, Zoologia Adriatica, 1792.

1759. Baster, Job, born 1711, died 1775 (Biographie Universelle).

Opuscula subseciva, observationes miscellaneas de animalculis et plantis quibusdam marinis, eorumque ovarii et seminibus continentia. II. Tom. Harlemi, 1759–65.

Natuurkundige Uitspanningen, behelzende eenige Waarnemingen, over sommige Zee-Planten en Zee-Insecten, behovevs derzelver Zaadhuisjes en Eijernesten. Haarlem.

The original Dutch and Latin editions do not seem to differ from my own copy, which is a "new Dutch edition," published at Utrecht without date, and of which R. T. Maitland, in 1876, observes that it is "volkomen denzelfden druk als de oorspronkelijk uitgave van 1762 alleen met gewijzigden titel." In the first section of the first volume, pp. 37, 50, pl. iv. fig. 2, a, b, c., Baster describes and figures "a curious little animal found on Zee-mos," "mirum animalculum in corallinis," which Boeck thinks is without doubt the male of Linnaeus's Caprella linearis. Mayer does not feel so sure of this, for Linnaeus himself, Syst. (Zool. Chal. Exp.—Part LXVII.—1887.)

XXX 3
Nat., ed. xii., 1767, gives not *linearis* but *atomos* as Baster's species, defined as "Macrourus linearis articularius, manibus adactylos, pedibus undecim." Mayer remarks that Baster has given to the hand of the second gnathopod an armature of five teeth. In my copy there are only four. He also observes that Baster figures as the tailpiece a protruding portion of the intestinal canal. Probably the eleventh (!) leg in Linnaeus' account is due to this supposed tail. The figures from Plate IV., which "I. Rhodius ad vivum piuxit," are reproduced in the accompanying woodcuts. Figures A, B, are the natural size; C, the enlargement of B; "a, Deszelfs Antennae. b, Eerste paar pooten;" "g, Zyn Staartje en Anus."

---

1758--SEBA, ALBERT.

1760.

Locupletissimi rerum naturalium Thesauri, &c. Tomus iii. Amstelodami.

1760. LINNAEUS.

In an edition of the Systema Naturae, dated Halle Magdeburgicae, MDCCLX. (ad editionem decimam reformatam Holmiensem), "Canor" is the tenth among fourteen genera of the Aptera. It is here defined "Pedes utrinque VIII.; proter Manus 2 chelatus. Oculi II. distantes, pedunculati, elongati, mobiles. Palpi II magni, cheliferi. Cauda articulata, inermis." The
last division, headed "Mancroani manibus adactylos, testa thoracis brevissima, nec thoracum totum tegente," contains the following numbered species, 51 Maudis, 55 Seytharns, 56 Putei, 57 Locusta, 58 Salinus, and 59 Stophalis, with the note, "Species 54–59 ob thoracum Lorica destitutam et singularem structuram corporis adeo a reliquis Cucinis recolunt, ut facile genus distinctum constituerent." For Oiscus celi, see the note on the edition dated 1758, of which the edition 1760 is a copy.

1760. Gronov, Lorenz Theodor, born 1730, died 1778 (Biographie Universelle).

Pages 31–40 contain "Observationes de animalibus aliquot marinis aequo inconstantibus atque in littoribus belgicis obviis" by Laur. Theod. Gronovius. Among other things he found, he says, some very minute Crustaceans, seen by the microscope to come near to the creatures which go by the name of Pelliculi Marinii, which Linnaeus mixed up with the Canceri, though they differ from them toto cero. He therefore determines the name and generic marks as for a new genus, thus:—"Squilla. Corpus filiforme, articulatum, longum, teres, in dorso reclinatum natans. Antennas subulate, articulate, quatuor. Pedes prolongi gracies quatuordecim utrinque aciculati VII, binis anterioribus paribus cheliferis. Oculi duo, ad latera capitis, non stilliformes, simplices utrinque unicus. Squilla acutata pedibus quatuordecim. Fig. 8, 9. Corpus rotundum atique depressissimum superne planum. Oculi duo, spherici, simplicissimi, hand styliformes quaedam medium in aasta cirriferis, utrinque in lateribus unicus. Antennas quatuor, articulatas, subulate, simplices, in antico capite site, per paria dispositae. Corpus prelongum, teres, articulorum sex, excepto capite. Articulis secundo & tertio in gravidis intra pedes adhaeret pretensis atque utrinque convexa membrana ova includens; quaedam exhibi fig. 10. a. b. qui articuli respondent fig. 9. Litteris a. b. Pedes graciles, longi, in univisum quatuordecim, utrinque aciculati septem, horum bina priora paria chelis sunt instructa; reliqui vero pedes sunt subulati natatorii. Singulam par est adnexum articulo. Chela anteriorum pedum sunt monodactylo, prioris paribus non dentatae, secundis vero dentatae & aculeatae. Cauda nulla. Ultimum pedum par corpus terminat. Dum natat dorso incumbit atque velocissimn ope posticum pedum per aquas transiens. Color cinereus; Calida temporata in obscurum lucet dum vivit. Frequensissimum animal in nostro mari." A very good figure, much more accurate than the later one by Sibber of his Phthisica Marina, accompanies this description, which evidently applies to Prolo ventricosa, O. F. M.

1760. Godeheu de Riville.

He gives a figure, pl. x. fig. 6, of a Caprella from Ceylon, which in Boeck's opinion may be Caprella ultima, Sp. Bate. Mayer, however, finds nothing to justify a more definite determination than that it is the male of some species of Caprella. Caprella ultima, Sp. Bate, may itself, he thinks, be a synonym of Caprella aquilfera, Say. De Riville's figure has what for a Caprella would be a long tail, "G. sa queue armée aussi d'un crochet," but it probably only represents one of the hind legs.

Insecta Musei Greecensis, que in ordines, genera et species Juxta Systema naturae Caroli Linnaei digessit Nicolaus Poda. Greecii. Anno, M. DCC. LXI.

On page 121 this author, who lived at Grasse, in the south of France, gives the following description of an animal which he places among the Aptera in the genus Podura: 

"Cancer Pedis. 2, P. oblonga, nitens, ferruginea. Habitat sub saxis post maris refluxum Tergesti. Cl. Scurota in epis." This is referred to by Scopoli under Cancer locata. In the opinion of Pallas, 1772, it is his Oniscus gammarellus.

1761. LINNEIUS.

The entries relating to the Amphipoda are on pages 496, 497, 499-501. Among the Insecta Aptera in the genus Cancer are given:

"2041. Cancer Pulex macrourus articularis, rostro acuto manibus adactylis, cauda attenuata spinis bifidis.

"Raj ist. 44. Pulex fluviatilis.

"Frisch, germ. 7, p. 25, t. 18. Vermis aquatilis canceriformis.

"It. ool. 42, 96. Cancer Pulex fluviatilis dictus.

"Svecia Marta. Scania Sandhara.

"Habitat ad littorae maris vulgatissimus, frequens, rodens retia, conficiens sceleta piscium; natat in dorsa.

"DESCR. Pedes 7 parium, quorum 4 paria antorosum versa; horum paria antica chelifera digito mobilis sseque pollicis. Pedum 3 paria postrema retorum versa.

"2042. Cancer Locata macrourus articularis, rostro obtuso, manibus adactylis, cauda attenuata spinis bifidis.

"Habitat in montem Thorshurg in mari juxta Gotlandiam.

In the genus Oniscus there are given:

"2056. Oniscus Ceti ovalis segmentis distinctis, pedibus tertii quartique paris linearibus muticos.

"Habitat in Cetis Oceani.

"DESCR. Corpus ovale, 7 articulis distinctis. Caput, quod primus articulus, minimum. Pedes 1, 2, 5, 6, 7 chelis crasis uneque mobilii acuto terminati. Pedes vero 3, 4 paris filiformes muticos; primum par sub corpore situm est. Corporis articuli magni remoti et distincti, quam in reliquis speciebus.

"2062. Oniscus bicaudatus semicylindricus, caudis dubius longitudinalis corporis.

"Habitat ad littora maris Norvegici. Marten.

"DESCR. Corpus semicylindricus, fascia, 12 articulis. Pedes utrinque 7, albi, quorum solitarii
postici reflexi. *Caula* 2, protantes, longitudinalis corporis, 5 articulis; quorum tertius major, longior et crassior; primus et secundus brevis; quartus et quintus angustiores. Inter haec caudas, caulae 2 aliae, breves, subulate."

Boeck, under the obviously misprinted date 1771, remarks that as number 2041 of this work is identified with number 1253 of the earlier edition, the synonyms from Ray and Frisch, and Linnaeus's own Skånska Rea, ought not to have been cited. Lütken calls attention to the improved definition of *Oniscus ceti*. The *Oniscus bicaudatus* must not doubt be identified with the species which Linnaeus afterwards called *Cancer grossipes*, the antennae having been mistaken in the present instance for the tail, as O. F. Müller remarked in 1776. By Willughby and Ray, in 1710, this species was well-named cornutus, a name unfortunately excluded as pre-Linnaean. The *Astacus muticus* of Gronov, 1762, is only accidentally binominal. The *Oniscus bicaudatus* of Linnaeus, 1761, and his *Cancer grossipes*, 1767, must be given up as names founded on egregious mistakes. We are thus led to the *Oniscus volutator* of Pallas, 1766 and 1772, as rightfully determining the specific name. Though the *Corophium longicorne* of Latrille and numerous authors was highly appropriate, the name *Corophium volutator* is sufficiently suitable to an animal which may commonly be seen twisting and turning about at the entrance of its gallery in the mud, and which, according to Pallas, makes similar gyrations when in the water.

1761. Sulzer, Johann Heinrich, born 1735, died 1813 (Hagen).

Sulzer gives a figure of Röel's *Astacus (Scylla) fluvialitis* on pl. xxiii, fig. 152, and a. 4. He describes it on p. 192. On p. 65 of the explanations of the plates he says, "Fig. 152. Krebs, lange Scheerehen, gegeieterd, Hände ohne Finger, dünn angeheilender Hauz mit zweifassen Dörmen. Locusta. Linn. Syst. Nat. Cancer, 57."

1762. Baster, J.

Opuscula, Tom. II. Liber 1, Harlemi, 1762.

Natuurkundige Uitspanningen, &c.

In the first section of the second volume, on pp. 34–36 and 49, pl. iii. figs. vii., viii., 1–6, he describes the hopper or sea-flea, in the vernacular "Een springertje van Zee-Vlees," with references to "Palex marinus, Klein, Miss. v. Tab. iv. a, b, c.; Seba, Thes. iii. Tab. xxii., N. 11; Linn., Syst. Nat., N. 36. Cancer macrourus, articulis manibus adactylos, cauda attenuata, spinis bifidos; Röel, Suppl. Tab. lxiii. p. 351; Frisch, vii. Tab. xvii. 18, p. 26." This in Boeck's opinion is probably *Orchestia littorea*, but Baster's remark that it is found not only in sea and brackish water but also in freshwater rivers and even in ponds, especially among and under the fronds of *Algo marina*, implies that he did not distinguish the actual creature described from other species such as *Gammarus pulex* and *Gammarus locusta*. His figure may refer to *Orchestia (littorea) pinnamarelus*, but if so he has fallen into some confusion in describing the lower antennae, as well as in the synonymy.
1762. Desmarts.

Mélanges d'histoire naturelle. 1762.

1762. Geoffroy, Étienne Louis, born 1727 (1725), died 1810 (Hagen).

Histoire abrégée des Insectes, qui se trouvent aux environs de Paris; Dans laquelle ces Animaux sont rangés suivant un ordre méthodique. A Paris, m.dcc.lxii. (This edition is anonymous. The work was published with the author's name in 1764.)

In the second volume, under "Cancer, Le Crabe," Geoffroy gives two species, the first being l'écrevisse (Astacus fluviatilis), well known in France as an article of food. The second he thus describes, pp. 667–668: —

Pl. XXI

Fig. 8.

"Réf. ins., p. 44. Pulex fluviatilis.
"Her Odland. 42, 96. Cancer pulex fluviatilis dictus.
"Charlet. exercit. p. 57. Squilla."
REPORT ON THE AMPHIPODA.

*Rosel, ins. vol. 3, suppl. tab. 62.

La crevette des ruisseaux. Longueur 7 lignes. Largeur 2 lignes. 

Cette crevette est d'un jaune couleur de rouille; ses yeux sont noirs; ses antennes sont fines et assez longues, à peu près de la longueur des deux tiers du corps. Elle a cinq pattes de chaque côté & plusieurs appendices à la queue. Tout son corps est composé de douze anneaux sans la tête; quatre de ces anneaux composent le corcelet, qui dans l'écrevisse est d'une seule pièce. Cette crevette est appalitie par les côtés; aussi est elle toujours posée sur le côté, soit qu'elle se meue, soit qu'elle reste en place, & lorsqu'elle marche, elle approche par des mouvements vifs sa tête & sa queue de l'autre.

"On trouve communément cette crevette dans l'eau courante des petits ruisseaux, elle est en grande quantité dans la rivière des Gobelins. Souvent les plus petites se retirent & se mettent à l'abri sous le ventre & entre les pattes des plus grosses."

The figures, life-size and enlarged, are here reproduced. It is obvious that Rosel's species Astacus (Squilla) flaviventris, is represented, though Geoffroyis probably describing Gammarus palerus. Boeck rather singularly remarks, "Denne Abbildung er kopieret af Sulzer (233), Tab. xxiii, Fig. 152," the number 253 being a reference to the title of Sulzer's work in 1761, of which Boeck takes no further notice. The figure in question has fourteen segments, independently of head or telson, which is obviously too many, although in agreement with Rosel's description. The last seven are strongly dentate medio-dorsally. The figure, being a striking one, was frequently repeated, without regard to its accuracy or its fitting the species, the description of which it was supposed to illustrate. Herbst in his large work, does in his small one, alike use it, the former for Cancer (Gammariscurus) palerus, the latter for La Crevette des ruisseaux, Gammarus palerus. An interesting discussion of the subject will be found in Dale and Westwood, Brit. Sess. Crust., vol. i, pp. 388-396.

Geoffroy shows in the figure a series of seven feet, but does not take the trouble to reconcile this with the definition which he gives of Cancer, including "Dix pattes, les deux premières en forme de pinces." On the contrary, he describes his species as having "cinq pattes de chaque côté." The statement that the body is composed of twelve annuli without the head, is an improvement upon Rosel's account, but all the same not in agreement with the figure.

1762. Gronov, Lorenz Theodor.

and to "Pulex marinus, Klein. Pisc. Miss. 5. p. 9. Tab. 4. fig. A. B. C.", with the concluding remark, "Habitat in mari Septentrionali & stagnis aquae subsalae. Color cinereascens. Magnitudine et forma convenit cum precedentis." Number 291, the corresponding notice in his larger work, has, as will be seen, a very different concluding observation.

1762. STROM, HANS, born 1726, died 1797 (Hagen).

Physiske og Oeconomiske Beskrivelse over Fogderiet Sondmor, I. Deel, 1762.

He records a Pulex cancriformis or Cancer macronurus raflescens, which is found under stones on the beach or in the stomachs of fish. Further, he gives in plate i. figs. 12-13, a very recognisable drawing of Hyperia medusorum under the name of Pulex cancriformis, antennis brevissimis, corpore laticore, and states that it is found on large Medusæ (Boeck).

1763. SCOPOLI, JOHANN ANTON, born 1723, died 1788 (Biographie Universelle).

Entomologia Carniolica exhibens Insecta Carniolica indigena et distributa in ordines, genera, species, varietates. Methodo Linneoana. Vindobonæ, MDCCCLXIII.

Scopoli changes the Linnaean name Aptera into Pedestria for his seventh order. He defines Cancer thus: "Palpi (2) chelati. Ocelli (2). Cauda inermis," and names the species numbered from 1123-1137, Mæmus, Depurator, Pagurus, Maia, Gammarus, Astacus, Squilla, Bernhardus, Diogenes, Strenuus, Nutritus, Crucetatus, Mantis, Locusta, Pulex. The last two are described as follows:—

"1136. Cancer Locusta?
"Linn. Syst. Nat., p. 634.
"Faun. Soc. 2, 2042.
"Habitat abunde, circa littora Maris, sub saxis, prop. Tergastum.
"Statura fere Pedura Aquatilis. Habitat Cancri palpibus. Corpus pelius, ferrugineum, suturis (11), & denno septem alios utrinque ad bases femorum. Antennæ attenuatae, articulis

"1137. *Cancer Pulex.*

- Faun. Svec. 2. 2041.
- Fresch. Ins. 7. Tab. 18. fig. 1.
- *Habitat sub Hypnus, & saxis, ad secaturigines fontium.*
- *Hic certe idem, qui a Frescho pictus, sed semper habitans in aquis dulcisibus, non vero circa Mare, hinc dubitato cum priore a Linnaeo confundii, cum *Cancer Locusta* ab eo aliter describatur quam a nobis.* Hic, quando exsiccatus, fulvus reddittur, natat in latere, rarius in doro; os fulvum gerit, nec corpus postice acuminatum. Interim certum adeo nobis cum priore a *Cancer* alio diversum esse, ut novum Genus non inmerito constituet.

The "Cancer Locusta?" Pallas considers to be his *Oniscus Gammauridis*, since known as *Orchestia gammaurellus*. The "Cancer Pulex" is in all probability the *Gammauris pulex*, Audouin.

"1140. *Oniscus Bicaudatus*," with "cauda duplex : utraque biseta," which "habitat copiosus Torgesti ad litus maris, inter saxa curstans," is said by Franz Leydig to be the same as *Ligia italic*, Fabr.

Yents, Institutions of Entomology, 1773, says that Scopoli and Geoffroy call the shorter antennæ the palpi in the *Cancræ macorum*. It may therefore be noticed that Scopoli, in describing "Cancer Locusta?" says, "Palpi antennæ tripló longiores: articulis (20)," meaning, apparently, that the lower antennæ are three times as long as the upper.

1764. Brünich, Martin Thrane, born 1737, died 1827 (Hagen).

After describing the different parts of an "insect," and giving a list of the different writers on Entomology, Brünich unfolds his own classification under the title "Tabule Insectorum perfectorum." There are two principal groups:—

- A. Capite a thonne distincto, containing.—"I. Hexapoda:" "II. Polypoda." Of these the *Polypoda* include three subdivisions:—"Pedibus segmentis corporis utrque punccuribus; XIV. et plurès; Corpore ovali;"
- "(a) Antennis dubus, . . . . . . . .
- "(b) Antennis quator, . . . . . . . ."

In the second subdivision *Scograndula* is placed, and *Julus* in the third.

- B. Capite cum thonne unito," containing two sections, "I. Pedibus natatoribus omnibus," &c., for *Monoculus*; "II. Pedibus ambulatoriis," for *Acarus, Pycnogetum, Phalangium, Aranea, Scorpion, Cancer.* Of these the first four are Pedibus Octo, the other two Pedibus "Decem, anticis cheliféris; Cauda elongata, articulata." *Cancer* is defined "Oculus II, pedunculatis, distauibus; Cauda inermi;" with various (presumably specific) divisions,

(zool. chail. exp.—part lxvii.—1887.)
grouped under the designations Brachypus and Macrourus. The second section of the
Macrourus is defined "Testa thorace non tegente, brevissima: Manibus adactylos;" and
may perhaps include the Amphipoda, notwithstanding the pedunculate eyes in the definition
of Cancer.
In the preceding group, number 2 is the interesting new genus, which was soon after confounded
with the Amphipod Cymus. It is thus defined: "Oculum IV. Verticalibus; Corpori inciso
tuberculato; Oreo tubuloso producto: Pycnogonum (Fig. 7)." In the German rendering on
the opposite page it is called "Strandspintel (Fig. 7)." The reference should obviously have been to Fig. 4.
In the "Explanatio tabulae sensu" the following account is given:—"Fig. IV. Novum genus, a
R. D. Ström inter phalangia relatum, Siboni. T. 1. p. 209. t. 1 f. 17. Exemplar hujus
insecti, quod munificatia R. Autoris possideo, ita describo; Caput
cum thorace unitum, tubo b. excavato cylindrico, antice angustiore,
poistice in thorace repecto, prominens; Oculi IV. dorsales a. in gibbo-
ositate thorace positi; c. Antenae 2. tubo breviores moniliformes,
subtus in segmento thorace, cui oculi induct, radicate; segmenta
corporis, excepto tubo, IV. cum tuberculo e medio singuli segmenti
prominulo. Pedes VIII. singuli ex articulis VII. brevissimis com-
positi, unque valido terminati. Ex descriptione patet insectum hoc a
generibus antea notis omnino differre, ideoque novum genus, quod e crebris articulationibus
Pycnogonum dico, constitut."
REPORT ON THE AMPHIPODA.

culsa primus et secundus rotundus et inermes, thorace jam majores; Articulus tertius oblongus, utrinque compressus, marginis inferiore versus articulum quartum euspidale valida acuto. Articulus quartus teres, rectus, oblongus, tertio parum brevier. Quintus subculus, acutissimus, quarto dimidio brevier. Reliqui pedes brevissimi, exilitate axiim octofurum fugientes. Tris posteriora paria decusum et sursum versa. Color totius ex cinerco abdido. Longitudo tota, extensis etiam prioribus pedibus, est quinque linearum." From this he passes at once to the genus Squilla, as follows:—

990. Squilla cauda subulata, bifida: pede utrinque antico chelifero; tribusque utrinque ultimis natatoris.

Pulex marinus. Baster, Opusc. subsec. tom. 2. lib. 1. p. 31. tab. 3. fig. 8.

991. Squilla cauda subulata integra: pedibus utrinque antico binis cheliferis; quatuor subsequentibus natatoribus reflexis.

Cancer macrourus articulis, manibus adaequilis, cauda attenuata, spinis bifidis. Linn. Syst. Nat. Ed. 10. gen. 239. n. 561

Habitat in Mari Septentrionali. Baleans vexans mordendo."

The Iconographia sive Tabularum Explicatio, for pl. xvii. fig. 7, repeats the short definition of Astacus muticus, No. 989, of which the figure, though only life-size, is easily recognisable as Ovarius volutator, Pallas. The elaborate description of the first pair of feet obviously refers to the lower antennae, and, this, no doubt, together with the epithet croisperes, quoted by mistake from Pallas, led Linnæus in 1767 to call the species Cancer grossipes. See Notes on Pallas, 1766, 1772. Possibly the description of the "lateral or exterior" antennae may be derived from the second gnathopods. No. 990 cannot be determined from the inconsistent references or the indefinite description. The statement that "it lives in pools of fresh and salt water" would imply that Gammarus pulex and Gammarus locusta are both in question. The description of the eyes as "minimi" suits neither. Herbst unites it with "Cancer gummcrialus, Pallas," probably because Pallas does so. See Note on Pallas, 1772. No. 991, by the references, should be a Gammarus. The concluding observation points to a Cyamus. It is difficult to fit either to the description.
1765. Strom, Hans.

On p. 588 he describes "Et Hummer-lignende Insect med runde haar paa Bag-foderne. Cancer macourus articularis, manibus adactylis, femoribus posticis orbicularibus, spinis caudae bifidis." One of its most remarkable peculiarities, he says, is that it can hop half an ell high from the ground (en halv Alen høyt). He notices its likeness to the common Marplæ, or so-called *Pulex cancriformis*, but for the latter he gives seven good distinguishing characteristics, showing that he clearly understands the difference between his own species, which is *Orchestia gymnarrhila*, and the *Gammurus locusta*, which Linneus describes as *Cancer macourus rufescens thorace articularis*, Fn. Sv., §1253. Of this *Pulex cancriformis* he observes, "Linneus gives a second species, but nevertheless gives both one and the same name, as may be seen Syst. Nat. pag. 633 and 634; and though he gives a fresh description of each separately in his Ølandse Røsa pag. 42 and 260, still it seems to me that both descriptions refer to one and the same. At any rate neither of them suits the insect here described." He notices that his own *Pulex cancriformis, antennis brevissimis, corpore latiro*, from Søndom, is a third species, distinct from the hopper and from the Linnean species.

1765. Baster, Job.

Opuscula. Tom. II. Liber 3.

Natuurkundige Uitspanningen, &c.

On p. 155 (139) Baster remarks, that there is a creature which is called "Walvis-Luis," whale-louse, very different from the other fish lice, and which seems to him also to be a different creature from that described and figured under this name by Friderich Martens. Yet Linneus, he says, Syst. Nat., p. 636, deems it the same, placing it among the *Oniscæ*, among which Baster thinks it cannot stand, since they have fourteen feet, while this animal, which Gronovius calls *Polygonopus*, has only eight. According to Lütken, 1873, Baster here described, and on pl. xii., figured *Pycnogonum littorale*, supposing it to be Martens' whale-louse, and so mistook Linneus (see Note 1767); but Linneus in 1767 and Pallas in 1766 must have misunderstood Baster's accurate statements. Baster further points out that in Houtty's Natural History, I. Deels 3. Stuk, p. 457, there is mention made of a Walvis-Luis which is in reality a *Batanae*.

1766. Pallas, Peter Simon, born 1741, died 1811 (Biographic Universelle).

On page 189 he notices that his *Aecans marinus* seu *Polygonopus*, the *Pycnogonum* of Brünnich, is very different from the *Pediculus cetti* of Martens, which, he says, should properly be reckoned with the *Oniscæ*. "Non intelligo eum col. Bastaur Linneum reprehendat, Pediculum Cetti Martensianum Oniscis adnumerantem."
As *Oniscorum cancriformium* species, he enumerates and describes, "1. *Oniscus Pulex, compressus pedibus quatuor anticus cheliformibus," with references to Linnæus, Frisch and Boeck; "2. *Oniscus Locusta, compressus chelis nullis; pedibus secundis parvis mariculis," with reference to Linnæus, Scopoli, Ray, and Dodonaeus, p. 476, and figure, Tab. XIV. fig. 15, this being the Amphipod since known as *Talitrus locusta*, Pallus; "3. *Oniscus Gammarellus, compressus pedibus secundis parvis cheliformibus maximis," "spad anctores nusquam occurrit, meruique idco Tab. XIV. fig. 25, delineari;" this being since known variously as *Orchestia littorea* or *Orchestia gammarus*, the latter name having priority beyond all contradiction. The next species is thus introduced: "Adfinis est *Oniscus cancriformis* singularis species, cui *Onisc volutator* nomen dedit, quia in aqua superficiali singulari modo capite cum autennis previo volutatur.

"*Oniscus volutatorum* inveni in fossis maritimos, prope Hesviem Essexarn. *Cel. Gromovius* in fossis stagnantium prope Leydam legerat. *Tabula nostra XIV. fig. 20. a latero visum exprimit."

The descriptions of the above species are given more fully in the *Speciologia Zoologiæ, Fasc. ix. 1772*.

1767. Linnæus.

The definition of *Cancer* now runs "*Pedes VIII. (10 s. 6 rar*) insuper Manus 2 chelatae. *Oculi II, distantes, plerisque pedunculati; elongati, mobiles. Pulsi II, cheliferi. Cauda articulata, inermis.* The last division, with the same heading as in 1758-60, now contains twelve species. Among these, at pages 1055-1056, are the following Amphipods: No. 80, *Cancer grossipes*, thus defined, "C. macrourus articularis, manibus alactylis longitudine corporis.* Gron. Zooph. 989 Astacus muticus, pede antico subulato edentulo longissimo crassissimo," the specific name *grossipes*, evidently based on the confusion made by *Gromovius* between the antennæ and gnathopods, being bound to yield to the earlier and more appropriate *volutator* of Pallus, as explained in the notes on that writer, under the dates 1766, 1772; No. 81, *Cancer pulex*, said to occur both in salt and fresh water, and to judge by the synonyms including, in Boeck’s opinion, *Gammarus pulex*, *Gammarus roeselli*, and *Gammarus bocdza* of later authors; No. 82, *Cancer locusta*, probably including *Gammarus locusta* and *Orchestia gammarus*, *Linnæus’s remark about the urupods, “Patienstius unius pars cauda lateribus adstant, biligilati,” not being very intelligible or decisive; No. 83, *Cancer linearis*, which in Boeck’s view is without doubt the same as *Caprella lobata*, Müller, notwithstanding the reference to Martens’s *Caprella opalinularis*; No. 84, *Cancer atomos* with "pedibus undeclim" and a reference to Easter, and the observation "habitat in Europe aquis fluctuantis dubibus, nudis oculis vis visibilis, precedenti
THE VOYAGE OF H.M.S. CHALLENGER.

affinis," which, together with No. 85, Cancer filiformis, Boeck considers to represent Caprella lobata. Mayer's opinion as to Nos. 83, 84, 85 is that the descriptions given by Linnaeus are practically worthless, that the reference to Martens is useless, since his species also is quite indefinite, so that, though he inclines to take Baster's nitrum animaleculum in corallinis as equivalent to the modern Caprella linearis, he only retains the latter name with the addition of "Bate" as an authority, because the so-called species has been commonly employed as type of the genus.

At page 1059 is given the definition of "Oniscus. Poles XIV. Antennæ setacee. Corpus ovale."

On page 1060 the following Amphipods are referred to this genus: —

"Habitat in Baleinis, distinguendus a Phoalangio Balaenarum, similis.

"2 caudatus. 8. O. semicylindrins, caulis duabus longitudinalibus corporis, Fn. spec. 2062.

"Habitat in O. Norvegico."

Thus Oniscus cetti appears with the same definition as in the Fauna Suecia, 1761, with the slight change of ovaticis for nitricis, probably by a misprint, but Lütken points out that the reference to Martens is now omitted, while his whale-louse is now made a synonym of Phoalangium balaenarum (Brünnich's Pycnogonum), introducing a confusion that was not for a long time to be thoroughly dispersed. The Oniscus bicaudatus had been identified by Pallas in the previous year, 1766, with the Astacus multens of Gronovius, which Linnaeus here calls Cancer grossipes, but the suggestion may have come too late to be available for the present edition of the Systema Nature.

1768. Adelung, Johann Christoph., born 1734, died about 1806 (Biographie Universelle).

In a note to page 320, Adelung states that Fr. Martens made his journey to Spitzbergen "als Schiff Barbier auf einem hamburgische Schiffe." The two first plates of Martens' work he does not consider worth reproducing, but all the rest of it, both figures and text, he gives in

full, only polishing and modernising the language. To some of the figures also he seems to have thought it necessary to give a little extra finish. It has been already mentioned that he apportions Martens' fig. t. to Der Garnell, reproducing it as fig. 5 on Taf. xvi. in his own work, without any explanation of the inconsistency between the figure and the description. How highly Martens' book was valued may be inferred from Adelung's notice that "in the year 1685 a Dutch translation appeared at Amsterdam; an English one is to be found in
the Account of several late Voyages and Discoveries to the South and North by Sir John Narborough [Narborough], Cap. Tasman, Cap. John Wood an Frederik Marten, London 1694 in 8., French one in the Recueil de Voyages au Nord Th. 2. S. 1."

1769. Houttuyn, F. (Publisher).

In chapter 82, p. 295, of this voluminous work, the anonymous author begins the description "van 't Geslagt der Krabben en Kreeften." On page 436, among "de Kreeften," is given the following description:

—"lxxx. Grossipes, Dikpoot, PL cvi. Fig. 1. (80) Kreeftje, gebeel in Leden verdeeld, met de Schaaren ongewingerd en zo lang als 't Lyf. De Heer Pallas, thans Hoog- leeraar te Petersburg, hadt aan den Heer Gronovius de Kenmerken toegezonden van een Insekt, 'twelk zyn Ed in het Water der Vaarten by Leiden ontdekt hadt, en thans omstandig als een middelsoort tuschen de Garnaalen en Zee-Vlooijen, voorgesteld wordt. Die van onze Afbeelding, Plaat cvi. Fig. 1, schynen van de beide de volgende Soorten aanmerkelig te verschillen, en, indien men de Hoornjtes op den Kop voor ongevierarde Schaaren neemen mogt, nader met de opgegavene Kenmerken overeen te komen; inzonderheid, dewyl de dikte der agterste Pooten gedagten Bynam op dezelen toepasselykt maakt. Zodanige Springertjes komen hier, op natte zoute Gronden, zelfs in de Kelders der Huizen voor: zynde de Afbeelding in langte ongevaar drie of vier maal vergroot." A note says "(80) Cancer macrourus articularis, Manibus adactylis longitudine Corporis Syst. Nat. xii. Astaens mutiens, Pede antico subulato, edentulo, longissimo, crassissimo, Gron. Zooph. 989." While therefore the reference is to Cancer grossipes, Linn., the figure is clearly one of the Orchestidae, probably Talitrus locusta. Under these circumstances, to account for the name grossipes, recourse is had to the thickness of the hindmost foot, "de dikte der agterste Pooten."
The following names are then attached to species which the writer describes but does not figure, depending for his information on the authors, various and numerous, to whom he gives references:—81. "Patez. Zoe-Vloo." 82. "Leconia, Springer," and "Rivier-Vloo." 83. "Linneaus, Smala," with a reference to "Martens, Spitzberg, 56. T. F. L." 84. "Atavos, Zeer kleine," with references to Linneaus and Baster. 85. "Filaformis, Zeer dunne," from Malaca, with a reference only to Godbelen de Rivilla, whose species from Ceylon the author considers to resemble this filiformis. 85. Salinus, and 87, Stagnalis, are not Amphipods.

Chapter 84, page 481, contains "Beschrijving van 't Geslaag der Pissebedden; het welke, behalve de gewone Land- en Water-Pissebedden, ook veel van die men gemêlelyk Zoe-Luizen noemt, en de eigentijds Waalsch-Luizen bevatt." On pp. 491-493 he gives an account of Gyranus mysticeti, Lytken, beginning as follows:—"Ceti. Groenlandse Walvisch-Luis. Pl. cv. Fig. 4. 5. (6) Pissebed, die ovaal is met duidelyke verdelingen; de Pooten van het derde en vierde Paar egaal van breedte, smal en stomp.

"De Insecten, op onze Plaat cv. in Fig. 4 en 5, afgebeeld, zijn voor eigentijds Walvisluiën uit Groenland gebragt, en komen overeen met de beschrijving, welke Linneaus geeft van deze Soort, zeggende, dat die het Lyf ovaal of cyrondvorm heeft, bestaande uit zeven onderscheidelyke Lodjes, waar van de Kop het kleinste is: dat de Pooten van het eerste, tweede, vyfde, zesde en zevende Paar, dikke Schaaren hebben, die uitloopen in een bewegelyke scherpe Klauw; doch, dat die van het derde en vierde Paar Drasdagtagt en stomp zyn. Het eerste Paar is onder het Lyf geplaatst. De Verdelingen zyn meer van elkander afgezonderd, dan in de overige Soorten." Some observations upon earlier authors are then made. The description continues, "Die van onze Plaat zyn, in langte en breedte, ruim driemal zogroot als natuurlykt gemaakt, en geelgriyt wit van Kleur, doch de smalle Pootjes zwart." "Wy hebben er Fig. 5, van de onderzyde, bygevoed; om een groot Biaas te vertoonen, die sommigen van deze Insecten voor aan den Buik voeren, komende hier in met de Water-Pissebed van Baker overeen. Mooglyk zullen zy, in dezelve, haare Eijertjes of jongen draagen. Dat die zwarte smalle Pootjes haar tot Riemen dienen, om eenigermaate te kunnen swemen, is niet onwaarschynlyk. Zy zyn meer duidelyk voorziën met Sprietjes of Hoornijtjes en hebben voor, op den Kop, twee kleine gladde Oogjes."

1769. Slabber, Martinus, both 1741, died 1835 (Bovallius).

Natuurkundige Verlustigingen, behelzende microscopise Waarneminghen van in- en uitlandse Water- en Land-Dieren. Door Martinus Slabber. Te Haarlem, 1769. (First title-page dated 1778.)

The "tiende Stukje," pp. 79-83, describes a Zoe-Scherminkel (Phthisica marina), which P. L. S. Müller renders Scopendel. "The figure shows it pretty evidently to be Proto ventricosa O. F. M." The author says "each foot is on the under side at its base covered with a little elongate leaf as can be seen at c [in the figure] and at all the seven feet." The legs and hands are all represented as filiform, the first pair shortest, the next four pairs equal to one another, the last two pairs much longer than those preceding.

The "elfde Stukje," pp. 92-96, describes what he calls een Zand-Pissebed (Oniscus arenatius), Oniscus Arenarius in the preliminary List of Names. It is strikingly figured, pl. xi. figs. 3, 4. It has been made the type of several successive genera, different only in name, Haustorius, Müller, Lepidactylis, Say, Pterygoecra, Latvillia, Bellia, Sp. Bate, Salcator, Sp. Bate. See notes on P. L. S. Müller, 1775, Bovallius, 1878, and S. I. Smith, 1880. It seems reasonable to accept the date 1769 for Slabber's book in preference to 1778, since the translation of it by P. L. S. Müller is dated 1775.
1770. **Pallas, P. S.**

Dierkundig mengelwerk. 4° m. Pl. Utrecht, 1770.

This, I suppose, is the Miscellanea zoologica, of 1766, in Dutch. It is mentioned by R. T. Mairland, 1875, who refers to it under the species *Orchestia littorea*, Leech, and *Talitrus saltator*, Edw.

1770. **Ström, Hans.**

On p. 5 he describes "En Marilien, eller liken Krabbe, med Kjøkkennet og Sav-signende Ryg. Cancer macrourus articulatus, dorso earinato serrato, spinis caudae bilidis," and figures it Tab. ii. figs. 1–8. The mandibular palp in fig. 3 seems to show the onemer joint divided into three, a mistake perhaps owing to some folding of the palp accidentally in the course of dissection. Boekk identifies the creature described, no doubt correctly, with *Gammarus* (now *Amathilla*) *sabini*, Leech. The species appears to be the *Gammarus homari* of Fabricius, and the *Amathilla sabini* of Bate and Westwood, in which case its name will properly stand as *Amathilla homari* Fabr.

1772. **Pallas, Peter Simon.**

Spicilegia zoologica, quibus novae imprimis et obscurae animalium species iconibus, descriptionibus atque commentarius illustrantur cura P. S. Pallas. Fasciculus nonus. Berolini, mdcclxxii. pp. 50–80, Tab. iii. iv. (To the German version by E. G. Baldinger, Mayer, Caprelliden, p. 199, assigns the date 1769, probably referring only to the commencement, not to the ninth fasciculus, of the work.)

He here says "Canceris proximum est *Oniscorum* genus, transitum indicantibus *Squillis*," and "Oniscorum *squilliformium* e plaghne quatuor species mili cognitas sunt." Of these he proposes to leave out Roesel’s already well-known species, and to describe the remaining three.

The first is a new species, peculiar to Siberia, as far as he knows, "abundat acdem in Lena, fluvio ulterioris Siberia, & omnibus que in illius colliguntur fluentia, praecipe Angara & Lena Baikal e quo profuit Angara." He has learnt some facts about it from Steller, "in cuius schedis de hac specie (quam ‘Squillam fluviatilem seu Phryganae fluvii Angaræ’ appellavit) quaedam memoriae probata inventi." Steller, he says, states that "individua dari quaedam macronibus dorsibus destituta, quæ alterius sexus esse putat, nisi diverse potius speciei fuerint." E. Laxman, from whom Pallas received a specimen, called it "Cancerum baikalesæm," but Pallas himself describes and figures it (Tab. 111. Fig. 18) as *Oniscus cancellus*. This Dybowski in 1874 is content to retain under the name *Gammarus cancellus*, Pallas, adding a variety *Gerstfeldtii* of his own discovering. By Spence Bate, however, in 1862, the species was made the type of a new genus *Pallasea*, which must not be corrected into *Pallasia*, and thereby confounded with the Dipterus genus *Pallasia* instituted by Robineau-Desvoidy in 1830.

*(Zool. Chall. Exp.—Part. LIXII.—1887.)*

XXX 5
Pallas next discusses the synonymy of "Oniscus Locusta," and thus decides,—"Præter Rajem itaque, qui (hid. ins. p. 44). Pulicem fluviatilem, a marino distinguat, et forte Dodonæum (pentopt., p. 476, &c.) nominem ad Locustam citari posse arbitrat; quam enim Scopoli (Exom. carniol., p. 411). Locustam dedit descriptionem, sequenti potius speciei nostre, Onisco nemen Gammarellum convenit." In the description of Oniscus locusta, Tab. iv. fig. 7, he says "Podos septem parium (non octo, ut in Miscellaneis fugitivo calamo scriptum); priores anterorum versi, sex postici retrorsum. Par primorum crassius reliquias; secundarius pedes exiles, velut atrophia absunti; mutici." This is now accepted as Talitrus locusta, Pallas.

For the next species he refers, as above, to Scopoli's "Cancer Locusta," and also to his friend Gronov's Fasc. II. p. 232, nom. 900, where, however, he thinks that all the synonymy, except perhaps the reference to Baster, belongs to Polder. That Boeck is right in assigning the name Orchestia gammadimellus, Pallas, precedence over Orchestia littorea, Montagu, is clear from the following: "Descriptio Onisci Gammadimellus, Tab. IV. Fig. 8. Magnitudine Onisci Pulicei. Formae quasi media inter Pulicem & O. Locusmat. Priores scil. brevier, posterioris gracilior est; capitis tamen parvitate Pulici simillim. Antennæ exterioræ majores quam in utrolibet, secundus harum articulus presentim notabilis, majusculus, linearis, quadrangularium, superiori latere scaber. Antennæ intermedii minime; ut in O. Locusmat; quum contra in O. Pulice exteriore internum sequent. Pedes septem parium; primi parvis parvuli, exiles; secundarii chela magna, ventricosa, adactyla terminata; quum in O. Pulice quatuor priores sint cheliferi, et subequales. Pedes quarti parvis (non quinti, ut habet Miscellanea) omnium brevissimi, et cum sensim longioribus sex postici retrorsum versi; vel saltem ambigii quarti; postici vero, ut in affinis plano reclinati. Et hi quaeque femoribus planis, foliaceis, ovatis singulares, qualis in O. Cancellio supra observavimus. Stylis caudalis bifurci duorum parium, et macro duplex terminalium, pedunculique subcandales, setacei, ut in affinis. In spiritu vini alien habe species, viva subcinereosa; at sicca rubescit, ut coctae Crangones. Magnitudinem exprimit icon." The Boeck in his chronological review, p. 35, assigns the locusta and gammadimellus of Pallas respectively to the female and male of Orchestia littorea, while in the body of his work, pp. 101, 104, he takes "Oniscus gammadimellus, Pallas, (Cancer gammadimellus, Montagu)," as type of the genus Orchestia, Leach, but Talitrus (Oniscus) locusta, Pallas, as type of the genus Talitrus, Latreille. Moineart considers that the figures and descriptions by Pallas do not suffice to separate his Oniscus gammadimellus from his Oniscus locusta, and that therefore Montagu's Cancer (Gammadimellus) littorea should determine the specific name of Orchestia littorea, but surely the "chela magna, ventricosa" in gammadimellus sufficiently proves that that species is an Orchestia, while Montagu himself identifies the locusta of Pallas with his own saltator, which is a Talitrus. It may be noted also that for "Cancer gammadimellus, Pallas," Herbst gives Baster's figure, which pretty clearly refers to the Orchestia in question.

On Oniscus volutator, after repeating some of the observations already made in the Miscellanea, Pallas says, "Distincte satis Oniscum nostrum indicatus Reiss (hid. ins. p. 43.) Pulicem maris corami nomine. Vix enim dubium est Oniscum bicaudatum Linnae (Faun. Sw. ed. II. p. 2062. Syst. Ed. XII. p. 1060 sp. 8.) hunc ipsum nostrum esse, ubi Linnehus, e siccato forisitum specimen, antennas exteriores pro candidi nominavi. Anvisius Gronovius omnium novissime, ante edita Miscellanea mea, hanc speciem descripsit & Ascanum vocavit, Zoophylocos Fasc. II. p. 232. num. 988, ubi quem iconem a me communicantum, in tab. 17. fig. 7. addidit. Ex Gronovio Herem adoptavit speciem nostram Linnehus & vocavit Cancerum grossopolum (Syst. nat. XII. p. 1655, sp. 80.) " It is obvious therefore that the name volutator given by Pallas should take precedence, unless Linneus alone of all men had a right to change suitable names already given for unsuitable ones of his own devising.

On Oniscus ceti, Pallas says, p. 76, "Oniscus Ceti primus, quantum video, et accurate quidem
REPORT ON THE AMPHIPODA.

35
descripsit FRID. MARTENS, (itin. Spitzberg, ed. germ. p. 85. n. 4.) adjecta etiam radiori icone (tab. 8. fig. d.). MARTENSII locum LINNÆUS olim (System. ed. X. p. 636. sp. 6.) ad Oniscum Ceti, quae graphicum exprimit, recte citaverat. Verum eundem in editione novissima nesses quo permotus argumento, perperam de Aracn polygnomos nostro, quem inter Phalaugia collocat (System. Ed. XII. p. 1028. p. 6. sp. 6.), perperam interpretatus est; Oniscum Ceti autem absque synonymo ullo reecensuit (pag. 1060. sp. 6.). Distinctissime tamen speciem delineat etiam Sehle thes. Vol. I. tab. 90 fig. 5. quae icones LINNEO ignote esse haud potuer. Of the young, he says, "Appriune minutas sum, quod corundem forma gracilis, scolopendroides exacte esset similis species sequentis, equis minima, vulgaribus Pedusius vix longiora specimina ita referunt, ut, nisi intra matris diversa alvum pene reperti, pro idem omnino haberentur." He gives a description of Oniscus ceti, Tab. iv. fig. 14, A. B. C., probably, in Lätken's opinion, referring to the species which Lätken calls Cyamus mysticeti.

This is followed by a discussion of Oniscus scolopentroides, in which he says, "Primam, ni illor, hujus Insecti distinctam notitiam debemus Celeber. Bastero. In honore tamen Optimi Steleeri momentum est, accuratam descriptionem hujus insecti marini, ad Kamtschatkam ab illo observavit, in schedia ejs usque.

"Oniscus scolopentroides quaem Basterus describit, quem LINNEUS (System. ed. XII. p. 1056. sp. 84.) satis paradoxo nomine et genere Caurcum atomon vocat, forte ab Eugenum Caucrum fasciati aequo filiformi, vel horum saltum priore, nonnisi esse differt. Certo quod F. MARTENS (itin. Spitzb., p. 83. n. 3. Tab. F. fig. 1.), nomine Squilla parve describi & delineat insectum, vix alium quam Oniscus scolopentroides notor videtur fuisse. Et adiunctiones, quas LINNEUS dedit de Caneis lineari & filliformi suis, ambo in nostro speciem sat bene quadrant; ut summa saltum horum trium insectorum debet esse affinitas.

"Quod vero hae Insecta ad Caucrum malo omine reduxerit LINNEUS, neque nature corum genus perspexerit, eo magis miror; quia Oniscum Ceti ad legiunm genus jamadunum judiciose retuit. Adeoque structuram praedicitrum specierum cum Onisco Ceti contulisse non videtur; Nemo enim, qui ocusit utitur, non videt eundem esse hujus Onisci scolopentroidis affinitas unum compositionem, & structuram quod omnes partes, truncum, autem, pedes perfectos, & pedunculos. Imo tanta, ut jam monui horum est similitudo, ut minuta ab Onisco Ceti edita proles, quae gracilis adhuc et macienda est, vix ab Onisco scolopentroidse discerni quas, . . . .

"Onisco Ceti etiam in eo convenit hae species, quod ovula femine sub medio corpore mem branulis inclusa circum ferant; inter aestate adlatos, copiosisimas semper observavi feminas hoc more gravidas; quae res a Diligentiss. Bastero adnotata hanc fuit; probatque corpora pedum mediorum vicaria minime esse ovula, quanvis sub ipsis illis globus ovulorum in fastificantibus haeceat. Figura Martensi supra citata id beni habet, quod exprimat situm, quod Oniscus scolopentroidis in aqua & spiritu vini convulsus movi constantur observatur."

The description which follows of Oniscus scolopentroides, and the figures, Tab. iv. fig. 15, A, b, c, do not suffice to establish its specific name. Lätken considers that Pallas presses rather too far the resemblance between the young of Caprella and those of Cyamus, though giving him due credit for having called attention to it, as well as for being the first to remark on the incubatory pouch of Cyamus, and on the difference between the young and adult forms, besides correcting Linnaeus' reference of Martens' Cyamus to Acrurus polygonopus (Pyenogonum).
1772. Olafsen, Eggert, born 1726, died 1768 (Biographie Universelle).

§ 687. Von den Insecten, unter VI., the Athera. E. Cancr., &c., gives “d) Marflo ist Cancer pulex Linnaei Fns. Sv. 1253. Sie verdient das Netz, welches nach den Forellen und Räppen nahe an dem Ufer gestellt wird, und frisst die darinnen gefangene Fische. Macht man die unteren Maschen aus Pferdehaaren, soll sie selbstige nicht vernagen.” This relates to the West-ford. In § 746, Marflosen are also recorded from North Iceland. The destruction of nets by some species designated as Cancer pulex is confirmed by Ödmann’s observations at this period, but that it attacks live fish he denies; the fish, on the contrary, he says, as any cook can tell you, devour the Cancer pulex.

1773. Yeats, Thomas Pattinson (born ?), died 1782 (Maunder’s).

Institutions of Entomology being a translation of Linnæus’s Ordines et Genera Insectorum; or Systematic Arrangement of Insects. Collated with the different systems of Geoffroy, Schaeffer, and Scopoli; together with observations of the translator. London, MDCCLXIII.

He says that Schaeffer in his Elementa Entomologica, Eatisbon, 1766, has followed Geoffroy. His own work opens with a glossary of the terms used in entomology. In his account of Cancer, Genus X. in Order VII., the Athera of Linnæus, Syst. Nat., p. 1038, he gives as the second family the Macroura or long-tailed crabs, with five subdivisions, of which the fifth may possibly refer to the Amphipoda. It is obscurely defined as “Those in which the shell of the thorax is shorter than that part, which it does not cover entirely.”

1774. Phipps, Constantine John (afterwards Lord Mulgrave, born 1734, died 1794 (Biographic Universelle).

A Voyage towards the North Pole, undertaken by his Majesty’s Command, 1773. London, MDCCLXIV.

In the Appendix, under the heading Insecta, pp. 189–193, pl. xii., Phipps gives two species which are not Amphipods; “Cancer Squilla, Linn. Syst. Nat., 1051, 68. The Prawn;” “Cancer boreas,” with a description and figure; and three Amphipods thus described:—

“Cancer Ampulla, macrurus, articulatus, corporae ovali, pedibus quatuordecim simplicibus, laminis femorum postei pari ovato-subrotundis. Tab. xii. Fig. 3. This singular animal was also taken out of the stomach of the same seal in which the two former were found. Its place in the Systema Naturae is next to Cancer Pulex. Description. Insectum ex ovali-oblongum, ghabrum, punctulatum, articulis quatuordecim compositum, quorum primum capitis est, septem thoracem montium, et sex cando tegunt. Capitis clypeus antice inter antenas in processum conicum, acutum descendit. Antennas quatuor, subulate, articulatae, simplices, corpore decuplo breviore. Pulex quatuordecim, simplices, unguiculatit; femora
REPORT ON THE AMPHIPODA.

postremi parvis postice acuta, lamina dimidiato-subrotunda, integra, magna, quattuor lineas longa. Cauda foliata, foliolo unico brevi bisifo: Lacinia lanceolata, acute. Neusteri duodecim, duplicati, subulati, pilis longis ciliati, posteriores retroversum porrecti. Obs. Specimina magnitudine variant, uncialia et binicialia rurum. This is now the type of the genus Stegecephalus, Kroyer, 1842.

"Cancer niger, macrourus, articularis, pedibus quatuordecim simplicibus, lanimis femorurn sex posteriorum dilatatis subrotundo-cordatis. Tab. xii. Fig. 2. This animal, which has not before been described, should be inserted in the Systema Naturae near Cancer Pallas; it was taken in the trawl near Moffen Island. Description. Insectum oblongum, compressum, dorso rotundatum, glabrum, sesquinuculate, articulis quatuordecim compositum, quorum primus capitis est, septem thoracei mentientur, et sex caudam efficiunt. Capitis et genis simae obtuso antice pro antennis omarginatis. Antennae quatuor, subulate, multianiculata; superioris corpore sextuplo breviores, bisifo; articulo basico communis, magno; Rami interiori exteriori duplo brevior. Inferiores simplices, superioribus duo longiores. Pedes quatuordecim, simplices, unguiculati, unguibus parum incurvus. Femora sex posteros postice acuta. Laminae foliaceae, subrotundo-cordata, dimidiata, margine integra, magna, (tres lineas longa). Cauda spicis foliata. Polioli duodecim, oblongis, obtusis, parvis. Neusteri duodecim, duplicati, linear-lanciculata, posteriores retroversum porrecti, ut facile pro appendicidis caudae sumantur." Kroyer, Nat. Tidsskr. 2 R. í. p. 578 (1844), mixes up Cancer amputa, Phipps, and "Cancer niger, Phipps?" with his own Anonyx lagena and Anonyx appendiculatus under the title Anonyx amputa, Phipps. Cancer amputa, as already stated, belongs to Stegecephalus. Cancer niger, Phipps, is almost beyond the doubt as Anonyx lagena, Kroyer, and accordingly E. J. Miers, with good reason, gives precedence to the specific name niger.

Of his third Amphipod species, Phipps only says: "Cancer Pater, Lin. Syst. Nat. p. 1955, 81. Taken up in the trawl along with the former."

1774. STELLER, GEORG WILHELM, born 1709, died 1746.

Mayer, Caprelliden, p. 4, remarks, "Pallas, dessen Spicilegia zoologica ich nur aus der Ubersetzung von Balbinger kenne, fasst 1777 die ihm bekannten Amphipoden unter dem Namen Oniscus zusammen und beschreibt als O. Scapodemulodes (Kehrpolypenlaus oder kennerte Afterasell) einen halbdurchsichtigen, gelben, nach der Abbildung zur heutigen Gattung Caprella gehörigen Krebs, den Steller schon als Pediculus marinus in Kamtschatka beobachtet haben solle." He appendes a note to explain that he has not himself had an opportunity of examining Steller's work on Kamtschatka. The only passage in it at all applicable, that I can find, is on page 129, where, in a note, Steller says, "An der See soll sich ein Insect befinden, wie eine Lause, welches durch die Pores der Haut in das Fleisch und immer weiter kriechet." This causes horrible pain, and can only be got rid of by cutting it out. Steller had not himself seen it, but promises to look out for a chance of doing so. His account of it so far is little suitable to Caprella. In the note on Pallas, 1772, it will be seen that he ascribes to Steller the credit of having accurately described Oniscus scaphodemulodes observed by him in Kamtschatka, but it is the description "hujus insectuli marini," not of a pediculus marinus, that he has left in his papers. See also note on Tilesius, 1815.
1774. GINNANI, Co. Francesco.

Storia civile e naturale della Pinetta Raetenatei, 1774.

G. D. Nardo says that this author mentions, on p. 137, "il Pulex d'aqua dolce, *Gammarus*." I have not been able to meet with his work.

1775. HAMMER, Christopher.

In the Fauna Norvegica, with which the work begins, under "Krabbe, Cancer," there are given:—

On page 17, to his mention of "Sletbag, Grønlandsk Hval. *Balena mysticetus;*" he appends a note: "Den naerer sig af smaa Orme, som af Hr Egede kaldes Hvalfiskaas."

The above Amphipoda are sufficiently explained by the references to Strøm and Egede.

1775. FÖRSKAL, Pehr, born 1736, died 1763 (Encycl. Brit., 9th Ed.).

Among the Insecta, in the genus Cancer, division R. Macrouri, he describes, pages 95–96, what is now known as *Phronima scutellaris*, as follows:—"59. *Cancer scutellaris*; *macrourus*; *articulavis*; *macrourus adactylis*.

On page xxi. it is briefly described with the words "pedibus utrinque 10; domifex."

1775. Müller, Philipp Ludwig Statius, born 1725, died 1776 (Hagen).

In this translation the account of Phthisica marina, i.e., Prote ventricosa, occurs on pages 41-43, tab. x. fig. 1, 2. The account of Oniscus arenarius or Sandsselwurm is on pages 48-52, tab. xi. fig. 3, 4. At page 52 the translator gives the following note on his own part, "I cannot find the relationship of this species to either of the genera above-mentioned [Squilla and Oniscus], since the remarkable structure of the feet must certainly be regarded as a characteristic. And I think the author might have regarded this little animal as forming a quite distinct genus, and under the name Haustorius arenarius, or Sandschöpfer, I would place it in a genus by itself between the Monoculi and Onisci. If it were not for the absence of a carapace (Schild), I should not hesitate to place it among the Monoculi; it is best therefore to place it in a genus by itself."

Bovalius, who adopts the name Pterygoecra arenaria assigned to this Amphipod by Latreille, after praising the figures and description of it given by the Dutch naturalist, makes the following observations:—"Although appreciating its numerous peculiarities, Slabber nevertheless abstained from creating a new genus for its reception, and placed it in the genus Oniscus L., one of the three great Linnean genera, into which the whole of the Crustaceans, known at his time, were distributed, thereby also indicating his impression of its affinity to the Isopods of the present day. Statius Müller, his German translator, observed that the animal might be the type of a genus of its own, for which he proposed the name Haustorius, but this appellation, being an adjective, and consequently contrarious to the rules of Linnean nomenclature, has been justly forgotten." On the other hand, I venture to suggest that the reason mentioned is not sufficient to justify the rejection of Haustorius in favour of Lepidactylus.

The British Association Rules, 1878, include that against "Adjective generic names" only among "Recommendations for improving the Nomenclature in future." Lepidactylus, scale-fingered, is itself an adjective. Anonyx, Eunonyx, Eurytene, and many other approved names of genera, are adjectives. Haustorius, on the other hand, not being an actual Latin word at all, can scarcely be an adjective, while the termination -ius is kept in countenance by the comparatively recent change of Calliopie into Calliopius. The excellent name Sulcator might well have been allowed to stand, but since that has been displaced, on grounds of priority, first by Pterygoecra and then by Lepidactylus, it seems only just to go back a step further to Müller's Haustorius.
1775. Fabricius, Johann Christian, born 1742, died 1807 (Biographic Universelle), born 1745, died 1808 (Enc. Brit., 9th Ed.), or died 1810 (see Hagen).

Systema Entomologiae, sistens Insectorum Classes, Ordines, Genera, Species, adjectis synonymis, locis, descriptionibus, observationibus. Flensburgi et Lipsiae, 1775.

In the Prolegomena, after commenting on the confusion which had prevailed in entomology before, and even since, the labours of "the immortal Linne," he says, "Novum idea viam tentabu, characteres et classium et generum ex instrumentis cibaris desumus. Prebent sane sufficientes, prebent constantes et genera multo naturaliora." He proceeds to describe in general the labia upper and lower, the maxilla upper and lower, the palpi, 2, 4, or 6, the lingua spiralis, the rostrum, proboscis, and haustellum. Specific differences he takes from colours (coccus) against his better judgment. The classes of insects are eight, "Os maxillris palpisque quatuor aut sex." They are named Elaterata, Ulomata, Synistata, Agonata, Ungulata, Glossata, Ryngota, Antiata. The Agonata are defined "Os palpis quatuor, aut sex. Maxilla inferior nulla." This class includes Scorpio, Cancer, Pagurus, Scyllarus, Astacus, Gammarus. Among the definitions of these are "125. Cancer. Palpi quatuor os oblegantes. Antennas quatro filiformes; posticus articulo ultimo bifido," and "129. Gammarus." "Antennas quatuor simplicissimae, sessiles; antice breviores, subulate, postice setaceae." This latter contains the species Gammarus locusta, Gammarus pulex, Gammarus linearis, Gammarus salinus, Gammarus stugnalis, of which the first three correspond respectively to the numbers 82, 81, 83 of the Systema Nature, ed. xii., the remaining two not belonging to the Amphipoda. It should be remembered that the name Gammarus, which had hitherto been a specific name among Stalk-eyed Crustacea, now becomes a generic name among the sessile-eyed.

Among the Synistata, "Os palpis quatuor. Maxilla inferior comata cum labio," on page 296, is given a definition of Oiscus: —"93. Oiscus. Labium quadriradium; incisi intermedialis palpigeria. Antennae setaceae." Among the Oisci, descriptions referring to Amphipoda (of Gammarina 1, Hyperina 3, Caprellina 1) are given as follows:—

spinosus. 13. O. oblongus, corpore spinoso, pellucidulo.

Habitat in Oceano Lusitanico. Fig. pict. in Mus. Beishiano.

 Corpus parvum, gibbum, glabrum. Caput retusum. Oculi maximi, mensa magna lunata,
REPORT ON THE AMPHIPODA.

“Ceti. 16. O. ovalis, segmentis distinctis, pedibus tertii quartique parvis linearibus, muticis.

Among the Antlous the definition of Pediculus is as follows:—“184. Pediculus. Os haustellum atque proboscides. Haustellum retractile, recurvum. Antenna subulata.” Under this genus, on p. 810, though, as will be seen, with doubts, he retains the confusion which Linnaeus had introduced between Martens’ whale-louse and Brünich’s Pycnogonum, in the following entry:—“Balnunarum. 35. Pediculxxx dilitato, muricato, restro porrecto, subulato.

Phalangium balanarium, Lim. Syst. Nat. 11. 1028. 6.

Pediculus ceti, Mart. Spitz., 85, Tab. Q. fig. d.

Pediculus ceti, Bart. subs. v. 2. tab. [pars] 3. 146. [156] tab. 12. fig. 3.

Phalangium litonale, Stroem. Sdlin., 203. tab. 1. fig. 17.

Pycnogonum, Brünich. Ins. tab. 1. fig. 17.

Habitat in Oceano Norvegico.

Hujus generis videtur mihi hand rite notus.”

Cyathiona neptani, Guérin, 1842, which had anticipated Thaumops pellicida, Willemoes-Suhm, must obviously itself yield priority to Oniscus spinosus, Fabr., above-described.

1776. PALLAS, P. S.

On page 709 he describes Oniscus muricatus—“Magnitudo fere Squillae vulgaris, sed conformatio que Oniscis squilliformibus reliquis. Segmenta corporis separtae, cauda tria priora utrinque ad dorsum aequalis conico mucronata. Pedes 4 priores cheliferi, primi minores. Cauda stylis sex terminata, quorum duo medii breviores, crassiores. Color vivi cinerascens-albidus; sieati, coeti vel a liquore spirituoso conditi cocineus. In Angara inferiori circa morticia et quiesquillasque injectas colligitur copiose.” He appended a note that a description of this species is to be found in the ninth fasciculus of the Spicil. Zool., p. 52, but that the figure there is not a good one, in particular the dorsal spines being omitted. Its seems therefore clear that Oniscus cancellus is here for some reason renamed. Herbst mentions that in the German translation of the Spicilegia Oniscus cancellus is called Oniscus muricatus.

1776. BOMARE, JACQUES CHRISTOPHE VALMONT DE, born 1731, died 1807 (Hagen).

Under “Pou de Baleine, pediculus ceti,” p. 314, will be found an account, not of Gymnaus, but of a Cirripede, probably Coronula diadema. It is “un animal testacé, commun dans les mers du Nord.” “Quand on presse avec les doigts ce coquillage encore vivant, il répand une liqueur noirâtre. Sa tête ne se montre guère à découvert; elle est presque toujours cachée sous son enveloppe pierreuse.” “Cette coquille est percée dans le milieu d'un trou roulé; divisée en plusieurs cellules étroites et profondes.” Nevertheless a reference is given (Zool. Chall. exp.—Part XVII.—1887.)
to "Saba (Thos. 1, Tab. 90, n. 5.)" which is the figure of a Cyamus. The writer notices that Saba mentions also "poux marins de Grønland, qui font la nourriture des baleines."

On p. 361, "Puces de mer, pelillus marinus, est un petit animal carassier, qui se trouve en grand quantité sur les bords de la mer du Cap de Bonne Espérance." Its name is derived from its power of leaping. It is armed "d'un petit aiguillon," by which it fixes itself on to fish and drives them to desperation. Rondel's account of the ape-like shrimp is then given, with the concluding remark, "Peut être que les puces de mer sont le même animal connu à Amboine et à Banda, sous le nom de Fotok, voyez ce mot." Under "Fotok," Tom. 3, p. 550, he only says, "Voyez Pous de mer." There may be other information of importance in other parts of this work and in the three other editions of it. I have given specimens to encourage research. The Danish translation by H. v. Aphelen is dated, according to Hagen, 1767–1770, and must have been made therefore from the first or second edition.

1776. MÜLLER, OTTO FRIEDRICH, born 1730, died 1784 (Hagen).

Animals are here divided into six classes, the Insecta being the fifth. The Insecta include seven orders, of which the Aptera are the last. Among the Aptera (p. xxvii.) he gives "c. Crustacæ," with the genera Polyphemus, Cyclopa, Squilla ("Pedes 10 vel 14. Antennæ 4 integrae"), Cancer ("Pedes 10. Antennæ 2 integrae"), Oniscus ("Pedes 14. Antennæ integrae"), Scolopendra and Julus.

Under the genus Cancer, pp. 196–197, he gives:

"2353. C. gacialis, semicylindricus, corporis segmentis octo subequalibus.† LINN., Mant. 542.

"2355. C. Medusaæro antennæ brevissimis, corpore lato. GR. Urksærod. STR. S. 1. p. 188. t. 1. f. 12, 13.

Under the genus Squilla—

"2359. Squilla lobata pallida pellucida, lobis intermediae quatuor, pedibus decem ungualiatis. GR. Napporseriel vel Il Darth. CANE. linearis vel filiformis per illustriis a LINNÉ.

"2360. S. ventricosa rubra depressa, pedibus quatuordecim setaceis secundo pari elevato. A. Helv. 4. t. 4. f. 8, 9, 10*.

Under the genus Oniscus—

"2362. O. volutator antennis crassis abdominis longitudine. O. bicaud. LINN. antennas vero pro cauda sumit.

"2366. O. pallæ compressæ; pedibus quatuor anticus cheliformibus. N. MARFAT. GR. KINÈS STR. S. 188. APH. 2, 399; 5, 295. CANER LINN. In littore maris & in ripis annuim & hecuum frequens."
Aph. stands for "Domares Natur-historie af H. von Aphelen."

Of these species No. 2355 is generally accepted as Hyperia medusorum, Müller; No. 2356 remains obscure; No. 2357 repeats Ström's description from the Acta Havn., 1765, of what is probably Orchestia gannarellus; No. 2358 in like manner refers to Ström's species of 1770, now become Amatililla homari, Fabr.; No. 2359 is synonymous with Caprella linearis (Linn.), Bate; No. 2360 is now called Proto ventricosus, Müller; No. 2362 answers to Corophium volutator, Pall.; No. 2366 includes probably two or three species, such as Gammarus locusta and Gammarus pulex. No. 2353, Cancer glabriangulis, is probably not an Amphipod; No. 2354 may be a Caprella.

1776. Førskål, Peter.

Icones rerum naturalium, quas in itinere Orientali depingit curavit Petrus Førskål, Prof. Haum. Post mortem auctoris ad Regis mandatum eir incisas edidit Carsten Niebuhr. Hauniae. MDCCLXXVI.

In the Explicatio Tabularum, under Tab. xxi, is given the reference, "D. d. Cancer sedentarius. Pag. 95, n. 59." Figure "d" is a recognisable figure of Phronima sedentaria free; figure "D" represents it in its semitransparent case. For the description of this species, see note on Førskål, 1775.

1777. Fabricius, J. C.

Genera Insectorum corumque characteres naturales secundum numerum, figuram, situm et proportionem omnium partium oris adiecta Mantissa specierum nuper detectarum. Chilonii. (Prolegomena dated Kilie die xxxvi Decem. 1776.)

Here the genus Scorpio is transferred to Class V., the Unogata. The other five genera of the Agonata are retained in the same order as in his earlier work. The account of the genus Gammarus is as follows:—"Gammarus. Cancer Linn. Geoff. Oicusus Pallae. Os mandibullos palpisque abaque maxillos. Palpi sex, inequales, filiformes; anterioribus quatuor porrectos, os oblongitubus. Anterioros longiores, compressi, bifi. laeina interiori quadriarticulata; articulo ultimo inerevo, exteriori brevius, vix articulata. medius paulo breviores, bifi. laeinae subequales. interiori triarticulata, exteriori subulata, acuta. posteriores breves, filiformes, triarticulata mandibula dorso inseri. Mandibula brevis, cornae, crassa, fornicatea, obtusa, vix dentata, dorso palpiger. Labium triplex membranaceum. exteriors quadriarticulato; laeinae subequales, linearias. medium bifi. laeinae rotundatis, divisis, aquilinis. Inferioris bifi. laeinae aequilibus, rotundatis, extorsum erossibus, divisis. Antennae quatuor inequales, pedunculata, simplicissima. Anteriora breviores, subulate; pedunculo biarticulato, posteriores longiores, setaceae; pedunculo triarticulato. Metamorphosis completa larva puppake omnibus partibus completis, agilibus. Vitus e rapina miniorum aquatilium plantisque aquaticis," pp. 142, 143. The species grossipes is
THE VOYAGE OF H.M.S. CHALLENGER.

1777. PENNANT, THOMAS, born 1726, died 1798 (Webster).

In his advertisement he says, "In my arrangement of the present work, I have taken the liberty of making a distinct class of the Crustaceous Animals; and separated them from Insects, among which they are usually placed." Among the lobsters, Astacus, which he defines with the words "Cylindric body. Long antennae. Long tail," he places "Cancer linearis Lin. syst. 1056. Lesser garnel or shrimp. Martens, Spitzberg. 115. tab. P. fig. 1," "with long slender claws, placed very near the head." From the figures, pl. xvi. fig. 31, it is pretty clear that these "claws" are the antennae, and that Corophium volutator, Pallas, is intended, the two references being quite inappropriate. He next gives "Cancer atrosus. Lin. syst. 1056. Mirum animalculem in corallinis, &c., Baster, 1, 43, tab. iv. fig. 11." He mentions for this "a slender tail between the last pair" of legs, which would apply to Cereops, but the figure, pl. xii. 32, gives no plea. He gives "C. Pulex. Lin. syst. 1055, No. 81," "very common in fountains and rivulets," probably Gammarus pulex, and "C. locusta. Lin. syst. 1055, No. 82," "which leaps about with vast agility," and which may therefore refer to Orchestia or Talitrus, or both.

1778. DE GEER, CARL, born 1720, died 1778 (Biographie Universelle).

Mémoires pour servir à l'histoire des Insectes, Par M. le Baron Charles De Geer. Tome septième. Ouvrage posthume. A Stockholm, MDCCCLXXVIII.

On pages 525-533 he describes "Squilla (Pulex) aquaticus, corpore compresso, pedibus quatar antiosis, chelatis, oruida setis sex bifercis terminatis," with references to Gronovius, Zooph. 390., Linn. Syst. Nat., ed. 12, p. 1055, 81. Geoffr. La crevette des ruisseaux, Ray, Frisch, Klein, Roessel, and Baster. From the remarks which he quotes from various authors, we may suppose that he regarded Orchestia, Talitrus, Gammarus locusta, and the like as all agreeing with Gammarus pulex, which is apparently the actual subject of his description and of plate 33. On pages 540-544 he describes "Squilla (Balani) corpore ovale, depressum; segmentis distinctis, pedibus cheliferis; testii quarto parte linearis muticis," with references to "Oniscus (Ceti) orulis," &c., Linn. Syst., ed. 12, p. 1060, No. 6, and Martens Iter Spitzb., Tab. Q, fig. D. This he figures on pl. xii. figs. 6-10. In the detailed description, in regard to "les pattes de la troisième et quatrième paires," he says, "Elles sont longues, deliées, filiformes et très-flexibles, de grosseur partent égale et à l'extrémité arrondie, où l'on ne trouve ni ongle, ni crochet, en sorte qu'elles ressemblent plutôt à de longs filets qu'à des pattes." Nevertheless, the enlarged figure he gives them the appearance of being tricaricate, probably under the impression that if they were feet, they must be jointed. He also quotes the observation from Martens, that when the animal is sucking the skin of the whale, these four filiform feet are elevated over the back, so as to touch from opposite sides, and specimens, he says, in his own collection show them in this position.
REPORT ON THE AMPHIPODA.

1779. FABRICIUS, JOHANN CHRISTIAN.

Reise nach Norwegen, mit Bemerkungen aus der Naturhistorie und Oekonomie. Hamburg, 1779.

At page 247 Fabricius says, "Unter den Insekten ist nichts selteres; doch fand ich eine Menge kleiner Krebse, in Weingeist aufbewahrt, die in Norwegen unter den Namen Aat bekannt sind. Dieses Aat schwimmet in Sommer bey warmer Witterung in unendlicher Menge in dem See. Man kann keiner Eimer voll Wassers schöpfen, ohne Millionen dieser Thiere mit hineinzulegen. Diese sind, welche den Fischen, insbesondere den Heringen, zur Nahrung dienen, sie unter das Land locken, da sie ihnen immer folgen, wie der Wind und der Strom sie treiben. Dieses Aat oder diese Krebsarten scheinen daher wenigstens mit die Ursache zu seyn, warum sowol die Menge der Fische, als das Glück der Fischereyen so sehr vom Strome und dem Winde abhängt. Ich beschrieb hier

"Astacus Homari" antennis posticis bifidis, corporis segmentis dorso subspinosis, caudae stylis serratis.

"Hummer Aat Norvagis."

This species Fabricius seems afterwards to have regarded as the type of his genus Gammarus, and since the references identify it with what has since been known as Amathilla sabini, Leach, with which the description fairly corresponds, there seems no reason for withholding from the specific name given by Fabricius its right of priority. The species should therefore be called Amathilla homari, Fabr.

On page 258, after mentioning the occurrence of Gammarus locusta in great numbers at small depths, he describes —

"Gammarus longisporus" manibus adactylis, antennis corpore longioribus cauda obtusa.

"Cancer ericopis" Linn. Syst. Nat. 2. 1655. 80.

"Astarta mutica", pede antico subulato, edentulo longissimo, crassissimo Gronov. Zooph. 989. tab. 17. fig. 7.

Why he rejects the earlier specific names, he does not explain. In the synonymy he seems to have used the word crassipes twice by mistake for grossipes, misled perhaps by Gronov. See Note on Palphs, 1766. What is meant by "Gen. Ins. App." I have not been able to discover. It may refer to some appendix prepared but not published. In the Species Insectorum, 1781, the reference is not repeated.

On page 328, he says, "Unter den grossen Melanis hielt sich ein kleiner Gammarus auf, der mir noch gleichfalls unbekannt war.

"Gammarus melanurus", manibus quattuor monocolaclylis, capite obtusissimo.

This description is accepted as applying to Hyperia medusanum, O. F. Müller.
At page 385 he describes the new species:—
"Gammarus corniger manibus adactylis, rostro incurvo subulato, thoraces lateribus cornu duplici.
This has since been recognised by Boeck as identical with Epimeria tricristata, Costa, and is accordingly named Epimeria cornigera, Fabr.

1780. Fabricius, Otto, born 1744, died 1822 (Hagen).

Fauna Groenlandica, systematica sistens Animalia Groenlandiae occidentalis haec—
tenus indagata, quoad nomen specificum, triviale, vernaculumque; synonyma
auctorum plurimum, descriptionem, locum, victum, generationem, mores, usum,
capturamque singuli, provt detegendi occasio fuit, maximaque parte secundum
prorias observationes Othonis Fabricii. Hafniæ et Lipsiæ, MDCCXXX.

On pp. 212, 213, No. 179, he describes a Podura maritima from the sea shore, with a reference
to Ström, Act. Hafn. ix. p. 582, Tab. v. (?), which does not appear to be a Crustacean, and
must therefore be distinguished from Poda’s Podura maritima.
Squilla lobata, p. 248, for which he refers both to Squilla lobata, Müller, and to Cancer filiformis,
Linn., Pall., may be either Caprella septentrionalis, as supposed by Kroyer in 1838,
and afterwards by Boeck, probably on Kroyer’s authority, or Caprella linearis, as Mayer
seems to prefer, while half inclined to make septentrionalis itself a synonym of linearis.
The Oniscus ceti, No. 230, as Lütken points out, is not entirely free from the early confusion
about Cyamus. The definition is taken with slight change from Linnaeus, and the description
by Pallas is referred to as making further details needless, although both Linnaeus and
Pallas had to do with Cyamus mystaceus, while Fabricius was evidently concerned with what
Lütken has named Cyamus boops, as shown by the statement “mea exemplaria accepit
in balaena boope.” Lütken remarks also that Fabricius is wrong in the detail supplied
by the words “fumora postica biculata.”
Oniscus pater, No. 231, is no doubt, as Kroyer and Boeck say, Gammarus locusta. Fabricius
himself in the synonymy gives “Cancer Locusta, Syst. nat. 1, 1055, Faun. Suec. 2041,
indice Pallade l. c. locum pertinent; et certum est, descriptionem cancri coeundi It. Gothl.
260, ibi citatam Onisco pulici omnino convenire, licet ab autore ipso pro distincto
habitus.”
Oniscus medusanum, No. 232, is by Bovallius (1886), called “Hyperia Kroyeri.”
Oniscus cicada, No. 233, with “color totus pulchre rubiscundus, oculis sanguineis,” is considered by
Kroyer, in 1838, to be probably the same as his own Amphithoe inermis. Milne-Edwards,
in 1849, Hist. des Crust., III. p. 25, thinks that it is very likely the same as the Amphithoe
serra of Kroyer, which he would place in the genus Acanthocera, Owen and Ross. But
on p. 34 of the same volume he questions whether it may not be the same as Amphithoe
inermis, Kroyer. Kroyer himself, Thl. Sc., iv. 161, note, in 1842, repudiates Milne-Edwards’s,
first suggestion, and says, “Oniscus cicada is probably a species of the genus Amonyx.” In
Tidsskr., scr. 2, vol. i. p. 611, in describing the new species *Anonyx galosus*, he remarks in a note, "It is, however, possible that this species is not new. *Fabricius* *Onicus cicada* seems in many, if not in all, respects to come very near to it, and is obviously in any case an *Anonyx*. By means of the Greenland name this doubt seems capable of solution, at least if the name applies to but one species." With such testimony from Krøyer himself, it seems only just to reduce his *Anonyx galosus* to a synonym of *Onicus cicada*, O. Fabricius. It shares with the so-called *Gammarus arcticus*, Scoresby, the reputation of exercising extreme voracity upon dead seals.

*Onicus abyssinus*, No. 236, Krøyer in 1838 identifies, though very hesitatingly, with his own *Amphithoe corculata*. Subsequently Krøyer united *Amphithoe corculata* and *Amphithoe incrustis* as the two sexes of one species, which Boeck places in his genus *Pontogaea*, as *Pontogae a incrustis*.

*Onicus serratus*, No. 237, Krøyer, in 1838, renamed *Amphithoe serrata*, and afterwards *Acanthoanum serrata*. Boeck calls it *Acanthoanum serratum*, the generic names *Acanthoanum*, Owen, and *Vertamus*, White, to which this species had been successively assigned, being both preoccupied.

*Onicus arenarius*, No. 234, is defined as "*Onicus cancriiformis*, antennae impressusculi, pedibus 4 anticis cheiliformibus levibus, antennae subequalibus, &c." followed by Ström's definition in the synonymy, "Cancer macronura articulatus, manus sollicitus, dextra carinata serrata, opinis canalis bijulus, Act. Hafn. x. 5. Tab. ii. f. 1–8 et Müll. prod. 2358?" The references imply that *Amathilla hovari*, Fabr., 1779, is intended, a species to which Krøyer, Grøn. *Amph.,* expresses his surprise that one so large should not have been noticed by Otto Fabricius. The name *Onicus arenarius* is preoccupied by Slabber.

*Onicus Stromiannus*, No. 235, is defined as "*Onicus cancriformis compressus, pedibus 4 antici cheliformibus subdentatis, antennae summis brevissimis, &c." followed by Ström's definition, Act. Hafn. ix. 588, Ström being spoken of as the discoverer. Ström's species is identified by Boeck with *Orchestia (littorea) gawmarridus*.

1780. DE QUÉRONIC.

The "insect" from Morbihan which he figures, and describes as *Puce de mer arpenteur*, giving the latter epithet from its mode of walking, is clearly the skull-headed skeleton shrimp, *Caprella arenifera*, Leach. Boeck says that de Quéronic "figures a *Caprella* which seems to be the female of *Caprella linearis* and a variety of it, which has been made a separate species, *Caprella arenifera*." This latter Mayer identifies with *Caprella arenifera*, but inclines to regard de Quéronic's species as the two sexes of *Caprella tuberculata*, Leach and Westwood. It is, however, only the *Caprella arenifera* which has the peculiar skull-like head figured by de Quéronic. There is nothing in his paper, either in the description or the figures, which are here reproduced, that refers to more than a single form. He draws it, indeed, in two postures, but without any intimation that the figures are taken from more than one specimen. His actual words are, "Notre insecte est couvert d'une écôre semblable à celle des Puces de mer, de même consistance, et aussi d'un rouge lâvé, sur-tout après la mort de l'animal." C'est ce qui me porteroit à lui donner le nom de Puce de mer, auquel j'ajouterois celui d'arpenteur pour caractériser sa marche. La figure A représente l'animal de grandeur naturelle, et à-peu-près dans l'attitude où on l'a vu marcher.
THE VOYAGE OF H.M.S. CHALLENGER.

$B$, est le même insecte vu à la loupe, et dessiné avec toute l'exactitude possible. L'œil qu'on lui voit à chaque côté de la tête, est pendant sa vie, ainsi que lorsqu'il est mort, du rouge le plus vif, semé de petits points jaunes. Sa gueule est ouverte comme celle des poissons, et non comme celle des crabes, écrevisses, etc. On l'a vu remuer les mâchoires qui ont plusieurs plis tels qu'ils sont représentés; mais il n'a pas été possible d'apercevoir si l'intérieur est garni de dents, comme l'insecte de Ceylan. $CC$, sacs membraneux, velus, et blancs, dont il y a deux de chaque côté, en dessous l'un du second, l'autre du troisième annuaire. Ces sacs servent probablement à l'insecte, à se soutenir dans l'eau et à nager. $D$, bras garnis chacun d'un gros crochet, parfaitement semblable à celui qui termine tous les pieds de l'insecte de Ceylan. La comparaison de notre figure avec celle de M. le Commandeur Godet, page 276 du troisième volume des Savans Étrangers, fera voir en quoi ces animaux se ressemblent, et en quoi ils diffèrent l'un de l'autre.

1780. Lepechin, Ian. Lepechin, Ivan Ivanovich (or Lepechin, Ivan), born "vers le milieu du 18e siècle," died 1802 (Biographie Universelle), born 1737, died 1802 (Hagen).

Of these three species, the second, Oniscus scorpionis, Tab. viii. fig. 2, is not an Amphipod; the first and third are described as follows:—"Oniscus aculeatus. Tab. viii. Fig. 1. Oniscus
REPORT ON THE AMPHIPODA.

49

thorace nudus, dorso tribus ordinibus cuspidebus notato. Descriptio. longitudo totius animalisculi, exceptis antennis, XI linearium. Caput hemisphericum, occuli magni, protuberantes, cocculi. Os inferior situm in fronte rotundata pone insertionem antennae, protubernans dentillicus quatuor, quorum duo superiores, maxillam efficientes, validiores sunt, instructum. Antennae IV, per paria dispositae; par inferior magis validum quam laevius et articulatum; articulis capitii proximis breuissimis, secundus longior crassior que complanatus, tertius brevior secundo et debilior, quartus longissimus setaceus. Thorax semionatus gibbus, segmenti VI, quorum vnumqueque in medio tuberculo, vix nudo oculo conspicuo, notatur; at in viiimo segmento inferior margo cuspidebus cuspidebus armatur; reliquum corpus tribus constat articulis, quorum latera sunt plana in formam semilunae efficit, in abdomine appendicibus trium parium pediformibus, articulatis, extremo setaceis, instrucrum; in dorso ante tribus ordinibus cuspidebus armatu, quorum debiliora medio dorsum, fortiore vero vicinam, latera, occupat. Pedes VII, parium, quorum duo anteriores echiliformia, vnum acuto terminata, breviora, reliqua longitudine crescent, ita vt viiimum sit longissimum, quadrilateratum, femora latera fere triangularia."

The first of these Arctic species was again described as a new species by Sabine in 1821, under the name Tidius ruptorhi, which Owen in 1831 changed to Cystophthodes solenobii Milne-Edwards, probably by an oversight, omitted it from his Hist. des Crustacés. Kroyer in 1841 fully described it, but without reference to Lepechin, under the name Cystophthodes solenobii, while Stimpson in 1866, without reference to Kroyer, transferred it to Costa's genus Amphitheronus as Amphitheronus solenobii. Goës in 1865 gave it the name Amphitheronus aculeatus. Bock in 1870 renamed it Tritopus aculeatus, under the impression that Costa's Amphitheronus, 1851, was preoccupied, for he says in his larger work, p. 510, "Jeg har i 1870 indekænket denne Sletts Omfang til de Arter, der staa nær A. cataphractus, Stimpa, og emblet tet Slettsavnet, da det alledre forhe, i 1843, er af Fitz benyttet til et Reptil." Curiously enough, it is Tritopus, not Amphitheronus, which not Fitz but Fitzinger uses for a genus of reptiles. In 1883 S. I. Smith changed Bock's Tritopus, because it was thus preoccupied, into Rhachotropis. In 1874, that is, before the second volume of Bock's last work was published, Buchholz restored the name Amphitheronus aculeatus, uniting with this species Bock's Tritopus Helleri, but retaining the name Tritopus fragilis which Bock had given to Paramphithodes fragilis, Goës. Amphitheronus, though not preoccupied, lapsed at its first institution as a synonym of Dexamene.
Oniscus euspidatus, the remaining species, was supposed by Boeck in 1870 to be identical with Owen's Acanthosoma hystrix, 1853, which was renamed Amphiphilus hystrix by Kroyer in 1838, and Paramphithilus hystrix by Bruzelius in 1859. The latter name was accepted in the Brit. Mus. Catalogue, the authors before Boeck not taking notice of Lepechin's Oniscus. Owen's name Acanthosoma being preoccupied, among Hemiptera in 1824 and elsewhere, was changed by Boeck into Acanthosoma, who therefore calls Lepechin's species Acanthosoma euspidatum. Under this name the species still stands, but upon the synonymy above-mentioned from Owen, Kroyer, and Bruzelius, which was accepted by Buchholz in 1874, E. J. Miers has since thrown doubt. See his Spitzbergen Crustacea, 1877, in which he points out that Oniscus euspidatus, Lepechin, Acanthosoma hystrix, Owen, and Acanthosoma hystrix, Buchholz, though all belonging to the genus Acanthosoma, are probably distinct species.

1781. Fabricius, J. C.

Species Insectorum exhibentes corum differentias specificas, synonyma Auctorum, loca natalia, metamorphosin adiectis observationibus, descriptionibus. Tom. I. Hamburgi et Kilonii, MDCCLXXXI.

The Agonata are here still the fourth class, with the genera, Cancer, Pagurus, Sepiilurus, Astacus, Synilla, Gammarus.

On page 511, Astacus includes the following entry:—

"Habitat in Oceano Norwagico." For the probability that this species is in fact an Amphipod, the type-species of Bate and Westwood's genus Amatilus, see notes on Fabricius, 1779 and 1798.

Among the Synistata, Class III., Oniscus includes, on pages 377, 378, the same Amphipods as in the Syst. Ent. of 1775. These are, 10. Oniscus biciculatus; 14. Oniscus spinulosus, which is Guérin's Cystisoma; 15. Oniscus gibbosus, transferred in 1877 to Gammarus, but properly, like the next species, belonging to the Hyperinæ; 16. Oniscus quadriradiatus, subsequently recognised as a synonym of Gammarus medusaram; 17. Oniscus ceti. While
REPORT ON THE AMPHIPODA.

51
curtailing some of the descriptions previously given, Fabricius enlarges that of *Oniscus ceti* with the following synonymy:

"Squilla Balcanae corporis ovoidale depresso, segmentatis distinctis, pedibus cheliferis, tertii quartique paris linearibus mutatis. *Deprec Ins.* 7. 541. 6 tab. 42. fig. 6. 7.

"Pediculus Ceti. Martens Spitalh. tab. 8. fig. D.

"Sch. Miss. 1. tab. 90. fig. 5.

"Pall. Spizel. Zool. fasc. IX. 76. tab. 4. fig. 14.

"Eyesle Groenl. tab. 37.

"Habitat in Oceano boreali balanis molestis.

"Ah hoc genere differe videtur victus examinandus."

Thus Martens' whale-house is rightly placed, and not, as in the earlier work, erroneously referred to *Pediculus (?) Balcanarum*.

1781. Ödman, Samuel, born 1750, died 1829 (G. O. Sars).

Ödman was doubtful whether the Crustacean mentioned in Linnaeus Ölands-ssa, p. 42, and Gothlands-ssa, p. 260, should be called *Pulex* or *Locusta*. It is clear from the account he gives of his own species that it is marine, and therefore not *Gammarus pulex*, but in all probability *Gammarus locusta*. See his further account 1790.

1781. Schrank, Franz von Paula, born 1747, died 1835 (Hagen).

Enumeratio insectorum Austrie indigenorum. Avgvste Vindelicorum, MDCCCLXXXI.

"Cancer macrourus articularis compressus, manibus quatuor adactylis, pedibus decem.

"Habitat in aquis, rivis, fонтibus; albissimus, dum natat; eincerus, dum in aere essisse: si vel molius accessit calor, rubescit.

"Nomen germanicum Austriaci usitatissimum."

From the habitat "in rivis," it may be inferred that Schrank was acquainted with *Gammarus pulex*. From the habitat "in fontibus," coupled with the remark "albissimus, dum natat," it seems fair to suppose that he had also seen one of the well-shrimps, such as *Niphargus aquilex*.

Johann Franz van Berckley's Naturgeschichte von Holland, aus dem Holländischen übersetzt," has the first volume dated Leipzig, 1779, the second, Leipzig, 1782. This German translation of the work is the only one I have been able to obtain, and in the second volume the translator gives notice that he has taken the liberty of considerably curtailing the original. In point of fact, all the zoology seems to be omitted. From local notices in the work it may be inferred that the author's name was certainly van Berkhey.

"He published in Dutch a history of Holland, geographical, physical, natural, and civil, of which a French translation appeared in 1782. He was the first to change the Linnean classification of the Crustacea, forming them into a separate class, which he placed immediately before that of the Insecta. But besides that he only characterised his divisions in a complicated, vague, and often unmeaning way, he departs from the natural order, by placing the Testacea below the insects, so that the Crustacea come next to the bony fishes." Lartillé, Consid. gen., pp. 18, 19, 1810. Compare note on Brisson, 1756, in regard to the question of priority, since in regard to arrangement the classifications by Brisson and Berkhey seem to have been practically the same.

1786. Mohr, Nicolas.

Forsøg til en Islandsk Naturhistorie, med adskillige økonomiske samt andre Anmærkninger. Kioøenhavn, 1786.

Among the Apterous Insects he gives, on page 107, "243, Cancer pulex (Faun. Scic. 2041). Marflue," which, he says, is not only in very great numbers on the strand, but also out in deeper water, where it does great damage, as well to the nets as to what is caught in them. He thinks that it would be difficult to get a sufficient supply of horse-hair for making the under part of the nets, which was the preventive believed in against these depredators.

For "244, Cancer medusarum," he refers to "Strom's Sc. Skr. 188, Tab. 1, fig. 12, 13," and considers that the description and figures given by Strom are very accurate, he himself having had the opportunity of comparing them with specimens taken from Medusa aurita.

246 is given as "Cancer macrorum articularis manibus adactyle femoribus posticis orbicularibus spinis caude bifidis (Act. Soc. Sc. Hafn. 9, D. 588, Tab. viii.), Og. Nat." It is like a little Marline, but nearly white, with red eyes, and is much fatter, though smaller than the Marline. Another species, like it, but much larger, is called by the inhabitants, Grænlands-Og. Ogn, the presence of which indicated the speedy arrival of fish and whales. 247 is "Cancer filiformis (Syst. Nat. 1056), Squella lobata (Müll. Prodr. Zool. Dan. 2359)."

The Latin description of 246 relates to Strom's Orchestia, 1765, whereas Mohr's own account of it probably refers to some species of Anonyx, at any rate not to an Orchestia. 247 is identified by Boeck with Caprella septentrionalis, Kroyer, but for this identification there seems to be no adequate ground. Mohr's own references have to do with Caprella linearis, Lin.
1787. Fabricius, J. C.

Mantissa Insectorum sistens corum species nuper detectas adjectis characteribus genericis, differentiis specificis, emendationibus, observationibus. Tom. I. Hafniae MDCCCLXXXVII.

The Agonata here comprise seven genera, Cancer, Pagurus, Hippa, Scyllarum, Astacus, Squilla, Gammarus. Gammarus contains the same list of species as in the Species Insectorum of 1781, with the addition of Gammarus gibenous. The reference to its synonym Oniscus gibenous in the earlier work is misprinted 577 for 377. Cancer linearis, Pennant, is given as a synonym of Gammarus longicornis. Oniscus bicaudatus is retained among the Synistata, where also Cyamus is still represented by Oniscus cetti.

1788. Müller, Otho Fridericus (Otto Friedrich), born 1730, died 1784 (Hagen).

Zoologica Danica seu Animalium Danic et Norvegiarum rariorum ac minus notorum Descriptiones et Historia. Volumen secundum explicacioni iconum fasiculi secundi ejusdem operis inservientibus. Ad formam tabularum denovo editid frater auctoris. Hafniae, MDCCCLXXXVIII.

On pp. 20–21 is described Squilla ventricosa, "Squilla rubra depressa, pedibus quatuordecim setaceis secundo pari clavato. Zool. D. pr. 2360." On pl. lvi. this is figured together with Squilla quadrilobata. For the latter, on pp. 21–22, references are given to "Zool. D. pr. 2359." "Faun. greeii. 225." "Act. helv. 5. p. 368." "Cancer atomos, Linne. Syst. p. 1526." "Brit. Zool. 4, p. 17 f. 32." "Baster subsecis, i. t. 4 f. 2." "Oniscus Scopoliendi, Pall. spicil. 9. p. 78." The description is followed by these remarks: "Descriptio Canceris linearis et filiformis Linnei, synonymique a Martinus petitum nostrae Squillae aequi convenient, at citata Basteri figura Cancrum atomum esse jubet; in aquis dulcis fluctuantis habitare hallucinatione dictum est; cur in fluctuantis non percipio. Cauda in figura Basteri certe errore delineata Linneum, ut has species cauda prorsus carentes macrourus seu longe elongata dicet, seduxit. Exactissimam clariss. viri Pallis, Gronovius et Otho Fabricius descriptionem dedere; ille a Cancero jure solemnem Oniscus junxit, hic messum Squilla vindicavit. Gronovius his insecta olim Squillae, Linnei deim Cancri, Pallas Oniscii nomen constituerant: minus bene igitur in systemate entomologico novum Gammaurum nomin et quidem insecti maximi valde minuit actum est. Vesiculis Gronovius pedes, pedum vicarias claris. Pallas quidem nominant, ut nec pedes sunt, nec homina vices gerunt. Animal Zeylonicum G. de Rivile in Mem. de Mathem. et Physique vol. 3 et Bel. Samml. vol. 9. p. 42, t. 1, f. 6 nostram vesiculis orbatam sistit." Müller’s indignation at seeing the name Gammarus, which belonged specifically to that "very large insect," the common lobster, applied to a genus of "very minute" shrimps, does not appear wholly unreasonable. But if Fabricius committed an error of judgment in this respect, it is too late now to correct it.

1788. Gmelin, Johann Friedrich, born 1748, died 1804 (Hagen).

In this edition the Insecta Apter a are to be found at the end of "Tom. I. Pars. V." On page 2963, to the definition of Cancer is added, Pulpi sex inaequalis, Mandibula cornua, erassa,
THE VOYAGE OF H.M.S. CHALLENGER.

Labiatus triplex. Under this extensive genus "Cancer," in the groups of species corresponding to the "Astaci Fabricii," is given, "homari. 155," with references to Fabricius, Müller, and Stroem, and the observation "Habitat in Oceano norwegico, minutas" (p. 2987). The epithet minutas would be inapplicable to Abaculina sabini as an Amphipod, but would very well apply to it when grouped among the Astaci. It gives, therefore, an additional reason for supposing that Astacus homari was originally misplaced. See the note on Fabricius, 1779 and 1798. Under the same genus "Cancer," the group of species headed "arenae pedunculatus simplexsimius, Gammae Fabricii," (p. 2991), includes, with the addition of atomus and filiformis, the same list as that given for Gammae by Fabricius in his Mautiss, 1878. The Linnean name grossipes is reinstated for the species Gammae longicornis. For "Cancer Pulex," besides the references to Fabricius, Spec. Ins., the following are given "Geogr. ins. par. 2. p. 667. t. 21. f. 7. "Edna. nov. act. Stockh. 1782. 11. 9. Habitat ap. Pull. n. nord. Beogr. 4. p. 396. Habitat frequentissimius ad Oceani littora, atiam in fungibus, fossis, lucubus adae Siliviria salsis, dorso immatuis, salices, in piscium branchiatis ulcera excitando piscibus, et incisis retia destructndo piscatoribus tujetis, a recurrenstra conestus, roest lucena." After Cancer linearis, 83, is given "Atomos, 84. C. lineatis, manubius adactylis, pedibus undecim. Brit. zool. 4. t. 12. f. 32. Habitat in Europe aquas fluctuantes dulcisimius, modo occultis visibilis, et vero a linearis distinctus?" and "filiformis, 85. C. linearis, pedibus decem, medias majoribus. Amon. acad. 6. p. 415. n. 99. Habitat in Malaccia, politicis longissimis, debilis." For Cancer medusarum reference is made to "Fibr. spec. ins. 1. p. 378. n. 16. Oniscus (quadricornis) oblongus, stylis candidulis senis, antennis quaternis," as well as to "Fibr. spec. ins. 1. p. 518. n. 12. want. ins. 1. p. 355. n. 13. Muhl. zool. dad. prodr. 2355," and "Stroem surnan. 118. t. 1. f. 12. 13. Pulex cauchiformis." The genus Oniscus contains the Amphipod, Oniscus ceti, 6, with references to Linnaeus, Fabricius, Degger, Marcus, Seba, Pallas, Egle, and the remark, "Habitat in Oceano boreali, borealis modestus, an longus generis?" p. 3011. It contains also Lepechin's two Amphipod species, Oniscus aculeatus, 23, p. 3013, and Oniscus capillatus, 28. p. 3014, and concludes with the following notices, of which the first, not being an Amphipod, is only here inserted for the sake of comparison with Turton's Linnaeus:

"Stroem surnan. 1. p. 188. t. 1. f. 12. 13. Cancer medusarum.

"Habitat sub medullis capillata foliamentis, 10 lineas longa.

"Cicada. 34. O. compressus sublinearis, manubius quatuor spuriis, antennis summis brevioribus, caudae dorso levii. O. Fabr. fn. groenl. p. 258. n. 235. Habitat in mari Groenlandian altissimae, polyisum ad ostia rivorum, 5 lineas longe.

"Habitat in Groenlandiae littoribus arenosis, supra alczum umbilicalem, cum 2 precedentibus et 3 insequentibus conceris, presentem pulci affinis.

1789. RÖMER, JOHANN JACOB, born 1761, died 1819 (Hagen).

Genera Insectorum Linnaei et Fabricii iconibus illustrata a Johanne Jacobo Roemer. Vitæduri Helvetorum. MDCCCLXXIX.

In the Systema Linnaei here given the Aptera are on pages 32-36, not including any Amphipoda. In the Systema Fabricii, the Agonata, pages 61-63, include "437, GAMMARUS, antennæ quater simplicissime pedunculata: antica breves subulata: postica subacuta. Longicornis, Fabr. Sp. Ins. I. p. 516, n. 4. Manibus aliséatis, antennis corpore longioribus, caudis obtusis. Tab. xxxiii. f. 6. Habitat in Europæ oceano." This is Corophium volutator, Pall. The Antitetara, pages 82-86, include "193, PYCNOGONUM, Haustellum tubulosum, conicum, absque setis, Palpibus duo ad basin haustelli. Balanarum, Fabr. S. Ent. 810, 33. Sp. Ins. II. p. 475, n. 1. Phalangium Linn. Pediculus Fabr., in Syst. Palpis dubius, corpore ovato. Tab. xxxvi. f. 17. Habitat in Oceano Norwagico." The figure is obviously borrowed from Brümich, although that author is not mentioned. In the figures of Cyamus by Martinus, Egede and Adelung, the head is represented pointing downwards, as though the artists did not know which was the head and which was the tail, since the general rule in older, as well as in recent, times is to give vertical figures with the heads uppermost. Brümich figures his Pycnogonum head downwards, perhaps for purposes of comparison with the old figures of Cyamus, since he at any rate well knew the structure of the creature he was drawing.

1789. MÜLLER, OTHO FRIDERICUS. ABILDGAARD, PETER CHRISTIAN, born about 1740, died 1808 (Nouvelle Biographie générale).

He figures, pl. cl., and on pp. 33-34 describes, Gammarus pedatus, "Gammarus linearis corporis articularis sex, pedibus quatuordecim unguiculatis ultimis quatuor longioribus, cauda nulla..."
distincta," referring to "Squilla acuata pedibus quatuordecim Gronovius in Actis Holc. 4, p. 39, t. 4, figs. 8, 97" and "Cancer linearis, Linn. Syst. nat. p. 1066, n. 831." To the fuller description he appendeth the observation, "Ad genus Gammarorum Celeb, J. C. FABRICIUS hoc insectum refero, quia primus certis caracteribus cancerum familium ab onisce distinctum; proprium tamen genus cum Squilla quadrabiloba et ventricosa Mulleri, quius cauda nulla et pedes omnes unguiculati constitutur videtur." It is now recognised as *Proa ventricosa*, O. F. M. On pl. cxiv., figs. 11, 12, and p. 58, he figures and describes *Gammarus quadrabiloba* 2, with references to "Squilla lobata, Zool. Dan. prodr. n. 2339."

"FABRICIUS Faun. Groenl. n. 225." "Squilla quadrabiloba, Zool. Dan. fasc. 2, p. 21, tab. 56, fig. 4-6." On pl. cxvi., figs. 1-6, and p. 59, *Gammarus podurus* is given, considered by Milne-Edwards to be an *Amphithoe*, by Spence Bate a *Pharsus*, by Boeck with more probability an undoubted *Gammarus*. It has a red spot on each of the seventh, eighth, ninth, and tenth segments. Dorsal spines are shown on the penultimate and antepenultimate segments. *Gammarus mutillus*, figured on pl. cxvi., figs. 1-11, described on p. 60, in Boeck's opinion is like but not the same as *Gammarus locusta*. Milne-Edwards compares it with his *Gammarus suivi* (called *Meca suivi* by Spence Bate), but thinks it distinguished by the long accessory flagellum, the narrow first joint of the hind legs, and the large rami of the last uropods. He says, Hist. des Crust., iii. 53 n., "La première figure représentant cette crevette de grandeur naturelle est très-mauvaise, et a été reproduite dans l’Encyclopédie, Pl. 336, fig. 43; mais les autres, qui peuvent réellement être utilisées pour la détermination de l’espèce, n’ont pas été données dans cet ouvrage." The name *mutillus* is itself not very easy to understand. It agrees, indeed, very well with the fig. 1 which Milne-Edwards censures, for in that the animal abruptly ends with the third pleon-segment. It might have been suggested that the other three segments were accidentally missing, but that Abildgaard has carefully figured the first, second, and third uropods. In the enlarged figure of the antennae, the flagella of the upper and lower are drawn as equal in length, and the accessory flagellum has about four and twenty joints. If this figure can be trusted, it should be of essential service for determining this still doubtful species. There are dorsal spines or teeth on the hind margins of the last segment of the pleon and the first three of the pleon, which constitute an additional mark of distinction between this species and *Meca suivi*. *Gammarus spiniarius*, pl. cxix., figs. 1-4, pp. 66-67, is known now as *Lencatho spiniarius*. *Oisicus ceti*, pl. cxix., figs. 13-17, pp. 69-70, with references to numerous authors and the synonyms "Oisicus Ceti, Linn.,” "Pediculus Ceti, Martens,” "Squilla Balene, DeGeer,” corresponds with *Cyamus nodous*, Lk., according to Lütken, the synonymy being erroneous.

1791. OLIVIER, ANTOINE GUILLAUME, born 1756, died 1814 (Hagen).

The article Crevette extends from page 182 to page 190. The genus is thus defined:—

REPORT ON THE AMPHIPODA.

regardées comme des mâchoires. Elles sont au nombre de six, trois de chaque côté. Elles sont larges, aplatis, un peu ciliées à leur extrémité interne.

"La lèvre inférieure qui se trouve en-dessous, est longue, recourbée, et couvre presque toute la bouche. Elle est membraneuse, échancrée, et terminée par deux petites antennes.

"Les antennes sont au nombre de huit; elles sont courtes, presque sessiles, et composées de trois ou quatre articles peu distincts. Les deux antennes sont insérées au dos des mandibules. Les quatre qui suivent, ont leur attache au dos des mâchoires, et les deux dernières sont placées à l'extrémité de la lèvre inférieure."

Some of the subsidiary observations show that the author was not fully aware of the distinction between the Orthestiâde and the Gammaride, nor is any special criticism exercised upon the synonymy. Faxon, Bibl. Embryol. 1882, calls attention to his "observations on young Gammarus, p. 183."

1791. WULFEN, FRANZ XAVIER L. BARON von, died 1805 (Hagen).

From the subjoined account of "Cancer Pulex," it would seem that this author has carried to the highest point the confusion of species under this title, which to his apprehension probably included almost all the Gammarina. At page 312, he gives:

"52. Cancer Pulex.

"Cancer macrourus incurvus articularis compressus; pedibus quattuordecim; antieis duorum parium subcheliferiformibus, retractili-uncinatis; stylis caudae bifurcatis trium parium.

"Vulgatissimus ad maris littora sub lapidibus; adhaerens etiam passim Fucis Ulvis Spargis. In dulciibus ita fluviorum lacuum stagnorum aquis frequentissimus. Non difftt Cancer Linnæi Seopolique Locusta, ab eorumdem Cancer Pulece specific. Magnitudine, colore, etc. varitat admodum. Vidi aquo saltem, excoliorem alias, et transparentem, nunc album, jam et aquo fuscescens, subnigricarem interdum etiam; commune fu aquae griseeet; escissione plus minus flavescimp. Nunc non nisi tres quatuor lineas est longus; alia octo, decem, pollicaris reperitur etiam, ac eum proportione magis, minusve corpulentum. Bini quoque extimi caudae styli longiores quandoque, alias contra ulce parvi, ut vixdum liberis

instructe; extinque contra itidem tres, et ipsae quoque ad lateralem utrique margine pinuncula
pediformi natatoria terete bifurca longiuscula retrovers versa, et velut adscendentc, ciliisque
adperso, instructe.

The above carefully detailed account probably refers to Gammarus pulex alone, without taking
any notice of the other Amphipoda, differing in colour, size, and shape of tail which Wulffen
supposed to be merely varieties of it. The Crustaceam which he next describes, he calls
"Cancer Locusta," the largest of all the Cancri he had ever seen, and a specimen of which
had cost him two florins in the market of Trieste. He thought Linneaus unlucky in having
attributed the name Locusta "non tam peculiari Cancri alicujs speciei, quam exiguae verius
Cancri Pulicis varietati."
three dissertations "De Apon. Thermis Patav. 1758." G. D. Nardo, 1869, explains it by "Orchestia littorea," a designation which he also applies to the Cancer locusta, L., of Chiereghin, but the figure which he gives of that species shows that the doubts which he expresses about it are well founded, since it is certainly not an Orchestia. Olivi is not sure of the specific determination of the little marine animals which he had found akin to Cancer linearis, but he takes the opportunity of stigmatising the method of Linnaeus as artificial, better suited to facilitate the knowledge of the student, than to show the progression of nature. Hence in the present instance he approves the separation of these insects from the other Graschj, either as was done by Pallas in a separate order of Onischi cancroformi, or as by more recent naturalists in a genus expressly instituted, which he thinks still more convenient.

1793. Fabricius, J. C.

Entomologia Systematica emendata et aucta. Secundum Classes, Ordines, Genera, Species adjectis synonymis, locis, observationibus, descriptionibus. Tom. II. Hafnire. mdcxxviii.

The Agonata are here the eighth class, with eleven genera, Limulus, Monoscelus, Cymothea, Cancer, Pagurus, Scyllarus, Hippa, Galatheca, Astacus, Squilla, Gammaurus. Gammaurus has fourteen species, Gammaurus carinatus being now included, of which the present name is Astacus carinatus. The account of Gammaurus gibbosus does not vary from that which Fabricius gave of the same species in 1775, under the name Oniscus gibbosus. It belongs to the Hyperina, possibly Bock suggests, to Amphipronoë, Sp. Bate, a genus which Claus, 1879, though with much hesitation, supposes to be perhaps the same as his own Parapronoë. Opposed to Bock's suggestion are the facts that in Ampipronoë and Parapronoë the peron is not especially gibbous, its first segment is not very short, and the pleon has five distinct segments besides the telson, with which the fifth and sixth are not coalesced as in Dithyrus or Henityphie. To Cymothea, a new genus among the Agonata, Fabricius in this work refers "Oniscus ceti, Mant. Linn. p. 509." The genera Oniscus, Scolopendra and Julus form the class Mitosata. For "Astacus Homari" of this work, see notes on Herbst, "58," and on the Supplementum Ent. Syst. 1798.

1796. Herbst, Johann Friedrich Wilhelm, born 1743, died 1807 (Hagen).

In this volume, pages 2, 3, Herbst quotes the definitions given by Fabricius in his Mantissa of Cancer, Gammaurus, and the intermediate genera, and rejects them on the ground that they draw marks of distinction only from the antennae. He himself makes six divisions of Crustacea (das ganze Krebsgeschlecht), the sixth of these divisions being the Garnaclasse, with the definition "diese haben mehr als acht Füsse, und oft gar keine Scheeren."

On page 105 the Garnaclasse are also called "Onisci gammarelli," the name given by Pallas. Of these he forms two families, the first "mit ungeheiltem Brustbilde" containing no Amphipods, unless, as seems most probable, Amadillia aubini, Leach, be in reality the
subject of No. 58, which Herbst, combining scraps of information after his usual method, thus describes:

58. Der Hummerkrebs. Cancer (Gammarellus) homari.

The second family of Garnelasseln "have a more aus mehreren Gliedern bestehenden Brustschild, gröstenthileis festzitzende Augen und 7 Paar Füsse." These appear in the Table of Contents as "Zweyte Familie, mit gegliedertem Rückenschilden," the generic name Cancer being in that table applied to all the species not only of this but of all the other divisions. Pages 116–116 contain the "Garnelasseln mit getheiltem oder gegliedertem Rückenschilden," as follows:

63. Der Pfützenkrebs. Cancer (Gammarellus) paludosus," O. Müller; not an Amphipod.

64. Der Poduraskrebs. Cancer (Gammarellus) podurus," Müller. See Abildgaard, 1789.

68. Das Krebschen. Cancer (Gammarellus) cancellus," with the references "Fabric. Spec. Ins. 510. 3. Gammur, manibus quatuor monodactyliis, pedibus sedecim. Mant. 1. 334. n. 3," and "Pallas Spéc. Zoof. Fasc. 9. 59. tab. 3. fig. 15. Oniscus cancellus;" und in der deutschen Übersetzung Oniscus muricatus." Steller, he says, calls this Siberian fresh-water species "Syllla fluviiotilis or physiana fluvii Angara." Dybowski, in 1874, mentions that the form from the river Angara differs from that out of Lake Baikal by having shorter upper antennae and the lateral spines on the fifth segment of the trunk less developed.

69. Die Heuschreckengarnäle. Cancer (Gammarellus) locusta," with references to "Fabric. Spec. Ins. 510. 5;" "Mant. 1. 334. 5;" "Pallas Spéc. Zoof. 9. 56. tab. 4. fig. 7;" "Gesner aqualis, 834." Upon this species he remarks: "This kind (Gattung) is Bellon’s, Mougel’s and Gesner’s sea-flea, in Ray. hist. Ins. 43, and is reckoned by Liné with the common water-flea (water-flesh) of the German rivers among the Krebse. In Linneus’s Syst. Nat. he has attempted to distinguish the two kinds by the number of the feet, and to the species which he calls locusta he attributes, including the four gnathopods (Fangfüsser), eighteen feet, a number due probably to some mistake, and thus far not discovered to exist in any single related genus. Still more incorrect are the citations of authors under the same heading of locusta; for Rösel’s figure T. 3 Tab. 62, here cited, obviously represents C. pulex, as also
REPORT ON THE AMPHIPODA.

Frict. 7. Tab. 18; indeed, in the twelfth edition Rösel's figure is actually referred to two species, to locusta and to pulex, and yet it can only represent one species; as also the figure referred to in Sulzer's Kennz. Tab. 23. Fig. 152. represents Rösel's C. pulex. Klein's bad description and figure in his Dub. circa Lin. class. quadr. et amphib. p. 36. tab. fig. 8. * ζ. might appear doubtful, but because in the Baltic (Ostsee) only pulex but not locusta is commonly noticed, Klein's figure will have to be referred to pulex, as well as that in Klein hist. pisie. Miss. V. p. 9, tab. 4. A. B. C. Consequently not one of Linnaeus's references is left for locusta; he must therefore either have taken the larger Pulex-species occurring in the Baltic (in der See) for Locusta, or have intended a quite unknown Locusta. I therefore here describe under the name Locusta not Linnaeus's, but the species found in Pallas Spicileg. Zool. Fase. 9, and really distinct from C. pulex; of which no author makes mention unless it be Ray, hist. ins. p. 44; who distinguishes a sea-water flea from that in fresh water, and refers to a figure in Daudunx pemptol. p. 4, 76." The species here discussed is now known as Talitrus locusta, Pallas. Ray's Daudunx should be Daudunx, i.e., Rembert Daudunx.

70. Die Gammaride. Cancer (Gammaridæ) pulex," with references to Pallas, Gronovius, Baster, and Scopoli. This is the Ostsee gammadæus of Pallas, now known as Orchesta c. pulex. Herbst gives Pallas the credit of having distinguished it from Cancer pulex, and it will be noticed that he emits the generic (Gammaride), perhaps not knowing exactly what to do with a generic name the same as the specific.

71. Der Seeblöte. Cancer (Gammaridæ) pulex," with references to fifteen authors and eighteen different works, beginning with "Linn. Syst. Nat. 81," and ending with "Scopoli. Ent. Carn. 1137." He ends his description by saying, "whether the Cancer pulex of Linné be the same as C. pulex of Scopoli, may rightly be doubted, since the latter lives always in fresh water." Herbst borrows his figure from Rötel, but neither makes his description tally with the figure, nor takes notice of the differences.

76. Der Mönch. Cancer (Gammaridæ) seolentarius, Forskål.

79. Die Modusengarneele. Cancer (Gammaridæ) modusorum," with references to J. C. Fabricius Ström. O. F. Müller, Otto Fabricius, and Bomare. n. 235. He here therefore combines the species now named respectively Hyperia modusorum, O. F. Müller, and Hyperia kroegeri, Bovallius.

82. Der Fadenkrebs. Cancer (Gammaridæ) linearis," with references to the species linearis

The section or family concludes with three species which are not Amphipoda.

"84. Die Salzgarnecke. Cancer (oniscus) salinus.

"86. Der Heringfreund. Cancer (oniscus) esca."

Figures are given on plts. xxxv. and xxxvi., from various sources, for all the species except those numbered 72, 73, 74, 77, 78, 79, 80, 81, and the last three."

Herbst's work is spoken of with great commendation by Milne-Edwards, but it must be confessed that, however great its merits may be in regard to Crustacea in general, on the Amphipoda this compilation throws but little light.

1796. LATREILLE, PIERRE ANDRÉ, born 1762, died 1833 (Hagen).

Précis des Caractères génériques des insectes, disposés dans un ordre naturel.

Par le Citoyen Latreille. À Paris, et à Brive, an 5 de la R.

In the preface Latreille defines the word _insecte_: "Animal sans vertèbres, dont le corps et les pattes sont de plusieurs pièces." The work opens with a Tabular "Division générale des insectes," showing fourteen classes, the first seven belonging to the Athé, the remaining seven to the Aptères. Classe xii. is formed by the "Entomostraca, Mull," corresponding to "Synistates, Agonates, Fab." Classe xiii., containing "Crustacés, Crustacea. Agonates, Fab," is defined:—"Tête confondue avec le corps renfermé ordinairement sous une capsule. Antennes. (Quatre)

"Plusieurs rangs de feuillets maxillaires et d'antennules, dont deux insérés et couchées sur les mandibles. Lèvre inférieure. o.

" Dix pattes communément."

Classe xiv. containing "Myriapodes, Myriopoda. Synistates, mitovates, Unogates, Fab," is defined:—"Tête distinguée du corps, antennifère.

"Mandibles ayant un avancement conique à leur base; des dents émoussées implantées sur le contour de l'extrémité.

"Deux rangs de mâchoires au plus. Une lèvre inférieure. Quatorze pattes et plus."

On pages 193–201 the genera of the two last classes are given. Under "Crustacés. (Cancer Linn. Geoff.)," are given Cancer, Pogurus, Squillaros, Hippa, Galathée, Astacus, Squilla, Gammarus, Carcinus, Entomon. Of these the eighth and ninth are thus described:—

**Creyette.** Gammarus, Fab. Oliv., Squilla, Fab.

"Antennes pédunculées, très-simples; antérieures courtes, subulées; postérieures séparées. Antennules bifides. Feuillets maxillaires extérieurs ayant plus de divisions que les intérieurs.

"C. H. [Caractères habituels.] Corps petit, long, comprimé, glabre, agile, de plusieurs segments. Tête distinguée du coracolet; yeux souvent petits, arrondis et sessiles. Antennes rapprochées, insérées dans l'entre-deux. Pattes de dix à seize; antérieures quelquefois en pinces on en faux. Quatre terminée par plusieurs poils ou styles.

In the Myriapodes the genera are *Aelurus*, *Cyamus*, *Oniscus*, *Julus*, *Scolopendra*. The second of these is thus described:

"*CYAME. CYAMUS. Oniscus*, Linn. *Fab. Squilla*, Géé."

"Quatre antennes très-courtes ; antérieures coniques, de quatre articles, dont le dernier fort court ; postérieures insérées inférieurement, plus courtes que la tête, de trois articles. Antennules absentes."

"C. H. Corps ovale, déprimé, crustacé. Tête distincte. Six anneaux. Quatorze pattes ; les deux premières plus petites, insérées sous la tête ; les 1, 2, 5, 6, et 7e paires terminées par un crochet."

The genera called in French *Carcin*, *Entomon*, and *Cyane* are marked each with an asterisk to show that they are new, instituted by Latreille himself. The first two have not maintained their ground against earlier designations.

1797. Anonymous.

This work refers to another apparently of the same character, entitled "Nomenclator entomologicus secundum entomologiam systematicam ill. Fabricii. Conscriptiona a Friderico Weboro. Chiloni et Hamburgo. 1795."

Among other derivations it gives, together with the definitions, for Synistata, "palpi quasnor maxilla connata cum labio. *Kiefersippen a ovierden*," to unite ; for Mitosus, "palpi duo, maxilla filiformis membranacea, *Fadenmäuler a piros*," a thread ; for Unogata, "palpi duo porrecti, maxilla conneta magniculata, *Haakenmauler ab ovri*; a nail ; and for Agonata "palpi sepius sex, maxilla omnino nulla. *Kinnlose ab dyövono*, which properly means without a knee or without joints, but is here seemingly taken to mean without a jaw, as though from *γέρανο* instead of *γέρον*.

Among the Agonata are given *Astacus homari* on page 117, *Cymoethoa oeti* on page 119, and on the same page a list of the species of *Gammarus* in accordance with the Ent. Syst. emend. et auct., of 1793. In another list, among the "Agonata sec. Dalilorium," on page 125, "G. Homari (Ast. F.)" is added to the previous catalogue of Gammari.

1797. Cuvier, Georges (alias Léopold-Christien-Frédéric-Dagobert), Baron, born 1769, died 1832 (Encycl. Brit. 9th Ed.).

In the seventh book, which treats "des insectes et des vers," at page 450 Cuvier says, "Sceunmerdat divise les insectes d'après la métamorphose ; *Linnæus*, d'après la présence
THE VOYAGE OF H.M.S. CHALLENGER.

ou l’absence des ailes, leur nombre, et leurs téguments; Fabricius, uniquement d’après leurs organes de la mastication ou de la déglutition. Nous adopterons une méthode combinée d’après ces trois points de vue, de manière à faire connaître les classes établies par ces trois auteurs, et nous les subdiviserons jusqu’à ce que les réunions de genres nous paraissent entièrement naturelles.” This notice is followed by a chapter headed “Des insectes pourvus de mâchoires, et sans ailes.” In this order he includes—“A. Les crusctés, qui ont plusieurs paires de mâchoires. (AGONATA, Fabr.);” “B. Les MILLERIÉDS, qui ont le corps composé de beaucoup de segments, portant des pieds, mais qui n’ont pas plusieurs mâchoires. (Mitosata, Fabr.);” “C. Les ARACNÉIDES; une seule pièce pour la tête et le corps, portant huit pieds; l’abdomen sans pieds. (UNOGATA, Fabr.);” “D. Les PHYTREIDES; à tête distincte; l’abdomen portant six pieds; abdomen sans pieds.” Section L. comprises—“I. LES MONOCLES. (Monoculan). “II. LES ECREVISSES. (Cancer).” “III. LES CLOPORTES. (Oiseus, Lin.).” These divisions are again divided and subdivided, but in none is any reference of any kind made to the Amphipoda, a curious omission on the part of an author on terms of intimacy, as he explains in his preface, both with Fabricius and Latreille. Among “LES ECREVISSES proprement dites. (ASTACUS, Fabr.),” are included “Le homar. (Cancer gammarus, Lin.)” and “La crevette ou salique. (C. squilla, Lin.),” two stalk-eyed Crustacea, in describing which, the names gammarus and crevette might naturally have called Cuvier’s attention to the sessile-eyed section, especially as in regard to the insect he says that Fabricius has helped him with the mouth-organs, “et, en général, il a bien voulu parcourir toute cette portion de l’ouvrage, et m’aider de ses conseils.”

1798. Fabricius, J. C.

Supplementum Entomologiae Systematicae. Haefniae, mdccxviii.

In the preface Fabricius says “Agonatorum classem inprimis et omnino et charactere e speciminibus bene conservatis ab amicissimo Daldorffio ex India orientali allatis mutavi, divisi et classes magis naturales characteresque firmiores obtinui.” He is here referring to Baron Dagobert Carl de Dalderff.

The Agonata no longer appear, but in their place Classis VIII. Polygonata, “maxilla plures intrabium,” containing Oiseus, Ligna, Idota, Cymathon, and Monoculan; Classis IX. Kleistagnosta, “Maxilla plures extrabium et labiales;” the genera beginning with Cancer and ending with Limnus; Classis X. Exochanta, “Maxilla plures extrabium ventricose palpis,” the genera included being Albeana, Scylla, Palmarus, Palmoen, Alphei, Astacus, Penaeus, Crangon, Pagonus, Galatheus, Squilla, Posidou, Gammarus. The old definition of Gammarus is given, based only on the antenna; and a single species, “Gammarus Homari,” is thus described:—“15. Corporis segmentis dorso sulcatisimis, caudâ falciculata: stylos serratis. Astacus Homari Ent. Syst. 2. 481. 10. Stroom. Act. Hafn. 10. 5. tab. 2. Myll. Zool. Dom. 197. 2358. Habitat in Oceano Norwegico. Antenna simplices haud bifidae.” These references to Ström and Müller’s Zool. Dan. prod, as earlier notices have stated, are probably concerned with Anomella Sohini, Leach, while “Astacus Homari,” Fabr., has apparently nowhere found admittance into the ranks of the Amphipoda. Milne-Edwards and Spencer Bate do not include it in their lists, Bock definitely, de Skand. et Arkt. Amph., p. 38, rejects it from his. But from the fact that Fabricius here singles it out as an example of the genus Gammarus, it is not unreasonable to suppose that he has changed his mind about its systematic position, especially as we find him adding the remark, “antenna simplices haud bifida,” as though to correct an error in his previous description, which contains the expression, “antennas posticae bifidas.” By antenna posticae Fabricius apparently means the upper antenna, not, as might more naturally be supposed,
REPORT ON THE AMPHIPODA.

65

the lower. *Amoldilla subina*, it is true, has an accessory flagellum on the upper antenna, but of that feature Fabricius took no notice in his definition of the genus *Gammarus*.

On page 570, in Clasis XIII. Antilia, “Os haustello inarticulato,” the genus *Pycnogonum* is given and defined as having “Haustellum tubulosum, conicum abaque setis. Palpi ad basin haustelli.” The only species mentioned is *Pycnogonum ceti*, with *Cymothoa ceti*, Ent. Syst., and *Onciscus ceti*, Linn., as its synonyms. In the Systema Antlia torum, 1805, *Pycnogonum* no longer appears.

1799. ÖDMANN, SAMUEL (alias Ödman).

On the much disputed question whether the Crustacean in question does or does not injure fishing nets Ödman pronounces most decidedly that it does, on the ground of repeated experiments. With equal decision he denies that it attacks live fish. “Ipsos autem a piscibus minoribus copiis de gluti, in culina discurus quotidie. Pre primis vero genus anatino sapidas exhibent dapere.” He says that at the beginning of November they come in from the deeper sea to the sheltered parts of the shore in incredible numbers, and that it is from then till May that their destructive industry chiefly needs guarding against by steeping the nets in a decoction from the bark of the elder (Betula Alnus). In January and February he repeatedly saw the *Starnus Cicacos* spend the morning hours, from 7 to 10, in catching these *Caneri Pulices* before his windows in the island of Ingaró.

1799.-1800. CUVIER and DUMÉRIL.

Leçons d'anatomic comparée, tom i. Paris, An viii.

The tableau septième of this work, as quoted by Desmarest, *Cons. gén.*, 1825, shows “C RUSTACÉS. Classe VII. Animaux invertébrés, ayant des vaisseaux sanguins, une moelle épinière noy euse, et des membres articulés,” including “1. MONOCLES. Limulés, Caligés, *Apy, Cyclops, Polyphemus*. 2. ÉCREVISES. Crust. *Inachus, Pagurus, Astacus, Poliurus, Scyllalus, Spilla.*” These are followed by “INSECTES. Classe VIII. Animaux invertébrés, dépourvus de vaisseaux sanguins, ayant une moelle épinière noy euse, et des membres articulés,” of which section A are provided with “mâchoires.” Of these a subsection are “sous ailes,” one division of which are “GNATHARTHÈRES. Plusieurs paires de mâchoires,” containing the “POLYXANTHES. A pelis ou Physocles, Oniscus, Cymothoa.”

On this classification Milne-Edwards, Hist. nat. des Crust., i. p. 207, observes that the progress of science has withdrawn the Polyxanthes from the Insecta, and has necessitated the employment of additional characters to distinguish the Crustacea from the Arachnids, which also have blood-vessels.

1801. PALLAS, P. S.

Of Crustacea in the Crimea he says, page 475, “in den Flüssen endlich häufige Krebs von gutem Geschmacke, und in der See zwey Arten von Taschenkrebsen, deren die eine im (Zool. chaff. exp.—part lxvii.—1857.) XXX 9
1801. **Lamarck, Jean-Baptiste-Pierre Antoine Demonet, Chevalier de**, born 1774, died 1829 (Hagen).

Lamarck here divides invertebrate animals into seven classes, the mollusques, the crustacés, the arachnides, the insectes, the vers, the radières, the polypyes. The Crustacée he divides into Crustacés pédiocles, forming two groups, and Crustacés sessiliocles, also with two groups. For the class at large he gives this description, "Caract. Le corps et les membres articulés. Peu crustacée that the animal quite and renouvelle à certaines époques. Organ. Un cerveau et des nerfs. Des branchies pour la respiration. Un cœur musculaire et des vaisseaux pour la circulation." "Il engendrent plusieurs fois pendant leur vie." He considers that "les balanites et les anatifë" form the passage from the Mollusque to the Crustacée in a remarkable manner. The respiration by branchie instead of by stigmate and trachée, the muscular heart, and the capacity for repeated procreation strongly in his opinion distinguish the Crustacée from the Insecta.

He thus defines the Crustacés sessiliocles, his second order of Crustacée:—"Il ont deux yeux distincts ou réunis en un seul, mais constamment fixes et sessiles." In this order the Première Section, pp. 161-163, is defined:—"Corps couvert de pièces crustacées nombreuses, soit transverses, soit longitudinales." It includes:—

déprimé, à six segments pédifères. Six paires de pattes; chaque patte terminée par un crochet.

1802. Bosc D'Antic, Louis Augustin Guillaume, born 1759, died 1828 (Hagen).

The first edition of this work has some historical interest, as being perhaps the first popular treatise ever written in the vernacular on Crustacea. The introduction remarks on the extreme and unjust neglect which had been shown by science to this branch of natural history. The author remarks that the Greek and Latin writers, as Aristotle, Athenœus, Pliny, had all considered the Malacostraca as fish, or intermediate between fish and shell-fish, that the earliest modern naturalists who had written upon them, such as Rondelet, Bélon, Gesner, Aldrovandus, Jonston, had placed them immediately after fish or Mollusca, that even the great Linnaeus, who classed them with apterous insects, had left their genera and species in its primitive chaos, merely distinguishing Crustacea brachyura from Crustacea macronura, and leaving out of sight almost all the minute species. The improvements in classification introduced by Fabricius, Daldorf, Müller, Geoffroy, Cuvier, Lamarck and Latreille, are then explained. An account follows of the different organs of the mouth and the limbs, of the muscles as described by Cuvier, of the viscera after Roesel, of the renovation of limbs, and the phenomena of exuviation after Réaumur. In regard to the fierceness and size of Crustacea in warm countries there is a remark worth citing in the words of the original, "on dit qu'ils sont d'une grandeur si démesurée, qu'ils attaquent les hommes, et on ont mangé plusieurs, entre autres le fameux navigateur François Drake, qui, quoique armé, ne put éviter ce sort." Of this great sailor's death on the Isthmus of Darien, Hume says, "Drake himself, from the intemperance of the climate, the fatigues of his journey, and the vexation of his disappointment, was seized with a distemper, of which he soon after died." A rationalist would perhaps attempt to reconcile the two accounts by suggesting that Drake may have died of cancer.

Of Amphipods Bosc gives four genera, Gammarus, Fabr., Talitrus, Latr., Coprella, Lamarck, and Cyamus, Latr., with coloured figures of one species of each genus on pl. xiv., xv., and xvi. He describes one new species from North America, Talitrus grillus, with the reference "figes pl. 15. et 2." At the foot of pl. xv. we read, "1. 2. Talitrus terrestre." In accordance with the suggestion of Milne-Edwards, Spence Bate, in the Brit. Mus. Catal., names this Orchestia grillus, with a synonym "Scambella Sayana, Leach, MS."

Bate and Westwood, vol. i, p. 14, note that the name Talitrus first appears in the year 1802, both in Latreille's Hist. Gen. des Crust. et Ins., vol. iii., and in Bosc, vol. ii. the latter writer giving Latreille the credit of the invention, while Latreille subsequently, in 1806, refers the genus Talitrus to Bosc as its author. This may be explained by the fact which Bosc mentions, vol. i, p. 48, that Latreille had given him permission to use the classification of Crustacea which the lender had prepared for a new edition of his own work. Thus Latreille's Talitrus makes its first appearance in Bosc's treatise. It is defined as follows:—"Quatre antennes simples; les intermédiaires, supérieures, plus courtes que le pédicule des inférieures. Corps allongé, couvert de pièces crustacées, transverses, presque égales, et appendiculées sur leurs côtés. Dix à quatorze pattes; les antérieures terminées par des mains. Des appendices bifides à l'extrémité du corps."
THE VOYAGE OF H.M.S. CHALLENGER.

Under Crevette, Gammarus, Fabricius, Bose gives the species ampulla, Phipps; 
vugax, Phipps; carinatus, author not named; cancellus, Pallas; longicornis, with references to 
Grunw., Pallas, Pennant, Herbst; pulcer, Crevette des ruisseaux, defined as having "Quatre pinces 
sans doigts; dix pattes," with references to "Bester. Subs. 2 tab. 3 fig. 7. Geoff. Ins. 2. 
tab. 21. fig. 6. Deguer. Ins. 7. tab. 33. fig. 1, 2. Herbst. Canc. tab. 36. fig. 4, 5," and 
to his own fig. 4 on pl. xiv., which is in fact a representation of Röel's species; the account 
concluding with the remark "se trouve en Europe dans les eaux douces, elle est fort 
commune aux environs de Paris"; corniger, no author named; gibbosus, no author named; 
eeca, no author named; mediornum, with reference only to Stroem, Sundm. tab. 1, figs. 12, 
13, where the word "Sundm." is spelt as it is in Herbst's account of mediornum; and badly 
komari, also with reference only to "Stroem, Act. Afr. 10. tab. 2."

Under Talitru, Talitrus, Latreille, Bose gives locusta, with references to "Pallas, Spicil. Zool. 
fig. 1;" and grilles, his own species, figured pl. xv. fig. 2.

Under Chevrolle, Caprella, Lamark, he gives Caprella limitaris, "Quatre mains à un seul ongle; 
dix pieds dans le mile," with references to "Cancer linearis. Linn.—Gammarus linearis. 
Martin. Spitz, tab. 7. fig. 1. Herbst. Canc. tab. 36. fig. 9 et 10, A. B.," his own figure, 
pl. 15. fig. 5, being presumably borrowed from Herbst, who copies from the Zool. 
dan. tab. 56. fig. 5; he also gives Caprella ventricosa. "Deux mains avec un seul ongle; quatorze 
fig. 8, 9, 10."

In his general remarks on "les chevrolles" he says, "La première espèce, 
qui a été observée par Muller, présente un phénomène remarquable; le mâle est fort différent, 
et a un plus grand nombre de pattes que la femelle." Bose thinks that Muller must here 
have confounded two species. The confusion, however, must be laid to the charge of Bose 
himself.

After chapters on Asellus, Iloda, Spharoma, Ligia, Calliges, Bisoculina, Bose comes to Cyane, 
Pygmonomum, Fabricius, for which he borrows from Lamarck without acknowledgment the 
following definition:—"Quatre antennes inégales; les deux antérieurs plus longues, 
sétées. Un suçoir simple, retraitable, sortant d'une fente courte, située sous la tête. 
Deux antennes insérées à la base de la bouche. Deux yeux. Corps ovale, déprimé, à six 
segments pédières. Six paires de pattes; chaque patte terminée par un crochet." Liitken 
criticises the inapplicable expression suçon, and is of opinion that by the two antennules at 
the base of the mouth, the first gnathopods, not the maxillipods, must be understood here; 
he notices also the attribution of a crochet to each foot of six pairs. In the specific account 
Bose clearly distinguishes the shape of what he supposed to be the third and fourth pairs 
of feet from that of the other five pairs. He speaks of the species as le pou de baleine, and 
figures it, pl. xvi. fig. 2, as the Cyane of Cétacés, representing, according to Liitken, a 
figure (?) of Cyamus mysticeti. Bose himself gives no Latin name either for this species, 
or for the Pygmonomum that has been confused with it. To the Pygmonomum he refers as 
"le cyane des baleines," and after finishing his account of "le cyane des cétacés," he 
says, "La seconde espèce a été placée par Linnæus parmi les phalangium; par Pallas 
parmi les acarum; par Fabricius, d'abord parmi les poux, et en dernier lieu, avec la première, 
parmi les pygmonomum, sous le nom spécifique de balearem. Brumier la regarde comme 
formant un genre nouveau, et probablement il a raison; car cet animal paroit bien différencé 
pour la description du pou de baleine."
Jagttagelser over tvende sieldne og ligdet bekiendte Krebsarter. (Oplæst den 24 May 1799.) Skrivter af Naturhistorie-Selskabet. 5te Bind. 2det Hefte. København, 1802.

The two Crustacea in question are here called *Dromia alpaca* and *Gammarus sedentarius*. The latter, Forskål's now well-known species, is fully described and fairly figured. Of it the author says, "In mari Tingidem aluenae unica tantum vice plura specimena inveni mense Febr. 1793." He criticizes Herbst's rendering of Forskål's account, and his copy of Forskål's figure, as not quite accurate. He suggests that some unknown Mollusc may have been the first and original owner of the dwelling in which the creature is found.

1802. **Turton, William.**

A general system of Nature, etc., etc. Translated from Gmelin’s last Edition of the celebrated Systema Naturae, by Sir Charles Linné. Amended and enlarged by the improvements and discoveries of later naturalists and societies, with appropriate Copper-plates, by William Turton, M.D. Vol. iii. London, 1802.

Among the Insecta Aptera, following “118. Scorpio,” comes “119. Cancer. Legs, 8 (rarely 6 or 0) besides 5 chelate hands or claws furnished with a moveable thumb: feelers 6, unequal: eyes 2, distant elongated moveable, and generally placed on peduncles: mandibles horny thick; tip triple; tail articulated and unarmed.”

Under Cancer, Section “F. Antennæ pedunculæ and very simple. Gammarus,” contains the following information:

"**Ampulla.** Hands without fangs: legs 14: hind-thighs compressed dilated.
Inhabits the Northern Ocean. *Phipps, tab. 12. fig. 3.*
Body nearly white; probosces short incurved and very sharp: tail with 6 leaves, the last joint bifid.

"**Nugax.** Hands without fangs: legs 14: 6 hind-thighs compressed dilated.
Inhabits North Seas. *Phipps, tab. 12. fig. 3.*

"**Carinospinosus.** Hands without fangs: legs 14: back carinate and spinous.
Inhabits—— In the British Museum.
Body whitish subcompressed; the hind segments a little spinous.

"**Cancellus.** Hands 4 without fangs: legs 16.
First pair of antennae incurved.

* * Grossipes.** Hands without fangs: antenna longer than the body: tail obtuse.

Inhabits Europe on sandy shores and in stagnant waters; leaps about with great agility.

* * Pulex.** Hands 4 without fangs: legs 10.
*Degcr. Ins. 7. tab. 33. fig. 1. 2. *Dast. tab. 3. fig. 7.*
Very common in fountains and rivulets, and swims in an incurved posture upon its back: is very troublesome to fish by getting between their gills, and is said to shine by night.
"Corniger. Hands without fangs: proboscis incurved subulate: sides of the thorax with a double horn.
Inhabits the Norway Seas.

Body of 11 short segments, whitish edged with red, the 5 hind ones carinate and spinous on the back: under the thorax each side are 2 horns united at the base: tail with numerous bifid styles.

Pall. Spicil. Zool. 9. tab. 4. fig. 15. Baster, tab. 4. fig. 2.
Inhabits the shores of Europe and America.

"* Atomos. Hands 4 with a single fang: legs 14, with two oval vesicles each side between the fourth and fifth pair.
Inhabits Europe, in running water, and is very minute as to be seldom visible to the naked eye.

"* Salinus. Legs 20 spreading: tail subulate, &c. (not an Amphipod).

"Gibbous. Oblong, gibbous; antennae folded and very long.
Inhabits Portugal; small.

Body smooth yellowish speckled with brown: head thick obtuse with a large green spot: antennæ bent under the body, folded and 3 times as long as the body: tail with 3 sharp cleft leaves.

"Esca. Hands without fangs: tail jointed subulate and cleft at the tip, &c. (not an Amphipod).

"Medusarum. Hands 4 with a single fang: head very obtuse.
Stroem. Sundin. 188. tab. 1. fig. 12, 13.
Inhabits Norway, under Medusa.

"Filiformis. Linear; legs 10, the middle ones larger.

Under section "A. Peeler 0: antennœ often 4, sessile: Cymothoa," are given among many others:—

"Ceti. Ovate with distinct segments: third and fourth pair of legs linear and unarmed.
Sela. Mus. 1. tab. 90. fig. 5. Dyeer, 7. t. 42. p. 6, 7.
Inhabits the Northern Seas, on Whales."

"Aculeatus. Thorax naked: back with 3 rows of spines.
Inhabits the White Sea. Body carmine.

Inhabits the White Sea. Act. Petrop. 1778. tab. 8. fig. 3.
Antennæ 4: tail tufted at the sides."

"Fuscus. Brown; shell carinate with a white spot on the thorax.

"Medusarum. A little compressed: front obtuse; antennœ very short and pendant: hands 4 compressed and cut.
Stroem. Sundin. 1. p. 188. tab. 1. fig. 12, 13.
Found under the folds of the Medusa Capitata.

"Gicata. Compressed, sublinear with four spurious hands: upper antennæ shorter: tail smooth on the back.
REPORT ON THE AMPHIPODA.

Inhabits the Sandy Shores of Greenland, on the Ulva umbilicata.

"Stroeminus. Compressed; 4 fore-legs cheliform and slightly toothed: upper antennae very short.

Inhabits the Shores of Greenland. Body violet.

"Abyssinus. Subcylindrical; 4 fore-legs cheliform and 1-toothed: antennae subequal setiferous and serrate at the base on the inner margin.

Body with white and saffron bands: darts with great velocity in the water.

"These 6 last might probably be referred to the genus Cancer."

In this list, Cancer (Gammarus) carino-spinosus, being without references, is apparently intended for a new species. In the Brit. Mus. Catalogue, Spence Bate names it Amathia carino-spinosa, distinguishing it from Amathia sabini: more in deference to the opinions of Rathke, Liljeborg, and Bruzelius, than from a conviction of there being any real distinction between them. Boeck accordingly makes "Cancer carino-spinosa, Turton, Linn. Syst. Nat. III. p. 760. (ifolge Spence Bate)" a synonym of Amathilla sabini, without observing that Boeck and Westwood, vol. i. p. 362, declare that Turton's species is Atylus carinatus. On page 365, they say further, "it is quite evident that the latter [Turton] never examined the animal of unknown habitat in the British Museum, which he cites, but that his knowledge was derived from the Fabreian description of Atylus carinatus, the name of which he unnecessarily altered." The species, Cancer (Gammarus) cariniger, though also without references, is clearly the Gammarus cariniger of Fabricius, now called Epimeria carinigera. It will be observed that for Cancer (Gammarus) melusarum and for Onicus (Cymothoa) melusarum, Turton gives the same reference to Stroem without any attempt at explanation.

1802. LATREILLE, P. A.

In vol. i. p. 45, he recognises that the Stalk-eyed Crustacea or pédiodes of Lamarck have an organization evidently distinct from insects, but the Sessile-eyed Crustacea come so near the insects, by the form of the vessel regarded as the heart, that he would have been well content for the present to leave the Crustacea at the head of the insects, only forming a subclass of them.

Vol. ii. opens with a table giving "Divisions générales des animaux invertebrés et pourvus de pattes." The Crustacea, Class I. have "Mandibules palpigrènes. Des pièces articulées doubles ou bifides, disposées sur plusieurs rangs, et formant la bouche. Quatre antennes." These form two orders, Les Décapodes, "Tête confondues avec le corps. Branchies cachées," and Les Branchiopodes, "Tête distinITTLE. Branchies extérieures." The Insectes, Class II., include four subclasses, the first of which is named les Tétracéres, and the fourth les Entomostracés.

An explanation of earlier classifications is given pp. 292–365. After Aristotle he considers that Aldrovandus was the first systematicist to make any advance, then Willughby
[Willughby], whose method is more commonly attributed to Ray, who adopted and developed it.

In vol. iii. p. vii. n. 1, Latreille remarks that, since the publication of his Précis in 1796, the name insect had been restricted in its application, he therefore now says, "je nomme Condyliopodes les animaux que Linnæus appelle insectes, et qui forment, dans la méthode du professeur Lamarck, trois classes; les crustacés, les arachnides et les insectes."

He alters the classification of the preceding volume, making the Entomostacca now the first subclass of the Crustaceae, the second subclass being the Malacostraca. In these latter the Branchiogastria, p. 35, are the second order, with two families; 1. Squillares; squilla, including the genera Squilla and Mysis; 2. Crevettes; gammarus, thus defined:—"Corps formé d'une suite d'articles de longueur à peu près égale, ou dont le premier du moins n'est pas beaucoup plus grand que les autres. Yeux sessiles. Extérité postérieure du corps sans appendices, ou à appendices styliformes, "and including the genera Phronima, Talitrus, Gammarus, Caprella, Cymamus.

Next he defines "Genre, Talitri; talitrus. Antennes simples: les intermédiaires supérieures et plus courtes que le pédicule des latérales et inférieures. (Dix à quatorze pattes.) Une queue; des pièces articulées au bout. Exemples. Gammarus locusta, Fab. Oniscus gammarus, Pall." He then proceeds to define the genus "Crevette; gammarus," adding a remark on this and the preceding genus:—"Othon Fabricius a décrit plusieurs crustacés qu'il faut, je pense, rapporter à ces deux genres. On placera parmi les talitres les suivants: oniscus serratus, cicuta medusarum; avec les crevettes les autres: oniscus arenarius, streumianus, abysinicus."

He defines "Chevrolle; caprella, Lam," with Gammarus linearis, Fab., and Squilla lobata, Oth. Fab. as examples.

Then follow the Insecta as Classe Seconde, with the Tetracera as first subclass, containing the two families "asellota" and "oniscidea."

At the opening of vol. iv. Latreille repeats his reasons for using, instead of the Linnéan insectes, the denomination Condyliopodes, condylopa (pattes noueuses), and for placing the Crustaceæ at the head of the division. As before, he relies on the observations especially of Swammerdam in olden times, and of Cuvier and Lamarck, his contemporaries. Among other remarks on classification he says, p. 8, "Si j'examine attentivement, en effet, la série naturelle des genres, je vois que les crabs ne conduisent aux écrevisses, que de celles-ci j'arrive presque sans saut aux crevettes (gammarus F.); de là aux aselles, aux eloporte, enfin aux ourres et aux scolopendres; et comme je découvre dans ces derniers animaux des stigmates, je dois penser que les arachnides, les insectes proprement dits doivent leur succéder."
REPORT ON THE AMPHIPODA.

1803. LATREILLE, P. A.

Histoire naturelle, etc. Tomes V.–VI. A Paris. An XI.

This volume opens with the Histoire des Malacostracés, notices how little attention was paid them from the time of Aristotle till we come to Belon, Rondot, Gesner, Aldrovandus, with whom they still remain between the Mollusca and the Testacea. Johnston was only a compiler. Swammerdam in *Bernard Tornaill* discovers a heart or at least a principal organ of circulation “différent du vaisseau dorsal et noueux des insectes. Ce crustacé trouve son rang avec eux; il est compris avec les insectes du premier ordre, ou ceux qui sortent de leur œuf parfaitement formés et pourvus de tous leurs membres.” Kleiu rejected Linnæus’s arrangement of Aptera. “Les animaux multipliés sont partagés en deux sections. La première est destine à ceux qui sont eutastés, *bicornis*; elle est remplie par six ordres, dont les cinq premiers appartiennent aux crustacés, et le sixième aux scorpions. La seconde section est celle des insectes; là se voient les scolopendres, les lutes, les cloportes, et les araignées, etc.” Latreille then gives the system of Lefrancoq de Berkley, who, he says, “de nos jours, a le premier séparé les malacostrèmes ou les crustacés des naturalistes des insectes.” But this seems to be an error, as, except that he places Man in a first division by himself, the nine groups of his second division correspond with those of Brisoon.

1803–BOSC and LATREILLE.
1804.

Nouveau Dictionnaire d'Histoire naturelle, appliquée aux arts, principalement à l'agriculture et à l'économie rurale et domestique. Par une Société de naturalistes et d'agriculteurs, avec des figures tirées des trois régnes de la nature. Paris, 1803–1804. (Twenty-four volumes).

In this work the Crustacea are described by Bosc, who, it is said, merely repeats what had already appeared in his Histoire naturelle des Crustacés. Desmarest says that "Latreille a inséré dans le dernier volume un tableau méthodique de ces animaux." The work must not be confounded with the so-called new edition in thirty-six volumes, Paris, 1816–1819, for which the Crustacea were described by Latreille.

1804. MONTAGU, GEORGE, born 1751, died 1815 (W. Pengelly, e Biblio. Cornub.).

In this paper three Amphipods are described:—

"Cancer Phasma. Tab. vi. Fig. 3. Cancer linearis, Linne. Syst. p. 1056. Gmelin Syst. p. 2992. / Bost. Op. Syst. 1, p. 32, t. 4, f. 11. Turton Linn. iii. p. 761. / Onisus scolopendroides. / Pall. Spic. Zool. 9, t. 4, f. 15. Cancer atomus. Linne. Syst. p. 1056. Gmel. Syst. p. 2992. / Brit. Zool. iv. t. 12, f. 32. / Turt. Linn. iii. p. 761." Montagu thought he had good reason for uniting the species mentioned in the synonymy with his Cancer phasma, but nevertheless thought it well to retain the new specific name to prevent further confusion. This species was named Astacus phasma by Pennant in 1812, referred to Caprella by Leach in 1814, and to Protella by Spence Bate in 1862, where it still stands (see Mayer, Caprell. p. 29) at the head of a long list of synonyms, though one quite different from Montagu's list. His imperfect description is as follows:—"With a slender body of six joints, independent of the head: on the first joint are two spines, a third on the fore part of the second joint, and a fourth on the head, all pointing forwards: the rest of the body smooth: antennæ four, the upper pair nearly as long as the body; lower pair half that length, and the extreme joint of each pectinately clothed with bristles: eyes fixed, reticulated, usually of a red or brown colour: close to the mouth are two very short palp, or feelers, with hooked claws; behind these are two others much longer, armed with single moveable fangs: on the first joint of the body are two long arms, with very large oblong oval hands, furnished with a strong spine on the inside, and a long moveable fang, which is capable of closing upon the spine, in order to secure its prey: the front of the hand in some is also narrowed and elongated into a spine; the second and third joints of the body are each provided with a pair of flat oval fins; the three posterior joints are each furnished with a pair of long slender legs, with a single hooked claw; the hindmost are the longest, and originate from the extremity of the body, the animal being destitute of tail. Length rarely exceeds three-quarters of an inch, and seldom so much: colour various, sometimes red, but more commonly pellucid olive green. The female differs in possessing several plates or valves beneath the body, situated between the two pairs of fins: the office of these is to carry and protect its eggs or young, at which time they extend very considerably, and form a kind of pouch. We have seen this receptacle distended with eggs, from fifteen to twenty, readily distinguished through the transparent plates. In this part a very strong pulsation is observable."
"Cancer palmatus" Tab. vi. Fig. 4. With a smooth, somewhat compressed body, with thirteen joints: colour, when dead, pale yellowish brown; antennae four, superior pair longest, half the length of the body; each pair composed of three large joints, with several small articulations at the end; eyes large, fixed: arms two; hands remarkably large, flat, triangular, furnished at the upper angle with a moveable fang, capable only of closing upon the middle or palm, which is formed a little concave; the back of the hand convex; joint of the wrist deeply cut or indented on the lower side: legs six; thighs broad, flat: caudal fins two pairs, subulate, with two joints each; the extreme joint of the tail is furnished with two small appendages; the next joint with two minute spines; the third joint with a single spine. Length, three-eighths of an inch. This is now called Melita palmata.

"Cancer articulosus" Tab. vi. Fig. 6. With an oblong, smooth, glossy body, a little compressed on the sides, with eleven joints, of a cream colour when dead: antennae four, the upper pair longest, but not half as long as the body: eyes large, of a garnet colour, immovable: arms four, of a very singular form; the foremost pair with a subglobose, cheliform hand, with the fixed claw very slender, and the moveable one, or thumb, long and double-jointed, or furnished with an additional hooked fang at the end; second pair with an ovate, oblong hand, furnished with one long moveable hooked fang; at the wrist arises a compressed slender plate, projecting forward, and almost meeting the fang when closed: legs five pairs, small, subulate: tail terminated by several slender, flat, caudal fins. Length, half an inch. Inhabits the deep: taken by the dredge amongst shells and algae. This, having since been identified with Gammarus spinicarpa, Abildgaard, 1789, and made the type of a new genus, is now called Leucothoe spinicarpa.

1805. Viviani, Domenico.

Phosphorescentia maris quatuordecim lucescentium animaculorum novis speciebus illustrata a Dominico Viviani. Genus, 1805.

In his discussion of the causes of the phosphorescent appearance of the sea, Viviani says: "Lucescentibus animaculis immixtis, nonnullae reperientur in mari species, quae licet ob parvam
corpus molam, et reliquam ejusdem compagem, maxima adfinitate uniantur, nulla vero phosphorica facultate gaudent. (Gammarus crassimanus nob. Gammarus Pulex, stagnalis,
Brayichiales segmentis anterius magnitudine ultra Fig. Gammarus articulus 4) internodia articulatione apice Gammarus remarque Color The articulo Gammarus annulo inferiores suhsequens 76 .... Gammarus "Gammarus"Gammarus Gammarus articulatione breviores, latera hispidi, triarticulati, antennas corporis truncatum, flavesoens. brevissimis tribus extuberantes, ellipticis subsequentes angustius. Capitis Eeperi flavescens. pedibus emarginatura caudalibus segmento medium turgidi, pair. phosphorescente." .... Gammarus longicornis (Tab. II. Fig. 3, 4). Gammarus Antennis (4) brevissimis, subsequalibus: annulo caudali medio setigero. Reperi ... in aquis Portus Genum: Sotto il Molo Vecchio. Corpus oblongum, rubescens, decem segmentis compositum, capitis segmento obsuse [obtuse] conico. Ocelli duo nigrescentes, turgidii, secus antennas siti. Antenae quatuor, quadruplo corpore breviore. In antennis superioribus, articuli duo primi elongati, medium earundem longitudinem sequentes; ultra medium setaceae. Inferiores basi a superioribus ita tecta, ut nunquam earundem structuram perlustrare potuerim, ultra medium tamen et ipsae setaceae. Pedes duodecin, 3-4 articulati; in articulatione verticillato setigeri; apice uncinulo recurvo armati. Laminae natatoriae ovatae, margine setigere, utrinque subtus secundum, et quinque segmentum erumpentes, in segmento octavo utrinque geminai. Cauda segmentum superne squamulosum, quadrilobum, emarginatam mediis setalium fasciculo valde mobilium munita. Color pallide rubescens."

"Gammarus truncatus (Tab. II. Fig. 5, 6). Gammarus capitis segmento antice truncato, caudae recurvo, antennis superiosioribus duplo breviore. Reperi cum precedenti. Corpus subcylindricum, postico attenuatum, segmentis duodecin, caudalibus recurvis, caput antico truncatum, subtus concursum. Antenae quatuor: inferiores superiores duplo longiores, corporis totius medium longitudinem non excedunt; in utroque pari articuli primi paulo exstibantes, reliquis breviore, sensimque tenuiores, ut articulationibus setigeri. Ocelli pone antennas inferiores siti. Tentacula duo cylindrica, filiformia, inarticulata. Pedes decem, triarticulati, brevi uncinulo muniti, hispidi: Branchiates sex, est tuberculo prodeuentes, cylindrici, apice setalium longo fasciculo muniti. Cauda appendices, cylindrii quatuor recurvi, hispides, pesulimum inter, et antieros caudae segmentum inserti. Color dilutissime flavescens."

"Gammarus circinnatus (Tab. II. Fig. 9, 10). Gammarus subcylindricus, segmentis 2-6 ad latera utrinque in appendicem circulararem exuuentibus, caudalibus reliqua subsequantibus. Reperi cum precedenti. Corpus subcylindricum, segmentis decem conflatum, tribus caudalibus latere inferiori postico angulatis, reliqua fere magnitude subsequantibus. Capitis segmentum cylindricum, antice rotundatum. Antenae superiores, corpore duplo breviore, ultra medium setaceae. Articuli tres primo sensim minores, spinulis setul兼职 in articulatione armati. Par inferiori, superiori duplo breviore; post primum articulum elongatun antennae setaceae evadunt. Tentacula duo triarticulata: articulo primo cylindrico, altero
REPORT ON THE AMPHIPODA.

cordiformi, tertio ovato, uncinulo instructo. Segmenta 2, 3, 4, 5, 6 utrinque in appendicem rotundum exunt pelliculum ovulum glomerem tegentem (Fig. a). Caudales appendices: cylindrula duo recurva, quibus duo tenues, inarticulata spinulosa, longitudine subequalia, adiicientur. Pedes decem, quorum duo antiores, articulo primo cylindrico, dixobus subsequentiibus majoribus apicis emarginatis, ultimo oblongo, uncino armato componuntur. Pedes reliqui triarticulati, longo uncinulo aucti: Branchiades sex, unico articulo formati: apice setigero. Color ex flavescenti dilutissime rubescens.

"Gammarus heteroclitus (Tab. II. Fig. 11, 12)" appears to be a species of Tanais. Of it

Viviani says "Antennarum formâ et insertione species hæc novum fortasse genus exposceret. quod habitus totius corporis a Gammaris diversissimus confirmandet."

"Gammarus crassimanus (Tab. II. Fig. 7, 8), Gammarus ventricosus: caudâ reflexâ; anterioris pedum pars tarsi incrassatis, chelâ granulata. Reperi cum precedentibus. Corpus oblongum, ventricosum, antice truncatum, in cauda attenuatum curvum, segmentis 17 compositum. Capitis segmentum subcylindricum, subus veluti in rostrum breve concurrit. Antennas quattuor, medium totius corporis longitudinem paulo excedentes, setaceas, articulo primo brevi ventricosae, subsequentem elongatum tenue, reliquis sensim tenuioribus brevissimis.

It might be possible for some one residing at Genoa to identify these Genoese Amphipoda. The figures given to represent the natural size are so minute as to suggest some error. Fig. 4, pl. i is suggestive of Hyperia mediterranea, though the eye is represented only by a small o. Fig. 6, pl. ii may represent Hypera sp. Fig. 4, pl. ii ought to be capable of identification by the extreme length of the antennae of both pairs, but of the upper pair especially. The name Gammarus longicornis is preoccupied among the synonyms of Corophium volutator. Spence Bate has suggested the identity of Gammarus crassimana with Merx trunca. Desmarest, Consid. gén. sur la Cl des Crust., p. 265. n. also thinks it probable that it belongs to the same genus as Merx grossimana. Bocck thinks it is perhaps a Gammarus. In his view, Gammarus cirratus seems to be a species of Amphithoe. Mine Edwards and Spence Bate alike omit Viviani’s species from their general lists of Amphipoda, and in the special lists of Mediterranean species by Costa, 1830, by Hope, 1851, by Stasik, 1877, and by Carus, 1885, no notice is taken of them.

1866. Duméril, André Marie Constant, born 1774, died 1860 (Hagen).

Zoologie Analytique, ou Méthode Naturelle de Classification des Animaux, rendue plus facile à l’aide de tableaux synoptiques. Paris. m.dccc.vi.

Duméril rejects the precept of Linnaeus and Fabricius to draw the characters of classes, orders, and genera from one and the same part, as inapplicable to zoology, however suitable it might be to botany. He prefers the natural method, which studies all the parts of an organism, with a view to its classification. In regard to the Crustacea he follows Latreille and Lamarck. He makes nine “general divisions” or classes, the Crustacea being the sixth, between the Mollusca and the Insects. The Crustacea are defined as “Animaux sans vertébres, munis de vaisseaux et d’organs respiratoires sous forme de lames ou de branchies; pattes le plus souvent au nombre de dix.” They form two orders, Entomostracés and Astacoïdes. The latter, “à creole calcaire,” contain four families, Meroures, Carcinoïdes, Oxyniques, and Arthrocephalés. These last, “à tête séparée du corselet,” correspond to the Branchiogastres of Latreille. The name is derived “De Aphrod membre qui se meut, et de Kephalo tête.” An alternative name is Capités. The following definition and table is given:—“Crustacés à pattes ordinairement au nombre de quatorze; à branchies apparentes vers la queue et à tête articulée sur le corselet.

He makes the following remarks upon the Amphipoda—"Le genre phronime (phronima) est encore du même naturaliste [Latreille]. Il comprend un animal très-singulier, qu'on a observé dans un corps gelatineux transparent, qui n'a que deux antennes et dix pattes dont la troisième paire, plus longue que les autres, est armée de deux pinces; le corps se termine par plusieurs filets fourchus. Le genre thalitre (thalitrus, du même auteur) ressemble beaucoup à celui des crevettes. Les crevettes (pammarus, Fab.) diffèrent de tous les autres astacoides par la forme du second segment du corps, lequel n'est pas plus long que ceux qui viennent immédiatement après, par les appendices fourchus qui se remarquent à l'extrémité et sur les côtés de la queue; enfin par l'immobilité des yeux, qui sont à-pet-près disposés comme ceux des aselles et des cloportes, insectes avec lesquels les crevettes semblent se lier. Ces crustacés vivent dans les eaux douces et salées; ils nagent fort rapidement et toujours sur le côté."

The sixtieth or last family of the Insects, among the Aptera, is called Quadricornes or Polygnates, and contains three genera, Physode, Cloporte, Armadile, with the remark that physode (physode, Fab.) answers to the asellote family of Latreille. He considers that the "Polygnates semblent faire le passage des insectes aux crustacés, dont ils différent seulement par le défaut de branches."

1806. Latreille, P. A.

Genera Crustaceorum et Insectorum secundum ordinem naturalen in familias disposita, iconibus exemplisque plurimis explicata. Tomus Primus, Parisiis et Argentomati, 1806. (The other three volumes 1807, 1809.)

Of the twelve classes into which Latreille here distributes animals, the Crustaceae are the eighth, invertebrates with distinct nerves, "Cor; branchiae; medulla spinalis gangliai plurimis; pedes." Of the Crustaceae, the Malacostraca form the second Legion; containing two Orders, the Decapoda and the Branchiogastra, the latter thus defined, "Caput thorace distinctum; branchiae externae, infere; pedes sepissime quintodecim." Of the Branchiogastra, the first Family are called Squillares, the second Gammarinss or Crevettines. These latter include the genera Phronima, Talitrus, Gammarus, Corophium, Caprella, Cygnus. The new genus Corophium is thus defined:—"Cauda appendicibus articulatis, subcylinandrinis. Antennae inferae crassissime, articulis quinque, seta nulla articulata apicali. Pedes duo antici nanum purva (ungue mobilis, police instructus)." The type species is Corophium longicornis, taking its specific name from the synonym, Gammarus longicornis, Fab., instead of taking it, as it should do, from the earlier synonym, Oicus volutator, Pall. A final note remarks, "Genera Sychnethis, Pseudon, mihi ignota." Phronima sedentaria and its habitation are figured on pl. ii.

The Tetracera are the first Legion of the Ninth Class, Apterous Insects, and comprise two Families, the Asellota and the Oniscides.

1808. Montagu, George.

antennae is not noticed, this is clearly *Gammarus locusta*, Linn., and as Montagu professedly mentions it only to clear it from confusion with other species, it is singular that he should place in the synonymy *Oniscus gammarellus*, Pallas, which is an *Orchestia*. He describes the eyes as "lunate, fixed," with an explanatory note, "Not pedunculated, or moveable, but fixed under the shell of the thorax; a circumstance common, I believe, to all this family." The epithet in "hands sub-cheliformes" he also explains in a note, as "A term adopted for a single fang capable of closing upon the hand, answering the purpose of a fixed claw, in contradistinction to cheliformes, or such as are formed with double claws."

On page 93 he gives "Cancer *Gammarius* Pulex. Tab. iv. fig. 2. Cancer Pulex. Gmel. Syst. p. 1055. Tab. Linn. iii. p. 780. Brit. Zool. iv. p. 21. No. 33." This, he remarks, "is as incapable of living in salt water as the *C. Locusta* is in fresh, although we have the authority of Linnaeus and many of his disciples to the contrary. It is also incapable of leaping, and very soon dies when taken out of water."

On page 94 is "Cancer *Gammarius Saltator*. Tab. iv. fig. 3. Cancer Locusta. Brit. Zool. iv. p. 21. No. 34. *Oniscus Locusta*. Pallas Spec. Zool. 9. t. 4. f. 7. Misc. Zool. t. 14. f. 15." Of this Montagu says, "The *C. Saltator* is without doubt the animal referred to by Pallas, and this confirms the opinion that Gmelin has confounded it with his *Cancer Locuta*, having quoted both the *Oniscus Gammarellus* and *O. Locusta* of that author for it. That it is Pennant's *C. Locusta* there can be little doubt, as he particularly mentions the quality of leaping, a power denied to the other species." Montagu's figure very clearly depicts what is now known as *Talitrus locusta*, Pallas. As he makes no reference to Klein's *Squilla saltatrix*, 1743, the specific name *saltator* was probably not borrowed from that source.

On page 96 he gives "Cancer *Gammarius littoreus*. Tab. iv. fig. 4. Pulex marinus. Boeck Op. Subs. ii. p. 31. t. 3. f. 7. 8." "The *C. littoreus*," he says, "is doubtless the species figured by Boeck as above referred to, and which Gmelin has erroneously quoted for the Linnean *Cancer Pulex*." This is pretty clearly the *Oniscus Gammarellus* of Pallas, which Montagu himself has erroneously quoted for the Linnean *Cancer locusta*. Its name, therefore, should be, as Boeck gives it, *Orchestia gammarellus*, Pallas.

On page 97 he gives "Cancer *Gammarius grossimanus*. Tab. iv. fig. 5." This is a new species. It is now called *Maja grossimana* (better, *grossimanus*).

On page 98, "Cancer *Gammarius Talpa*. Tab. iv. fig. 6." now called *Aplysia talpa*, belongs to the Tanaidae.

On page 99, "Cancer *Gammarius rubricatus*. Tab. v. fig. 1." is a new species, which was referred by Leach to his genus *Amphithoe*. It includes, I believe, *Amphithoe littorina*, Sp. Bate, and three or four other synonyms from species founded chiefly on immaterial distinctions in colouring.

On page 100 is given the new species "Cancer *Gammarius falcatus*. Tab. v. fig. 2." This Leach considered to belong to the genus *Jassa*, which he instituted with the species *Jassa pulchella* and *Jassa pelagica*, establishing at the same time the genus *Podocerus* with the species *Podocerus variogatus*. Milne-Edwards gave *Cancer falcatus* and *Jassa pelagica* to *Ceranus pelagicus*, to *Podocerus variogatus* he left its name, and changed *Jassa pulchella* into *Podocerus pulchellus*. Spencer Bate gave the four as separate species of *Podocerus*, to which more recently all four have been assigned as a single species. Boeck united the names *pelagicus* and *pulchellus* as synonyms to Montagu's *falcatus*, no doubt correctly, but it seems curiously perverse that he should assign Leach's three species of *Jassa* to *Podocerus* and Leach's species of *Podocerus* to *Jassa*, altered without due reason from *Jassa*. *Jassa* may well fall to *Podocerus* as being too near for generic distinction, but, if not, the species in question would have to be named *Jassa falcata*, Montagu, and *Podocerus variogatus*, Leach. It is rather singular that Montagu should finish his account with the words "This curious and rare species inhabits the deep, amongst *Sertularia*, and *Algyx*, and has
only been taken by dredging at Torcross.” As a matter of fact now-a-days at Torquay and Ilfracombe, in shore-pools, the *pelagicus and paludicellus* forms are extremely, not to say tiresomely, abundant.

After describing two species of *Phalangium*, on page 102 Montagu gives “Oniscus Testudo Tab. v. fig. 5. Body sub-ovate, composed of eight joints rising to a ridge on the back; the plates elevated at their edges; the four first fall very low on the sides, and obscure the anterior legs; along each side of the body a row of small tubercles; the front sub-bifid; antennae four, very short, lower pair hid beneath: eyes prominent, black; posterior end obtusely pointed; caudal fin beneath, obscure; legs fourteen, short and strong, the three posterior pairs longest; all furnished with a simple claw. Length two lines. Colour dull red, with a white spot on the anterior part of the back, but as the insect dies this mark is lost. Rare.” By Bate and Westwood, Brit. Sess. Crust., vol. i. part 5, p. 228, 1862, this is made the type of a new genus *Pereionotus*. See also Brit. Mus. Cat., p. 375, 1862. These authors recognise that “this genus bears a near relationship to that of *Phlius* of Guérin,” 1836. They only find indeed one distinction of importance, that while *Pereionotus testudo* has the last uropods uniramous, *Phlius serratus*, taken on the voyage from the Falklands to Port Jackson, has these uropods biramous. A specimen from the Mediterranean which Spence Bate has named *Phlius rissoanus*, he unfortunately left unexamined in regard to the last uropods. Grube’s genus *Icridium*, 1863–4 would seem undoubtedly synonymous with *Pereionotus*, but that its author declares that his *Icridium fuscum* has no telson. Carus, Prodr. Faun. Medit., 1885, gives under “Icridium Grub (Phlius Gué.)” “I. Rissouanum Catta (Phlius Rissoua Sp. B., I. fuscum, Gr.).” That further investigation will unite *Phlius*, *Pereionotus*, and *Icridium* in one genus seems not improbable. In that case *Phlius*, Guérin, will take precedence, with *Oniscus testudo*, Montagu, for the type species.

1810. LATEILLE, P. A.

The first part, pages 9–87, reviews in general the work that had been done up to that time in regard to the classification of the groups mentioned in the title. In the second part, the Crustacea are divided into two Orders, Entomostraca and Malacostraca. The Malacostraca are divided into seven families, the first five with “tête confondu avec le corcelet,” the sixth and seventh with “tête distincte du corcelet.” The sixth, or *Squillares*, has “Yeux pediculés.” The seventh, *Crévétinaxes*, *Gammarinae*, has “Yeux sessiles.” In this last, two groups are formed, the first containing but a single genus, the second much subdivided, as follows:—

On pp. 422–3, species are given for these genera as follows:—“*Phronyme, Cancer selentarius, Forsk.* Crèvette. Gammarus pates, Fab. Talitra. Oniscus gammarinus, Pall. *Corophie, Gammarus longicornis, Fab.* Chevroll. *Cancer linearis, L.* *Cyame, Pycnogonum ceti, Fab.* The asterisks indicate the genera instituted by Latreille himself.

(ZOOL. CHALL. EXP.—PART LXVII.—1857.)
1811. Stewart, Charles.

Among the Aptera, under the genus Cancer, he gives the names Gammarus, Pulex, and Loeusta. Cancer gammarus of Linneus, it should be remembered, is not an Amphipod.

1812. Thomas Pennant.

1813. Montagu, George.

Descriptions of several new or rare Animals, principally marine, discovered on the South Coast of Devonshire. Transactions of the Linnean Society. Vol. xi. First Part. mdcocxiii. Pp. 1-26, pls. i.-v. Read April 7, 1807. (The bound volume is dated 1815, but the separate first part as above.)

On page 3 Montagu gives "Cancer Gammarus spinosus. Tab. ii. fig. 1," which Leach afterwards called Dexamine spinosa. He hints that Turton's briefly described Cancer gammarus carinospinosus may be the same species, but this is decided by Bate and Westwood to be Atylus carinatus, Fabr.

On page 4 is given "Cancer Gammarus galba. Tab. ii. fig. 2." Body ovate, somewhat elongated at the tail, smooth, glossy, and when alive of an olive-green minutely speckled with brown, but by drying becomes rufous-brown; antennae of the male remarkably short; in the female two pairs extremely long and slender, nearly equal to the length of the body; joints of the body, independent of the head, and the joint to which the caudal fins are attached, eleven; the head is large, and much resembles that of a maggot, and in the male appears to have no division between the eyes, but a continuation of the same transparent membrane covers the whole; the eyes of the female are very large, but distinctly marked by a division; the two pairs of anterior legs, like those of C. spinosus, are small, and not subcheliferous, but occupy the place of arms, and scarcely differing in any respect from the other five pairs, all of which are furnished with a very small claw; abdominal fins three pairs; caudal fins
five, flat, and bicol; the middle one very broad, concealing the others which are capable of spreading laterally. Length, half an inch or more. The female is rather more slender in the body, and does not so suddenly decrease towards the tail. The eyes, as before-mentioned, are distinct, and are of a bright red when alive, reticulated, and marked with two streaks of black, one on each side of the eye, probably the reflection of a pupil. This is another species of Cancer that very nearly approaches the genus Oniscus, and is readily distinguished by the larva-like appearance of its head. It is not uncommonly taken with the last. It should be noticed that this description differs strikingly in some respects from that given of Hyperia galba by Tate and Westwood. Their species is fawn or faint yellow speckled with red, and has green eyes. Montagu's species is olivaceous speckled with brown, and has red eyes. Boeck unites both of them as synonyms of Hyperia (Cancer) medusearum, O. F. Müller, but does not notice the colouring, nor that in the expression five caudal fins. Montagu attributes to his species only two instead of three pairs of uropods, nor that he gives the long antennae to the female instead of the male. Montagu's remark that his species is not uncommonly taken together with Deçarme's spinosa, if applied to Hyperia medusearum, seems scarcely in accord with common experience, although various Gammarina are occasionally taken upon Medusea. In the figure, it is the first uropods, not the last, that extend furthest backwards.

On page 5 he gives "Cancer Gammarus Monoculoides. Tab. II. fig. 3." "This species," he says, "seems to connect the Cancer with the Monoculus, but is more allied to the former in the conformation of its members." Its name at present is Stenothoe monoculoides. On the same page is given "Cancer Gammarus obtusatus. Tab. II. fig. 7," now known as Militum obtusatum.

On page 6 he gives "Cancer Gammarus pedatus. Tab. II. fig. 6. Gammarus pedatus, Mull. Zool. Don. iii. t. 101." He does not seem to have been aware that this had been earlier described by Müller as Squilla ventricosa. It is now known as Proto ventricosa, Müller.

1813-1814. Leach, William Elford, born 1790, died 1836 (Webster).

Crustaceology. The Edinburgh Encyclopedia, conducted by David Brewster, L.L.D., &c., &c., with the assistance of gentlemen eminent in science and literature. In eighteen volumes. Vol. vii. Edinburgh, m.dccc.xxx. (The issue of the work lasted from 1810-1830, but the title page for each volume bears the date 1830. The earlier numbers ran through several editions. Leach's article, Crustaceology, is referred to by Desmarest, 1825, and others, with the date 1813-1814. Whether it originally appeared with or without the appendix seems uncertain.)

Leach in this article considers that Crustaceology treats of two classes, Crustacea and Arachnides, as distinct from Insecta. Of Brison he does not as yet seem to have heard, as he thinks that Pennant first separated the Crustacea from insects, although capriciously. Leach himself takes from the Arachnides the orders Tetracera and Myriopoda of Latreille to add them to the Crustacea, and Latreille's Parasita to add them to the Insecta. He divides the Crustacea into three orders, Entomocrraca, Malacostraca, Myriopoda; the Malacostraca into three tribes, Brachyura, Macouri, Gasteruri. The Gasteruri are thus defined, "Eyes sessile. The joint of the body which receives the head, of the same size with the rest." This tribe contains the following families, Gnathonii (also spelled Gnathionii), Gammarii, Corephoni (also spelled Corephini), Caprelli, Apsyindii. Of these the first, with the genus Gnathia,
since called Ancus, and the last with the genus Asterias, are not usually considered Amphipod families.

In this system we have the following arrangement of the genera and species which came soon after to be called Amphipoda.

"Family XIV. Gammarinae.

"1. Superior antennæ shorter than the peduncle of the inferior antennæ. Feet fourteen."

"Genus LII. Talitrus."

"Sp. 2. Littoralis."

"Talitrus littoralis, Leach's MSS." This was afterwards dropped. "Genus LIV. Orchestia."

"Sp. 1. Littorea."

"See Plate cxxvi, fig. 6. Pulex marinus of Baxter [Basler]; Cancer gammarus littoreus of Montagu; Orchestes littorea, Leach's MSS.; Talitrus gammarellus, Latreille?"

"Latreille quotes Baxter's figure which renders it highly probable that this may be his Talitrus gammarellus; but as he quotes also the Oulocus gammaris of Pallas, it still remains in some doubt." This confusion on Leach's part probably originates with Montagu. See Note on Montagu, 1808.

"2. Superior antennæ longer; or at least as long as the inferior. Fourteen feet, the third and fourth pair smallest."

"Genus LIV. Gammarus."

"Fresh water. Sp. 1. Pulex."

"Cancer pulex of Linne and Pennant; Gammarus pulex of Fabricius and Latreille."

"A species which Mr. Leach considers as distinct from pulex" is then mentioned, but not numbered. It came from a well in London. "It differs principally from Gammarus pulex in having the upper process of the tail much longer. The colour, when alive, was cinnereous, but so translucent, that the eyes could not be discovered; it stands in Mr. Leach's cabinet, under the specific name subterraneus." This is probably the same as Niphargus aquilex, Schicht. The species of Gammarus are continued under the heading "Marine." "Sp. 2. Locusta."

"Sp. 3. Cymolopas."

"This is probably only a casual variety of Gammarus locusta."

"Sp. 4. Rubricatus."

"Cancer gammarus rubricatus of Montagu. Amphiöæ rubricatus, Leach's MSS."

"It is a rare species, and possibly does not belong to this genus."

"Genus LVI. Aemera."

"Anterior pair of feet with a moveable nail; the second pair with a compressed hand and moveable thumb. Peduncle of the antennæ with three joints; the superior antennæ longest."

"Cancer grossimana of Montagu. Mara grossimana, Leach's MSS."

"Genus LVII. Melita."

"Anterior pair of feet very small; second pair with a compressed hand, and moveable nail which bends on the palm. Superior styles of the tail very long and large."

"Sp. 1. Palmata."

"Gammarus palmatus, Montagu. Linnae Transact. vol. vii. tab. 6. Melita palmata, Leach's MSS."

"Genus LVIII. Leuctrothoe."

"Anterior feet with a finger and thumb; the thumb jointed; second pair with a moveable thumb but no finger. Peduncle of the antennæ with two joints. Superior antennæ longest."

"Sp. 1. Articulosa."

"Cancer articulosa of Montagu. Leuctrothoe articularis, Leach's MSS." This is now known as Leuctrothoe spinicarpa (Müller) Abildgaard.

Leach then observes that Phommis solentaria of Latreille, "Cancer solentaria Forsk. F. Arab. page 95," probably forms a distinct family, but as he had never seen a specimen, he merely quotes some remarks of Latreille upon it, and then proceeds to give:

"Family XV. Corophini."

"Genus LIX. Corophium."

"Sp. 1. Longicornis."

"Cancer grossipes of Linne; Oulocus solutator of Pallas; Gammarus longicornis of Fabricius; Astacus linearis of Pennant; and Corophium longicornia of Latreille."

"Family XVI. Caprellinae," with a note:—"The body of these animals, exclusive of the head, is composed of six joints, all except the second and third bearing feet. The second and third segments furnished on each side with two processes, which probably serve as fins.
Feet ten, all armed with a moveable nail; the anterior pair very small, and originating from the head. Mouth with two jointed palpi, armed at the point with a little hook. The female is furnished with a pouch, situated between the fins, in which she carries about the eggs and her young after their exclusion, until they are enabled to shift for themselves. "Genus IX. Caprella." "Sp. 1. Linearis." "Head with one little tubercle. Hand of the second pair of feet with three teeth on the inner edge. Cancer linearis of Linné; Astacus atomos of Pennant; Caprella linearis of Latreille; Oniscus scolopendroides of Pallas." This Mayer is unable to identify, but the tridentate hand points pretty clearly to Müller's Spicilia quadrilobata, Zool. Den., pl. lvi. figs. 4–6. "Sp. 2. Phasma," Montagu, Lin. Trans., vol. vii., which is now Prodelia phasma, Montagu. "Sp. 3. Pemantis," "Astacus atomos of Pennant." This has since been identified with Caprella acetifrons, Latreille. "Sp. 4. Acanthifera." "Caprella acetifera, Leach's MSS." "Genus LXI. Panope." Body depressed. Eyes situated on the vertex of the head. Antennæ four-jointed; the upper pair, with the basilar joint, largest; the second and third equal, but rather shorter than the first; apical joint very small; inferior pair also composed of four joints, shorter than the first joint of the upper pair. Feet compressed and armed with strong nails; the anterior pair situated on the base of the head, the wrist jointed. Hands of the second pair armed with teeth on their inner edge. Fins of a leathery-membranous substance, cylindrical and elongated. Anus produced, having a few obscure small tubercles on each side and under. The pouch of the female with four valves. "Sp. 1. Calli." "Oniscus calli of Linné; Pycnogonum calli of Fabricius; Panope calli, Leach's MSS." Latreille's authority is quoted for the (erroneous) statement that it attaches itself to fishes of the genus Scember, as well as to whales, but no notice is taken of Latreille's name for the genus, Cyamus.

Under 'Order III. Myriapoda.' Family XVII. Asellides," upon "Genus LXVI. Cymothola," the observation is made:—"It is highly probable that Oniscus testudo of Montagu (Transactions of the Linnean Society of London, vol. ix. page 102, tab. 5, fig. 5) is referable to a genus akin to this." Leach having never himself seen the species, merely quotes Montagu's description.

1814. LEACH, W. E.

Article Crustaceology. Appendix. The Edinburgh Encyclopædia. Vol. vii. pp. 429–437. (That the date of this Appendix is not later than 1814 may be inferred from the fact that the genera Pherusa and Proto appear in it as new, without any reference to the mention of them in the Tabular View read before the Linnean Society in April, May and June of 1814.)

Leach has here "divided the Tribe Millipeda from the Crustacea, and considered them as a distinct class, under the title of Myriapoda, and has placed the Oniscides and Asellides with the Gasterurid. The two orders Entomostraca and Malacostraca are now considered as subclasses. The three Tribes of the Malacostraca are called orders. The Gasterurid now include seven Tribes called Gnathides, Gammerides, Phoronides, Caprellides, Apsocides, Asellides, Oniscides. Of these we find that the second, third, and fourth, belong to the Amphipoda. The Tribe Gammerides, answering to the previous Family Gammarini, is thus divided:—"Family I. Orchestidae." "Genus I. Talitrus," in which Leach has discovered that Talitrus littoralis is only the other sex of Talitrus locustus; "Genus II. Orchestidae."

"Family II. Decameridae. Antennæ three-jointed, the last joint composed of several other minute articulations; upper ones longest," with two sections, "Two anterior pairs of feet..."
THE VOYAGE OF H.M.S. CHALLENGER.

monodactyle. Genus III. DEXAMINE. Four anterior feet nearly equal; hands sub-ovate, compressed and filiform, type species Dexamine spinosa, Montagu; "* * Anterior pair of feet didactyle; second pair monodactyle. Genus IV. LEUCOTHOR." "Family III. GAMMARIDE. Last joint of the antennae composed of several minute articulations; upper pair longest, four-jointed; under ones five-jointed," with three sections, "* Second pair of feet larger than the first, with a compressed hand. Genus V. MELITA," "Genus VI. MAFRA." "* * Four anterior feet nearly equal in size and form with ovate hands. Genus VII. GAMMARUS." "Genus VIII. AMPHIHE, superior antennae, without a seta at the base of the last joint; lack of the tail without fasciculi of spinules." "* * * Four anterior feet with a filiform hand. Genus IX. PHERUS," left otherwise without definition, the type species *Phersonia* variegata receiving this description — "Colour whitish, nutted with reddish. Found on the rocky shores of Devon, under stones at low tide, on fuci."

"Family IV. PODOCERIDE. Superior antennae shortest four-jointed, the last joint solid or obscurely articulated; inferior antennae five-jointed, with the last joint solid, or very obscurely articulated." In the first section, "* Superior antennae very short, the last joint composed of many minute articulations," he places "Genus X. Corophium [i.e., Corophium];" in the second, "* * Superior antennae shorter than the under ones; the last joint scarcely articulated," he places "Genus XI. Podocerus," "Eyes hemispherical and somewhat prominent; four anterior feet didactyle, anterior pair smallest with an elongate sub-ovate hand; second pair with an ovate hand, and the internal side nearly straight," type-species, Podocerus varicopus; "Genus XII. JASSA, eyes not prominent; four anterior feet didactyle with ovate hands; the anterior pair smallest; the hand of the second pair with the internal edge furnished with teeth," with two species, Jassa pitchella, var. a, var. β, and Jassa petalica, both these species being referred to as already established in the genus Jassa, Leach, "Mem. Wern. Soc. vol. ii." He adds that "Cancer gannicurus falcatus of Montagu, Lin. Trans. vol. ix. tab. 5. fig. 2. seems referable to this genus." Modern opinion groups all the four last-mentioned species under the name Podocerus falcatus, Montagu. Jassa or Jassa would claim priority as the generic name, only that there seems to be nothing in the Mem. Wern. Soc. corresponding to Leach's reference. Tribe III. PHRONIMARIDES, only contains the genus PHRONIMA. Of Tribe IV. CAPRELLIDES, Leach says, "This includes our family CAPRELLINI, to which we can add another genus, differing from Caprella in having true legs instead of the gelatinous fine [fin]-like legs, which is named Gen. Proto. Sp. 1. Podata. Cancer gannicurus podatus, Montagu, Lin. Trans. vol. xi. p. 6. tab. ii. fig. 6." This is Proto ventricosa, O. F. Müller.

The Article "Animal Biography" concludes in July 1814, on page 354, with giving in Class V., Insects, "Order VII. aptera, or insects without wings. The genera are: — 1. Podura, spring-tail. 2. Pediculus, louse. 3. Pulex, flea, chigger. 4. Acarus, tick, mite. 5. Aranea, spiders. 6. Scorpio, Scorpion. 7. Cancer, crab, lobster, crawfish, shrimp. 8. Monocelus, water-lea. 9. Ovisucus, wood-lea. 10. Scabocent, centipede." This contribution, "by the most celebrated modern authors," or some one of them, is a high compliment to the enduring influence exercised by Linnaeus, whose earliest views on this portion of the animal kingdom are here reproduced, in spite of all that had been done in the interval by his distinguished successors throughout Europe.
1814. Rafinesque-Schmaltz, Constantin Samuel, born 1783, died 1849 (Hagen).

Précis des découvertes et travaux Somiologiques entre 1800 et 1801, ou choix des principales découvertes en zoologie, et en botanique. Palerme, 1814.

Somiologie is explained by this eccentric author to mean "la Science des Corps vivans," applying both to botany and zoology, to each of which he assigns ten classes, which he sets one over against the other. The Crustacea are placed in the fifth class, the Plaxologia, in which he had observed about 180 species, nearly half of them new, to be described and figured in his Plaxologie Sicilienne. He describes a new genus *Pisitoe*:—"Antennes nules, yeux irréguliers, bouche sous la tête, recourbée postérieurement, munie de crochets; Corps à 6 articles et 6 paires de jambes inégales, la quatrième paire la plus grande, queue à 4 articles, les 3 antérieurs à appendices.—Obs. Il appartient à l'ordre Brongniartia, et famille Phruminia, il diffère particulièrement du G. Phirmina par son moindre nombre de jambes," with the species, "*Pisitoe bispinous*, Front à deux épines antérieurement, les trois premières paires de pattes à un seul angle," and "*Pisitoe levifrons*. Front lisse, sans épines, les trois premières paires de pattes à deux angles." Boeck thinks that this genus may be the same as *Phroenia*, Risso. Costa makes *Pisitoe levifrons* a synonym of *Phroenia solenaria*, and regards *Pisitoe bispinous* as equivalent to Risso's *Phroinea secalinuma*, though apparently not thinking it right to displace Risso's name in favour of Rafinesque's inaccurately described genus and species.

1815. Tilesius von Tilenau, Wilhelm Gottlob, born 1769, died 1857 (Hagen).

This author divides the Crustacea into three orders—1°) *Entomostraca*, "2°) *Astacoidea*, quorum corpus et cauda elongata et crura calcaria obtectum est," 3°) *Caricoidea* seu Brachiuri. A note to the *Astacoidea* says, "Pulinarus, Astacus, Hippa, Squilla, Gammarus Pulemon Crago Penaeus et plura genera ad formandum familiaria Astacoideorum microscopicius vel Arthrocephalorum Dumerilli ad maximam partem noctilucentus marinorum subjungenda, v. g. Caprella Lamarckii, Mysis Latreillii ejusque Phronime vel Canecr sedentarius Forskalli, Thalitrus Latreillii, Amblyrrhynchos vel obtusirostris, Erythrocephalus, Acanthocephalus, Anarhthus, Symphysopus et alii, quorum sermo erit in Secundis VIII. de Entomostracis inscripta."

At page 369, section IX. is devoted to the Oniscii, in regard to which he prefers the views of Pallas to those of Linnaeus. He gives a description of "*Oniscus sodopodoniodes*, Pallas, spicil. Zool. fasc. IX. tab. 4, fig. 15. Martens, Spitzb. t. P. f. i. a.b.c. Longitudo digitii transversi, rarissime pollicaris. Corpus filiforme varicosum, septum articulorum, e quibus posteriores sensim minores. Antenneae majorae dimidia corporis longitudine, intermediae sub majoribus dimidio breviarioribus, exiliores. Palpi ad os exites et propo os brachiodia minuta echilios, qui primum par eicientium pelum. Ad finem articuli secundii prolongi brachia duae insignia chelis maiisque ventricosis instructa. In terio et quarto articulo utrinque vesicula ovata loco pelum, et in femellis ovariorum receptacula foliaca. Articuli posteriores pedibus ambulatoriais instructi in postremo articulo longioribus parva chela.
terminatis. Hæc oniscorum species a Cancro linearis atomos et filiformi Linnæi vix differt, jam a Stellero nostro 1741 in portu divi Petri et Pauli Cantochastico observata et a me in fruticosi Sertulnarium longissimæ et spinose fasciculis per auriculæ dentes avulsis, et cum ancora sublatis vis.

1815. Rafinesque-Schmaltz, C. S.

In the "Tableau des Classes Somobiques," the Règne Animal is divided into ten classes, of which four belong to the first Sous-Règne, "Zoëtols;" the remaining six to the second Sous-Règne, the "Anastis, Anastisien," which have "Point de squelette osseux, ni d'épine dorsale vertébrée, un cerveau ou une moelle longitudinale noyau du système nerveux." The first "Sous-Classe" is the "Condylopia, Condylopes," with "des membres articulés et une tête; jamais de coquille." This contains Class V., the "Plazolite, Crustacés," with "des Branchies, un œur et des vaisseaux sanguins," and Class VI., "Entomia, Insectes." He disapproves the classifications of the Crustacea made respectively by Fabricius and Latreille, preferring Lamarck's division of them into Pédioles and Sessiliodes.

The subclasse Sessiliolæ he thus defines:—"Yeux sessiles, non mobiles, ou effacés ou un seul ou aucun; tête articulée; ordinairement plus de 10 pattes exagonulées et chaque paire inscrite à un article." He includes in it the orders "4, Ostracina;" "5, Pseudophia;" "6, Branchypia." The sixth order, "Branchypia, Les Branchypes" contains the following:—

2. Pisibe R.

5. Protosia R.

15. Famille. GAMMAIA. Les Gammaïriens. Quatre antennes, quelques pattes chéliformes ou pincifères, corps ordinairement cylindrique ou comprimé, la tête plus longue du dernier article caudal.

16. Famille. ONISCIA. Les Onisciens. Quatre antennes, quatorze pattes, dont aucunes chéliformes ni pincifères, corps déprimé, le dernier article de la queue plus long que la tête et à appendicibus articulés.

7. Prosetrhe R.

2. S. F. Lygias, in which all the genera mentioned are Isopods, as indeed also are those under Aselloïa, although Cymothoa at one time included Cynamus and the name Primino was subsequently used by Guérin for one of the Hyperina.

It will be understood that the letters S. F. stand for sous-famille, R. for Rafinesque, G. for genre or genus.
1815. Leach, W. E.

On page 21 Leach defines the new genus Atylus:—"Antennæ 4-articulatae segmento ultimo e plurimis articolis minutorum efformata; superiores sub-breviores articulo secundo tertio longiores; inferiores articulo secundo tertio sub-breviores. Oculi sub-prominentes rotundati inter antennas in capitibus processum inseriti. Pedes 14; paria 1 et 2 monodactyla manu parvula, compressa, 3, 4, 5, 6 et 7 ungue simplex instructa. Cauda utrinque stylos duplicis tribus et supernae stylo utrinque mobili instructa. Corpus (capitii includente) 12-articulatum." Stylos duplicis tribus is translated "with a triple series of double stylos," and (capitii includente), "(including the head)." The type species Atylus carinatus is figured the natural size, and the description is taken from the specimens of Gammarius carinatus described by Fabricius, Ent. Syst. 2. 515. 3, so that Leach feels justified in correcting that author's statement that the hands are simple, "G. manilus adactylis." On page 23 the genus Dexamine, already established in the Edin. Encycl., vol. vii. p. 432, is here more fully characterised:—"Antennæ triarticulatae segmento ultimo e plurimis articolis minutorum efformato, segmento primo secundo breviore; superiores longiores. Oculi oblongi hand prominentes pone antennas superiores inseriti. Pedes 14; paria 1 et 2 monodactyla manu parvula, compressa, 3, 4, 5, 6 et 7 ungue simplici instructa. Cauda utrinque stylos duplicis tribus, supernae stylo stylo utrinque mobili instructa. Corpus (capitii includente) 12-articulatum." The type-species is Montagu's "Caner Gammarius spinosus," now Dexamine spinosa.

1815. Leach, W. E.

A Tabular View of the external Characters of Four Classes of Animals, which Linne arranged under Insecta; with the Distribution of the Genera composing Three of these Classes into Orders, &c., and Descriptions of several New Genera and Species. The Transactions of the Linnean Society of London. vol. xi. Part the Second, mdcxxv. pp. 306–400. (Read April 19, May 3, and June 1, 1814.)

He here proposes to include in a new class the Syngnatha and Chilognatha of Fabricius [the Myriapoda], which Latreille and Lamarck had arranged with the Arachnides. He therefore distinguishes into four classes the Crustacea, Myriapoda, Arachnides and Insecta. The Crustacea with "Branchiis pro respirazione," form two subclasses, the Entomostraca and the Malacostraca; to the latter he unites the Tetracera, which Latreille had placed with the Arachnides, and divides the subclass into two Legions, the Podophasma and the Eriophasma, the latter being defined as having "oculi sessiles." This Legion comprises three sections, the first with "corpus laterali inferior compressum. Pedes 14. Antennæ 2 in frontem inserita, una utrinque. (Cauda stylos instructa)," one genus. The second section has "corpus laterali inferior compressum. Pedes 14 coxi lamarilliformes. Antennae 4 per paria inserita. (Cauda stylos instructa)." It includes five divisions with thirteen genera. The third section has "corpus depressum. Antennæ 4. Pedes 14." with four groups, seven divisions and twenty-four genera, the first division with two subdivisions and three genera belonging to the Amphipoda.

Sectio I. contains only "Gen. Phronima, Latr.," which is fully described, and has "Spec. 1. Phronima sedentaria."

(Zool. Chall. Exp.—Part LXXVII.—1887.)
THE VOYAGE OF H.M.S. CHALLANGER.

**REPORT ON THE AMPHIPODA.**

_Squilla pedata_, forte stiam ventricosa? Müller. “Gen. 16. CAPRELLA.” with the note, “ad hoc genus Asterias atomos, Pennant, Squilla lobata, Müller, et Cancer Phaea Montagu pertinent,” but Leach declines to disentangle the confused synonymy.

There are thus no new genera properly speaking in this paper, but Leach probably regarded those which had just been instituted by him in the appendix to his Article Crustaceology in the Edinburgh Encyclopedia as practically new. These are Decamnus, Amphipoda, Phorma, Poecocerus, Jassa. In the Encyclopedia he refers to Mom. Wern. Soc., vol. ii., for Jassa, but apparently by mistake, as the genus does not appear in that volume, and the reference is not repeated in the Linnean Transactions. _Attylos_ was instituted in the Zoologist, Misc., vol. ii. _Proto_ appears here as a new genus, or at least without reference to any previous work. It appears indeed in the appendix above-mentioned, but that appendix may have been in fact contemporaneous in its production with the present “tabular view.”

Leach does not give any reasons for rejecting the earlier name Cyamus, Latreille, or his own Panope, in favour of Larunda. Panope he may have thought too near to Panopea or Panopea employed among Mollusca in 1807. Cyamus he perhaps rejected as a name already employed in botany, but Lütken points out that, so far as the Linnean era is concerned, its zoological use takes precedence of the botanical.

1816. Leach, W. E.

The Annulosa are explained to comprehend five classes—Crustacea, Myriapoda, Arachnida, Insecta, Vermes. The Crustacea are distinguished as having “Branchiae or gills for respiration. Legs for motion.” By “legs” are meant “those organs which actually perform the functions of legs.” A review is given of the earlier systems of classification for the Crustacea, concluding with that adopted by Leach himself in the Linnean Society’s Transactions, vol. xi. part 2, which was read in 1814, and published in 1815. This system is here repeated, in English instead of in Latin, but otherwise as far as the Amphipoda are concerned, practically unaltered; two or three immaterial observations are added, and in Section III., the definitions of Divisio I. and its two subdivisions are omitted. In both papers Phormina is sometimes spelled Phormyna, and in the English notes on Phormina sedentaria Leach observes that “all authors have erred in giving but ten legs to this animal.” This is unjust to Forskål who attributes to the species “pedes utrinque decem; paria enim septem thoracis septem articolis aderent.” ToGammarus pales of his earlier work, Leach, in this and the preceding paper, gives the name Gammarus aquaticus, as a new species distinct from the Gammarus pales of Latreille and Boe, arguing from their borrowed figures, which represent the hands much dentated within. That, however, is very little to the purpose, since their figures are only taken from Rösel’s Squilla fabrica without regard to the creature described. On Plate XXI., Moesta palmata, Phorusa fucicola, and Larunda eti are figured.
Savigny tells us in the preface that he based his theory on the examination of some 1500 species of insects and crustacea, most of them scarcely four or five lines in length, and some far smaller. These were carefully dissected, and complete descriptions drawn up and accurate drawings made of the organs of nutrition, motion, sensation, respiration, &c.

The theory in brief is, that whatever form of mouth the insects may take, it is always composed of the same elements. In the second mémoire he divides the Insecta of Linnaeus into two classes, 1. insects Hexapodes, which in the perfect state never have more than six feet attached to the first three rings of the body, including all the winged insects with "la Puce, le Pou, le Rien, les Forbicines, les Podures," the latter two more doubtfully added; 2. insects Apiropodes, with more, sometimes many more, than six feet, including "les Entomostracés, les Crustacés, les Pycnogonum, Scorpions, Araignées et autres insectes sans antennes, les Scolopendres, les Iules." He shows that in the mouth of the crab are to be found the elements which constitute the mouth of the Hexapod insect, but in addition other elements which must of necessity be analogous to the six feet of the Hexapods. All doubt on this point, he says, is removed by what we find in Gammarus. This, like the crab, has two compound eyes, four antennae, a large upper lip, a tongue deeply bifid (the labium inferius), two mandibles, two first maxillae, two second maxillofem with four nails. After them come ten but fourteen feet, four more than in the crab, a number just equal to the auxiliary maxillae which Gammarus has fewer than the crab. In truth, he says, all Crustacea properly so-called have sixteen feet, of which more or fewer are converted into auxiliary maxillae. He noticed that in removing the head from some of the smaller Crustacea, the Cyamus for example, the maxillipeds remain attached to the first ring of the body. This I have found with some of the Amphipoda.

The mistake which Fabricius made in placing in the same genus the Pycnogonum without antennae, and the Cyamus which have four, Savigny attributes to the real relations "in the habitation, mode of life, and above all, the general form of body of these parasitic insects." But in a note he says, "les Pycnogonum ne sont point parasites à la manière des Cyamus, il paraît qu'ils s'attachent principalement aux coquillages bivalves." In comparing Cyamus, a close relation of the Gammaria, with Nymphon of the Pycnogonum family, Savigny hopes to show how Nature passed from the mouth of the Crustacea to that of the Arachnides. He states that the head of Cyamus is "pourvue de gros yeux composés," and in describing the eyes of Nymphon, "tres-petits, lisses et groupés près de la tête sur le dos," he adds "ce qu'il y a de singulier, c'est qu'on trouve aussi deux petits yeux lisses au Cyane. Ce sont même les seuls que les naturalistes aient aperçus." The singularity, however, is on the part of Savigny, who, Lütken says, introduced the fiction of the large compound eyes. He does not figure them either in the upper or under view which he gives of the animal. In the "Rapport fait à la première Classe de l'Institut," by the "commissaires MM. Cuvier, de Lamarck et Latreille, rapporteur," Savigny's mistake was accepted without question, to
judge by the quotation he gives from it on page 72, "On n'avait encore aperçu que deux petits yeux lisses des Cymus, et M.S., en découvrant les yeux ordinaires ou composés, nous montre un fait dont nous n'avions pas encore d'exemple parmi les Crustacés, et qui indique un nouveau rapprochement des Cymus avec les Arachnides sans antennes."

In Plate IV. "Gammarus . . . Cyamus filosa," n.s., now called Amphithoe filosa, and "Gammarus . . . Lycesta furina," n.s., now called Leucothoe furina, are figured in part; and on Plate V. Cyamus ceti, Latreille, which is Cyamus mysticeti, Lütkem. In the description of details it may be noticed that the lower lip or labium is called "bouche", the maxillipeds "Yeux annexe", and to the six free joints of the legs are given the designations, 1. hanche, 2 and 3. cuisse, 4 and 5. jambe, 6. tarse.

1816. POLLINI, CIRO.

Viaggio al Lago di Garda e al Monte Baldo in cui si ragiona delle cose naturali di quei luoghi aggiuntovi un cenno sulla curiosità del Bolca e degli altri monti Veronesi. In Verona, 1816.

He remarks, pages 22, 23, "Oltre del Gambere comune, Cancer Astacus, rinvenesi al nostro Lago due granchetti. L' uno è il Cancer Sfintia (Gamberozoli volg.), che abita infra l'erbe palustri tanto del Benaco, quanto delle risaie nostro, ed è la varietà a rostro dritto. L'altro è il Cancer Pulce (Salterello volg.); ritrovasi nel greto a quattro dita, dove si multiplica prodigiosamente. Dalla sua bocca esce un umore corrosivo, alto a sciogliere la terra. E poiché nelle ore calde suole essere dal covaceolo, reca sommo danno alle tele di lino e di canape, che si stendono dai benacensi ad asciugare ed imbiancare sulla spiaggia, mentre le foracchia di mille modi con l'amore onde si prepara l'alimento. Fu scoperto anche in alcuni pozzi di Verona, e nelle terme di Caldiero." G. D. Nardo, in 1868, states that the "Gamberozolo" is Anchystia palustris, Heller, but of the Cancer pulce so destructive to linen on the beach, when it issues from its burrows in the heat of the day, he gives no explanation. It may be conjectured that this burrower is one of the Orchestide, and that when Pollini speaks of its being found also in wells and warm springs, he is confounding it with other Amphipods, such as Niphurus putacaus and Gammarus pungens.

1816. BLAINVILLE, MARIE HENRY DUCROTAY DE, born 1778, died 1850 (Hagen).

De Blainville declares his object to be to group animals "d'après l'ensemble de leur organisation." For the purposes of his system, he says, "Je suis arrivé à mettre en première ligne la disposition des différentes parties ou la forme générale des animaux, ce qui se trouve concorder avec celle du système-nerveux quand il existe. Puis l'organe qui soutient cette forme ou la peau et ses annexes. Après cela les appendices qui s'y ajoutent, et s'y développent. Enfin, les différentes modifications et combinaisons de ces modifications des appendices, c'est-à-dire des organes des sensations, de la locomotion, dans ses différentes espèces, de la mastication, et jusqu'à un certain point de la respiration."

In the Tableau Analytique he divides "ANIMAUX" into "1° Sous-règne Pairs ou Actinomorphes. 2° Sous-règne Rayonés ou Actinomorphes. 3° Sous-règne sans forme régul-
THE VOYAGE OF H.M.S. CHALLENGER.

Within the Heteromorphs, the first subkingdom is again divided into "Type I. Vertébrés or Ostéozoaires. Type II. Invertébrés or Anostéozoaires." This second type has three subtypes, I<sup>st</sup> Sous-type, non-articulés; Mollusques Malacozoaires. II<sup>nd</sup> Sous-type, Sub-articulés ou Sub-Entomozoaires. III<sup>rd</sup> Sous-type, Articulés à Append. Entomozoaires." The second of these contains Classe VIII. Polyplophores. Classe IX. Cérripodes. For the third subtype the following Table is given:—

In the notes, he says, "Dans cette nouvelle distribution des animaux articulés, qui fait le sujet d'un Mémoire communiqué à M. Latrille, le 19 Juin 1815, et lu à la Société philomathique le 24 du même mois, on voit que le principe a été de ne tirer les caractères que des organes de la locomotion, on mieux, de la combinaison des différentes espèces d'appendices dont peut être accompagné chaque annexe du corps." Note 4, to les Epizoaires, says, "Cette sous-classe, dont j'ai fait le sujet d'un travail particulier, contiendra, outre les Lernées et plusieurs genres nouveaux que le Dr. Leach et moi avons cru devoir établir, les Calyces, Cyanes, Chévroles, etc., de manière à passer insensiblement aux Tétrapodes."

1816. BLAINVILLE, M. H. D. DE.

This is merely a report of Leach's paper in the Linnean Society's Transactions, as the title intimates.
Nouveau Dictionnaire d'histoire naturelle, appliquée aux arts, à l'Agriculture, à l'Économie rurale et domestique, à la Médecine, &c. Par une Société de Naturalistes et d'Agriculteurs. Nouvelle Édition. A Paris. m dccc xvi. (Thirty-six volumes, of which the first seven belong to 1816, the remainder to 1817, 1818, 1819. The Crustacea are by Latreille.)

In the first volume, pp. 467-469, Latreille institutes the order of Amphipoda, with the following divisions:

In the fifth volume under "Chevrolle, Caprelia, Lam.," Latreille refers to the genus "Proton," as containing "les espèces qui ont dix pieds attachés successivement par paires, et sans discontinue, à autant d'anneaux," while "le genre des Leptomères" contains the species "où les pieds sont au nombre de quatorze." Of Caprella he makes two groups:

"I. Tête ovale point on peu rétrécie postérieurement," containing Caprella acutifrons, Leach, and Caprella acuminifera, thus described:—"Les quatre antennes presque sans cils; corps ayant en dessus de petits tubercules pointus; premier segment roulé, en forme de neud, vers son extrémité postérieure, à l'insertion de la seconde paire de pieds, avec deux tubercules en dessus; les pieds allongés, avec leur somme échancre en forme de croissant et armée d'une forte dent en dessous; leur doigt ayant aussi une dent au même côté. Je l'ai reçu de M. Leach sous le nom d'acuminifera." This is probably Caprella acutifrons, Leach.

Group "II. Tête allongée et rétrécie postérieurement" contains Caprella linearia, Linn., and Caprella mantis, n. sp., thus described:—"La seconde paire de pieds est plus courte; ses articules inférieurs sont comprimés et anguleux; leurs fesse ont à leur base et à l'extrémité opposé, une dent assez forte; on en distingue une troisième, mais plus petite, sous celle de bout. Sur nos côtes baignées par l'Océan."

He adds that "il faut encore rapporter à ce genre le cancer fliformis de Linnaeus. Forskål en a décrit une autre espèce, comme une larve d'un genre incertain, Pam. arab., pag. 87."

In the eighth volume the article Crustacés extends from p. 487 to p. 494. It contains a brief history of Carcinology, and definitions of the five orders into which Latreille at this epoch divided the class. The situation and form of the branchies, the manner in which the head articulates with the trunk, and the masticatory organs, have, he says, furnished the principal characters for his classification. He explains the name Amphipoda, which he gives to the third order (see Glossary). He supposes them to have two kinds of branchies, the one set vesicular, placed at the inside of the base of the leg, the other set setaceous, under the tail ("en forme de pois ou de soies, annexés à des espèces de fausses pattes, situées sous la queue.")

The article "Cystibranches, Cystibranchia, Latr." receives what are now called the Caprellina as a "section des crustacés, de l'ordre des isopodes," but distinguished from other Isopods by so many characters that Latreille thinks they might well form a separate order. Hence in the seventeenth volume, 1817, we find the article "Lemonourones, Lemonocéphala. (Gorge à deux pattes.) Ordre de crustacés qui, dans l'ouvrage de M. Cuvier, sur le règne animal, compose la section des cystibranches de l'ordre des isopodes, mais que j'en ai ensuite séparé..."
pour en former un ordre spécial. Ses caractères ont été développés à l'article Cystibranches.
V. ce mot." Already to the article on the Isopods, his fourth order, he had appended a note, "On pourrait former un ordre particulier, sous le nom de lamapidodes (lamapidode), des isoopes cystibranches. Leurs quatre mâchoires sont disposées sur le même plan transversal, en forme de livre, comme celles des myriapodes; la première paire de pieds proprement dits est annexée à la tête; ils n'ont point de branches sous la queue; de petits corps vésiculeux, analogues à ceux qu'on voit à la base des pieds des amphipodes, paraissent en tenir lieu."

These Lamapidodes, he thinks, lead towards the Myriapods or the Pycnogonides.
Throughout the work the various genera of Amphipoda and Lamapidodes accepted at this period are discussed in the alphabetical order of their French names, but without, so far as I have seen, any novel information being contributed. In most instances the French and Latin names begin with the same letter, but Gammarus is an exception, being in French Crevette or Chevette. Of the "Crevettes, Gammarines," Latreille says, "J'ai, dans mes ouvrages précédents sur l'entomologie, désigné sous ce nom une famille de crustacés composée de ceux qui forment aujourd'hui l'ordre des amphipodes et la division des isoopes, que j'appelle Cystibranches."

1816. Risso, A., born 1777, died 1845 (Hagen).

Risso begins with a quotation from Cuvier, "La détermination précise des espèces, et de leurs caractères distinctifs fait la première base sur laquelle toutes les recherches de l'Histoire Naturelle doivent être fondées," &c. Risso's own intention, doubtless, was to act in accordance with this maxim. Nevertheless, the species he established have in several cases caused great perplexity, owing in part, perhaps, to the want of repeated researches in those localities in which Risso's specimens were taken. In discussing the habitats of Crustaceae, he regards Talitrus as amphibious, delighting in the rocks; Caprella (les chevrolles) hides under stones covered with fucus; Gammarets attaches itself to cartilaginous fishes; Phronima floats on the surface, leaps lightly out, or penetrates to small depths below. Typhis is found beyond the Zostera zone.

He divides the class Crustaceae into two orders, the first "Cryptobranches. Tégunums durs; branches cachées sous le corelet; yeux pediculés; sans palpes ou antennes; dix pattes foliacées ou mutiques," subdivided into two sections (1) Brachuries, with two families containing between them eleven genera, and (2) Macroures, with three families containing among them seventeen genera; the second, "Gymnobranches. Téguments coriaces; branches cachées ou inconnues; yeux le plus souvent sessiles; mandibules palpigères; dix pattes ou plus; terminées par des crochets," subdivided into three sections (1) "Squillines. Tête distinct du corelet;" (2) Tétracères; (3) Entomostracés. The Squillines include two families, "Squillares. Queue munie de lames ou de filets; yeux pediculés," with the genera Squille et Mysis; "Crevetines. Queue avec ou sans appendices foliacées, yeux sessiles," with the genera, "31. Phronime. 32. Typhis. 33. Ephée. 34. Talitre. 35. Crevette. 36. Chevrolla. 37. Cyane." The second section, Tétracères, contains two families, Ascolotes and Céloportides, each with six genera; the third section, Entomostracés, contains two families, the Clypéacés with one genus, and the Ostracodes with two genera.

The Isopod Anceu, it may be noticed, is here given as a new genus, among the third family, Paguriens, the first of the Macroures. It is, in fact, a synonym of the genus Gnathia,
named by Leach in his Article Crustacology, 1813–1814. Leach himself appears for some unexplained reason to have allowed his genus Gnathia to drop, but the name retains its right of priority notwithstanding.

Pages 119 to 132, and Pl. II. figs. 3, 9, are concerned with Amphipoda, arranged as follows:—

Espèces.

(1) "P. Sediens, R.quot; "(2) P. Sentiellle, N. P. custos, N. Planche. 2, fig. 3. P. Corpore lineari, albissimo ; pedibus decem, tertia pari longiore sequi, didactylis, N. Cette phronme a le corps lineaire, cylindrique et blanchatre. Son corcelet est formé de trois-petits segmens. Sa tête est conique, plane sur le devant. Ses yeux sont noirs et sessiles. Ses pattes sont oviformes; la troisième paire est un peu plus longue que les autres et armée de pinces égales, les postérieures sont courtes et grêles. L'abdomen est composé de quatre longs segmens. La queue se termine par une petite plaque qui sert de support à des appendices bifurqués. Dimens. long. 0,040, larg. 0,004. Séjour: dans les écorces et graviers. (Genres de mulesces)." This species is, in Claus's opinion, the same as the preceding. "G. xxxii. Typhs. N. Typhis N. Corps arrondi, abdomen plié sous le corcelet dans le repos; pattes de la première paire didactyles; celles des deux dernières en forme de lames avec un ongle crochu à l'extrémité. Espèce. T. Ovoide. N. T. Ovoide."

N. Planche. 2, fig. 9. Cette espèce ne peut entrer dans aucun des genres connus de la classe des Crustacés. Son corps est ovoide, lisse, d'un beau jaune clair et laissant, parsemé de petits points rougestres; sa tête est oblongue, très-large et trouée sur le devant. Ses yeux sont petits ainsi que ses antennes. Sa bouche est garnie des pinces soyeux. Son corcelet est composé de segmens très-rapprochés, qui sont munis sur leurs bords de lamelles, sur lesquelles les pattes s'articulent. La première paire est presque aplatie, à cinq articles dont le dernier est didactyle; la seconde et la troisième paires sont petites, monodactyles, et les deux dernières, consistent en deux grandes et larges lames terminées par un crochet. L'abdomen est convexe, composé de cinq segmens. Les écailles caudales sont arrondies, ciliées; la pièce du milieu est conique et aiguë. "Dimens. long. 0,024. larg. 0,012. Séjour: dans le golfe de Nice." This species has been called Thyropus ovoide by Spence Bate, and Eutypis ovoide by Claus, but Ditlyrus, Dana, being the earlier synonym of the preoccupied name Typhis, will take precedence for the genus, and the species will be Ditlyrus ovoide. Risso's own figures are drawn with very fine lines and give the details more clearly than might be supposed from my copies of them.

Risso continues as follows:—"2. Antennes terminées par des filets. A. Queue ayant des appendices. G. xxxii. Euphyse. N. Euphena. N. Corps cylindrique, terminé par de longs filets; pattes de la première paire didactyles." This genus is now generally regarded as belonging to the Isopoda, and its one species, Euphena ligoides, as being identical with the earlier Cancer (Gammareus) talpa of Montagu, Leach's Aspaeus talpa. "G. xxxiv."

1816.-Treviranus, Gottfried Reinhold, born 1776, died 1837 (Hagen).

Abhandlungen über den inneren Bau der ungestülen Insekten. Siebente Abh.

Beeck says that the anatomy of Cyamus is given, with figures of the male and female, the mouth- organs, and intestines. The mouth-organs are considered to resemble those of Oisicus, but to be simpler in construction. The author was uncertain as to the form of the second maxilla, and could not make out whether the mandibles had a pulp or not. The stomach he found to be quite simple, without salivary or biliary duct. To the nerve-cords he attributes seven knots or ganglia; the heart he describes as an organ broad in front, narrow behind. He also describes the cylindrical branchiae. He considers that the genus may stand in the same family with Oisicus, and that it does not belong to Squilla, as de Geer, or to Cancer.
puder, as Latreille supposed. In full accordance with Boeck's account of this paper, Lichten
says that the figure and description given of the exterior of the animal are good, the account
of the mouth-organs very incomplete, and the contributions to the knowledge of the internal
structure, if on the whole correct, not very far-reaching.

1817. Latreille, P. A.

Le Règne animal, distribué d'après son organisation, pour servir de base à
l'histoire naturelle et d'introduction à l'anatomic comparée. Par M. le Ch".
Cuvier. Avec Figures, dessinées d'après nature. Tome III contenant les Crustacés,
les Arachnides et les Insectes, Par M. Latreille, de l'Academie des Sciences, &c. A
Paris, 1817. (pp. 44-53.)

Latreille here divides the class of Crustacea into five orders—Decapods, Stomatopods, Amphipods,
Isopods, and Branchiopods. In regard to his order of Amphipods, after giving a general
description of the structure and habits, he says we might embrace this order under the
generic name of Gammarus. He then proceeds to distinguish Les Phronimes (Phronima,
Latr.), the Chevrettes (Gammarus, Lat.), which include, with various characteristics, les
Lecocides and les Dessinius de Leach, les Melites, les Marx, the Chevrettes, properly so-
called, or Gammarus, les Phorases and les Amphiloe, all of Leach, and la Chevrette des
ruisseaux of Geoffroy. These are followed by les Talitres (Talitrus, Lat.), which, he says,
Leach subdivides into his Atyes, Talitres, and Orchestes. Finally, les Corophies
(Corophium, Lat.) are mentioned, with Cancer grossipes of Linnæus for the type, and to this
group he refers "les Podocera et les Jassa de M. Leach."
The Isopods he divides into three sections, according to the form and position of the branchiae.
The first section, les Cystibranches (compare page 95), contains the genera Leptomera,
Latr., and Protos, Leach, which are in fact identical, Caprella, Lam., and Cypusus, Lat., with
Larvula, Leach, given apparently as an alternative name. In the second section, the
Pterygibranches, Typhlops, Risso, is included with other genera usually reckoned as Isopods.
The third section, the Pterygibranches, contain only Isopods. In a note on page 7, he
recognizes that the branchiae in Cypusus, Caprella, and Protos were not thoroughly under-
stood, but makes a good guess as to their true position.

1817. Rafinesque-Schmaltz, C. S.

Synopsis of four New Genera and ten new Species of Crustacea, found in the
New York, 1817, pp. 40-43.

The portion of this paper apparently referring to the Amphipoda is as follows:—
"III. Psmopyla. (N. Order Branchypod, N. Family Gammarid.) The two upper antenas,
with two long segments at the base, and many small articles at the top; lower antenas very
short; all the feet with one nail, the last pair much longer and larger: each segment of the
body with a lateral appendage, tail with four bifid unequal filaments.—Obs. The name is
abbreviated from Psmopopa, which means sand-dea. The family Gammarid is the
fifteenth in my natural classification, and is distinguished by fourteen feet, four antenas, body
not depressed, etc.
"1. Peanymylla littorali. Longer antennae doubly than the head, short antennae not longer than their first segment; last pair of feet double in length; body rufous above, white beneath.—Obs. I have found this animal in great numbers on the shores of Long-Island and New-York, and on the Hudson river, jumping about like fleas, whence its vulgar name Sand-flea; it jumps by means of its hind feet and tail, like locusts. Length about half an inch, often less; eyes large and round.

"IV. Pephredo. (Natural order and family of the foregoing.) The two upper antennae longer and with six long segments; all the feet with one nail, and nearly equal, the two first pairs with thick swelled hands; body without lateral appendages, tail with simple filaments.—Obs. This genus was noticed in my Analysis of nature, and formed on an European species; the name is mythological. It may be deemed a singularity in this family, that this genus should be a freshwater one, and the last a land one!

"1. Pephredo potamogeti. Long antennae, scarcely longer than the head and double of the short ones; body fulvous, transparent, with a central brown or longitudinal stripe.—Obs. It lives on the Potamogeton perfoliatus in the Hudson and the Fishkill, near Newburg. Length three lines, creepers, eyes very small."

Peanymylla littorali is obviously one of the Orchestidae, a "beach-flea." The upper and lower antennae of Rafinesque's terminology would be respectively the lower and upper antennae of ordinary language. If the two genera Peanymylla and Pephredo, could be identified, they might probably enough fall as synonyms to others already known. It is possible that the acute American observers of the present day will be able to identify the two species here given with some that have been since named.

1817. Say, Thomas, born 1787, died 1834 (Hagen).

The new genus Ceratus, assigned to the order Macoura, is thus defined:—"Essential Character.—Thumb of the second pair of feet bi-articulate; interior antennae four-jointed, exterior ones five-jointed. Artificial Character.—Antennae subequal, interior ones 4-jointed, exterior ones 5-jointed. Two anterior pairs of feet monodactyle, the second pair with a two-jointed thumb. Natural Character.—Body semicylindrical, somewhat linear, decreasing towards the tail, ten-jointed. Head distinct from the first joint and larger, quadrate, a little elongated into an angle near the base of the interior antennae, each side, for the reception of the eyes, which are hardly prominent. Antennae nearly equal, very large, interior ones with the first joint thick, second and third nearly equal; exterior antennae five-jointed, the first joint placed in a deep sinus beneath the eye, short, not projecting beyond the margin of the head above, second joint hardly longer than the first, third and fourth equal to the second and third of the interior antennae. Anterior pair of feet moderate, with a small ovate hand and moveable nail, not closing on the hand, attached to the first segment of the body; second pair with the basal joint attached to the edge of the body (as in Cymothoe, &c.), second joint broad, compressed, with an incisure near the base before, third small, medioliform, carpus cylindrical, narrower than the preceding joint; hand very large, compressed, subtriangular, attached to the carpus by the inferior edge of the acute angle, which is a little curved, tip emarginate and armed with a strong, acute spine on the anterior angle, thumb two-jointed, first joint incurved, linear, second acute, closing on the spine of the hand. Third and fourth pairs of feet equal, similar to each
other, first joint dilated, equal to that of the preceding feet, remaining joints small, nearly equal to each other, submoniliform; two posterior pairs of feet reflexed above the back; tail incurved, furnished on each side near the tip with a pedunculated bifid process, and a minute, conic, acute papilla. The type species, Cerapus tubularis, is further described thus:—"Heal with a mucronate carina before; eyes oval, black. Hand and first joint of the thumb of the second pair of feet with one or two obtuse teeth within. Body above blackish, with irregular paler spots; antennæ and feet white, joints tipped with blackish; two hind pairs of feet and tail white. Inhabits a tube. Length about one-quarter of an inch." Say would place it between Grammarus and Caprella, next to Jasna in the family Podoceridae of Leach. He cannot believe that the tube is fabricated by the Crustacean itself, though he notices that it is always proportioned to the size of the inhabitant, which moves actively with its neatly fitting house, making use of its four antennæ as feet, and deftly turning within its tube, if any impediment is offered to its progress in one direction. It is figured in the following number of the Journal for September, 1817.

1817. Stewart, Charles.

Elements of the Natural History of the Animal Kingdom: comprising the characters of the whole genera, and of the most remarkable species, particularly those that are natives of Britain; with the principal circumstances of their history and manners. The second edition. In two volumes. Edinburgh, 1817.

In the preface Stewart says that, as editor, "he has, with Cuvier and others, disjoined the Crustaceous Animals from the Class of Insects, in which they had been included by Linnaeus. In vol. ii. p. 308, after the Insects, he places the Class Articulata, containing "two Orders, viz. 1. Crustacea, or those animals which constituted the genus Cancer of Linnaeus; and, 2. Arachnides, including the genera Aranea, Phalangium, etc." For this arrangement he gives references to Latreille, Lamarck, and Leach (Edin. Encyc. vol. vii. Crustaceology, and Mal. Pod. Brit. London, 1815. On pp. 316, 317, he gives under Cancer the following section or group of species:

1) Antennæ pedunculated and simple.
   32. Cancer grossipes. The claws want the finger; the antennæ the length of the body; the tail obtuse. Inhabits the European Ocean. B.—Pennant British Zool. 4. pl. 16. f. 31. The linearis of Pennant. Found in the sand on the shore of Flintshire and other places.
   33. Cancer Palæz. With four claws which want the finger; ten feet. Inhabits Europe. B.—Depeur. Ins. 7. tab. 33. f. 1, 2. This species is very frequent on the shores of the sea; likewise in fountains and rivulets; it swims on its back, and leaps; it causes tears on the gills of fishes, and destroys the nets of fishermen; it is eaten by the Avecceta; it shines in the night.
   34. Cancer Locusta. With four claws, which want the finger; fourteen feet; the thighs simple. Inhabits Europe. B.—Frisch. Ins. 7. tab. 18. Found very frequently on the seashore; also in fountains and ditches, swimming on its back, and leaping.
   35. Cancer Atomus. Linear; the claws wanting the finger; with eleven feet. Inhabits Europe. B.—Pennant Brit. Zool. 4. pl. 12. f. 32. Found in fresh waters; hardly visible by the naked eye; a slender tail between the last pair of feet, makes the eleventh foot; in the middle two pair of oval vesicles.
   36. Cancer lobatus. Linear; four claws wanting the finger; ten feet. Inhabits Europe. B.—Müller, Zool. Dan. Icones, tab. 56. f. inf. This is the Squilla lobata of Müller's Zoologia
Danica; it is found among the confervae on the sea-shore at Leith; but, perhaps, is not really different from the preceding species."

The two remaining species in the group are "Cancer salinus" and "Cancer stagnalis," not Amphipoda.

1818. Say, Thomas.

Here assigned to Order III. Amphipoda, Latr., is the new genus Lanceola, thus described:—

"Essential Characters.—Antenna four, terminal joints not articulated; antennaeform processes above the mouth; caudal styles, three pairs, peduncle depressed linear, supporting two lanceolate lamellae. Natural Character.—Body soft, external covering membranaceous; head very short, transverse; eyes longitudinal, placed opposite the base of the superior antennæ; clypeus projecting into an acute angle; front concave; antenna four, unequal, inferiores longest, four-jointed, compressed, basal joints very short, third and fourth longer, equal, the latter entire, superiores abbreviated, compressed, triarticulate, basal joints short, robust, concealed by the clypeus, terminal joint not articulated, linear, compressed, obtuse; mouth protuberant; labrum emarginate, supporting two filiform, triarticulate processes, of which the first joint is very short, second linear, third shorter, subulate; labium (pedipalpi) bifid, closing the mouth, laminæ linear, inner edges hirsute, tips rounded; thorax oval convex above and beneath, seven-jointed, sutures imbricate; feet fourteen, simple, two anterior pairs compressed, terminal joints conic compressed, remaining pairs somewhat cylindric, armed with a minute subterminal nail, sixth pair much the longest; vesicular branchiae oblong, distinct, placed at the inner base of the feet, excepting the first and seventh pairs; abdomen abruptly much narrower than the thorax, of three subcylindrical segments, each furnished with natatory feet; tail depressed, three-jointed, joints furnished each with a lateral style, which consists of a foliaceous linear peduncle, supporting two acute lanceolate, subequal lamellae, two anterior styles equal, posterior pair rather shorter, terminal segment attenuated between the posterior styles."

The type species, Lanceola pelagica, Q, is thus described:—"Antenna, inferiores more than half as long as the thorax, superiores attaining the middle of the third joint of the inferiores; antennaeform processes surpassing the second joint of the inferior antennæ; thorax, first segment shortest, acutely angled before near the clypeus, second and third segments longest, equal; feet, anterior pair shortest, third, fourth, and seventh equal, fifth longer, sixth longer than the thorax. Length one inch and one fourth. Inhabits—Gulf Stream. Say further says that "it is allied to the Amphipoda by the vesicular branchiae and by the caudal appendices to the genus Phoronis, more than to any other of this order; in the external appearance of the mouth there is a great similarity to the Linnean Onisell, the labium being nearly the same in form." Spence Bate, "in consequence of the obscurity of Say's description," makes the genus a synonym of the later Vibilia, Milne-Edwards. The species he therefore calls Vibilia pelagica, not as Milne-Edwards had done Hyperia pelagica. Bovallius, 1885, reinstates Lanceola as a distinct genus, assigning to it six new species.
1818. Say, Thomas.

Say here describes the new species Gammarus fasciatus from the rivers, Gammarus minus, found in brooks under stones, Gammarus microrhatus, Gammarus appendiculatus, which has "caudal segments, and three terminal segments of the body, dentated on their posterior edges."

"The remarkable elongation of the inner lamella of the second pair of feet in one sex [?] is a very striking peculiarity of this species." "It is probable," he adds, "that this animal will form a new or subgenus, which would very probably arrange under Gammarus." Spence Eate leaves the name unaltered, but says, "Certainly it does not belong to Gammarus. It appears to be related to Podocerus." It is more suggestive of Macra.

The new genus Lepidactylus is thus described:—"Essential character.—Antennae four-jointed, furnished beneath with plumose ciliate, intermediate ones with an accessory seta placed at tip of the third joint. Clypeus produced between the bases of the intermediate antennae, and acute. Feet, two anterior pairs simple, equal, third and fourth subequal, didactyle, fingers lamelliform; remaining feet spinous, without nails. Natural character.—Body compressed-oval. Head distinct, subquadrate, extended into a short acute rostrum between the intermediate antennae; antennae subequal, four-jointed, inferiora rather longer, incurved, second and third joints dilated beneath, compressed, and ciliated beneath with plumose, elongated hairs, these two joints, when at rest, form a continued oval, the former is delabridiform, terminal seta eight-jointed, ventricilare, superiora prorected, basal joint dilated, depressed, second one much smaller, placed on the inner tip of the preceding, and with that joint furnished with plumose ciliate beneath, third joint much smaller than the second, and furnished at the tip with a tri-articulate accessory seta, parallel with the terminal joint; terminal joint of about eight segments, and not longer than the preceding joints conjunctly; eyes convex, touching the anterior edge of the head; thorax with seven segments, and lateral scales; feet fourteen, two anterior pairs in each sex simple, filiform, equal, third and fourth pairs equal, didactyle, hands compressed, not dilated, finger rounded, thumb oval, lamelliform, remaining feet gradually larger, compressed, armed with short spines, and destitute of a nail; hind pair largest, antepenultimate joint lengthened above, and nearly attaining the tip of the following joint, which is crenate and spinous on the edge, terminal joint compressed, serrated, and spinous on the edges, and truncate at tip; anterior pairs of feet furnished at their inner bases, with oblong oval movable lamelle. Abdomen of three segments, abruptly narrower than the thorax, each furnished beneath with natatory feet, consisting of short, rounded peduncles, supporting double setae, of which the outer ones are longest, third segment abruptly inflected at tip; tail inflected, armed with bifid styles."

The species Lepidactylus dytiscus has "Eyes orbicular; body when recent, white, with an abbreviated internal ferrugineous vitta, including the alimentary canal; accessory seta of the intermediate antenna, attaining the tip of the fourth segment of the terminal joint; anterior pairs of feet hairy. Length, male one-quarter, female three-twentieths of an inch." In shallow pools left by the receding tide "its presence may be ascertained by the numerous and irregular tunnels which it forms in the sand, like miniature representations of those of the mole, only less rectilinear." It is the same as Oniscus arenarius, Slipher. See notes on Slipher and P. L. S. Müller.

To the genus Ampithoe, Leach, Say assigns the new species Ampithoe serrata and Ampithoe punctata from Egg-harbour, and Ampithoe dentata, "a very common inhabitant of the fresh water marshes of South Carolina." Ampithoe serrata is thus described:—"Antennae equal, short, stout; eyes large, approximated, suboval; eighth, ninth, and tenth segments
of the body serrate."

"Cyphus acute; antennæ nearly equal, short, stout, attaining the base of the sixth segment of the body; eyes large, black, oval, placed at the outer base of the superior antennæ, and approximated above; hands with about three equidistant, prominent, spineæ teeth on the inferior edge or palm, the nail or thumb curved, acute, and attaining the third tooth; eighth, ninth, and tenth segments of the body serrated, the last more conspicuously so. Length, two-fifths of an inch. Remarkable by its large eyes, short, stout antenna, and serrated appearance of the hind part of the back, occasioned by the elevation of the tip of each of those segments above the base of the succeeding one."

Spence Bate renames it *Arcaanatomus Sayi.* Say's *Talitrus longicornis* is transferred by Milne-Edwards to *Orchestia,* as his *Talitrus grillus,* Latr. from Dose, is by Spence Bate. He thus describes his new species, *Podocerus cylindricus,* which S. I. Smith, 1874, withdraws from the synonymy assigned to it in the Brit. Mus. Catal., p. 256, renaming it *Corophium cylindricum:* "Hands of the second pair somewhat cylindrical; eyes small, not prominent. *Inhabits Egg Harbour.*" "Eyes small; front acute; superior antennæ attaining the tip of the third joint of the inferiores, inferior antennæ much thickened, hairy, the terminal joint shorter than the preceding one; hand of the second pair not longer than the carpus, palm longitudinal, rectilinear, thumb much shorter than the hand; third, fourth, and fifth pairs of feet short, much compressed, nail as long as the preceding joint, which is suboval and narrower than the one before it; sixth and seventh pairs reflected, and of the usual cylindrical, elongated form. Length less than three-twentieths of an inch."

The new genus *Unciola* is described as follows:—"*Essential Character.—Antennæ subpediform,* superiores with an articulated seta at the base of the fourth joint; anterior feet monodactyle; second pair with adactyle compressed hands; coxae not dilated. *Natural Character.—Head* deeply emarginate beneath the eyes to receive a segment of the base of the lower antennæ (ear?), and projecting into an acute angle between the bases of the upper antennæ; eyes hardly prominent, placed on a somewhat advanced portion of the head, between the bases of the upper and lower antennæ; antennæ robust, terminal joint of the superiores rather longer than the preceding one, furnished at base with an articulated seta, inferiores rather shorter, thicker, terminal joint shorter than the preceding one; *Thorax* composed of seven segments, each furnished with feet, of which the first pair are longest, hand dilated, monodactyle, second pair with a dilated, compressed, subequal carpus and hand, the latter simple, with two minute hooks at tip, posterior pair longest; coxae simple or not remarkably dilated; *Abdomen* of three segments; *Natatory feet* with the filaments subequal; *tail* of three segments, the first and second bearing each a pair of bifid styles, terminal one suborbicular; with a pair of simple, depressed styles, concealed by the others."

The type species *Unciola irrorata* is thus described:—"*Eyes hemispherical; hands of the anterior feet with a longitudinal palm, and prominent tooth, those of the second pair compressed, ciliated. Inhabits Egg Harbour.*" "Accessory seta of the superior antennæ, attaining the fifth articulation of the terminal joint; eyes conspicuous, rounded; palm of the anterior feet a little convex in the middle, a large obtuse tooth at base; nail attaining the carpus, which terminates so as to appear like a second tooth of the hand; second pair of feet ciliated, with a subtriangular hand, segments of the abdomen uncinate each side behind; colour when recent, pale with very numerous red points. Length, three-teeths of an inch." Say remarks that it approaches *Gammarus* by the accessory seta to the superior antennæ, *Thersus* by the form of the second pair of feet, but by various points and general habit "it seems to arrange naturally with *Podocerus,* Jassa, Cerapus, Atylus, etc."

The species next described, *Caprella geometrica,* is identified by Mayer with *Caprella acutifrons,* Latreille; *Caprella equilibra* is still accepted, with the improved spelling, as *Caprella equilibra.*

In describing the genus *Cyamus,* Latreille, Say mentions "eyes two; stemmata two," apparently borrowing an error from previous writers, instead of observing his own specimens. On
REPORT ON THE AMPHIPODA.

these, which were "less than one-tenth of an inch," he founds the species Cyamus abbreviatus, from a Balea, species unknown. This Cyamus Lütken considers scarcely recognizable. Spence Bate says of the specimens in the British Museum "they appear to me to be only the young of Cyamus ovalis."

Milne-Edwards, 1840, takes it for granted that Say's Gammarus minus is merely a slip of the pen for Gammarus minimum, and inclines to identify the species with Gammarus fasciatus, which in its turn he considers very near to the French "crevette des ruisseaux." Gammarus macronotus is transferred by Sp. Bate to Gammaracanthus, but S. I. Smith, 1874, objects to this, "for the dorsal margin is not distinctly carinated, and the third, fourth, and fifth segments of the abdomen are furnished with fascicles of spines;" he therefore restores the species to Gammarus.

1818. Chiereghini, Stefano, born 1745, died 1820 (Nardo).

Descrizione de' crustacei; de' testacei e de' pesci che abitano le lagune ed il golfo Veneto rappresentati in figura a chiaro-scuro ed a colori. Manoscritto in foglio in vol. 12, esistente presso il R. Liceo di Venezia (Santa Catterina, ora Marco Polo).

G. O. Nardo assigns to this work, though still in manuscript, a quasi publication in 1818, about which date it was acquired by the imperial government and consigned to the public library in Venice, where it has been, and still is, consulted by naturalists. The first two volumes, Nardo says, treat of Crustacea, one containing the descriptions, the other the figures. The species there described and figured by Chiereghini are sixty-four, thirty-three of which bear the Linnean names, while thirty-one he considered to be new. After certain necessary deductions from this number, Nardo allows Chiereghini the credit of having described and figured twenty-four species, either new, or till then obscure. Among these are two Amphipods, called respectively "Cancer Scolopaidus" and "Cancer Alguesia," for which see note on Nardo, 1847.

1818. Lamarck.

The Crustacea are the eighth class. The Isopods, the second section, contain, among the Isopods, corresponding to the Phylilibranches of Latreille, Risso's Typhis ovatus, which is an Amphipod, along with Ancus, Pranida, Aupascles, and Ione. Risso's Euphasia longipes becomes Aupascles longipes. The "2e. Classe" of the Isopods contains les Caprellines, answering to the cystilibranches of Latreille. In this group Proto is dropped from the synonymy of Leptomera. The species are Leptomera rubra and Leptomera polata, both synonyms of Proto (Spallia) ventricosa, O. F. M.; Caprelia scolopendriae, which Boeck and Kroyer identify with Caprelia (lobata) linearia, but which Mayer thinks indecipherable; Caprelia phasai, now known as Procella phasai, Montagu; and Cyamus ceti, which Lamarck says has fewer relations with "Pycnogonon" than was generally supposed. He notes a second very small, still undescribed species, from the East Indies, as known to

(ROOL. CHALL. Exp.—Part LXVII.—1887.)

XXX 14
1818. Latreille, P. A.

The Amphipods, of which figures from various sources are given in this volume, are thus named in the "Explication des Planches":—Planche 327. 3. Athlus carinatus, Leach. "Planche 328. 1 and 2. anonymus sagax, Fabricius. 3. Appendice de sa queue. 4 et 5. Gammarus sagax, Fabricius. 6. Gammarus cancellus, Fabricius. 7 et 8. Gammarus (corrophorum, Latreille) longicorne, Fabricius. 9. Talitrus locusta, Leach. 10. Talitrus gammarides, Latreille. 11 et 12. Gammarus pulcher, Fabricius. 13—grossi. 14. Ses oufs, de grandeur naturelle. 15—grossis. 16. Item, lorsqu'ils sont plus avancés et que le foetus commence à s'y montrer. 17 et 18. Phronima . . . . , Latreille. 19. Appendices de sa queue, très-grossis. 20. Gammarus (caprella, Lamarck) linearis, Fabricius." In this list 1. 2. 3. belong to Stenocephalus ampulla, 4. 5. to Anomia sagax, 6 to Pallareus cancellus, 7. 8. to Corophium volutator, 9 to Talitrus locusta, 10 to Orchestia gammarides, 11. 12. 13 to Rosell's Gammarus fluvatilis, 17. 18. 19 to what Latreille afterwards named Hypérie de Leseur, 20 to Caprella, sp?

Planche 329 has "14 et 15. Gymnus ceti, Latreille. 16. La femelle, en dessous." Planche 330 has "3. Oniscus arenarius, Slabber; nouveau genre, voisin de celui que j'ai nommé Ione. (Cuvier, Règne animal, tom. iii. p. 54). 4—très-grossi." This is Slabber's figure, of which Latreille subsequently complains that it only exhibits eight legs. Nevertheless, the figure is sufficiently characteristic.

1818. O'Reilly, Bernard.

Greenland, the adjacent seas and the north-west passage to the Pacific Ocean illustrated in a voyage to Davis's Strait, during the summer of 1817. London, 1818.

In the "Journal in Davis's Strait" it mentions for June 2, "a male whale killed this morning measured seventy feet." "groups of the oniscus ceti, whale-louse, attached to the epi-
dermis of this whale, particularly about the fins and anna," p. 166. For July 18 it says, "The monodon appeared in great number this day, and the Thomas's men succeeded in killing one male and two females; the latter were destitute of the tooth: they are always taken without that instrument, which is solely conferred on the male either for ornament or annoyance: . . ., a female whale (balaena mysticetos) killed this day, measured sixty feet; it received the harpoon but once, and dived away under the ice, drawing down three boats' lines, being 1080 fathoms, and died at the bottom: immense groups of the oniscus ceti attached to the under lip and to the under part of the fin: the edge of the fleshy covering embracing the root of the monodon's tooth was covered with insects of the same description."

1818. Leach, W. E.

The Crustacea are said to form two great groups or subclasses, of which the first comprises the Malaconotae, which has a pair of mandibles, and two pairs of maxille, furnished with palp, and eight pairs of feet provided with branchie at their bases. All the genera devoid of these characters belong to the second group, the Entomostraca. Leach then briefly reviews the various classifications of Crustacea, including those by himself, that had been proposed up to the date of this article. He gives a list of authors who have written on Crustacea, and deferring the details about genera and species to the articles on the several families, he winds up with an alphabetical list of the crustacean genera recognized at that date, including for the Amphipoda, Acrepe, Ampithoe, Atyle, Caprelle, Cerapoda, Corophie, Crevette, Deramine, Jassa, Larande, Lencalhov, Melilée, Orchestée, Phenee, Phiroigne, Podocére, Pro, Talitre, Typhée, mixed up in alphabetical order with the rest. That Acrepe belongs to the Amphipoda, my only authority is Desmarest.

1818. Leach, W. E.

Leach refers to this volume for his species, Jassa pulchella and Jassa petalica, but since the references occur in the Appendix to his Article, Crustaceology, in the Edinburgh Encyclopaedia, which cannot well be of later date than 1814, and these memoirs seemingly were not published till 1818, he probably refers to some paper intended for this volume, but withdrawn before publication.

1819. Leach, W. E.

Zoological Memoranda. Descriptions of the New Species of Animals, discovered by His Majesty's Ship Isabella, in a Voyage to the Arctic Regions. By Dr. W. E. Leach. A Voyage of Discovery, made under the Orders of the Admiralty, in His Majesty's Ships Isabella and Alexander, for the purpose of exploring Baffin's

Under “Type Annulosa,” “Class Crustacea,” is given “Genus, GAMMARUS, Latreille. Species 1. Sabini, segmentis dorsalibus postice falcato-productis. Baffin’s Bay, Captain Sabine.” This is the Amphipod, so often described both before and after this date, called Anamithilla sabini by Tate and Westwood, and in this Report identified with Gammarus homari, Fabricius.

1819. Samouelle, George.

The Entomologist’s Useful Compendium; or an introduction to the knowledge of British Insects, comprising the best means of obtaining and preserving them, and a description of the apparatus generally used; together with the genera of Linné, and The Modern Method of arranging the Classes Crustacea, Myriapoda, Spiders, Mites and Insects, from their Affinities and Structure, according to the views of Dr. Leach. Also an explanation of the terms used in entomology; a calendar of the times of appearance and usual situations of near 3000 species of British insects; with instructions for collecting and fitting up objects for the Microscope. London, 1819.

The preface explains that “The Modern System is nearly the same as that given in the Supplement to the Encyclopædia Britannica, article Crustaceology, and Dr. Brewster’s Edinburgh Encyclopædia, article Entomology, with the exception of the foreign Genera and the alteration of Tribes to Families, terminating in Æda.” Notwithstanding this notice, the three Families belonging to the Amphipoda are given, pp. 101–106, as “Fam. I. Phœnixmæde. Leach’s MSS.” “Fam. II. Gammaride. Leach’s MSS.” “Fam. III. Caprelladæ. Leach.” All the information is derived from the papers by Leach. The articles referred to in the Preface are probably the Crustaceology of the Edinburgh Encyclopædia and the Annulosa of the Supplement to the Encyclopædia Britannica.

1819. Samouelle, George.

A nomenclature of British Entomology, or a Catalogue of above 4000 species of the classes Crustacea, Myriapoda, Spiders, Mites and Insects, alphabetically arranged, and intended as labels for cabinets of British insects, etc. From the Entomologist’s Useful Compendium. London, 1819.

This work is merely the index of the preceding, adapted for the purpose mentioned in the title.

1819. Tilesius, W. G.

Tilesius says that the sea-water is illuminated not only by the Mollusca contained in it, but also by the marine insects or microscopically luminous shrimps (Krebsehen). Of these he
figures and describes several, with a warning that the figures indicating the natural size are in reality somewhat exaggerated. The following portion of his account is worth quoting here:

"Fig. 4. Amblyrrhyncotus glaucus. Der bläne Stumpfrüssel, einer von der grössern Art, bisweilen von der Grösse eines Hirsenkornes. Der ganze Raum zwischen dem Banche und Schwanze war mit blauen Eiern angefüllt, welche in einer Haut verschlossen zu liegen schienen.

"Fig. 5. Erythrocephalus melanophthalinus. Der Rothkopf mit den grossen schwarzen Augen, gehört zu denjenigen Astacoiden, welche keinen soliden Thorax oder kein besonderes Bruststück, sondern viele fast gleichgrosse Glieder längst dem ganzen Körper haben, wie die Arthrocophali oder Gliederköpfe Dumenils [Duméril], und wie der Cancer sedentarius Forskæli. Der ansrige aber steht mit jenem der Grösse nach in keinem Verhältnisse. Pallas hatte diese vielgliedrigen kleinen Krebse als die Squilla und Gammarus des Fabricius, Thalitras und Mysis des Latrille schon alle unter das Geschlecht der Scolopendern gebraucht.

"Fig. 6. Der blinde Rothkopf, Erythrocephalus exculus, er hat zwei grosse dreigliedrige Klauen am Kopfe und statt der Augen zwei kleine kaum merkliche Sternchen.

"Fig. 7. Der füslose Süsswasser, Prionorrhyncotus Apus."

"Fig. 8. Der Spriitzenkrebs mit dem Stachelkopfe, Acanthocophalus syringodes."

"Fig. 9. Der bläne Fadenkrebs, Phasmatoeracarina glaucus, ebenfalls ein sehr dünner und langer, aber vielgliedreter und vielfüssiger Krebs, welcher den Latres'schen Fadenkrebs (Cancer linearis L.), oder Gaspenterkrebsen (Gammarus pedatus O. Müller, Squilla quadriloba und ventricosa [Zool. Den. Tab. LVI. u. CXIV.] und den Caprelles oder Chevrollen des Lamark am nächsten steht, so wie auch der folgende Fig. 10, nämlich der langhalste gehörnte Gaspenterkrebs oder das Scheibenauge, Fig. 10.

"Fig. 10. Phasmatoeracarina discophtalmus. Sic haben zwar alle Stielenaugen (podophthalmi); aber dieser trägt anstatt des Augen-bulbus, eine breite platte Scheibe auf dem langen Augenstück, (aus der Südssee, bei den Marquezasinseln)."

Fig. 4 represents rather a Nebalia-like form than an Amphipod.

Fig. 5 belongs no doubt to the Hyperina. Templeton thought that it might be the same as his
Thananea deckii, which Spence Bate considers to be a Vibilia. But while Thananea appears to have the characteristic antennae of a Vibilia, this Erythrocephalus is certainly without them, so that Templeton's guess must be wide of the mark. In the figure here copied from TILESius we may probably recognize the first two pairs of pereopods, one limb of the third pair, and one of the fourth. If this be correct, it may be inferred that the gnathopods and fifth pereopods were either wanting in the specimen examined or, from their position and insignificant size, escaped the attention of the draughtsman. In addition to the appendages above mentioned, I interpret the figure as showing a vertical head produced below the pereon, a pereon of six segments, without side-plates, and a pleon of six segments and a telson, with pleopods attached to the first three segments and uropods confusedly in attachment with the fifth and sixth segments and the telson. It will be observed that the third pereopods, as in Pronoe capito, Guérin, and many other Hyperidea, greatly exceed in size the other pairs. In saying that Pallas referred such animals to the genus Scolopendra, TILESius has fallen into error, and should have said Oniscus.

Fig. 6 evidently belongs to the Hyperidea and probably to the Hyperidea. The front pereopods not unfrequently lie across the sides of the head and protruding beyond it. They have apparently here been mistaken for antennae. The species intended remains for the present uncertain. It can scarcely belong to the same genus as the preceding species, and the want of well-developed eyes, to which the specific name refers, must itself be regarded as very doubtful.

Figs. 7 and 8 appear remote from the Amphipoda. Figs. 9 and 10, with the large stalked eyes, to which TILESius himself refers, have no connection with the Caprellina, though they show a general resemblance. Amphyracanthus and Phasmatocheirus, occasionally referred to as if among the Amphipoda, have evidently no right to be so placed.

1820. Rafinesque-Schmaltz, C. S.

For the title page and other extracts from this rare little book I am indebted to my friend and former pupil, William Bradford, Esq., Counsellor at Law, New York. In the course of his plaintive preface Rafinesque remarks, "I shall not be prevented from publishing my new species because it may happen that one out of fifty may be previously noticed in some costly and inaccessible work."

On p. 2 he gives "Animals. I Class. Mammata—the Sucklers;" on p. 4 "II Class. Ornithia—the Birds;" "III Class. Reptilia—the Reptiles;" on p. 6 "IV Class. Ichthyesia—the Fishes;" "V Class. Plazomia—the Crustacea." In this Class he enters:

"III. N. G. Specioscit: Antenna double than the head, four nearly equal, with two long truncate articles, the upper pair rather broader and longer. Body compressed, with seven segments, each with a large lateral appendage or scale. The fourth larger and with an additional posterior appendage, the corresponding feet larger and with a large rounded and
thick hand, all the feet with only one claw. Rump with four large segments, without lateral appendages, but with the usual ones beneath. Tail with short and recurved appendages.—It belongs to the family *Ganymaria*, the name was that of an ancient fluvialile God of Thessaly.

"39. *Sperchius Luculus*. Shining brown, eyes black, nearly round; appendages of the tail shorter than the last article, curved outwards, with two articles and a terminal filament. Discovered in the springs and brooks near Lexington, Ky. Length about one-third of an inch, almost black when in the water, olivaceous brown when out of it, and pale when dry. Body arcued, antenna descending. It swims well.

"iv. N. G. *Lepleurus*. Four antenna shorter than the head, nearly equal, truncate, with a single segment. Body rather compressed and straight, with twelve segments, all with a large lateral scale except the three anterior and the last, posterior segments and scales longer. First par of feet with a large oblong cheliform and euspidate band; the second and third pair cylindrical pinciferous or with two cylindrical and truncate fingers, the four other pairs slender; all the feet without real claws. Appendages beneath the rump almost similar to the hind feet; those of the tail short and with single segments.—Another fresh-water genus of shrimps, of the family *Ganymaria*. The name means lateral scales.

"40. *Lepleurus Rivularis*. Olivaceous, eyes very faint irregular; appendage of the tail truncate straight oblique; antenna nearly horizontal, feet longer than the breadth of the body.—I have detected it in the brooks of the mountains of Pennsylvania and at Shannon run, near Bedford Springs. Length about half an inch; it crawls on the stones rather than swims or jumps."

He then describes the new genus *Lirceus* in the family *Oniscia*. His remaining Classes are, Entomia, the Insects; Holmiuthia, the Worms; Apalosia, the Mollusca; Polypia, the Polyps; Porostomia, the Porostomes.

Desmarest objects to the name *Sperchius* as too near to the *Sperchius* of Fabricius, among the Coleoptera. Neither *Sperchius nor Lepleurus* has yet been identified. In the descriptions of both there are perplexing obscurities. The short antenna of *Lepleurus* are suggestive of *Hyalella*, but the identification must be left to naturalists in Kentucky.

1820. SCHLOTHEIM, ERNST FRIEDRICH, Baron von, born 1765, died 1832.

Die Petrefactenkunde auf ihrem jetzigen Standpunkte durch die Beschreibung seiner Sammlung versteinerter und fossiler Überreste des Thier- und Pflanzenreichs der Vorwelt erläutert. Gotha, 1820.

At page 41 he gives "5. Trilobite problems. Aus Höhlenkalkstein von Glückbrunn, der Gebirgsart aufstiegen.

An account of the Arctic regions, with a history and description of the northern Whale-fishery. In two volumes. Edinburgh, 1820.

At page 541 he gives in the Class Articulata, "Gammarus arcticus (Leach).—The characters of this animal (Pl. XVI. Fig. 14), I have been favoured with from Dr. Leach. They are as follows:—"G. ocellis sublunatis; pedum pari tertio, secundo majori." The actions of this species suggest as a familiar name, the montebank shrimp. It frequently turns over when in the water, with singular celerity, and swims with equal ease in every position. The four feet raised in the figure above the back are made use of in that position, whenever its back comes in contact with any solid substance. This species occurs in all parts of the Spitzbergen Sea, and at the greatest distance from land; it inhabits the superficial water, and affords food for whales and birds.

"Gammarus—!—Another small species of this family, was found in large quantities in the stomach and mouth of some mysticete. It is remarkable for the largeness of its eyes."

He also mentions "Cancer Pulsus (Linné)," "Cancer Ampulla (Phipps)," from the stomach of a shark, "Cancer Nucifer (Phipps)," and "Oniscus Ceti. (Lin.), Larunda Ceti (Leach), Whale's house.—This little animal, about half an inch in diameter, firmly fixes itself by its hooked claws, on the skin of the mysticete. It is found principally under the fin, or in other situations where the skin is tender, and where it is not liable to be dislodged. A similar animal, but smaller, is sometimes found on the body of the narwhal."

Boeck judges that Gammarus arcticus is identical with Gammarus locusta. The tolerably useless figure shows some seventeen or eighteen segments besides the head. The large-eyed Gammarus is probably one of the Hyperina.

1821. d'Orbigny, Charles, born 1806.

He gives an accurate description of Corophium longicorne, which is Cancer grossipes, Linné; he enters into details as to its mouth-organs, omitting to notice the under-lip. In regard to its mode of life he states that about winter-time it leaves the strand and goes out into the deep water, returning in the spring and occupying during the summer its holes in muddy shores. The structure of its body is evidently adapted for this mode of life (Boeck).

In the British sessile-eyed Crustacea, vol. i. p. 495, it is not considered certain whether the small tubular galleries in which this Corophium spends the summer "are perforated by these Crustacea or by the numerous Annelids that it preys upon." No one, however, who has examined these creatures in their own home could have the smallest doubt that the galleries are perforated by the Crustacea themselves. A stretch of mud may sometimes be seen speckled all over with asterisks, formed by these creatures turning round in their tubes with their antennae projecting on the surface and marking the mud much as a cook marks pastry with the prongs of a fork. That they prey on Annelids is a very doubtful opinion. An Annelid and a Corophium, which I kept for some time alive together in a bottle, made no attempts to injure one another.

After mentioning the *Cancer magaz* and *Cancer ampulla* of Phipps respectively as *Gammarus magaz* and *Gammarus ampulla*, Sabine proceeds to describe *Gammarus boreas*, with a reference to "Squilla Pulex. Deg. Ins. v. 7, p. 525., t. 33., f. 1. and 2." "Individuals, vary in size from half an inch to an inch and half." The fourth, fifth, and sixth segments of the tail, he says, are "slightly tricarinate on the back, and spinous." In general his account of it agrees well with *Gammarus locusta*, with which it is united by Boeck. The remarks with which Sabine winds up his account are of some interest. "The Squilla Pulex," he says, "figured by Degoe, l. c., differing in no respect from the above description, is considered to have been an individual of the same species, and it is therefore believed to be common to the northern shores of Europe and America; the Squilla Pulex has been considered a synonym of the Gammarus Pulex of modern authors, but erroneously, as may be seen by comparing the figure in Degoe with that of the Gammarus Pulex, Herbst., vol. ii., 130, tab. 36, fig. 4 and 5, which is the Gammarus Pulex of J. C. Fabricius, Ent. Spel., and of Latreille, Encycl. Mél. pl. 328, figs. 11-15; the species are very distinct, differing in the lateral lobes, in the mucronate production of the caudal segments, in the absence of the carinate and spinous on the three posterior segments of the latter, and in the shape of the eyes; the Gammarus Pulex of Montagu, Linn. Tr. ix. t. 4. f. 2. is a third species, differing not merely in appearance, but in its habits, being found only in fresh water. The Oniscus Pulex of Othö Fabricius, Fæna. Genr., No. 231, differs from the present species in the relative proportions of the three posterior pairs of legs, the last pair being described by Fabricius as less than the two preceding, whereas in the Boreas the seventh are longer than the fifth and sixth pairs. The Oniscus Cancellus of Pallus, Spiecl. Zool. ix. p. 53, tab. 3, f. 18, is distinguished by the lateral scales on the segments of the body, but in other respects is not very dissimilar to the animal under description; it may not be amiss to notice incidentally that an error has crept into the specific character of the Cancellus in the writings of modern authors, commencing it is believed with J. C. Fabricius, of describing it with sixteen legs, instead of fourteen, which is the usual number in the genus; in the original account of the Cancellus, Spiecl. Zool. l. c., the number of legs is fourteen, both in the description and figure." The figures cited from Herbst and Latreille are in fact copies of Rösel's *Squilla fluvatilis*, with which Sabine seems to have been unacquainted. The description of Amphipoda with sixteen legs, occasionally met with in the old writers, may have arisen from the confusion among the maxillipeds. The Savigny, it will be remembered, regarded sixteen as the normal number of legs both for the Decapoda and the Tetradecapoda, the difference between those two groups being that in the former three pairs, and in the latter only one pair, of the legs were transferred to the service of the mouth.

The species next described has since been made by Spence Bate the type of the genus *Gammarocarthus*. Sabine's account is as follows:—"Gammarus Loricatus. G. Rostro corniformi dentato, dorso carinato, segmentis posticis acutæ productæ. Plate 1, fig. 15. This species was found associated with the preceding, and of the same size, but less abundant; body laterally compressed, especially the posterior segments; shell smooth,
and much harder than in its congeners, resembling a coat of mail, whence the specific name; back carinate, the segments increasing in length from the first to the tenth, from whence they decrease; and beginning with the third or fourth, are produced in sharp and strong points directed backward: lateral lobes oblong, enlarging from the first to the fourth segment, and decreasing to the seventh; those of the three first caudal segments are larger than those of the body, and are acuminate; head produced into a strong, arched, carinate, and sharp-pointed rostrum, curving down between the antennae; eyes large, black, lateral, prominent and reniform; beneath the eyes is a small lateral lobe; antennae four-articulate, the upper pair having a small seta at the base of the fourth articulation; legs fourteen, two first pair with a large compressed monodactylus hand, those of the anterior pair being smaller than the others; third and fourth pairs of the same length as the preceding, slender, terminating in a nail; the three posterior pair directed backward, similar in formation, but differing in size, the middle and longest pair being as long as the body, and the seventh pair shorter than the fifth, all terminating in a nail; colour in some individuals pale, in others varied red and white." He points out that it differs from *Oniscus aculeatus* of O. Fabricius, from *Gammarus carinatus* of J. C. Fabricius, and from *Gammarellus pulex* of Herbst. *Atylus carinatus* is mentioned as the name given by Leach to the species *Gammarus carinatus*.

Sabine next gives "*Gammarus Sabini* Leach in Ross's Voyage, Ed. 8vo., Vol. 2, page 178.

G. segmentis dorsalis plusio falcato productis, capite inter antennas acumen minuto. Plate I, fig. 8–11. On the shores of Baffin's Bay, but not met with in the Polar Sea: the head of this species which terminates in a point between the antennae, instead of being produced in a rostrum, readily distinguishes it from the preceding species, and has been added to the specific character assigned by Dr. Leach, in whose arrangement it was unnecessary, the formation of the head making part of the character of the genus."

The next species, "*Talitrus Edvardisi*, T. Rostro corniforuni, antennis subequalibus, corporis ovado depresso, caudal compressa tricarinata spinosa. Plate II, fig. 1–4.," though here described as new, is the *Oniscus aculeatus* of Lepechini, now *Rhachotreps aculeatus*. The remarks which follow the description bear upon classification. "In conformity," the author says, "with the arrangement which is followed in the present account, this species has been considered a Talitrus, as the inferior antennae are somewhat longer than the superior; this character is, however, by no means remarkable either in this species, or in some others, which are distributed by it into the respective genera of Talitrus and Gammarus; if a subdivision be desirable in the well-defined and natural genera comprehending all these animals which so nearly resemble each other in general appearance and habits, the prolongation of the anterior part of the head into a rostrum, would seem preferable to a distinction founded on the relative length of the antennae, which in many of the species are so nearly the same; or, the genus Talitrus might be limited to those species in which the superior antennae are very short, not exceeding the length of the two first articulations of the inferior pair." He adds that "this species has been named in compliment to John Edwards, Esq., surgeon of the Hecla."

The remaining species "*Talitrus Cyanæ*, T. capite obtusissimo, antennis subequalibus, corporis laticorni, pedibus quatuor anticus inquinulanatis. Plate I, fig. 12–18," was taken "parasite on the Cyanæ Arcticæ, the individuals varying in length from two to eight-tenths of an inch: colour pale yellowish red, sprinkled with innumerable minute spots of deeper red; in about half the specimens, the number of which was considerable, the antennae were equal in length to the five first segments of the body; in the others they were scarcely one-fifth as long, but otherwise similar; there was no other perceptible difference in the specimens. The eyes are "extremely large, innate, of a brownish red colour." In the further course of the description he mentions "legs fourteen, the four anterior equal and
similar, five-jointed, being a long compressed thigh with four much shorter articulations, hirsute, and unarmed; the ten posterior legs similar and equal in size, five-jointed, the thigh being long and much compressed, followed by three short fleshy joints, (the first of which is the shortest,) and by a long and curved member, terminated by a nail.” He concludes by observing, “this description differs from that of the Causeur Medusorum, Otho Fabricius, Form. Groen., No. 332, in the number of joints of the legs, and in the four anterior being unarmed; the conformation of these legs distinguishes it also from the Gammarus Medusorum of J. C. Fabricius, of which a part of the specific character is ‘mauribus quatuor monodactylis.’” It is with the latter species nevertheless that Boeck identifies it, under the name *Hypeteria medusorum*, O. F. Müller, Milne-Edwards, Hist. des Crust. iii. p. 78, under the genus *Melobes*, after describing *Melobes medusorum*, Kröyer, says of it, “Le Talitrus cyanus de Sabine, que nous avions d’abord considéré comme une Hypérie, semble se rapprocher davantage des Métoques, mais devra peut-être former un genre particulier, car d’après l’auteur qui l’a fait connaître, cette Hypérie aurait les pates des deux premières paires obtuses et adactyles; mais la division en pinces a peut-être échappé à son attention. Du reste, cette espèce se distingue de la précédente, et des Hypéries mentionnées ci-dessus, par la longueur beaucoup plus considérables de ses antennes, dont le filet terminal est grêle et multi-articulé.” Spence Bate, in the Brit. Mus. Catalogue, p. 294, retains the species as *Hypeteria cyanus*.

1822. Mandt, Martin Wilhelm, born 1799, died 1858 (G. O. Sars).

In 1821 Mandt went in the “Blücher,” Captain John Rose, past Spitzbergen to the 81° of north latitude. He here makes record of his acquisitions, material and scientific, in those regions. In describing “Falena Mysticetus,” he says, page 10, “Partibus tenerioribus cutis, axillis, pudenlis Oniscus certi adhaeret, pressetim si tempus instat editionis,” and “Vulva praeципae hoc tempore ipsis obsessa apparat.” The *Oniscus certi* here mentioned is the *Cynus mysticeti* of Lütken.

On pp. 31-37 he describes two Amphipods, of which the first has since been referred to Guérin’s *Themisto*, and is the earliest described species of that genus, while the second has become the type of Lilljeborg’s genus *Eurytene*. The original account as drawn up by Lichtenstein is here subjoined.

“E crustaceorum ordine duas ex itinere reutili species, Oniscis marinis Lin: aut Gammais Fabricii ascensandas nec ab ullo auctore lucusque descriptas. Quae cum museo locupletissimo hujus Universitatis a me obtata essent, a vizo celeberrimo hujus Musei directore Lichtenstein accuratissimae examinatae, dignas visse sunt quorum descriptio amplior huic dissertationi inseratur. Quaem vir docetissimus benevolae assiduum communicavit lectoribus naturalistis hic offero.

1. *Gammarus Lilljebula* N.

2. *G. capite magno globoso, corpore segmentis undecim, polibus quatuordecim, octo anticus brevibus, uniusitis, raptatoris, sex posticus elongatis, saltatoris.*

3. *Longitudo tota aequat pollicem et dimidium.*

Antennis breves, scrobiculis profundis frontalis implantatæ, superæ breviores, (sesquilineares) articulo basali et seta apicali subtriquetra, confluent, infera paulo longiores, bilineares, triarticulata.

Mandibulae exiguae, inaequalis, argute dentata. Palpi mandibularum lateri externo inserti, quadriarticulati, in fossam inter antenas inferiores reclinandi. Segmenta corporis primum, secundum, tertium quaternumque, angusta (Notetur terminus angustum et latum hic a dimensione simili segmenti, minime autem a latitudine corporis esse intelligendus.), sensim latiora utrinque in appendicem foliaceam articulatum producta, subutas pedes gerentia breves rampatorios, fo—inde [periinde] e primo pari sensim maioris, femoris complanatis, manibus incrementatis subus spinescentibus, pro recipiendo unguiculo valido, elongato. Segmenta quintum, sextum et septimum paulo latiora, lateribus vix appendiculatis, marginem externum cum pedibus articulo iuncta elongatis, saltatoris, postice complicandis, corpore incurvato pedes octo anticos inter se occultantibus. Horum femora complanata, marginis postico foliaceo pra tegenda tibia reclinanda, tibiae geniculo basali brevi, elongate, compressa, antice spinescentes, postice glaberrimae; tarsi graciles, subcylindrici, rigidi, marginis antico spinescente tibias applicandis, apice unguiculo minuto acutissimo instructis.

Pedum par quintum omnium longissimum ferre pollicere, tibias quatuor et dimidiam lineas longis, sextum, septimum sensim breviora, postremo octo lineas longo.

Segmenta octavum, nonum et decimum, radialis omnium latissima fere cylindrica subutus appendicibus ovigeris natatoris, in singulo binius bifidis, articulo basali valido, conico, subutas uniuslatos, lacinia terminali duplici, acuminata, subtriquetra, ciliata.

Segmenta undecimum duodecimanque, fessibus caudalius efferentantibus, appendicibus utrinque tribus bifidis conflatum, quorum articuli basales elongati, compressi; laciniae terminales, in singulo binae inaequalis, altera longiore foliacea, altera brevior accessoria teretissula.

Color flavescence lividus.

Affinis hae species 1) Oisisco Cicade Orth. Fabricii a quo tamen differt capitis pedumque forma, colore et magnitudine;

2) Oisisco Medusarum O. Fabricii, cuius tamen oculi lineares, arcuati, coerulei, lateribus frontis inнати, nimirum discrepant. Cum hac utraque Gammarus Libellulae peculiare genus constitut, in familiæ hujus descriptione monographica arctic definiiium.

Unicum hujus animalici specimen die vice[s]ino nono mensis Junii anni praeterlapsi accipit vivum et mari prope insulam Ian Meyen protractum, plura autem mensae insufficient mortua in stomat[o] Procellariae glacialis reperi, integra quidem et digestione viv basa, nisi quod pedum subtilissima pubeves detritus esse.

Inter hae juvenilia queque, diminutæ reliquorum magnitudinis, ceterum similius illis.

II. Gaumarus Gryllus N.

G. Corporae segmentis tredecim, pedibus quatuordecim, quorum par secundum longissimum, debile multiarticulatum, scutis lateralibus maximis pedes obtectibus.

Longitudine tres pollicis aequat (corporis duos et quadrante[n], caudæ incurvata tres quadrantes poll.), circumferentia media duos pollices quadransaquem.

Corpus compressum, dorso fornicateo, rectinuclium, cauda brevi incurvata.

Caput cylindricum quasi primum corporis segmentum, antice obtusum, antennis quatuor coniciis, brevibus, superis pedunculo triarticulato bifide, inferior longioribus quadriarticulatis, articulo secundo seta peravus, postremo ceteris longiore.

1 "O. Fabricii Fauna Groenlandica, pag. 257–258. Procter hunc reliqui auctores omnes (Pallas, Müller, Stroem, Leach) de similie specie tacent. Unicum ob oculos amplus insignem Scoresby (Account of the arctic regions pag. 542) commen[emem], ceterum sita minus notam."

2 "Antennis in specimine nostro vix integra, apice obtuso detritis."
"Oculi satis ampli, ovati, laterales, sub insertione antennarum inferarum, (in mortuo) albicans et margine antico serrato.

Maxillae par primum elongatum, apice tricuspidatum utrinque palpe triarticulato et basi lamina foliacea, apice ciliata. Par secundum inferum mento ample geniculato, labio bifido utrinque palpe complanato triarticulato, apice obtuso ciliato.

Segmentum corporis primum latum, margine antico caput postico segmentum secundum excipiens, appendice scutiformi laterali exiguo, cuinis paginae interius pedes primi parvis inserti sunt compressi, mollissimi, palpiformes, quinquarticulati, articulis (basales femore excepto) unispinosi, terminali ciliato.

Segmentum secundum reliquii angustius, scuto laterali ampli ore fere quadrato, cuinis paginae internae indixum par pedum secundum, qui structura prioribus similis omnium longissimi (quatuordecim lineas) quinquarticulati, antice complicandi et abscondendi inter membranam teuenum, a ventrali huius segmenti pagina tendentem, scutum magnitudine adequantem.

Segmenta tertium quartumque aequae latae, scuti laterales maximis, rotundati, postice emarginatis, et quorum basi interna tenduunt pedes, aequi longi (decem lineas) anterum versi, quinquarticulati, unguiculo terminali iuxtrati. Accedunt ad singulum pedem a latero interno membra na tenuis, lanceolata, margine ciliis longis obsoeta.

Segmenta quinta, sextum et septimum eiusdem latitudinis, pedes gerunt retrosum versos quasi saltatorios, precedentibus vix longiores, inter se aequales, scuto amplissimo triarticulato iunatos, ut cu isi vis scuti articulum dignoscas femoralem, tibiadem et tarsi. Inde femur, tibia, tarsus vere alti. Non nisi extimus singuli pedis articulus cum unguiculo liter emergit. Par quinto intus membra lineaeri.

Segmenta octavum, nonum et decimum latissima postremum antice gibbum, pro incurvanda cauda, subitus gerunt appendices natatorias, singulum binos bifidos satis elongatos. Horum quoque margo lateralis foliaceous, protenden sed cum parte dorsali conutus, haud articulus uti priorum.

Segmenta undecimum, duo-decimum, decimum tertium incurvata, vix erigenda, sensim angustiora lamina caudales gerunt cornaes, rigidas, biarticulatas, bifidas sex, quibus accedit septima intermedia, miuuta, duplex et parte dorsali postremi segmenti oriens. Segmentum undecimum medio impressum quasi biarticulatum.

Color speciminis nostris fere careneus.

Uuicum quod ex itinere recit specimen a Procellaria glaciali, hamulo capta vomitu eiecit est, quam itu lethali in occipit perennus esset. Testa animali vix nisi forte apice antennarum lesa, sed quos binos non nisi alipe obseso, piscini illius odoris tota repleta. Celerrimam iigitar mutationem omnia ingesta vel tegumentis solidioribus inclusa in his avibus subire videntur."

It would seem fair to accredit these two very interesting species to Lichtenstein, since Maudt expressly acknowledges his indebtedness to that professor for the descriptions just as they are here given. Gurnanus griflus was redescribed by Milne-Edwards in 1848 as a new species under the name Lythamassa magellanica.

1822. Risso, A.

The new genus Phrosina is thus defined:—"Deux antennes à peine apparentes; yeux sessiles; tête prolongée sur le devant en forme de museau; mandibules palptères; corps oblong,
118

THE VOYAGE OF H.M.S. CHALLENGER.

un peu arqué, sub-arrondi sur les côtés, à segments crustacés transverses, dix pattes monodactyles, dissemblables, le dernier article faliforme, sign au sommet." The type species is *Phrosina semilunata*. *Phrosina macrophthalmia*, n. sp., is also described, a doubtful species which, in the opinion of Spence Bate, probably belongs to the genus *Anchylomena*.

1822. Schlotheim, E. F.

Nachträge zur Petrofaztenkunde. Gotha, 1822.

In this work, at p. 38, Schlotheim places *Trilobites problematicus* among the doubtful species. He gives figures of it, which are here reproduced, on Pl. XXII. fig. 8, a, b. He remarks further, "Ausser dem Kopfschilde mit dem beyden augenahnlichen Würzchen scheinen noch zwey Reihen anders gestellter Schilder zwischen dem Kopfschilde und den sehr schmalen Rückenschildern zu liegen, welche letztere an den Seiten mit einem durch feine Striche ausgezeichneten Saum versehen sind. Es hat den Anschein, als wäre der Hinterleib, nach Art des Asaphus, mit einem besondern Schwanzschild bedeckt; doch ist dies in der Versteinerung nicht deutlich genug ausgedrückt. Das Kopfschild scheint vorn mit kleinen Zähnen, vielleicht aber auch mit Fresswerkzeugen und Fühlspitzen ausgerüstet zu sein." It seems a somewhat wild conjecture that has placed this specimen, since mislaid or lost, in the ranks of the Amphipoda, and identified it with the *Palaeocranion problematicus* of Schlauroth, and the *Prosoponiscus problematicus* of Kirkby.

This, according to Desmarest, is the same essay, with some modifications, as that already noticed, published in the Bulletin des Sciences, 1816.

1823. Desmarest, Anselme Gaetan, born 1784, died 1838 (Hagen).

The articles on Crustacea for this dictionary were entrusted to Leach, but while the notices from G to M were being published, Leach was prevented by illness from attending to the work. The word *Malacostraca* gave Desmarest an opportunity, without breaking the alphabetical order of the dictionary, of supplying the past omissions in reference to the Crustacea by
one comprehensive article on the group. In 1825 this article, without material alteration, was converted into a separate volume. Its treatment of the Amphipoda may be understood from the note on Desmarets under that date.

In *Proto pedatus*, Fleming says that he readily distinguished “the four minute appendiculae of the posterior end, which are figured by Müller, but which Montagu was unable to detect in his specimens.” Of Latreille’s definition of the genus *Proto*, Leach, he says, “it is true that there are only ten feet, if we exclude the two pairs belonging to the first and last segments of the body; but if these be included, the number of feet should be stated at fourteen. This precision in enumerating the feet becomes the more necessary, since Latreille has added another genus, termed *Leptomera*, to the family *Caprellade*, which, in the character assigned to it, ‘Out quatroze pieds, disposés dans une série continue, depuis la tête jusqu’à l’extrémité postérieure du corps,’ would appear to differ only in having four additional feet. But the *Sygilla ventricosa* of Müller (Zool. Dan. tab. 96.), referred to as the type of the genus *Leptomera*, possesses the same number of feet as the *Gammarus pedatus* of the same author, referred to as the type of the genus *Proto*. The feet of the first and last segments of the body, however, have been enumerated by Latreille, in the character of his genus *Leptomera*, while they have been excluded from the character of the genus *Proto*. The two genera, in consequence of this arrangement, seem to differ in a character in which they agree.” He criticises Lamarck for retaining “dix ou quatorze pattes” as a character of the genus *Leptomera*, of which he made *Proto* a synonym, instead of giving *Proto* the priority. But Fleming himself would retain both genera on new grounds. “In the *Leptomera,*” he says, “the tarsi of the second pair of feet only are furnished with a movable claw; while in *Proto*, all the feet are unguiculated. In the latter genus, the second, third, and fourth pairs of feet have appendages at the base, which are wanting in *Leptomera*. We are not aware that the *Leptomera ventricosa* has ever been detected on the British shores.”

Of Cancer plasma of Montagu, which he refers to *Caprella*, he says, “it is subject to considerable variation in the number and position of the spines, and the hairiness of the different parts. In the example now before us, the claw and last joint of the first pair of feet were deeply serrated. It is probable that the *Caprella Pennantii* and *acanthifera* of Dr. Leach (Edin. Encyclopaedia, vol. vii. p. 494), are merely varieties of this species.”

1824. Martens, Georgio.

Reise nach Venedig. Ulm, 1824.

According to G. D. Nardo, he mentions *Gammarus pulex*, Fab., *Onices (Caprella) linearis*, Latr., with many other Crustacea. Zenker, 1832, speaking of the universal distribution of *Gammarus pulex* in the rivers and streams of Europe, adds, “vix tamen in tepidis aut calidis inveniatur aquis, licet Martens (Reise nach Venedig, Wien. 1824, II., 197) ipsum in thermis Albanis vivere contendeat, sine dubio *Gammarus Locusta* cum nostro commutabi.” Zenker had found that *Gammarus pulex* speedily died in warm water, but he had probably not put *Gammarus locusta* to the test.
1825. **Audouin, Jean Victor**, born 1797, died 1841 (Hagen).

Explication sommaire des Planches dont les dessins ont été fournis Par M. J. C. Savigny. Pour l'histoire naturelle de l'ouvrage. [See Note on Savigny, 1825.]

In regard to Pl. XI, which alone concerns the Amphipoda, Audouin assigns to figure 1 the name *Gammarus dulongii*, now known as *Tanais dulongii*. Fig. 2, he recognizes as Savigny's *Lycosa furina*, and adds, "Ce crustacé a beaucoup d'analogie avec la *Lencothœ articulata* de Leach, et appartient certainement au même genre."

He continues for the other figures as follows:

"La figure 3. I représente une espèce fort curieuse, qui doit constituer un petit sous-genre voisin des *Mesura* et des *Midta* de M. Leach, et qui se distingue facilement de celui qui précède, par la seconde paire de pieds développées autre mesure et en forme de pince (seulement du côté gauche); nous lui assignerons le nom de M. Fresnel *Gammarus Fresnetii*. Ce crustacé singulier est très-petit, ainsi qu'on peut le voir à la figure 3. 1."

"La figure 4. 1 est encore une Crevette que l'on doit rapporter au sous-genre Amphithoe, *Amphithœ* de M. Leach, et qui est très-voisine de deux espèces décrites par Montagu sous le nom de *Cancer Gammarus rubricus* (2), et par Pallas sous celui d' *Oicusus cancellus* (3); M. Savigny l'a mentionné (4) sous le nom de *Cymadusa flosa*.

"La figure 4. 2 représente de profil et au trait une portion de ce crustacé: on a découvert les flancs pour montrer les espèces de lamelles qu'ils renferment; la figure 4. 3 est une de ces lamelles isolée.

"La figure 5. 1 appartient au même genre, et représente peut-être la même espèce, ou bien une variété de sexe. On pourroit croire aussi que la partie postérieure de son corps, qui est tronquée brusquement en dessus, est un caractère spécifique; on retrouve ce caractère dans le *Cancer rubricatus* de Montagu.

"La figure 6. 1 appartient au même genre: cette espèce paroit distincte; elle est plus petite que les deux précédentes. Nous proposerons de lui donner le nom de M. Ramond, *Amphithœ* (Gammarus) Ramondii.

"Genre Talitre, Talitrus. Fig. 7, 8 et 9."

"La figure 7. 1 est une espèce d'assez petite taille (7. 1), et qui offre les caractères du sous-genre Orchestie, Orchestia de M. Leach; mais on doit la distinguer de l' *Orchestia littorea* de cet auteur, ou le *Cancer littoreus* de Montagu; nous lui donnerons le nom de Montagu, Orchestia Montagi. Les figures 8. 1 et 9. 1 sont des Talitres qu'on peut rapporter aussi au sous-genre Orchestie, à cause de la dissemblance des pieds et du développement de la seconde paire. Ces espèces nous ont paru nouvelles: la première sera dédiée à M. Deshayes, Orchestia Deshayesi, et la seconde à notre ami, le docteur Jules Cloquet, Orchestia Cloquetii."

The reference (2) is to "Montagu, Linn. Trans. tome ix. pag. 99. pl. v. fig. 1; et Encycl. méthod. pl. coeexxi. fig. 33." The reference (3) is to "Pallas, Spicil. zoöl. fascie. ix. pag. 52, tab. iii., fig. 18." The reference (4) is to Savigny, Mémoires.

**Handbuch der Naturgeschichte.** Eilfte rechtmässige Ausgabe. Göttingen, 1825.

In the preface a protest is raised against the use, affected by zoologists and botanists, of the word *Gattung* to mean *genre*, contrary to the older use of *Geschlecht* for *genus*, and *Gattung* for *species*.

While following in general the system of Linnaeus, Blumenbach agrees with the recent French systematists in separating "die Spinnen- und Krebsartigen Insecten, so wie die Tausend-
 REPORT ON THE AMPHIPODA.

121

This from the Aplera proper. In Suborder A, Arachnida, it may be noticed that he includes "Pleuropus Balanodium, die Gaulisclla. P. abdulino dilatato muricate, rostro subulato. Pennant's British Zoology. P. iv. tab. 18. fig. 7." In Suborder B, Crustacea, he gives Cancer divided into three Families, Branchyuri, Parasitica, Macrouri, the first with six, the second with one, the third with eight species. The 14th species is thus given:

"Innath häufig in der Brunnenfreide. Aber auch in Bunzahl an manchen Seestücken. Sehe gesammelt, wäre s verschwinden.”

The genera Monocerus, Oniscus, Scolopendra and Julus, complete the Crustacea. Oniscus has for its first species:—

"Ceti, (Cymothoa C. F.) die Gaulisclla. O. ovalis, segmentis distinctis, pedibus tertii quartique puris linearibus ovaticis.

"Pallas spicileg. zoolog. Fasc. IX. tab. 4, fig. 14.

"Innath eine Blase der Wallfische, bei welchen dieses Insect, besonders an den Zinnen und Zungenstacheln, aufs festeste sich eimnest.”

1825. De Brébisson, L. Alphonse, born 1798 (Hagen).

In the introduction de Brébisson promises a similar work “sur la classe des Arachnides et sur celle des Insectes,” if the years which are accumulating so rapidly on his head, leave him time for it. This seems an odd expression for a man of twenty-seven, which would be his age at this time according to the date of his birth given by Hagen. Further on, in treating of the difficulties of obtaining specimens of marine Crustacea, he says, “En effet, comment parvenir à connaître celles dont l'existence semble être confinée aux plus grandes profondeurs de l'Océan?” To this question the Challenger and similar expeditions have at least begun the answer.

In “Ordre 3, les Amphipodes, Amphipoda,” he gives, with short descriptions of the genera and species, Gammarus palex, Fab. Lat. etc.; Talitrus locusta, Lat. Lamk.; Talitrus gammaricus, Lat. Lamk., Boas, etc., the species now generally accepted as Orchelis gammarinus; Melita palpata, Montagu, sp.: Cryptidium longiceps, Lat. Lamk.

1825. Desmarest, A. G.

This very useful history of the Crustacea in general discusses, in the first eighty-two pages, their position in the scale of beings, their structure, functions, habits, and utility, together with

(Zool. Chal. Exp.—Part LXVII.—1887.)
a brief review of the systems successively adopted for their classification. The sixth chapter, containing this review, is admirably illustrated by five "tableaux synoptiques," which precede the plates at the end of the volume.

In Chapter VII. Desmarest gives notice that in his own classification of the Crustacea he proposes to follow essentially that inserted by Leach in the eleventh volume of the Linnaean Transactions, but modified and expanded to adapt it to the improved state of science on the subject. He had already explained in the preface that he had improved Leach's system by grafting upon it that of Latreille. Accordingly, he makes two suborders, the Malacostraca and the Entomostraca, each divided into five orders. The Malacostraca are divided into two legions, of which the first, the Podophthalma, includes two orders, the Decapoda and Stomatopoda; the second, the Euphthalma, contains three orders, the Amphipoda, Isomopoda, and Isopoda. As usual at this period, the mandibular pulp comes into the definition of the Amphipoda, and is denied to the Isomopoda. The Amphipoda are said to have five pairs of false feet under the tail.

The distribution of the Amphipoda is as follows:

"1st Section. Deux antennes inéquales une de chaque côté du front; queue terminée par des filets styliformes; tête grosse, verticale."

This includes Phronima, with the species sedentaria and costos.

"2nd Section. Quatre antennes; deux feuilles aplatis, servant de nageoires, placés au bout de la queue, et remplissant les styles; tête grosse, verticale." Herein he places Hyperia, Latr.

"3rd Section. Quatre antennes; queue terminée par des filets styliformes; tête médio-crémente grosse, non verticale.

"1st Division. Antennes formées de quatre articles dont le dernier est subdivisé en plusieurs autres fort petits; les supérieures très-petites et plus courtes que le péduncle des inférieures, qui est composé de trois articles." Talitrus with the species locusta, and Orchestia with the species littorea occupy this division.

"2nd Division. Antennes grandes, séparées, formées de quatre articles dont le dernier est lui-même multiarticulé; les supérieures de bien peu plus courtes que les inférieures." This division has only Atylus, Leach, with the species carinatus of Fabricius. But the remark is added, "M. Latreille prémisse que le Gammarus mugax de Fabricius, figuré par Philips (Voyage au pôle boréal, pl. 12, fig. 2), appartiennent au genre Atyile."

"3rd Division. Antennes formées de trois articles dont le dernier est multiarticulé, et dont le premier est le plus petit de tous; les supérieures étant les plus longues." The genus Decapontes is included, with the species spinosa, and this is followed by "Leucoxene (Leucoxenus, Leach; Gammarus, LAT.; Cancer, Montagu; Cuvieria, Leach)," with the species articulata, but no explanation is given to show where the synonym Cuvieria for the genus is to be met with.

"4th Division. Antennes formées de quatre articles, dont le dernier est multiarticulé; les supérieures étant les plus longues.

"Subdivision I. Les quatre premiers pieds monadactyles; ceux de la seconde paire dans les mâles, ayant la main dilatée et comprimée." In this subdivision is included "Mélita (Mélita, Leach; Gammarus, Latr., Lannek.; Cancer, Montagu; Boscia, Leach)," with the species palmata, and "Mara (Mara Leach; Gammarus, Latr., Lannek.; Mulleria, Leach), with
the species grossimanus. Whence he derives the names Bowin and Mullerin he does not explain. He adds in a note that probably Gammarus crassimana, Viviani, belongs to the genus Mera.

"Subdivision II. Pieds des deux premières paires monodactyles et semblables dans les deux sexes." In this are included three genera, "Crevettes (Gammarus, Fabr., Latr., Lamck., Leach; Squilla, Dugès; Cancer, Linn.; Carcinus, Latr.)," with the species Gammarus pulex, Fabr., Latr.; Gammarus marinus, Leach; Gammarus locusta, Leach; and Gammarus campylus, Leach. Among the synonyms of Gammarus pulex may be mentioned, "Squilla fluviatilis, Meret, Pin., pag. 102." Of Gammarus locusta, he says, "M. Surrinay, du Havre, a remarqué qu'elle est phosphorescente." The next genus, Amphithoe, has the species rubricula of Montagu and cancellus of Pallas. The third genus is Phereus, with the species jaculata.

"Ve Division. Antennes composées de quatre articles; les inférieures étant les plus longues et pentiformes; les quatre pieds antérieurs monodactyles.

"Subdivision I. Pieds de la seconde paire pourvus d'une grande main; antennes inférieures de bien peu plus longues que les supérieures." Podocerus with the species cariogaster, Jassa with the species pulchella and pelagica, are the genera included, Corophium, Latr., being given as a synonym to each.

"Subdivision II. Pieds de la seconde paire n'ayant pas la main dilatée; antennes inférieures bien plus longues que les supérieures." Corophium, with the species longicorne and its accustomed synonyms, stands here alone.

"Vi Division. Les quatre antennes très-grandes et fortes, presque aussi longues les unes que les autres; les supérieures formées de quatre articles, et les inférieures en latérales, de cinq." Cerapus, Say, with the type species tubularis, occupies this division.

In a note Desmarest here gives an account of several genera as probably belonging to the Amphipoda, though from want of figures and sufficient description remaining doubtful. These are Lepidactylus, Say, with the species dysticus; Lanccola, Say, with the species pelagica; Sperchius, Rafinesque, with the species lucidus, and a complaint that Rafinesque should have chosen a name for his genus so near to Sperchius employed by Fabricius among the Coleoptera; Lepelenus, Rafinesque, with the species rivularis; Pseitor, Rafinesque, with the species bispinosus and laxifrons. "Enfin, un genre nommé Alonopte, appartenant aussi à l'ordre des amphipodes, a été crée par M. Leach; mais il n'est inconnu, et M. Savignay a figuré (dans ses Mémo sur les anim. sans vert., 1e part., 1e fasc.), les parties de la bouche des deux autres, qu'il nomme Cymadera et Lycesta. Ce dernier me paraît très voisin du genre Maira de M. Leach."

The fourth order, Lamnodiopoda, Latr., is distributed as follows:—

"I" Section. Corps très-étroit et linéaire; des yeux composés situés en arrière des antennes supérieures; point d'yeux lisses; antennes supérieures ayant le dernier article aussi long que tous les autres ensemble; les inférieures un peu comprimées; pieds en nombre variable; main de ceux de la seconde paire souvent dentée en dentel. To this section he assigns Leptonera, Latr., Lamck., with Squilla ventricosa, Muller, for type, observing that Latreille founded this genus only upon published figures, and referred to it, besides Muller's species, which has no vesicular appendages figured at the bases of the legs, also Slabber's species, "qui a un appendice en forme de lobe, à tous les pieds, les deux premiers exceptés," and Montagu's Cancer pedatus, "qui en a tous les pieds pourvus, moins ceux de la première et des trois dernières paires." To the same Section he assigns "Proton (Proto, Leach, Latr.; Squilla, Muller; Leptonera, Lamck.). Dix pieds disposés dans une série continue depuis la tête jusqu'au quatrième anneau inclusivement, le corps étant terminé par deux ou trois articles, qui forment une espèce de queue," etc., with the type species, "Le Proton pedaire, Proton pedatum, Nob.; Squilla pedata de Muller." Though Desmarest says he had himself found it in abundance at Havre, there can be no
doubt that the account is based on imperfect specimens of *Proto ventricosa*, O. F. M. Lastly, in this section he places *Caprella*, Lamck., with the species *acutifrons*, Latr.; *acuminifera*, Leach (more correctly, *acanthifera*, Leach); *limarina*, Linn.; "montis", Latr., Nouv. Diction. d’Hist. nat. Tête allongée, rétrécie postérieurement; pieds de la seconde paire plus courts que ceux de l’espèce précédente, avec leurs articles inférieurs comprimés et anguleux. Des côtes de la France baignées par l’Océan”; a species which Mayer considers quite indefinite; *phasma*, Lamck., with *Cancer phasma*, Montagu, for a synonym, this being *Protella phasma*. He concludes by remarking that, “M. Latreille regarde encore comme appartenant à ce genre le *Cancer filiformis* de Linnaeus, et le crustacé décrit par Forskal, Fann. Arab., pag. 87, comme une larve d’insecte d’un genre incertain.”

"II’ Section. *Corpus large, déprimé; des yeux composés, et en outre deux très-petits yeux lisses disposés transversalement sur le vertex; antennes très-rapprochées à leur base; pieds au nombre de quatre, dont dix parfois, et quatre (placés sous le second et le troisième segment du corps), en forme d’appendices grêles, articulés, ou de fausses pattes; anus avancé et pourvu de tubercules peu saillants. “This section has the one genus *Cyanus*, Latr., with the species *cataet.* The various synonyms of the genus and species are given, followed by the remark, “de l’Océan d’Europe où il vit sur les baleines, et aussi, selon M. Latreille, sur les scombres ou maquereaux. Ce crustacé est vulgairement désigné par le nom de poi de baleine.”

In the fifth order, *Leopoda*, Latr., "I” Section. Branchies placées sous la queue,” etc., he defines the first division thus:

"I” Division. Pieds au nombre de dix seulement; corps formé de trois, cinq ou sept segments; abdomen (ou queue) en ayant quatre, cinq ou six, et terminé par deux ou quatre lames latérales; deux ou quatre antennes.” In this division he places the genus, now transferred to the Amphipoda, *Typhlonus*, Risso, with the species *ovoides*, Risso, remarking as to the definition of the genus that “M. Risso n’annonce comme didactyles que les deux premiers pieds; MM. Latreille et de Lamarck indiquent les deux suivants comme présentant le même caractère. Under the genus "Jones, Latr.,” in the second Division, Desmarest remarks that Latreille (Encycl. Méth., Expl. des pl.) considers Slabber’s *Oniscus armarius* suited to form a genus near to Jones, but Desmarest himself, though he thinks that Slabber’s species has only twelve feet, shows that it is at any rate quite remote from Jones.

Pages 424-427 contain a supplementary account of various species described by Risso, but not easily to be identified or classified. Among these are his *Talitrus subrostratus*, which Desmarest thinks may be an *Orchestia*, and his *Caprella prunata*, which Mayer agrees with Desmarest in thinking quite indefinite.

Figures of Amphipoda, borrowed from various sources, are given on plates 45 and 46. Fig. 1 on plate 45 is described at the foot of the page as "Phronima sédentaire, gr. nat." Yet it has evidently been copied with some care from Pl. 2, fig. 3, of Risso’s Hist. Nat. des Crust. des Environ de Nice, 1816, which represents Risso’s *Phronima custos*, a species, it is true, identical with *Phronima sedentaria*, but none the less distinguished from it by Desmarest, who remarks upon it, “Pattes natatoires caudales paroissant n’être qu’un nombre de quatre,” a mark of distinction which beyond doubt belongs to the figure only, and not to the species. Desmarest’s fig. 8, on pl. 45, of "Crevette des maresaux, gross," is no longer that of Rösel’s species, but no doubt taken from an actual *Gambusius pilcr.*

1825. ESCHSCHOLTZ, JOHANN FRIEDRICH, born 1793, died 1831 (Hagen).

This work is included in Bocke’s list, but I can find nothing in it relating to the Amphipoda.

Latreille here divides animals into three great series or divisions. 1. Les Vertébrés ou Spina-cérébraux. 2. Les Céphalopodes. 3. Les Acéphalés. The last two include the invertebrates. The Céphalopodes he divides into three races, "les mollusques, les elminthioides et les condylopes." Of the condylopes the "première branche" is "Les Hyperhexapodes, Hyperezapi. (Ariopodes, Sav.)." The première classe is Crustacea. Of these the première section is Maxillops, with nine orders, Decapoda, Stomatopoda, Lemodipoda, Amphipoda, Isopoda, Lephyropoda, Phyllopoa, Xyphosura, Siphonostoma. Of the third of these orders, "Lemodipodes. Lemodipoda (Isopodes cystibranches; Cuv., Règne Animal, tom. 3, pag. 50)," he says, "la tête étant confondue avec le premier segment du tronc, tandis que dans les deux ordres suivants elle en est séparée, nous commençons par celui-ci; autrement la série naturelle des amphipodes et des isopodes serait interrompue." Of the Crustacés sessiliodes he had already said in the preface, page 24, "ils composent l'ordre des amphipodes et ceux de lemodipodes et d'isopodes; on aurait pu les réunir en un." This latter opinion has not met with acceptance in its entirety, but the Lemodipoda are now by general consent united with the Amphipoda. Latreille here forms them into two families, the first, Ovalia, with the genus Cyane, the second, Filiformia, with the genera Glaerotae, Proton, Leptomère. To the Amphipoda he gives four families, the first, Crevetines, Gammarines, contient in groups the genera Cérape, Leucothoë; Mélifie, Amphipithoë, Decamine, Crevette, Phènise; Orchestie, Talitre, Atyle; Corophie, Podocère, Jasse; Phéronine. The three remaining families are given as follows: —

1825. Latreille, P. A.

3. Podocère, Podocerus, Leach, as to which he says, that it might be united to Corophium, by this observation leading up to the introduction of a long letter from M. d'Orbigny in regard to the habits of Corophium grossipes.

4. "Pterygoce, Pterygoce. Genre de Crustacés que j'ai indiqué à l'article Phytiibranches de cet ouvrage, et qui est formé d'après la figure de l'Oniscus arcticus de Slabber. (Oebur. microscop. tab. XL fig. 3. 4). Quoique nous n'ayons point vu cet animal en nature, il nous paraît cependant qu'on ne peut le rapporter à aucun genre de Crustacé connu. Ses quatre antennes sont très-garnies de poils barbus ou formant des peniules aux premiers articles qui sont beaucoup plus grands que les autres. Les quatre pattes postérieures présentent les mêmes caractères; les quatre premières, ou du moins celles qui semblent l'être d'après la figure, sont velues, courbes, et se terminent par une nageoire ou un article arrondi et mutique. L'extrémité postérieure du corps est touchée par plusieurs appendices ou styles velus. Ce Crustacé doit appartenir à l'ordre des Amphipodes ou à celui des Isopodes."

1825. Guérin (later Guérin-Ménéville), Félix Édouard, born 1799, died 1874 (Webster).

synonymy. Next is given "Atyle, Atylus, Lécq. Gammurus, Fab. Talirus, Lat.," with the species Atylus carinatus, Lécq, having for synonyma Gammurus carinatus, Fab. The remark is made that "Risso describes a species of Talirus (T. rubropunctatus) which might well belong to the genus Atylus."

"Typus, Typhlos, Risso, Lat. Lamk." is described in accordance with the views of Latreille among the Decepoedidae, where it is placed in company with Anomus and Pronus.

Under "Uroptère, Uroptera, Lat.," the genus Hyperia, Lat., is described. Desmarest is referred to for the species "Hyperia Scutellii." Montagu's descriptions of "Cancer gummarius Galla" and Cancer monoculoides, are translated in the belief that these species either belong to the genus Hyperia or come very near it. Phrosina, Risso, is next described, and Risso's accounts given of the two species Phrosina squalata and Phrosina macrophthalma.

Guérin's own genus Themisto follows, being very fully described, with Themisto Gaudichaudii for the type species. The account was repeated with but slight variation in a separate memoir in 1828. See note on Guérin under that date. In the Encyclopédia Gaudichaud presents to his description of Themisto, one of "Risso, Rhoe, Milne Edw.," observing, "à la suite des Uroptères, nous devons faire mention d'un nouveau genre que vient d'établir M. Milne Edwards dans les Annales des Sciences naturelles. Ce naturaliste pense qu'il forme le passage entre les Amphipodes et les Euphèses de M. Risso, que M. Latreille réunit à son genre Apseude. M. Edwards croit qu'en modifiant un peu les caractères de la famille des Uroptères, son genre s'y placent aisément et d'une manière naturelle." Lastly Guérin gives "Zuphée. Zuphix. Risso," and "Hexone, Hexona. Risso," but he is not able to add anything to Risso's statements about them. The volume ends with an alphabetical table of the articles which come into the dictionary not in their alphabetical order. Here Chevrolle appears as Chevralle, Cyane as Cyane, Hypérie as Hyspérie. Phrosine and Themisto are not mentioned.

1825. Savigny, Jules-César.

The illness of Savigny prevented him from writing the text to his elaborate Plates. After waiting for many years, the French Government at length entrusted the task to Victor Audouin. The brief account which he gave of the Amphipoda is quoted in the Note on Audouin, 1825. It may here be mentioned that 2. Lyceota furina, Savigny, is now known as Leucothoe furina; 3. Gammurus Fresnèli, Audouin, is now called Melita Fresnèli; 4. Cymadusa filosa, Savigny, is now called Amphithoe filosa; 6. retains the name Amphithoe Ramonii, Audouin, but is not easily to be distinguished from Amphithoe filosa, except that it has the ocular lobe of the head more sharply produced between the antennae; 5. which is not positively named by Audouin at all, though he hints at Amphithoe rubricata, Montagu, resembles Amphithoe filosa and Amphithoe Ramonii, except that the wrist in the first gnathopods is longer in proportion to the hand, the hand of the second gnathopods is rather densely setose on the anterior margin, and the third joint of the pedum of the upper antennae is by comparison elongate. 7. Orchestia Montagu; 8. Orchestia Deshayesii; and, with some authors, 9. Orchestia Cloqueti, retain the names assigned them by Audouin. Orchestia Cloqueti, the figure of which has met with some mishap in the British Museum Catalogue, was placed by Guérin-Ménéville in one of his divisions of the genus Talirus. Savigny's figure of it is here reproduced. It will be seen by the position of the larger
gnathopods that they are probably the first pair, not the second as has been hitherto supposed. The large fourth joint must be the wrist not the hand. The finger is not shown. Judging only by the general appearance, in the absence of other evidence, one may reasonably assign the species rather to Talitrus than to Orchestia. In fig. 1, which repre-

Fig. 21.

sents the mandible of Orchestia Montagui, here reproduced, it will be seen that Savigny represents the rudiment of a triarticulate palp. In his figure of the maxillipeds of the same species he represents the outer plate as articulated with the joint of which it is the expansion. This must be an error.

1826. Risso, A.

In the preliminary notice Risso observes that “tous les genres d’amphipodes aiment à se laisser balancer mollement par les vagues sur la surface des eaux,” a statement which must be received with some reservation in regard to the Orchestides and others. The crustacés amphipodes here form the third Order. Genera and species, which had been already described in Risso’s earlier works, are nevertheless here marked as new, sometimes without a reference to the earlier description. The genus Phrosina has the following fresh definition:—“Corps assez solide, oblong ; tête moyenne ; dix pattes, toutes monodactyles ; dernier article de la queue arrondi, sans appendices.” The expression “sans appendices” is intended to distinguish Phrosina from Phronima, in which Risso fancied that the telson had appendages. The genus Typhlus is re-described:—“Corps solide, ovoïde ; tête large ; dix pattes, la première paire didactyle ; dernier article de la queue conique, aigu, sans appendices.” A new species, named Gammarus marinus, is thus described “corpore sub-ovato, intusae grisae ; punctalis saturate grisae ornato ; antennis pedibusque pallidioribus.” The name being preoccupied by Leach, and the description very inadequate, this species has been allowed to drop by subsequent authors. Under the heading “les antennes supérieures presque aussi longues que les inférieures,” the new genus Ename is described:—
REPORT ON THE AMPHIPODA.

"Corpus elongatum, compressum, articulatum; styli caudales inferiores, superioribus longiores; oculi magni, reniformes; antenne superiores articulo primo elongato, secundo quintuplo longiore, articulis alii minutissimis; antennae inferiores articulo primo breve, secundo valde elongato, articulis alii exiguissimis; pedes aequales, monodactylis," with the type species *Enone punctata,* "Corporum hyalino, lutescente, lateribus rubro punctatis; chelis minutis; pedibus, secundo pari, longissimis, apice ovatis, acutis." This is obviously Risso's *Talitrus rubropunctatus* of 1816. Without noticing this synonym, the British Museum Catalogue names it *Allorchestes punctatus,* as a doubtful species, and with the alternative suggestion that it may be the young of *Amphithoe rubra*; but the description of the antenna and gnathopods excludes both these identifications. Guérin, 1825, suggests the genus *Atus* for the species *rubropunctatus.* It is characteristic of Risso that while in the generic description he gives "tous les pieds égaux, monodactyles," in the specific account we find "la première paire de pattes grêle, courte; la seconde fort longue; les autres longues et égales." The species was found in the spring, far from the shore, the female carrying transparent eggs. He says of the animals of this genus (p. 100), that they "restent toujours en pleine mer, et on les voit souvent sautiller à la surface de l'eau pendant les fortes chaleurs." This does not favour Guérin's suggestion above-mentioned.

*Talitrus niceneis*, n. s., is described as "corporum glaberrimo, hyalinum, vitreo, pelliculo; oculis purpureo-nigris; antenne, pedibus tarsisque viscidiscensibus." This pellicular species, more likely to be one of the *Hyperidea* than a *Talitres,* might, one would think, be identified and more fully described by some one residing at Nice or in the neighborhood. The same may be said of *Atus corallinus,* n. s., which Spence Bate believes to be probably *Dezamine spinosa.* The genus *Eupheus,* Risso, is thus re-described, "Corpus elongatum, pedes gradatim acuminatums; caput quadratum; oculi globosi; tentacula duo filiformia, multiarticulata; thorax quinquearticulatus, segmento anteriore majore, filamentis dubuis corpore longioribus instructus," with the type species *Eupheus ligioides,* of which its author says, "le corps de cette espèce est composé d'un segment assez large, rattaché à cinq autres plus étroits, qui sont suivis d'un même nombre plus petits, le dernier terminé par deux courts appendices garnis chacun d'un long fil très mince; la tête est tronquée au-devant; l'œil petit, noirâtre; les antennes inégaux; les quatre paires de pattes sont ciliées; une belle teinte jaune, blanche et verdâtre le coloré de toute part." Risso fancies that the genus has much in common with *Ligia.* Bate and Westwood, following the lead of Desmarest, make it a synonym of *Apesium,* Leach, in the *Taniae,* among their *Isopoda aberrantia.*

The Crustacés Lénodipodes form the fourth Order. The first section includes *Caprella,* with the species of his earlier work, "C. licavirae" and "C. punctata," and *Nymphon,* Leach, with a new species "N. arachnoidea," quite out of place in this group. The second section includes *Pygoconum* (Fub.), *Camae,* with a species "P. ceti, C. de la bateau," apparently a *Cyamus,* although the habitat assigned "sur les baleinoptères et les scombres" implies some confusion. It includes also the new genus *Hexama,* "Corpus ovatum, postice abrupte acuminatum; thorax sexarticulatus; cauda suberigens, quinque articulata; pedes sex aequales, ungulibus curvatis, acutis, armatis," with the species *Hexama parasitica.* As its habitat is on *Boggy* there seems to be little doubt that it is the male of *Boggy* which Risso had observed in its ordinary position. Another new genus included is *Zaphiae* "Corpus oblongum, convexum; caput subtriarctangularum; oculi magni, convexi; thorax quinquearticulatus, articulis integris, approximatis; cauda sex articulata, ultimo articulo elongato, triangulare; pedes sex aequales," with the species *Zaphiae spariola,* the habitat of which is "sur les spares (gill-head), dans le sillon des nageoires dorsales." This, like the preceding genus, is probably an Isopod, the description corresponding with the *Prana* form of the genus *Aucus.*

(zoool. chal. exp.—part lxxviii.—1887.)

Journal of a third voyage for the discovery of a north-west passage from the Atlantic to the Pacific; performed in the years 1824–25, in his Majesty's ships Hecla and Fury, under the orders of Captain William Edward Parry, R.N., F.R.S., London, mdcccxxvi.

In the Appendix, which is separately paged, under "Natural History" is included a paper entitled "Zoology, by Lieutenant James Clark Ross, R.N., F.L.S.," pp. 91–120. He says that in his "brief notice of the Marine Invertebrate Animals brought home by the late Expedition, the generic arrangement of M. Le Chevalier de Lamarck (Histoire Naturelle des Animaux sans vertébres) has been followed in every instance." On the Amphipoda his notes are as follows:—

"10. Caprella scolopendroides. Caprella scolopendroides. Lam. v. p. 174. Gammarus quadrirhabdus. Zool. Dan. iii. p. 58, Plate 114, fig. 11, 12, Female (young?) Squilla quadrirhabdus. Zool. Dan. ii. p. 21, Plate 56, fig. 4, 5, 6, Male (young?) Squilla lobata. Fabr. Fauna Green. p. 248, No. 225. Was found abundantly at Port Bowen, but considerably larger than those from which Müller's drawings were taken, and nearly as large as the magnified figures. They also differ in having a great number of small spines along the back, which, however, were not observable on the young ones found attached to the antennae of the females. They agreed in all other respects. I have therefore considered them to be of the same species, as it is probable that Müller's drawings were taken from the young.

"13. Gammarus loricatus. Gammarus loricatus. Supp. to Parry's First Voyage, p. ccxxi. Plate i. fig. 7. In the figure above referred to, each pair of antennae appear to be placed on a peduncle, which is not the case. They were found in considerable numbers on the ice in Port Bowen.

"14. Gammarus boreus. Gammarus boreus. Supp. to Parry's First Voyage, p. ccxxix. The specimens which I possess differ from Captain Sabine's description in having the superior antennae as long as the head and six first segments of the body, and the antennae, legs, and tail being fringed with most beautifully fine cilia, particularly the plates of the tail. The fifth, sixth, and seventh pair of legs increase successively in length, the fifth pair being the smallest. In all other respects my specimens correspond exactly with his description.

"15. Talitrus nugax. Gammarus nugax. Supp. to Parry's First Voyage, p. ccxxix. Cancer nugax. Philp's Voyage, Plate xii. fig. 3. By far the most numerous of the Crustacea inhabiting the Arctic Seas. The superior antennae are shorter than the inferior, which, according to the arrangement followed in this notice, separates it from the genus Gammarus, where it has been inadvertently placed.

"16. Talitrus Edwardsi. Talitrus Edwardsi. Supp. to Parry's First Voyage, p. ccxxviii. Plate ii. fig. 1–4. Was found on the ice at Port Bowen in great numbers. The plate and description above referred to are very exact."

In regard to Talitrus nugax, see Note on Coos, 1865. In regard to Caprella scolopendroides, see Miers' opinion in Note on Miers, 1877.
1827—Johnston, George, born 1797, died 1855 (Hagen).

Under “(Class. Crustacea. Order. Heterobranchia. Sect. Amphipoda. Gen. Gammarus) Lamarck,” he described “1. Gam. maculatus,” from sea coast near Berwick, with the observation, “it belongs to Leach’s restricted genus Gammarus, of which he has described four species. Three of these are well known to me. His G. aquaticus is common here, as everywhere in our wells and ditches; the G. torva swarms in the pools left on the recess of the tide; and the G. marinus, remarkable by its strongly ridged back, is frequently taken here, in great abundance, in the baskets used for catching crabs. Our animal is quite distinct from any of these, nor can it be the G. Campeus, which I have not seen, for that is characterized by having ‘flexuous eyes,’ a character not in the least applicable to our G. maculatus.”

“2. Gam. punctatus.” “Hab. Amongst coniferous in pools left by the tide, very common near Berwick. Obs. In the arrangement of Dr. Leach this is an Amphithoe. He describes one species, the Cancer Gammarus rubricatus of Montagu (Linn. Trans. ix. 99, tab. v. fig. 1), which differs from ours in the following particulars:—it is of a “reddish, or pale pink” colour; the eyes are crimson, in ours brown, and so dark that if not attentively examined they might be pronounced black; the hands have no notch or fissure between their articulations; and, if Montagu’s figure be correct, the outline of the body is different. Moreover, in the description, Montagu makes no mention of the punctatus on the dorsal portion of the segments, a character not likely to have escaped the notice of that excellent naturalist.”

“3. Gam. dubius,” which Johnston at one time thought synonymous with Pherusa fucicola, Leach, but in Gammarus dubius “the basilar joint of the superior antennae is longer than the second or third,” and this species has “arms with nearly equal hands, monodactyle, oblong, not much dilated, and sparingly ciliated,” whereas he observes, “in the figure of the Pherusa fucicola given in the Supplement to the Encyclopaedia Britannica, the second joint of the superior antennae is represented as elongated, the first pair of feet or arms filiform without any hand, and the hand of the second pair oval with a very small claw. There is also a considerable difference about the tail, the Pherusa having no terminal conical processes. Other distinctions might be mentioned, but those already specified seem of as high a value as many of those which divide the genera of Dr. Leach.”

“4. Gam. noless.” “Hab. amongst coniferous, not rare. Obs. To the preceding species I gave the specific appellation dubius, since it seemed doubtful to which of the genera of Dr. Leach it ought to be referred; this I have named noless, as it will arrange with none of them. It seems allied to the Gammarus monosceloides (Linn. Trans. xi. 5, tab. ii. fig. 3) of Mr. Montagu.”

He enumerates as also occurring at Berwick, “the Talitrus Locusta and Orchestia littorae of Leach,” the Merx grossimana and Jassa pubrella of the same author, “the Gam. monosceloides of Montagu,” and the Corophium kriegneri, all of them in abundance. At p. 490, the habitat of Gammarus punctatus is described.

The description of Gammarus maculatus is quoted by Tate and Westwood, vol. i. p. 339, who distinguish it from the later Gammarus maculatus of Lilljeborg, but can give no further clue to its identification. There can, I think, be little doubt that it is the same as Gammarus (Gammaropsis) cryphrophthalmus, Lilljeborg, which must in that case receive the name Gammaropsis maculatus, Johnston. Gammarus punctatus is identified by Spence.
Bate with his own Amphithoe littorina; both are by Beeck made synonyms of Rathke's Amphithoe podoceroides. All three should in my opinion fall into the synonymy of Amphithoe rubricata, Montagu. The description of Gammarus dubius is quoted by Bate and Westwood, vol. i. pp. 397-398. It seems likely to remain in the doubt in which both they and the author of the species left it. The description of the antenna points to some species of Calliopus or Amphithoeopsis, but the two "papillae," which seem to be meant for the telson, would be inconsistent with these genera. Gammarus nobles is likewise left among the doubtful species by Bate and Westwood, vol. ii. p. 19. It had been, without sufficient reason, renamed by White Typhlus nobles and subsequently Anomix (?) nobles. It is as likely to be the Hyale nitescens of Rathke as any other species that I am acquainted with, but the description is not sufficiently definite to enable it to displace Rathke's specific name.

1827. Meyer.

Supplemente zur Lehre vom Kreislaufe. 1 Heft, Mit 1 ill. Kupfert. Bonn, 1827.

Zenker, 1832, says that this author described the circuit of the blood and of vegetable sap more as a poet than a naturalist, maintaining that not only in the sap of plants, but also in the blood of animals monads are found, and that all trunks are zoophytes, inhabited by hemadryads. He quotes from him the following passages relating to Gammarus pallescens:

"Pag. 56: Globulos sanguinis, ait, recto pergere tramite et hoc (i.e. hunc directionem) ipsius utpote animalculis praelentibus ("simignus hieren") esse insanum.

"Pag. 69: Succus Gammari Palieis effuso in monades atque in globulos cenanuliformes monadiis distributae, qui inter se places habereat monades, idem auctor narrat.

"Pag. 70 legitur: Gammaris P. corpore disrupto globati suasi duplici generis profusum. Majoris cenanulitatis instiis movens, diversis versus directiones, minores monades velociter diversos sesquar suas regiones et variis velociter, et sic partes flammis instar!

"Pag. 74. Denique prodit auctor nostre, id est "Gammaris extirpata (pede) abierisse in massa musculatm (f) eoque aereum globularum separatum et cortice conchabaturum videtur configisse, cujus vel liberer ipsi fidem habeamus, num si phantasia insignis obtemperamus, tunc omnia ceremone possaunus, qua imaginatio nobis proponat."

Zenker's last observation would apply to his own ternary and quinary distribution of the parts of Gammarus pallescens.

The authors here say, p. 115, "parmi les Crustacés des ordres inférieurs que nous avons examinés, c'est les Talitres qui nous ont offert le système nerveux le plus simple et le plus uniforme. Le corps de ces animaux se divise en trois parties assez distinctes, la tête, le thorax et l'abdomen; mais chacune d'elles est formée d'anneaux qui ont entre eux la plus grande ressemblance, et dont le nombre total est de treize. Ces divers segments présentent à leur face inférieure deux ganglions nerveux placés sur les côtés de la ligne médiane, et réunis..."
REPORT ON THE AMPHIPODA.

entre eux par une petite commissure transversale; chacun de ces petits noyaux communique
avec celui du segment qui le suit et qui le précède, à l'aide d'un cordon médullaire, et
fournit un certain nombre de nerfs qui vont se distribuer aux différentes parties du corps.
Le volume de ces ganglions diffère peu dans les divers segments; au thorax, cependant, ils
sont un peu plus gros que dans l'abdomen. Enfin ils sont tous un peu aplatis et ont à peu
près la forme d'un losange.

"Il existe donc dans le Talitrus deux chaînes ganglionnaires parfaitement symétriques, distinctes
daussi toute leur longueur, réunies entre elles par des commissures transversales, et offrant partout
une disposition essentiellement la même. La première paire de ganglions, ou la céphalique,
est remarquable par sa simplicité, et ne diffère pas essentiellement des ganglions qui suivent; elle est située, comme dans tous les animaux articulés, au dessus de l'esophage, et
fournit des nerfs aux yeux et aux antennes: ces ganglions que l'on a désignés à tort sous le
nom de cerveau, se continuent postérieurement avec les cordons médullaires qui les unissent
daux ganglions du premier aumon thoracique, en passant sur les côtés de l'esophage, qu'ils embrassent. Ces derniers ganglions fournissent en dehors de deux nerfs, dont l'un
pénètre dans la patte correspondante, et dont l'autre paraît se distribuer principalement aux
muscles et aux teguments des parties latérales du corps. Les ganglions des autres segments
présentent la même disposition; seulement la distance qui les sépare nous a paru plus grande
dans l'abdomen qu'au thorax." Pl II. fig 1 exhibits the "Système nerveux du Talitrus."

The report on this paper to the Académie Royale des Sciences by M. Geoffroy S-Hilaire, "la dans
la séance du 25 février 1828," in describing the results of the investigations made by the
two authors, declares the conclusion to be that "the nervous system of all the crustacæ,
whatever the differences it presents among the species of the various orders, is formed of
the same elements: the solitary nerve-nucleus of the crab being practically nothing but an
agglomeration of the numerous nerve-ganglia arranged longitudinally in the cray-fish and
Talitrus."

1828. Guérin (afterwards Guérin-Méneville), F. E.

Mémoire sur le nouveau genre Themisto, de la Classe des Crustacés; par M. F. E.
Guérin. (Lu à la Société d'Histoire naturelle de Paris le 29 août 1828.) Extrait
Pl. xxiii.

The genus is described as follows:—"Corps oblong, composé de douze segments; tête occupée
entièrement par deux yeux à réseau, arrondie, non prolongée inférieurement en rostre.
Quatre antennes; les supérieures plus courtes que la tête, courbes au bout; les inférieures
beaucoup plus longues. Quatorze pieds; les quatre premiers courts, dirigés en avant,
eouchés sur la bouche, et représentant les deux dernières paires de pieds-mâchoires des
Crustacés supérieurs; les quatre suivants beaucoup plus grands, terminés par un crochet
dirigés vers la queue; la cinquième paire très-longue dirigée vers la bouche, ayant
l'avant-dernier articule grêle, fort long, garni d'épines en dedans et terminé par un crochet;
les quatre derniers, de moitié plus courts, dirigés et formés de même, mais sans dents
d'à l'avant-dernier articule. Queue terminée par six appendices natatoires longs, aplatis,
bifides à l'extrémité; trois paires de filets également natatoires sous les trois premiers
segments de la queue."

It belongs, Guérin says, evidently to Latreille's family of Uroptera. The type species is
Themisto gaudichaudi, found "sur les côtes des îles Malouines par M. Gaudichaud;" that
is, at the Falkland Islands. It is well figured and described in much detail. By some
misapprehension the mandibular palp is represented as 4- instead of 3-articulate.

The first of these new Crustaceans is considered by Milne-Edwards to be evidently an Amphipod. He says it resembles the Gammarids by its general form, the disposition of the antennae, and the appendages under the five first segments of the abdomen; it is separated from them by the structure of the two first pairs of feet, by the form of the terminal segment of the abdomen, and by the long filaments which this latter supports; these characters, he says, bring it near to Eupheclus, with which it cannot be confounded. Eupheclus had been withdrawn from the Isopods and placed among the Amphipods by Latreille in his last work, and Milne-Edwards believes that his new genus will here fill up a gap between "les Amphipodes uroptères et les hétéropes," though the characters of the Uroptera will require some slight modification. He thus defines the genus Rhae:\ — "Quatre antennes dont les supérieures sont grosses, bifides, et plus longues que les inférieures, quatorze pattes dont les deux premières terminées par une pince et les autres par un ongle crochu; le dernier article de l’abdomen allongé et supportant deux appendices terminés par de longs filaments." The type species Rhae latreillii has now been transferred to the earlier genus Apsenodes, Leach, of which Risso’s Eupheclus is considered a synonym. Whether this and the other Tanaids should be reckoned as Amphipods is a matter still sub judice.

In the introduction the author observes that animals had generally been classified in a simple series, but that the natural method is ramified, as Lamarck had first pointed out in his "Hist. nat. des animaux sans vertèbres, 1815; tome 1er, p. 457."

In the "Tableau synoptique des animaux articulés, avec l’indication des genres par lesquels les classes et les ordres s’avoisinent dans l’état actuel de la science," he passes from the first class, Annelids, to the Myriapods as the second class, and from these in a straight line to the third class, the Insects, but through a branching off at the genus Glomeris to the fourth class Crustacea, in which the 1st Order, Isopodes," descends through the "P. G. Araneolillo" to Spharoma and Proto. At Proto branches off the "2. Orde, Parasites," including the genera Nymphon and Lernon, while at Spharoma another branch carries down the lines as follows—3. Orde Amphipodes. P. G. Hietta. D. G. Phronima. 4. Orde Stomafodes. P. G. Grylula. D. G. Eriechthus. 5. Orde Decapodes. 1st Fam. Mancourus. P. G. My纯洁. &c.

He discusses, pages 33 to 88, the chemical composition of the integument of insects and Crustacea, and mentions that what Odier calls chitine, Lassaigne proposed to call Entomelitine, from ετονος, an insect, and ηλες, a covering.

In regard to his order of "Parasites," he says in the introduction, page 17, that in it he places successively "les Nymphon, les Phoxichitus, les Pycnogonum, les Cymus, les Cercops, les Calygus, les Dicholestes, les Choromacentes, et les Lernon," thus mixing up Cymus with animals very differently constructed. For Limulus he proposes a separate order with the name Gnathopodes.

Zenker here divides animals into ten classes, of which the Insecta are the fifth between the Vermes and Pisces. The Insects are divided into two orders, Crustacea, and Insecta vera. The Crustacea include four subdivisions, Branchiopoda, Isopoda, Decapoda, and Octopoda. To the Isopoda he assigns four families, numbered in his system, 55. Pycnogona, 56. Leptomera, 57. Juli, 58. Aselli; and to the Decapoda four, namely, 59. Squilla, Squillares, Gollif, 60. Pugilari, 61. Astadi, 62. Cancri.

At page 342, he assigns to “56. Fam. Leptomera,” the genera “1. Leptomera Latr. 2. Proto Leach. 3. Caprella Lam. 4. Cyamus Latr.” He mentions that Goldfuss calls this family Cystistomachia, that Leptomera rubra Lam. is Squilla centricosa, that the Caprella, as Caprella linearis Risso, live parasitically on Whales and fish in the European waters, and that “Cyamus Ceti,” the Walj Schwarzel has two great compound eyes on the front side-rim of the head and two small simple (glatte) ones on the head. He says it is also called Walj Schwarzel from its imbedding itself in the fat of the whale.

At page 349 he thus describes “59. Fam. Squilla, Squillares, Gollif, Heuschreckenkrebse. Kopf dick (1), klein (7). Augen gestielt (4, 6, 7) oder sitzend (1, 2, 3, 5). Fühler 4, untere länger, mit gegliederter Endborste (2) oder ohne dieselbe (3), obere länger (5). Bruststöcke mit den Leibesringen von gleicher Grösse (1–5) oder viereckig grüsser (6, 7). Füsse, fünfte Paar sehr lang mit einer Scheere (1), das zweite Paar (2) oder das vorderste (3), oder auch die zwei vorderen (5) mit solcher, oder ohne Scheere (4). Das zweite Paar der grüsseren Kieferfüsse mit einem glatten (6) oder gezähnten (7) Endgliede, welches sich in eine Rinne des nachfolgenden Gliedes ein legt. Schwanz mit mehreren stielformigen (1), walzigen, gegliederten (2, 3, 5) Anhängseln oder 2 Schwanzblätchen (4), und 2 oder 5 (6) oder bloß 5 Kiemenfusspaaren auf dem Schwanz. 1. Phronima Latr. 2. Telituris Latr. 3. Corophium Latr. 4. Phasmatoearcinus Tiles. 5. Gammarus Latr. 6. Erichthus Latr. 7. Squilla Puff.” It will be noticed that the numbers in brackets refer to the numbered genera, and the stalked eyes of (4, 6, 7) will sufficiently point out that the genera so numbered do not belong to the Amphipod-group as now accepted. In the appended observations Zenker takes note of Phronima sedentaria, Phronima custos, Corophium longicornum, which, he says, is “Cancer crassipes L.,” and of Gammarus putor. He then adds, “Tilesius fand unter den leuchtenden Meerthieren auch mehrere hierher gehörige, wie die Federkrebe, Phasmatoearcinus discophthalum und glandis. Andere mikroskopische Thiergeschlechter, wie Amblypygotes, Erythrosephalus, Acanthosephalus, u.s.w. verdienen vielleicht hier gleichfalls ihre Stelle. In reality it is only the genus Erythrosephalus, in this list from Tilesius, that can be reckoned among the Amphipoda.

1829. Audouin, V., et Milne-Edwards, H.

Vocabulaire; par M. V. Audouin. Complétée par une Iconographie de 48 Planches. Paris, 1829. (In the Encyclopédie portative, sous la direction de M. C. Bailly de Merlieux.)

1829. Bouchard-Chantereaux.

In the second volume (1829), at page 488, is given a catalogue headed "Animaux sans vertèbres Observés par M. Bouchard-Chantereaux. (Système du chevalier Lamarck)." In this catalogue among the Crustacés are found the following Amphipodes:—"Talitrus locusta, Talitre locuste. Orchestie littoræ. Orchestie littorale. Cyamus cæti. Cyane de la balcine." No descriptions are given, or remarks of any kind.

1829. Johnston, George.

He says "In a preceding communication I had occasion to mention that the Gammarus marinus of Leach was common in this neighbourhood [Berwick]; but from a subsequent examination of my specimens I am now convinced that I was in error, and that they constitute a distinct and uncharacterized species, which I proceed to describe."

At page 417 he describes "Gammarus spinipes. Gamm. corpore albo, levi, lineis rubris transversis picto; palmæ pedis secundæ dilatata, apicem triangularem, monodactylæ, spinæ validæ internæ terminata. Hab. littoral maris Britannici." A description in English is given, and a speculation as to whether it could possibly be the same as Jussa pelchella of Dr. Leach. White, loc. cit., p. 190, takes note of it under Jussa. Other authors leave it in its pristine obscurity.

1829. Latreille, P. A.

Here Latreille divides the Crustacea into two sections, "les Malacostracés et les Entomostracés." The former of these comprises five orders, "les Décapodes, les Stomapodes, les Lamidi-
podes, les Amphipodes, et les Isopodes." In the body of the work he transposes the Amphipoda and Isopoda. In treating "des Malacostracés à yeux sessiles et immobiles," he says, page 114, "Ces animaux se partagent en trois ordres: ceux dont les mandibules sont munis d'un palpe paraissent se lier naturellement avec les crustacés précédents, tels sont les amphipodes; ceux où ces organes en sont dépourvus composeront les deux ordres suivants, les isopodes et les isopodes. Les cyanes, genre du second, étant parasites, nous conduiront naturellement aux bopyres et aux cénométhes, par lesquels nous commençons les isopodes." That some Amphipoda are without, and that some Isopoda possess the mandibulipalp, had not yet been noticed.

Of the Amphipodes (Amphipoda), which he here makes the third order of Crustacea, he says, "ils pourraient être compris dans un seul genre, celui des Crevettes. (Gammarus, Fab.), Que l'on peut partager d'abord, d'après la forme et le nombre des pieds, en trois sections.

1° Ceux qui ont quatorze pieds, tous terminés par un crochet, ou en pointe et au nombre de quatorze.

2° Ceux dont le nombre des pieds est encore de quatorze, mais où ces organes, ou les quatre derniers au moins, sont mutiques et simplement natatoires.

3° Ceux qui n'ont que dix pieds apparents."

The first of these sections he divides into two, the Uroptera and the Gammarinx. To the Uroptera he assigns Phronima, Latr., with the species Phronime sédentaire, Forsk., and Phronime sessile, Risso; Hyperia, Latr., "dont le corps est plus épais en devant; dont la tête est occupée, en majeure partie, par des yeux oblongs et un peu échancrés au bord interne; dont deux des antennes sont aussi longues au moins que la moitié du corps, et terminées par une tige sédentée, longue et composée de plusieurs petits articles," with references to "Cancer monocoloitides, Montag., Trans., linn. Soc., XL, ii. 3;—Hyperia de Lessuer, Latr., Encycl. méth. nat. des anim. 2e. édit., 17, 18; Desmar., Consid., pag. 258." The figures in the Atlas of the Encycl. méth. are there called Phronima, without any specified name. Here after Hyperia he places "Les Phrosines (Phrosine, Risso.) Semblables, pour la forme du corps et celle de la tête, aux hyperies, mais dont les antennes sont au plus de la longueur de cette partie, de peu d'articles en forme de stylet, ou terminées par une tige en écoin allongée."

To this genus he refers, "Phrosina macroptaphina, Risso, Journ. phys., octob. 1822; Desmar., ibid., p. 259; Cancer galba, Montag., Trans., linn. Soc., XI, ii. 2." Next he places "Les Dactylocères. (Dactylocera, Latr.). Donc le corps n'est point épais en devant; dont la tête est de grosseur moyenne, déprimée, presque carrée, avec les yeux petits; et dont les quatre antennes, fort courtes et de peu d'articles, ainsi que dans les phrosines, sont de formes diverses; les inférieures étant menues, en forme de stylet, et les supérieures étant terminées par une petite lame concave au côté interne, et représentent une cuiller ou une pince." In a note to this description of Dactylocera, he gives references as follows; "Phrosina semilunata, Risso, ibid.; Desmar., ibid. La tige des antennes inférieures présente deux ou trois articles, au lieu que, dans les phrosines, elle est inarticulée. Tel encore les articles des pédoncules des mêmes antennes sont plus courts." In the corrections and additions at the end of the volume he says, "près des Hyperies, doit être placé un autre genre de crustacés, celui de Thémosto, établi par le même naturaliste, et décrit ainsi que figuré, avec le même sein, dans le Tome IV des Mémoires de la Société d'histoire naturelle de Paris." The naturalist thus indefinitely alluded to is Guérin. Latreille adds some remarks on the mouth-organs of Thémosto.

Under the "Crévettes, Gammarinae. Lat.," he places "un sous-genre, que nous avons établi sous la dénomination D'Ione (Ione), mais uniquement d'après une figure de Montagu (Oniscus thomaeus, Trans., linn. Soc., IX, iii. 3, 4)," which, he says, has very special characters, separating it from all the rest of the same order. It is now recognised as an Isopod. After Ione, he gives Orchestia, Talitrus, Atypus, Gammarus, Melita, Marx. (Zool. Chall. Exp.—Part LXVII.—1887.)
Les Podocères, "à yeux saillants," are distinguished from the Jasses, "à yeux non saillants.

The second section he calls "Heteropodes, Heterop. Lat." In a note he says, "Cette section et la suivante forment, dans la première édition de cet ouvrage, la seconde des isopodes, celle des phytiêbrames. Mais outre que nous avons aperçu, dans quelques-uns de ces crustacés, des palpes mandibulaires, la forme des appendices sous-caudaux nous a paru se rapprocher beaucoup plus des amphipodes que des isopodes. Au surplus, ainsi que nous l'observons plus bas, ces animaux, dont nous n'avons vu qu'un petit nombre, n'ont pas encore été bien étudiés." To the Heteropod he assigns Pterygoeca, Lat., and Aspœdes, Leach. A note to the generic description of Pterygoeca, says, "d'après la figure de Slabber (Pterygoeca arenarius, Encyclop. méth., atl. d'hist. nat., cccxx, 3, 4.), le nombre des pieds ne serait que de huit; mais je présume, par analogie, qu'il est de quatorze; au surplus, si la figure est exacte, ce genre appartiendrait à la section suivante." In Slabber's figure, the animal being viewed from above, many of the limbs are naturally concealed from the observer.

The third section, "Decamères, Decamopodes. Latr.;" includes Typhus, Risso; Ancus, Risso. —Gnathia, Leach.;" Planiza, Leach. The remark follows that, "À ce même ordre des amphipodes paraissent appartenir divers autres genres de MM. Savigny, Rânesque et Say, mais dont les caractères n'ont pas été donnés ou suffisamment développés." A note adds, "Je ne puis encore rien dire du G. ergina de M. Risso: il semble, par le nombre des pieds, appartenir à la dernière section des amphipodes, et par la manière dont ils se terminent et le nombre des segments du corps, se ranger avec les isopodes."

Of Les Lernobiopodes. (Lernobiopoda), which he here makes the fourth order of Crustacea, he says, "Dans la première édition de cet ouvrage, ils formaient la première section de l'ordre des isopodes, celle des cistibranches. On pourrait n'en former qu'un seul genre, auquel, par droit d'ancienneté, on conserverait le nom "De Cyane. (Cyamus, Latr.)." He does not, however, carry out this suggestion, but retains the old grouping into filiformia and ovalia. To the former he assigns three genera, as follows:-"Les Leptomères. (Leptomera, Latr., —Proto, Leach.)

"Ont quatorze pieds (les deux annexés à la tête compris) complets et dans une série continue.

"Les Xyphophanes. (Xyphophana, Latr.).

"N'ont que dix pieds, tous dans une série continue; les seconds et les deux paires suivantes ont à leur base un corps vésiculaire (1). [with note] (1) Sous-genre établi sur une espèce de nos côtes qui me paraît inédite."

**THE VOYAGE OF H.M.S. CHALLENGER.**

**Amphiastoe, Pharusus, Decamphere, Lencothor, Ceropodes, Podoceres, Jassa, Cyamphion,** with references to one species of each genus. Under Atystus, besides Atystus carinatus, he suggests as possibly a second species, "G. nepox? ejusd.;" Phipps, Voy. au Pol. bor., xii, 21. Under Amphithoe, besides Cancer rubricatus, Montagu, he gives, as a second species,—"Oniscus cancellatus, Pall, Spicil. zool., fasc. IX, iii, 18; Gammarus cancellatus, Fab." Les Podocères, "à yeux saillants," are distinguished from the Jasses, "à yeux non saillants."
REPORT ON THE AMPHIPODA.

"Les Chevrotines. (Caprella. Latr.)." Of these the generic description is given, and in the note references appear to various species which are, not wholly without reason, criticised as doubtful.

Of the Miletus Latreille says, "Ces hemilipodes forment le sous-genre des Cyames proprement dits. (Cyamus, Latr.—Laronde, Leach.)"

"J'en ai vu trois espèces, qui vivent toutes sur des cétacés, et dont la plus connue, le Cyamus de la baleine (Onicesus CETI, Lin.; Pall., Spicil. zool., fasc. IX, iv, 14; Sylphie de la baleine, Deg.Ér., Ins., VII, 6, vi; Pyoanogonus CETI, Fab.; Savig., Mém. sur les anim. sans vert., fasc. 1, v, 1.) se trouve aussi sur le maquereau; les pêcheurs l'ont désigné sous le nom de Pou de baleine. Une autre espèce, très analogue, a été rapportée par feu Delhalde de son voyage au cap de Bonne Espérance. La troisième, beaucoup plus petite, se trouve sur des cétacés des mers des Indes orientales."

1829. Müller, Johannes, born 1801, died 1858 (Hagen).

In this letter to the editors Müller criticises Straus-Durckheim's views on the eyes of insects, and Straus-Durckheim replies to him at p. 463 of the same volume. Müller refers to Straus-Durckheim's description of the eye of Daphnia, and adds "c'est la même structure que j'ai observée moi-même dans les Monoculus apus, Gammara pulex et Cyamus CETI," and in a note to this passage he says, "Voyez mon second Mémoire sur la structure des yeux chez les insectes et les crustacés.—Méckel's, Archiv für Anatomie und Physiologie. 1829. H. i."

1829. Straus-Durckheim, H. E.

This author considers that the Amphipods are distinguished from the Isopods, because "in the Amphipods the mandibles are palpiferous; the front pairs of feet are directed forwards, and the hinder backwards; the abdomen, generally flexed underneath, carries several pairs of broad false feet, like those of the Decapoda macrona, and the last which corresponds to the lateral appendages of the hinder segment in many Isopods, generally preserves the form of the other false feet, and is not enlarged into swimmers. The most obvious characters to distinguish the two orders are the presence or absence of the mandibular palp, that presented by the branchie, and that offered by the form and arrangement of the abdomen," Hiella he regards as a link between the two orders. He recognises its affinities with Themisto, Phronima, Hyperia, but is led away from perceiving its identity with the last by the inaccuracy of Latreille's definition. The genus Hiella is characterised as follows:—

"Tête hémisphérique, quatre antennes courtes en âline de quatre articles; bouche saillante, composée d'un labre, d'une paire de mandibules, de deux paires de mâchoires et d'une lèvre inférieure terminée par deux lobules; le trou et l'abdomen chacun de sept segments mobiles; sept paires de pates ambulatoires, dont quatre dirigées en avant et trois en arrière; une paire de fausses pates à chaque segment abdominal." The type species, "Hiella Orbignyi," from near Rochelle, does not appear to be mentioned in the Brit. Mus. Catalogue. Milne-Edwards, 1840, regards it as a synonym of his Hyperia latreilii, and both are by Bouck..."
made synonyms of *Hyperia medusarum*, Müller. Strasen-Durckheim gives elaborate descriptions and figures of the structure, nervous system, etc. For the six joints of the leg he uses the terms hanche, trochanter, cutisse, jambe, tarse and crochet.

1830. *Bosc, L. A. G.*

The Amphipoda are in the second volume of this little work, which, when completely out of date, was refurbished in a confused manner, probably to suit some publisher’s purpose rather than the cause of science. The Amphipoda are included in the numbered genera, XLVI. *Corophium*, Latr. XLVII. *Talitrus*, Latr. XLVIII. *Gammarus*, Fabr. XLIX. *Phronima*, Latr. L. *Cymus*, Latr. LI. *Caprella*, Lam. LII. *Leptonera*, Latr. LVII. *Typhis*, Latreille. At p. 106 Leach’s genera “*Pherusa*, *Merus*, *Melita*, *Leucothoe*, *Decamine*, *Aigles*, *Amphitheo*, etc.” are mentioned as “genres que nous n’adoptons pas.” Sixteen species are assigned to *Gammarus*, which include *longicornis*, *gibbosus*, “*Esca*,” “*Pherusa*,” “*Medusarum*” and “*Homari.*” *Corophium longicorne* had been given in advance. *Cymus cettii* “se trouve dans la mer du Nord, non seulement sur les baleines, mais encore sur les maquereaux et autres seombres.”

At p. 326, Eschscholtz says that while detained in the Baltic they were enabled to use their deep fishing-nets upon the great banks. These brought to light a considerable number of marine animals. Upon the branches of the *Spongia dichotoma* sat swarms of Star-fishes and Crustacea, the latter including *Caprella scolopendroides*, Lam.

The Crustacea are here divided into eleven orders, of which the seventh, eighth and ninth are the Isopodes, Isopodes and Amphipodes. Milne-Edwards feels bound to observe that at first he had placed the genera *Rhoea* and *Tanaids* among the Amphipods, but by Latreille’s advice had transferred them to the Isopodes, being thus enabled to assign more definite characters to these orders, without making them less natural. Some authors think that he was in this respect ill-advised, and that he would have done better to follow his own judgment.

The Amphipods he divides into two families, the *Crevettines* and the *Hyperines*. When he says that the Crevettines are never parasitic, he is naturally passing no judgment on the habits of *Guerina* and *Lophidium* or other later discoveries, and the relation of *Isca montagni* to *Maia spinicalo* seems to be only residential, not parasitic.
The Crevettines he subdivides into the tribe of the Santeurs and the tribe of the Marcheurs.

In the former he includes the following genera, the first two as arénicoles, the remainder as aquatiques:—

1. Orchestia, Leach, to which he transfers Talitrus longicornis, Say. He here describes Orchestia Fischeri, Milne-Edwards, with a reference to "Mém. de la Soc. d'Hist. nat. de Paris" t. 5, pl. 25, fig. 14. This species Spence Bate refers to Orchestidea.

2. Talitrus, Latr., including Talitrus Beauconcitii, n. s., which Spence Bate thinks is probably the female of Orchestia littorea, with Klein's Saltator and Audouin's O. Cloquetii.

3. Lysianassa, n. g., thus described:—"Les Crevettines, que nous plaçons dans cette nouvelle division générique, se rapprochent des Talitrès par la structure de leurs pattes, dont aucune n'est préhensile; celles de la première paire sont assez fortes, presque cylindriques dans toute leur longueur et terminées par un article court et presque inmobile. La forme des divers appendices de la bouche est au contraire la même que dans les Crevettes et les autres genres de la subdivision des Aquatiques; les antennes sont quelquefois très-courtes, mais les supérieures sont toujours au moins aussi longues que le pédoncule des inférieures et se terminent par deux tigelles annulées." He describes and figures "Lysianassa Costei," n. s., pl. 10, fig. 17, and gives brief notes upon "L. Chausica," n. s., which he afterwards transferred to a new genus Albrotes.

4. Gammarus, Fabr. in which he describes and figures Gammarus ornatus, n. s., pl. 10, figs. 1-8, in his account of this species calling attention to what he then thought a unique phenomenon, the calcoli, as they were afterwards called, on the flagella of the lower antenna, "une petite cupule membraneuse, transparente, invisible à l'œil nu, légèrement citée sur les bords, fixée à l'antenne par sa base et entourée de quelques poils (pl. 10. fig. 2, b);" he describes "Gammarus Olivieri," n. s., pl. 10, figs. 9, 10, which by both Sp. Bate and Boeck is referred to Gammarus marinus, Leach; he describes and figures "Gammarus Othonis," pl. 10, figs. 11-13 which by Bate is referred to Megamurus, by Boeck to Mura, longimarus, Leach; he gives brief distinguishing marks for Gammarus atlanticus, n. s., which he afterwards described as Lysianassa atlantica; "Gammarus Impostii," n. s. = Mura grossimarmus, Montagu (according to Spence Bate in the British Museum Catalogue of Amphipodous Crustacea); "Gammarus Dugesi," n. s. = Molita palma, Montagu; Gammarus podager, n. s. = Molita podager (B. M. C.); "Gammarus Savii," n. s. = Mura Savii (B. M. C.), but a doubtful species; Gammarus brevicaudalis, n. s. afterwards corrected into Gammarus brevicaudatus = Gammaricella brevicaudata (B. M. C.). As "Espèces douteuses" he gives 1. Oniscus arenarius, O. Fabr., referring to it Gammarus Homari, Fabr., and Strom's Marfie; 2. Oniscus abyssinus, O. Fabr.; 3. Gammarus marinus, Risso, and Gammarus palustris Montagu.

5. Amphithoe, Leach, in which he describes and figures Amphithoe costata, n. s., pl. 10, figs. 14-16, a species transferred by Spence Bate to the genus Pherusa of Leach, with a note of Milne-Edwards' error in attributing four joints to the mandibular-pulp in the text, though he correctly figures only three; he gives very concisely distinguishing marks for "Amphithoe Maricosis," n. s. = Dexamene spinosa, Montagu (B. M. C.); "Amphithoe Jurinei," n. s. = Pherusa facelota, Leach (B. M. C.); "Amphithoe Pausilippe," n. s., which he afterwards called Amphithoe Pausilipi; "Amphithoe Inda," n. s., afterwards called "Amphithoe Indica," and said to be very near the preceding species; "Amphithoe Reynaudi," n. s.; Amphithoe armorica, n. s., which "appears to belong to the genus Nicae," according to the B. M. C., p. 243, note; "Amphithoe Scamanderani," n. s., afterwards called Amphithoe Scamanderani = Athlus Scamanderani (B. M. C.); Amphithoe pelagica, n. s.; "Amphithoe Precostii," n. s., on which see below.

6. Issa, n. g., thus described:—"Dans le genre Issa, la forme générale du corps est la même que chez les Crevettes; les antennes supérieures se terminent aussi par deux appendices annulées;
THE VOYAGE OF H.M.S. CHALLENGER.

mais, au lieu de n’avoir que les pattes des deux premières paires préhensiles, ces Crustacés les ont toutes terminées par une griffe mobile qui se repose sur le bord de l’article précédent." The type species "Isaak Montaguï" is given without further description.

7. Leucothoe, Leach.

In the tribe of the Marcheurs are included 1. Eriothionus, n. g., thus described: — "Les Crevettes appartenant à ce genre nouveau ont beaucoup d’analogie avec les Leucothoes, dont elles diffèrent principalement par l’état rudimentaire des pièces épimétriennes des premiers segments thématiques. Les antennes supérieures sont simples et à peu près de la longueur des inférieures; les pattes de la seconde paire sont terminées par une main très-grosse formée par l’antépénultième article, et présentent en avant un prolongement sur lequel s’appuie la griffe qui est composée elle-même des deux derniers articles." This genus has been by some authors made the synonym of Cerapus, Say, but is now again separated from it.

Of his type species, Eriothionus deriforous, Milne-Edwards says only "point de prolongement spiriforme [spinoïforme] sur l’antépénultième article des pattes antérieures." 2. Atplus, Leach, probably placed in this inappropriate position through insufficient knowledge; 3. Uncola, Say; 4. Cerapus, Say; 5. Podocorna, Leach; 6. "Corophia, Lat.r.," in which to "C. longicorne Latr." is added a new species "C. Bonelli," only distinguished by the words "troisième article des antennes inférieures dépourvu de dents à son bord inférieur," to which in the Hist. nat. des Crustacés is added the further mark of "deux grandes épines au bord inférieur de l’article basilaire des antennes supérieures." Bock makes the species a doubtful synonym of Corophium crossticorne, Brunelles; G. O. Sars says it is easily distinguished from that species by the rounded side-lobes of the head and the far weaker structure of the lower antennae in both sexes (Ovensigt, p. 112, 1882).

The family of the Hypéries is divided into eleven genera: — 1. Vibilia, n. g. thus defined: "Corps grêle et allongé comme chez les Crevettes de la seconde tribu; tête petite et tronquée en avant; antennes supérieures grosses, courtes, non subalcalées et arrondies au bout; celles de la seconde paire, courtes et styliformes; thorax divisé en sept segments; pattes de la deuxième paire terminées par une petite main imparfaite de didactyle, dont le doigt mobile est formé par les deux derniers articles; pattes de la septième paire très-courtes, mais de même forme que les précédentes." The type species "Vibilia Peroni" is not further described. Latreille, in his Report upon this paper, supposes Vibilia to be a synonym of his own Dactylocera, but that genus, as Milne-Edwards points out in a note, corresponds only with Risso’s Phorone semilunata.

2. Hyperia, Lat., which Milne-Edwards thinks identical with Lanceola, Say. Sp. Late makes Lanceola = Vibilia, but he also drops the name on account of the obscurity of Say’s description, and Bovalius, 1866, vindicates the distinctness of Lanceola from both Hyperia and Vibilia. To Hyperia are here assigned "Hyperia Latreillii," n. s., pl. 11, figs. 1–7, Talitrus cyaneus, Sabine, both synonyms of Hyperia melbourni, O. F. M., Lanceola pelagiæ, Say, which is out of place, and Hyperia cornigeræ, n. s., later placed by Milne-Edwards in his new genus Tyro.

3. Phorone, n. g., thus described: — "Dans cette petite division générique de la famille des Hypéries, les antennes inférieures sont tont-à-fait rudimentaires; la tête est très-grosse; le second segment du thorax est notablement plus développé qu’aucun des autres; aucune des pattes n’est préhensile, ni terminée par une main; celles des quatre premières paires sont courtes; les cinquièmes sont très-longues, mais filiformes, et ne peuvent guère servir à la locomotion; celles de la sixième paire, encore plus longues, sont, au contraire, très-fortes; enfin celles de la dernière paire sont rudimentaires; la structure de l’abdomen est la même que dans le genre Hyperia." The type species is Phorone rayantelli, n. s.

4. Lestrogynes, n. g., thus described: — "Tête très-grosse et ronde; premier segment du thorax rudimentaire; abdomen plus grand que le thorax; antennes à peu près de même longueur,
REPORT ON THE AMPHIPODA.

143
cylindrique." Of quatrième Cancer genre la enfin a thus Phronima, sometimes Thieinido, les ce celles plupart though only Montagu les abdomen a genre différent s., lancéole Legfru/orms doigt antennes Dadylocera, pattes The g., Fabricius.

5. Diatra, n. g., thus described:—"Tête grosse et renflée; antennes styliformes et rudimentaires; thorax conique, très-étroit postérieurement et ayant le premier segment très-court; pattes des deux premières paires portant une main imperfectement didactyle, dont le doigt mobile est formé par les deux derniers articles; abdomen comme dans le genre Hypéric." Type species "Dutra Gaberti," n. s., described subsequently in the Hist. nat. des Crustacés. By many authors the genus Lestrigonus is considered to represent only the male forms of Hypéric, Latr.

6. Theneisto, Guérin.

7. Dactylocera, Latr., which Latreille, as already mentioned, supposed to be the same as Vibilia, Milne-Edwards, but which Milne-Edwards, probably against his better judgment and merely out of respect to Latreille, introduces here with the synonym "Phrosina? Risso." He assigns to it only the species "Dactylocera Nicteusus," n. s., with the synonym "Phrosina semilunata? Risso." In 1840 he called the species "Phrosina Neotensis," and distinguished it, though perhaps needlessly, from Phrosina semilunata, Risso, on the authority of Costa's figures of the latter species in the Fauna del regno di Napoli, pl. 4, figs. 1–5.

8. Anchylomena, n. g., thus described:—"Forme générale du corps la même que dans le genre précédent; antennes très-courtes et styliformes ou nulles; thorax divisé en six segments; pattes des deux premières paires terminées par un article aplati et lancéolé; celles de la troisième et de la quatrième paires terminées par une petite main formée par le troisième article; pattes de la cinquième paire grosses et subcylindriques; enfin celles des deux dernières paires terminées par une tige grêle et cylindrique." Two new species, Anchylomena Blecosellis and Anchylomena Hunterii, are assigned to this genus.

10. Typhis, Risso, to which he assigns Typhis fusus, n. s., pl. 11, fig. 8–18, and Typhis rapax, n. s. Of Typhis fusus Claus says that it is clear Milne-Edwards only knew the male of a species probably belonging to the genus Lemiophylus, Claus. Typhis rapax, Claus considers to belong to a different genus, perhaps that which he calls Schizocerus in his family Schelinus. An "espèces douteuses" Milne-Edwards places under this genus, Typhis ovalis, Risso; Gammarus monocalidens? Montagu; Cancer angulata? Philp; and Gammarus gibbosus? Fabrictius.

11. Oxycephalus, n. g., thus described:—"Ces Amphipodes s'éloignent de la plupart des Hypérines par la forme grêle et allongée de leur corps, par leur tête aplatie et lancéolée, etc. Les antennes sont semblables à celles des Typhis; les pattes des deux premières paires sont terminées par une main didactyle bien formée; les autres sont grêles, cylindriques et non préhensiles; celles de la septième paire sont très-courtes. La disposition de l'abdomen et de ses appendices est assez semblable à ce qui existe chez les Hypérines," with the type species Oxycephalus pescatorius, n. s., a name afterwards changed to Oxycephalus piscator. Among genera incerta solis he mentions Helle, Straus, as no doubt belonging to Hypervia, Lepidactylos, Say, as seeming to come among the Hypervia, Pterygocera, Latreille, Spercheina and Lepturus, Kaffinske, on which he ventures no opinion, Aegyptia, as probably near to Tanais, in the Order of the Isopoda, Family Idoteidae, and lastly Ione, Anconus and Prona as certainly belonging not to the Amphipoda but to the Isopoda.
In the Hist. nat. des Crustacés, Milne-Edwards gives a description of his "Amphithoe Prevostii," differing very little from his account of Amphithoe pontica, as he calls the Hyale pontica of Rathke. Rathke, in his Norwegian Fauna, p. 81, names a species, "Amphithoe Prevostii, M. Edwards?," which he thought had no telson, and was thereby distinguished from his own Crimean species Hyale pontica. But the want of a telson in such an Amphipod is obviously only an accidental defect. Rathke subsequently, p. 264e, without giving any reasons, makes his Norwegian specimen a separate species as "Amphithoe Nilssonii." This species Spence Bate in the British Museum Catalogue, p. 38, accepts under the name "Allorchestes Nilssonii," with references to Rathke, while Amphithoe Prevostii, Milne-Edwards, is made a synonym of Nissa prevostii, at p. 53. Milne-Edwards' species will stand as Hyale prevostii whether Hyale nilssonii be a synonym of it or not. Hyale pontica is a distinct species.

1831. LATREILLE, P. A.

The class of Crustacea is discussed from p. 311 to p. 469. The Lemocipoda are here the third order, without alteration within the order itself. The genus Nemprædes, Latreille, evidently founded on an imperfect specimen of a Proto, is still retained.

The Amphipoda are here the fourth order. "Envisagés sous la considération des habitudes," he says, "les amphipodes peuvent être partagés en trois sections, les sauteurs, les marcheurs et les parasites. Les premiers composeront la famille des crevettes, les seconds celle des podocérades, et la dernière celle des hyphères de M. Milne-Edwards. Les deux premières, composées d'amphipodes ornans ou vagabonds, se distinguent de celle-ci par les caractères suivants: pieds-mâchoires (ceux de la première paire, et présentant l'apparence d'une lèvre inférieure recouvrant les autres parties de la bouche) plurarticulés, et réunis seulement à leur naissance; deux paires de lobes triangulaires, et dont les deux supérieurs plus grands, mais n'atteignant pas l'extremité de ces organes dans leur entrelacs, et annexés à leur côté interne."

In the first family, Crevettes (Gammarins), while waiting for the new distribution by Milne-Edwards, Latreille forms two sections, one containing Leucothoe (leucothea) Leach; the other containing Crevette (gammarus); Phéruse (pheresa), Leach, (including in this latter genus "plusieurs autres de ce naturaliste, tels que d'amphithoe, de nova, melita et doceamine"); Talitre (taliurus), and Orchestie (orchestia).

In the second family, Podocérèdes (Podocerides), he mentions Corophium, with M. d'Orbigny's account of its habits, Podocerus, Jassa, Cerapus, Atylus.

In his account of the third family, Hypérines (Hypérins), he alludes to the genera "teatrion et duvier de M. Edwards." He also says, "Le genre Dactylocère (dactylocera, Lutr; vililia, Enw.) se distingue de tous les suivants par plusieurs caractères. La tête est de grosseur ordinaire ou moyenne. Au-devant de la fausse lèvre inférieure, à l'origine des loches latéraux, est de chaque côté un petit corps palpiforme; les antennes supérieures sont très courtes et terminées par un grand article lamelliforme. M. Edwards exposera les autres caractères de ce genre dans sa Monographie des amphipodes: j'y rapporterai la phrose en croissant de MM. Risso et Desmarest." He then gives an account of Tiphis, Pheroëna, Themisto, in regard to the latter explaining the origin of his term decapodes. The first four feet being small and closely applied to the mouth, he regarded them rather as mouth-organs than as legs in Themisto, in his own genus Hypérin, and in that which in the new edition of Cuvier's Règne animal, he had called Pheroëna, with phrose croissant of
1832. Cocco, Anastasio.

In the letter he makes mention of *Ischyrocheles Leachi*, *Chiroptis lithorea*, *Charybdis zanclea*, and various other Crustacea. He gives a long description of a Decapod which he names *Acheta arachnoidea*, and then continues as follows:—

"Agli schiropodi crioftalmi, ed a que' soprattutto, che a cagione del loro capo sprovveduto di antenne direi giuncocefali, spetta un nuovo genere di crustacei, che vo appellare dal nome del primo fondatore di Messina Orione.

"O. Becco d'uccello. O. Ornithorhampus fig. 2."

![Diagram of crustacean](image)

"Trovasi in sulle spiagge di Messina balzato dalle onde in marzo, di unita alle fremine, alla fressine, al mio Chiroptis, ed alla mia Charadstylis Zanclea. Ho voluto cambiare quest'"
ULTIMO GENERE IN QUELLO DI ORIO; PERCIOCHÉ MI SONO ACCORTO, AVERE IL CH. RAPHINESQUE APPELLATO CARIDDI UNI DEI CRUSTACEI MACROGASTERI PODOFAELMI.—TERRÀ ELLA ADUNQUE L'ORIO ZANCLEUS COME SINONIMO DELLA CHARYBIDES ZANCLEUS, IL QUALE DIFFERISCE ASSAI DALL'ORIO ORTHO-CHAMAENAS PER AVER QUELLO IL CAPO CORTO, OTTUNO, GLI OCCHI GRANDI, SEMILUNATI, IL CORPO CONICO, ED IL COLORITO CINEREO PUNTEGGIATO DI FOSCO. DIVERSO È ANCHE L'ORNITOMANO DA UN ALTRO ORIO, CHE IL MIO DISCEPULO NICOLÒ PRESTANEDREA DESCRIVERÀ, APPELLANDOLO O. OXYRHINGUS; CONCOSIÉCHE SI QUESTO PIÙ PICCOLO, ALQUANTO COMPRIMO, DI COLOR ROSSO, ED ABBA IL CAPO ASSAI SOTTILEMENTE ALLUNGATO.

"Vado finalmente a descrivere un piccolo crustaceo alla stessa sezione pertinente, che per aver il capo fornito di antenne, potrebbe con molti altri costituire la divisione della Cheratocephali, e piccini appellarlo.

**B. Zannara. B. Culicina Fig. 3.**

Il corpo di questo piccolo crustaceo è cristallino, molle, sparso di pochi e minuti punti ranci, lungo cinque linee, largo una. Ha il capo turgido più o meno di lati, reticolato, proboscide; la fronte piena; gli occhi sessili, rotondi, ranci, con due punti laterali dello stesso colore. Le antenne superiori poste tramezzo agli occhi sono capillari, lunghe tre linee sostenute da peduncoli grossi, lunghe una linea e mezza, composti di due articoli: il basale piccolo, rotondato, e l'estremo cilindrico, tre volte più lungo. Le antenne inferiori parimenti capillari, quasi eguali alle superiori, comprii i peduncoli di queste, sono sostenute da corti peduncoli tri-articolati. Il corsetto si compone di sei segmenti, l'anteriore del quali è strettissimo; l'abdomine di cinque è più larghi. Il primo e secondo pezzi d'occhi sono lunghi, assai sottili, e tunti in verso l'apice del ranci. Il terzo pezzo è più forte, ed ha una mano più o meno rigonfiata col dito anteriore corto, semplice, immobile, ed il terziore grande, incurvo, acuto, mobile. La mano inoltre è sparsa di minuziosi punti ranci, visibili col soccorso della lente, ed ha, come il capo e l'avambraccio, il margine anteriore destellato; il brecchio poi, ch'è dilatato all'apice, ha nella parte anteriore di esso una piccola punta. Le due pae di pezzi posteriori sono semplici con alla base una squama ovale-oblunga. La coda si termina con una piccola squama ottusa, puntigliata di ranci, e porta da ogni lato tre stili bifidi.

"Questo crustaceo, che come i precedenti viene in marzo balzato dalle onde in sulla spiaggia, a dirlo vero, mi f'è restare gran pezza in forse se dovessi farne d'esso un nuovo genero, ovvero una delle frimine riputarlo. Grandemente diffusi le si assomiglia; ma il numero delle antenne, e la loro costruzione me lo fanno bastamente distinguere. Ho voluto poi intitolarlo al mio compatriota barone A. Bivona Bernardi, com' ella sa, delle cose naturali della Sicilia illustratore amplissimo."

In the "Spiegazione della Tavola," he gives:—

**Fig. 2. Orione becco d'uccello.** (a) Capo di esso ingrandito che presenta la parte di sotto. (a2 a2) Piani muscolari esterni. (b) Coda con gli steli intransiti [ingrandita].

**Fig. 3. Bivonia zannara.** (a) Suo lunghezza naturale.

Coco's genus *Orso* is evidently synonymous in part with *Oxycephalus*, Milne-Edwards, 1830; while his *Orso zancleus* coincides generically with *Eupronoe*, Claus, 1879; and his genus *Bivonia* clearly belongs to the Phronimide, which will be discussed later on in this Report. Milne-Edwards, Hist. des Crust., vol. iii. p. 98, supposes that Cocco's *Orso* may be the same as Risso's *Typhis*, an opinion rejected by de Natale. See note on that writer, 1850.
1832. Guérin, F. E.

The general introduction to this part says, "Aucune classe d’articulés ne prouve mieux que celle des Crustacés combien la Morée est quelquefois pauvre en objets nouveaux." On pages 44—46 Guérin gives the Amphipoda numbered as follows:—"47 Talitrus saltator, Miln.-Edw.," "48 Orchestia Fischeri, Miln.-Edw."

"49 Talitrus platycheles Guér.—Corps compresso, glaberrimo; pedibus pare primo secundoque equilibus.—Long. 2 centim. (Voyez notre pl. XXVII.)

"Cette espèce remarquable pourrait à la rigueur constituer un nouveau genre, qu’on devrait placer entre les Talitres et les Orchesties, si on prenait pour caractères génériques l’organisation des deux premières paires de pattes; en effet, chez les deux genres que nous citons, les quatre premiers pieds sont terminés par un ongle crochu et pointu, tandis que dans notre espèce les seconds pieds n’ont plus d’ongles à l’extrémité; ils sont d’une consistance membraneuse, très-plats, transparents, et dépourvus des épines qu’on observe aux autres pieds; nous n’avons cependant pas cru devoir faire un nouveau genre pour ce petit amphipode, nous le plaçons parmi les Talitres, et nous établirons pour lui une petite division, à l’exemple de M. Milne-Edwards (Ann. des sc. nat., t. 20, p. 364.), ce qui apportera une légère modification dans le tableau que ce naturaliste donne des espèces du genre Talitre; voici ce tableau modifié:

"A. Pattes de la première paire beaucoup plus grandes que celles de la seconde. T. locusta

(Voyez notre pl. XXVII. fig. 4c.), Bancovitréi.

"B. Pattes des première et seconde paires égales entre elles. T. platycheles.

"C. Pattes de la première paire beaucoup moins grandes que celles de la seconde paire. T. Cloqueti. (Voyez notre pl. XXVII. fig. 4f.).

"On voit par ce tableau que notre Talitre est très-facile à distinguer des autres espèces connues; ses antennes sont plus courtes, proportion gardée, que celles du T. locuste; ses premières pattes sont fortes, à articles cylindriques, et terminées par un crochet simple, qui ne peut se replier en dessous. Les secondes sont de la même longueur, membraneuses et transparentes, avec leurs deux derniers articles presque égaux, aplatis, de forme ovale allongée; le dernier ne nous a pas offert de crochet terminal, quoique nous l’ayons placé sous une très-forte loupe. Les pattes de la troisième paire sont de forme ordinaire, plus longues de moitié que celles qui précèdent. Celles de la quatrième paire ont à peu près la longueur des deux premières. Les suivantes sont encore plus courtes, robustes, garnies d’épines; enfin les deux dernières paires sont les plus longues et dépassent notablement celles de la troisième paire.

"Hab. Cette espèce a été trouvée à Modon; nous l’avons aussi reçue du golfe de Gênes, et des mers de la Corse.

"50 Gammarus peloponnesius Guérin.—Antennis inaequalibus, posticis cupulis instructis; pedibus quatuor antecis subaequalibus, subdehiscentibus, ceteris longioribus, equilibus.—Long. 13—16 millim."

"51 Gammarus locusta Leach." This is followed by the Leomodipodes, represented by "52 Cappella lobata—Squilla lobata, Müller."

In the account of Gammarus peloponnesius, he criticises Milne-Edwards’ division of the genus Gammarus, "car la Crevette des ruisseaux (G. fluviatilis), qu’il place dans la division où
THE VOYAGE OF H.M.S. CHALLENGER.

le cinquième anneau de l'abdomen doit être lisse, a cependant ce segment garni d'un faisceau d'épines ou de poils raides, comme sa Crevette ornée et comme notre Crevette de Morée; en sorte que ces espèces doivent être placées, de moins quant à ce caractère, dans la même division." He then proceeds to call attention to the appendages of the antennae since called calceoli, which his species has in common with *Gammarus ornatus*. The characters by which he distinguishes the new species are in fact only the comparative shortness of its upper antennae and magnitude of its first gnathopods.

In the Brit. Mus. Catal., Spence Bate comments on the fact that Guérin has figured the mandible of *Talitrus platycheles*, with a very minute appendage (see Note on Atlas to this work, under date 1835). "This is a feature," Sp. Bate says, "that is absent not only from the genus, but from the whole tribe of *Saltatoria*." It will be remembered, however, that Savigny has likewise figured such an appendage for the mandible of *Orchestia montagui*. In the Iconographie des Crustacés Guérin appears to have used Savigny's figure of this mandible, and therefore his testimony is perhaps not independent.

1832. Schlotheim.

In this reprint at page 22 is mentioned in the description of Tab. xxii., "Fig. 8. a. b. *Trilobites problematicus*. Aus den jüngern Schichten des zur Kupferschiefereformation gehörigen Kalksteins bei Glücksdamm." The original figures are reproduced on the plate named.

1832. Zenker, Jonathan Carl.

Zenker believes that Degeer "(quem vulgo De Geer falso scribunt)" Gruiithuisen, Mayer, Wagner (*Locis, 1832, iii*), had observed the circulation of the blood in *Gammarus pulex* before him.

His section prior on the natural history of *G. pulex*, Fabr., begins with a "Conspectus generum praecipuorum familiae Squillarum, cui Gammarus unter adhuc meros est." Thus:—

"A. Anteóne quatuor

"a) antennae inferiores hand in pedis modum effectae, plurias articulatae.

"aa) antennae superiores inferiores subequales.

"1. Pollices manus in dictarum anteriorum 2-articulati:
   *Cerataspis et Lewithöe*.

"2. Pollices manus in anteriorum 1-articulati:
   *Melita, Erichius, Squilla, Phasmatocarcinus, Amphithoe, Dexamene, Gammarus et Phorusa*.

"bb) antennae superiores inferioribus breviorenes;

*Orchestia, Talitrus et Atylus*.

"b) antennae inferiores magne pedum instar efformatae (pedate), vix 4-articulatae:

*Corophium, Podocerus et Jassa*.

"B. Anteóne dve; *Phronima*."
He observes that many of the little animals belonging to this family are phosphorescent, as the Phasmatoecarini and perhaps the Amblyrhynchi, Erythrocephali, Acanthocephali, &c.
Under the heading Systematica, Synonymatea et Diagnostics he gives:—
3. Familia: Amphipoda Cuv.; Anthocephala Dancer; Squillares Goldf.; Gammarinae
   (Cervettes) Lettay; Squilla Zenk.
For the synonyma he refers to Gmeeen Zooph., no. 399. Lewekfeldt theor. Siles. p. 557.
He quotes the diagnosis generis Gammarus of Fabricius, 1778, Leach (Lin. Transact. xi. 2, 1819), Oken (Naturg. f. Schuleu, p. 735), Cuvier le règne anim.; trans. by Schinz), and his own "Antenne: quattuor, antice (inferiores) breviorae, postice (superiores) longiorae cum ramos parvo accessorio, uraeae articulatae. Zenk.," in which it will be observed that, like Fabreius, he applies the terms antice and postice to the lower and upper antenne respectively (see Note on J. C. Fabreius, 1798). He criticizes with some justice the earlier diagnoses, and gives a brief account of the distinctions between those genera in his Comceptus which he considers to come nearest to Gammarus. He then gives the diagnosis of the species "G. Pulex Fabr." by Linne, Scopoli, Fabricius, Oken, Cuvier, Leach, winding up with his own, in which he distinguishes two varieties, a) longicaudatus, β) brevicaudatus.
In the description he applies the term femur (in preference to corn) to the first joint of the leg. Of the six free joints he calls the first tibia, the second tarsus, the three following metatarsus, the last of these being terminated by an unguis.

The second section is on the Sanguinis circuitus, as to which his conclusions are not entirely in agreement with modern investigation. He sums up the results of his paper as follows:—
1. For the numerical law in all the external parts of Gammarus Pulex, the ternary arrangement is found to be the predominant, the quinary the subordinate. [See p. 13. Totius corporis annulii 3. 5 = 15. a) caput cum collo 3. b) pustus 3. c) abdomen superius 3. d) abdomen inferius 3. e) canas 3. &c. &c.] 2. The creature has three species of parasites, two internal, in the blood, orange-coloured, surprisingly large in proportion to their host, and one external, mouse-like, almost microscopic. 3. The dorsal vessel is rather to be compared with the swim-bladder of fishes than with a heart. 4. There are no special blood-vessels, but the blood flows freely round all the organs in the cavity of the trunk. 5. The globules of the blood are not animat (and therefore are not to be compared with monads). The last statement is in opposition to Mayer, Suppl. zur Lehre vom Kreislauf, 1827, some of whose statements he quotes with derision.

1833. Bouchard-Chanterdeaux.

Catalogue des Crustacés observés jusqu'à ce jour à l'état vivant dans le Boulonnais. (Soc. d'Agric., du Comm., et des Arts, de Boulogne-sur-mer, années 1831 et 1832. Boulogne, 1833.)

1833. COCCO, ANASTASIO.

At page 113 he says, "È da grandissimo tempo che mi è noto un Orione, e già appellavasi orio zancus (Ellem. n. VI. pag. 207) indicandone insin allora i principali caratteri, ché

dagli altri il distinguersi: ed ora vò qui completamente descriverlo.

"Orione Zancus Orio Zancus—Corpo conico subrotundato cinereo-reflescente, punctulis fascis

vir conspicuis adperso—Capite obtusum ocultis maximis semilunatis nigrescentibus.

"Perviene questo Orione infino alla lunghezza di otto linee, ed alla larghezza di tre: ha il corpo conico quasi rotundato cinciccio-carinico sparso in tutto di minutissimi punti bruni. Il capo aggaggiala la quarta parte o poco più dell' intiera lunghezza; è alquanto compresso, decline, ed ottuso. Gli occhi son grandissimi, bruni, semilunati, colla convesità volta in antivi. Il tomace è costruito di sette segmenti de' quali i due anteriori sono più ristrettì: sono tutti forniti nel margine inferiore d'un appendice quadrilatera cui appiccamo gli arti. L'addome ne ha cinque più larghi de'primi: di questi gli ultimi due sono più ristrettì: i margini inferiori sono rotundati, e gli angoli postico-inferiori ottusi, l'ultimo segmento e scavato sul dorso, e questo incavo prolungasi infino all'apice della squama codale—I piedi mascellari sono poco meno, o tanto lunghi che il corpo, e compongansi di quattro articiò quasi uguali—i piedi-mangi sono cortissimi, i quattro segmenti assai dilicati, le tre ultime paia hanno le cosce adhereute ad una squama: l'ultima è delle altre più piccola, ed in esso il piede è eziando cortissimo; le ugne in ciascun piede sono acutissime. I piedi natatori terminano con un appendice bi-partita. La squama codale terminale ha forma triangolare coll'apice assai acuto, e sopassa appena la lunghezza delle tre appendici styliformi bi-partite, che stanno in ogni lato della coda: quelle delle due prime paia sono ristrettì ed acutissime, e l'altre
dell'ultimo paio per alquanto rotundate terminano pure acutamente.

"Quest'Orione spondevolissimamente vien dalle onde giattito in sulla spiaggia, assieme al mio

Orio Orithoraephus ed all' O: Oxyrhynchus (Prestandrea) (1) i quali però son men comuni. ([1]) I caratteri specifici promossi dal Prestandrea alla descrizione di questo Orione non possono né punto né poco convenirgli; conciassché siano quelli stessi per me assegnati al mio genere Orio e tali quali leggansi nel nota. VI. dell'Effemeridi scientifiche, e letterarie per
della Sicilia—A far meglio adunque dovrebbero così venire indicati—Corpo compresso—

Rosso—Capite in rostrum acuminatum producto—Oculis maxillis semilunatis nigrescentibus.

N.]

"Un esame diligente de' tre orioni mi fece accorto, che i caratteri per me a questo genere

assegnati, em forza si riformassero; poiché i piedi squamigeri non al numero di due paia,

ma si di tre costantemente in quelli si rinvengono—Un buon carattere generico è pur quello
della forma del primo articolo de' piedi mascellari; perchè questo mio genere vò abbia

carattere segmenti: Orio—Capite fornicato, Pedibus maxillaris longissimis capillaris,

replicatis, capite obtectis, quattuorarticulatis, articolo basilari apice dilatato compresso. Bini

pedum articorum paribus, chelatis, brevissimis, tribus posticis basi squamā instructis.

Cauda styliformis. Effem. scient. e lett. per la Sic. Tom. VI. pag. 11."

"Fig. 3", a Orio Zancus alla grandezza naturale."  

Footnote.
1833. **Griffith, Edward, and Pidgeon, Edward.**

The Animal Kingdom arranged in conformity with its organization, by the Baron Cuvier. With supplementary additions to each order, by Edward Griffith. Volume the thirteenth. London, MDCCXXXIII. The Classes Annelida, Crustacea, and Arachnida, arranged by the Baron Cuvier, with supplementary additions to each order, by Edward Griffith, F.I.S., A.S., &c., and Edward Pidgeon Esq. London, MDCCXXXIII.

The Third Order of Crustacea, Amphipoda, and the Fourth Order, Lænomipoda, pages 204–215, are described “from the text of Latreille.” The supplement deals with these Orders on pages 315–318, but supplies no original information.

1833. **Johnston, George.**

He here figures and describes *Caprella acuminifera*, from Berwick. He remarks, “I do not know to whom the discovery of the animal just described is due; it is probably to Montagu.” In the eighth volume of this Magazine, page 670, under *Caprella acanthifera*, Leach, he gives as a synonym “Cap. acuminifera Desm., Crust., 277; Johnston, in Mag. Nat. Hist., vi. 40. fig. 7. a.” But though the *Caprella acuminifera* of Desmarest is the same as *Caprella acanthifera*, Leach, the species which Johnston names at first *acuminifera* and then *acanthifera* is, Mayer says, indubitably *Protella scabra*, Montagu.

1833. **Prestandrea, Nicolò.**

In this paper, pages 10–12, the following notices occur:

THE VOYAGE OF H.M.S. CHALLENGER.

—Torace di sette sezioni, che crescono gradualmente in lunghezza sino al quinto; il sesto, e settimo sono più stretti.—Addome di quattro anelli più stretti, ma più lunghi di quelli del torace, in guisa che l'insieme dell'animale si vede come diviso in due pezzi, cioè; il mezzo anteriore più largo, il posteriore abbracciantemente ristretto.—Sette paia di piedi propriamente detti, semplici, ganci, che conservano nella loro lunghezza l'ordine de' segmenti del torace; il quinto pajo più lungo di tutti è dentuto nel lato esterno per tutta la lunghezza del secondo articolo, che nel lato interno si prolunga oltre l'articolazione in una punta acuta.—La coda porta sei stilli molto sottili; quattro inseriti sulla stessa linea, e le altre due laterali alquanto più sotto, e sono più lunghi di quelli.

"Di questi bellissimo crustaceo, che viene dalle onde in febbraio balzato in sulla spiaggia insieme ad altri individui appartenenti al generi Phoxoena Phoxina Tiphia Philosophorum ho creduto farne un nuovo genere, perciocché la conformità del capo, il corpo trigono, le antenne esteriori forti, triangolari, ed i piedi del quinto pajo lo fanno da qualunque altro genere degli affipodi abbastanza differire.

"Ho voluto dedicarlo a dottissimo abate Cav. Domenico Scinà, qual celebre conoscitore delle scienze naturali.

"Affipodi. Orio (1) Oxyrhingus—Capite formico—Pedibus maculatibus exterioribus, longissimi, capillatis, replicatis, capite obtectis—Bisii pedum anteriorum paribus divulgatis, brevissimis, religis simpliciis; bisii posteriorum basi squama instructae—Cauda stilifera. [((1)) Questo nuovo genere di fresco stabilito per il sig. Cocco, e che nel fascicolo sotto delle Effemeride Scientifiche, e Letterarie per la Sicilia dell'anno 1832 trovasi posto, credo per errore tipografico, nell'ordine de' Schizopodi Eriothaln, devesi noverare nell'ordine degli Affipodi, come ne conviene l'asttimo Autore."

"Trovasi sulle spiagge di Messina balzato dalle onde in marzo.

"Differisce dall' Orio Orthithimnus (Cocco) per avere il corpo più piccolo, altamente compresso, di color constantemente rosso, il capo assai sottilmente allungato, gli occhi grandi, semilunati, e li stilli della coda proporzionatamente più grandi."

In the above account Ozyrhingus is apparently a misprint for Ozyrhynus, see note on Cocco, 1832. Ozyrhynus itself, we may suppose, is a malformation for oxyrhynus. The genera and species mentioned in this paper belong to the Hyperina, to be discussed in the later portion of this Report. The Orio oxyrhynus clearly belongs to the Oxycephalidae.

1834. Dewhurst.

The natural history of the order Cetacea and the oceanic inhabitants of the Arctic regions. 1834.

Lütken, 1873, quotes a passage from page 199 of this work alluding to Cunicus ceti, L., the Cyamus mysticeti, Lütken, parasitic on Balena mysticetus, being no doubt intended. From page

Footnote.
259 he quotes the observation that “the narwhal is liable to the annoyance of a similar but smaller animal,” but remarks that Dewhurst must certainly be wrong in the opinion which he expresses on the same page 259, that all species of whales are tormented by whale-lice.

The Introduction, pages i.—xxxv. is chiefly occupied with an interesting sketch of the literature of Carcinology down to the date of the work then in hand. The First Part, pages 1–200, in the first chapter, discusses the position of Crustacea in the animal kingdom, the character and various adaptations of the Crustacean integument, and its exuviation; in the second chapter, nutrition, respiration, circulation, and secretions; in the third chapter, the organs of sense, the nervous system and the muscles; in the fourth, the apparatus of reproduction and the process of development. In the Second Part, the first chapter, pages 201–236, describes the different systems and methods employed up to that date in the classification of Crustacea, concluding with that preferred by Milne-Edwards himself.

Milne-Edwards considers the normal number of segments of the Crustacean body to be twenty-one, the same segment never carrying more than one pair of limbs. Each segment he composes theoretically of two arcs, an upper one constructed out of two tergal pieces with an epineure or side-plate on either side, and a lower one constructed of two sternal pieces with an episternum on either side. He says that M. Audouin has arrived at this general principle, “que ce n'est que de l'accroissement semblable ou dissemblable des segments, de la réunion ou de la division des pièces qui les composes, du maximum de développement des uns, de l'état rudimentaire des autres, que dépendent toutes les différences qui se remarquent dans la série des animaux articulés.” After discussing the number of distinct segments in various groups of Edriocephtha, he concludes by saying, p. 22, “Enfin nous ajouterons que dans certaines espèces d'Amphipodes les deux moitiés latérales du septième annexe abdominal ne se réunissent pas sur la ligne médiane comme dans les autres segments du corps, et qu'il prends alors la forme de deux petites lames coriées ou de deux appendices styliformes, disposition très-curieuse en ce qu'elle offre un exemple frappant de la division d'un annexe en deux moitiés symétriques et latérales,” with the following note, “Cela se voit dans la Crevette d'Othon L., la Crevette loueste L, etc.; mais, dans la plupart des Amphipodes, ces rudiments des septièmes segments abdominaux manquent complètement. (Voy. Pl. I, fig. 5.),” as though he thought that the presence of a telson in the Amphipoda was the exception, whereas in the limits of this order which he accepted there is no instance of its absence which can be regarded as certain.

The appendages when fully developed, he says, present three distinct parts; the main portion, la tige, the stem which carries the other two and is almost always composed of several joints placed end to end; the second, or palp, is an appendage of the stem, on the outer side of which it almost always takes its origin, generally from the basal joint, but sometimes at the extremity of the second or third joint; the third portion, le fouet or flagellum, also arises from the stem, separating from it always above and on the outer side of the palp, p. 45. “In the natural group of the Amphipoda, the thoracic limbs almost always present in the females the maximum of composition above-mentioned; the stem serves for locomotion; the flagellum becomes membranous and serves for respiration; Lastly, the palp takes

(2001. CHALL. EXP.—PART LXVII.—1887.) XXX 20
the form of the flagellum of the maxillipeds of the crabs, and serves to retain the eggs in the thorax of the mother," p. 49.

The Crustacean mouth-opening is described, p. 61, as bounded in front by a small horny or bony plate called the labrum or upper lip, and behind by a plate, generally bifid, called the tongue, languette, but which "might better be called the lower lip." The sides of the mouth are occupied by the mandibles, "which often carry an articulated appendage, that has been called the mandibular palp, but which appears to be the continuation of the stem of the limb, and not the analogue of the part above-called the palp." After treating of the maxilla and maxillipeds, he comes to the Canal digestif, which runs from the mouth to the anus, which is always in the terminal segment. This canal is composed of three parts, the esophagus, stomach and intestine. In the Edriophthalma he observes that the stomach is constructed on essentially the same lines as in the Podophthalma. He notes, p. 72, that in Orchestia "there exist in the anterior part of the stomach, near its esophageal opening, two little ciliated teeth." These are the structures for which in this Report the expression triturating organs has been adopted. On page 80 he remarks that "in the Amphipoda and Lernaeopoda it is the flagella (les foncets) of the thoracic limbs that appear specially assigned to the exercise of the respiratory functions; these organs, from eight to twelve in number, take the form of large membranous vesicles suspended below the thorax between the ambulatory feet, and a current of water set in motion by the natatory feet of the abdomen continually bathes them."

In describing the antenna of Crustacea, p. 111, he says that the tige or stem is composed in general of a stouter part called the peduncle, with one, two, or three joints, and a more or less elongate terminal portion, many jointed, which he calls "tige terminale." The "palp" takes the form either of a second terminal multiarticulate lash, fixed at the extremity of the peduncle, or of a large horny plate inserted at the base of the antenna, while the remaining accessory portion, when present, also constitutes a terminal lash (un filet terminal).

He notices, p. 113, that the Crustacea known under "le nom de Talitres ou de Puces de mer" must have the sense of smell, as they gather round decaying food after it has been buried. On p. 116 he gives the following account of the eyes as examined in "Amphitoe Procustii" and a few other Edriophthalma; "chez ces animaux on trouve d'abord pour chaque œil composé une cornée lisse sans division; mais immédiatement derrière cette lame tégumentaire il existe une seconde tunique, de même nature et également transparente, qui y adhère intiment, et qui est divisée en une multitude de facettes hexagonales; derrière chacune de ces facettes ou cornéules est situé, comme d'ordinaire, un cristallin dont la face antérieure est convexe et dont la face postérieure, qui se prolonge en un cône à sommet obtus, est contiguë à un petit cylindre gelatineux, avec lequel le filet correspondant du nerf optique se confond." On p. 121 he says that in Cyamus there are two smooth eyes and two compound facetted eyes, as to which see Note on Savigny, 1816. He repeats the account of the nerve-system of Talitrus from a paper by Audouin and himself read in 1828, and at page 147 he says that, combining Rathke's observations with theirs, "on peut conclure que le système nerveux des Crustacés se compose toujours de noyaux médullaires dont le nombre normal est égal à celui des membres, et que toutes les modifications qu'on y rencontre, soit à diverses époques de l'incubation, soit dans différentes espèces de la série, dépendent principalement des rapprochements plus ou moins complets de ces noyaux, agglomération qui s'opère des côtés vers la ligne médiane, en même temps que dans la direction longitudinale; mais peuvent tenir aussi en partie à un arrêt de développement dans un certain nombre de ces noyaux."

In the chapter on development it is remarked, page 199, that among the Edriophthalma the head is much larger [proportionally] in the young than in the adults, that the abdomen often shows analogous differences, and that when in the adult one of the pairs of feet exhibits some peculiarity of structure, the anomaly is either not found, or is little apparent, in the
young. It should be remembered that throughout this portion of the work the Crustacea in general are dealt with, and that therefore, when the Edriopithalmain are not being described in especial, many of the observations made are calculated to throw light upon their structure.

In the chapter on classification, after noticing earlier systems, Milne-Edwards explains his own. He prefers the zoological method which is not daunted by great differences of structure from grouping animals of high organization with others in which it may be far less complex, yet of the same general type and recalling "les états transitoires par lesquels les êtres les plus parfaits de la série ont passé pendant la durée de leur vie embryonnaire." He gives the definition of the class as follows:

"Crustacés. Animaux ayant le corps divisé en anneaux, en général très-distincts, mobiles et d'une consistance assez grande (cornés ou calcaires), sans cavité intérieure proprement dit, et portant une double série de membres, presque toujours bien distinctement articulés, et constituant des antennes, des mâchoires, etc., et des pales dont le nombre est, le plus ordinairement, de cinq ou de sept paires; le système nerveux, en général bien distinct, ganglionnaire et longitudinal; la respiration en général aquatique, et se faisant toujours à l'aide de branchies ou de la peau; la circulation, en général bien distincte; presque toujours un cœur aortique et des vaisseaux sanguins propres; les sexes séparés." p. 231.

He makes three subclasses, namely the Crustacés maxillés, Crustacés seuers, and Crustacés xiphosurien. The first of these he subdivides into various regions, the first of which, the Podolithalmain, contains two orders, the Decapods and Stomapods, while the second, the Edriopithalmae, contains three orders, the Amphipods, Isopods, and Lamipods.

It is in treating of the Decapods, p. 243, that he mentions the designations which he says are often applied to the six joints into which the ambulatory foot is commonly divided. These terms are 1. tarse, 2. trochant, 3. cuisse or bras, 4. jambe or carpe, 5. metatarse, 6. tarse or doigt. The last two of these sometimes, "disposés en manière de pince," form a hand (main).

The Atlas, plate xi. fig. 1, repeats the diagram of the nervous system of Talitrus given in the earlier work.

1834. ROUSSEL DE VAUZÉMÉ, AUGUSTUS.

The author explains that he was able to study these parasites from a great number of whales harpooned under his own eyes in the Atlantic, in the neighbourhood of Tristan da Cunha, and off the Falkland Islands. He distinguishes three species, which he thinks had been hitherto confounded by authors under the same name. Litkoh points out that all the three species are distinct from the northern Cyamus mysticeti, with which Roussel de Vauzelme supposes his Cyamus ovatus to be identical. Of this species the anatomy is very fully described. The mistakes of Savigny and Treviranus are pointed out. Among other details of his own investigations, he says, "Des perquisitions inutiles pour trouver les glandes salivaires, m'ont fait remarquer souvent dans les tuniques de l'estomac des matières blanches, friables, de forme variée, dont je n'ai pu déterminer la nature, à moins qu'elles ne soient analogues aux pièces calcaires qu'on présume servir à la réparation du test chez les crustacés." He remarks that there is "parmi les viscères une membrane diaphane, parsemée de points
noirs en relief, interposée entre le vaisseau dorsal et le tube digestif." He notices the
different authors who have written about Cyamus, and the various names and systematic
positions which have been assigned to it. He himself considers that it comes nearest to the
Isopoda, though it ought not to be united with them. He objects to the term Lomodipoda,
because the anterior feet are affixed to a special segment, not to the head or neck, as that
epithet would imply. After a definition of the genus Cyamus, he defines his three species;
1. Cyamus ovalis, of which he says, "cette espèce vit agglomérée sur les éminences cornées
de la tête des Baleines franches (Balæna mysticetus)," herein, Lütken says, going astray;
2. Cyamus erraticus, of which he says, "il vit errant, on le trouve sur la peau lisse, à la
base des tubercules cornés, sur les nageoires, principalement aux aisselles et dans les plis
des parties génitales et anales;" 3. Cyamus gracilis, of which he remarks, "il demeure avec
les Cyames ovales sur les protubérances de la tête." In a chapter on their "manners and
customs," he speaks of the prodigious quantity of the Cyamus ovalis and Cyamus gracilis
which can be seen a good way off at sea whitening the head of a whale, when it comes up
to breathe. He had reason to think that they must cause the whale no little irritation with
their sharp claws. Some care is needed in their capture, since these claws penetrate the
human finger like a needle, causing a sharp pain. Cutting the branches did not seem to
affect these animals, but when their large antennae were cut, they would sway unceasingly
about, as if they were drunk. He never found any in the stomach of the Albatrosses or
other sea-birds, which are sometimes supposed to help the whales to get rid of the parasites,
but he believed that the winter storms might be highly useful in this respect. He decisively
rejects the suggestion of MM. Andoin and Milne-Edwards that the Cyamus gracilis might
only be the young of the other species.

1835. GERVAIS.

Note sur deux espèces de Crevettes qui vivent aux environs de Paris. Annales

The Crevettes d'eau-douce, he says, have been confounded under the names Gammarus pulex,
aquaticus or fluviatilis, as forming but a single species, whereas they really form two species,
 differing not only by zoological characters, but also by their habitats. "Jamais elles ne
s'accompagnent ensemble, et l'une a sur le dessus des anneaux de l'abdomen des épines que
l'autre ne présente pas." Rösel and Geoffroy have described and figured the one, Desmarest
and Zenker have figured the other. The former he proposes to call Gammarus Rosellii,
because the names fluviatilis and aquaticus are inappropriate, since there is another river
Gammarus, and all the Gammaris are aquatic. His definitions are "Gammarus pulex, Fabr.
Oculis reniformibus, antennis subequalibus; tingoquoque abdominis cinculoquo abdomen
lont, id est non spinigerum," and "Gammarus rosellii Nobis. Oculis ac antennis
gammari publicis, sole abominini cinculquo quce auleato, id est superne et posticé unspliaginero.
Astacus fluviatilis Rosell. Insecten beiderungen III. pl. 52. Crevette des ruisseaux Geoffroy.
Hist. des Insectes pl. 21. fig. 6." I do not for my own part consider Gervais justified by
the reason he gives in altering Rösel's name. What he states as to the two species never
matting is guarded in a note by the remark that such a thing might happen, without
disproving the distinctness of the species.

Gervais concludes as follows: "On trouve aussi dans les environs de Paris, mais seulement dans
l'eau de puits, une troisième sorte de Crevette, remarquable par la petitesse de sa taille, qui ne
dépasse pas en effet trois ou quatre millimètres. Cette Crevette, que nous considérons
comme une simple variété de séjour est constamment étiolée, et ses yeux, au lieu d'être
REPORT ON THE AMPHIPODA.

noirs, comme chez les précédentes, sont tout-à-fait sans pigmentum et non apparents. Nous
la nommersons *Gammarus pulex minutus* parce que c'est en effet à l'espèce sans épines qu'elle
appartient." As to this see note on Koch, 1835.

1835. Guérin-Ménéville.

On page 3, in the description of Pl. XXVII, what relates to the Amphipoda is thus given:—
"Fig. 4. *Talitrus platichelis*, Guérin; voy. p. 44. Grossi; a dernier segm. de l'abdom. plus
grossi; b mandibule très-grossis; e une patté de la seconde pair très-grossis; d patte
antérieure du *Thalitrus locusta* grossis; e celle du *Thalitrus Cloqueti* également grossis.
—Fig. 5. *Gammarus peloponnesiacus*, Guérin voy. p. 45. Grossi; a partie d’une antenne
externe très-grossis." On Pl. XXVII. itself, which has the inscription "E. Guérin
pinx", there is no figure 4. d. Figures 4. e. and 4. f. represent not single feet but the
whole anterior portion, head, antenna, gnathopods, etc., of two Orchestidae, the former
copied from Desmarest’s copy of Montagu’s *Gammarus saltator*, the latter from Savyngy’s
figure of *Talitrus cloqueti* (Audouin). In figure 5, the two last pleopods are represented
without side-plates, and attached to the fifth and sixth peraeon-segments, while the
pleopods are attached respectively to the seventh peraeo-and the first and second plea-
segments. The telson appears to spring from the fourth pleon-segment.

1835. Johnston, George.

Under "Class Crustacea. Subclass C. mandibulata," Johnston gives a definition, first of the
"Legion Edrophthalma," then of the "Order Lernodipoda Latreille, in Cuv. Rég. Anim.,
iv. 126," which he divides into
"(1.) Branchial lamellae 3 pairs, attached to the second and third segments, which are
apodal . . . . CAPRÉLLA.
"(2.) Branchial lamellae 3 pairs, attached to the base of the second, third, and fourth
pairs of legs, which are all monodactyle . . . . PROTO.

To Caprellia he assigns "1. C. Phasma;" "2. C. acanthifer," with "? var.," Leach’s *Cap-
linearis," in Edin. Encycl., vii. 404," and a reference to Fleming’s opinion that it is probably
only "a variety of C. Phasma;" "3. C. Pennanti;" "4. C. linearis."

To Proto he assigns two varieties of *Proto pedatus*, which he figures and describes. After the
fuller description of the species he distinguishes
"Variety 1.—Hands oval with a single denticle at the base: head rounded in front: branchial
lamelie larger and elliptical. *Obs.* To this variety the figures of Müller and Montagu
belong.

"Variety 2.—Anterior hands triangular, somewhat lobed at the base; the wrist deeply sinuate;
posterior hands oval, with two teeth at the base, and serrulate on the inner aspect: head
very obtuse in front: branchial lamellae smaller and cylindrical. *Obs.* All the specimens I
have seen belong to this variety."

"Latreille (Cuvier, Régne Animal, tom. iv. p. 137) and Desmarest assert that the figures of
Müller and Montagu refer to distinct animals, which do not even pertain to the same genus.
There is some error in this; for the figures are in reality more closely alike than could have
been anticipated, when it is remembered that they are both original, and taken by different draughtsmen; and they unquestionably represent the same species."

Mayer decides, in regard to the species here given by Johnston, that his *Caprella phasma* and *Caprella acanthifera* are alike *Protella phasma*, Montagu, his *Caprella penmanii* is *Caprella acutifrons*, Latreille, his *Caprella linearis* is rightly named, while his two varieties of *Proto pedatus* both belong to *Proto ventricosa*, O. F. M., the hands in variety 2, having become wrinkled after death. Johnston's figure of this variety, it may be observed, shows the marsupial plates of a female specimen.

1835—Koch, Carl Ludwig, died 1857 (Hagen).

1841.

Zusammenstellung der in Koch's "Deutschlands Crustaceen, Myriapoden und Arachniden," daneben so in "Deutschlands Insecten von Dr Panzer und Herrich-Schäffer," vorkommenden Crustaceen, 1847.

Of these works I have only seen portions, and therefore quote the titles and dates as given in Boscck's list. Apparently with a special view to the confusion of Bibliographers, Koch's work was issued in loose leaves. For each species there is a separate plate measuring about five inches in breadth by four in depth, and a separate leaf of description, six and a quarter inches broad by four in depth. A series of these in a loose paper cover forms a Heft. On the outside of this cover is the table of contents and the date. The date of the 162d Heft is "Den 1. Oktober 1838." The number of the Heft is repeated on each leaf, and the synonymy invariably gives a reference to "Koch Dtschl. Crust. Myr. u. Arachn.," with a different numbering; thus in Heft 138, the references are to h. 5; in 162, to h. 22; in 180 to h. 34; in 186 to h. 36. Mr. G. K. Fortescue of the British Museum tells me, on the authority of Hinrichs, that Heft 36 was published in 1841. Hagen, Bibl. Ent. ii. 27, states that Georg Wolfgang Franz Panzer (born 1755, died 1829), began his "Fauna Insectorum Germaniae initia" in 1793; that Heft 109, the last by Panzer, appeared before 1813; that after a long interval Heft 110 was published by Maler Geyer at Augsburg, and that the continuation was by Gtli. Aug. Willh. Herrich-Schäffer (born 1799), the title of his work being "Die Fortsetzung von Panzer Faune Insectorum Germaniae initia Regensburg, (Manz), 1829-1844. 8. Heft. 111-190. à 24 tab. col."

Mr. Edward Saunders, the well-known entomologist, informs me that Engelmann, Bibl. Hist. Nat. 1816, quotes the titles thus:

From the latter work Mr. Saunders sends me the following synonymy:

"Gammarus fossarum Koch

"Gammarus putatatus Koch

REPORT ON THE AMPHIPODA.

186. 1. **Gammarus pulex** Fab.

188. 1. **Gammarus puteanus** Koch

The following descriptions are quoted from the former work. There can be little doubt that the same plates have been used for both works, although, as Mr. Saunders observes, Engelmann applies the term "lith." to those in Koch, and "Kupfern" to those in Herrich-Schaeffer's continuation of Panzer. The two works would seem to be practically identical. It seems convenient to bring Koch's four descriptions together, but it must be remembered that in all probability the two numbered respectively 138.1, and 138.2, belong to 1835, while the numbers 186.21, and 186.22, belong to 1841.

138. 2. **G. testaceus**, vitta utriquec lateralici fusca, testis caudae inermibus.

"Squilla Pulex Degeer Abh. VII. p. 193. t. 33. f. 1. 2.

"Frisch. ins. 7. t. 13.

"Etwas schlanker und kleiner als Gaum. pulex; die Schwanzringe oben unbewaffnet, und ohne vorstehende stachelartige Spitzen. Das vorletzte Glied der vier Vorderbeine etwas schmal eiförmig.

"Das dunkel gebräunte Weibchen hat kürzere Schwanzspitzen; auch scheint der Eiersack an den vier vorderen Seitenflügeln schwarzlich durch.

"In Gräben mit fließendem Wasser. Bei Regensburg in dem Königswieser Graben und in dem kleinen Bach bei der Weichselmühle in grosser Anzahl."

138. 5. **G. diaphano-albus**, lateribus subochraceis, testis caudae inermibus; articulo penultimo pedum 4 anteriorum quadrato.

"Koch Dtschl. Crust. Myr. u. Arachn. h. 5. n. 2.

"Die Gestalt von Gamm. pulex, aber von diesem durch die fehlenden stachelartigen Spitzen auf den Schwanzringen leicht zu unterscheiden. Von Gamm. foss. unterscheidet ihn das vorletzte Glied der vier Vorderbeine; dieses ist sehr gross, breiter als lang, fast quadratisch, blattartig breitspitzig.

"Körper, Fühler, Taster, Beine und Schwanzspitzen etwas glasartig weiss; in den Seiten bis zum letzten Schwanzringe mit eckigem Anstich, und mit einem violettblauen Streif in den Seiten der Leibringe. Die Augen sind gelb.

"In Schöpf- und Zielbrunnen. Bei Regensburg nicht selten."

186. 21. **G. pulex** Fab.

G. casius, dorso fusco testaceus, segmentis posterioribus postice medio in deutem acutum producis.

"Fabr. syst. ent. II. p. 516. n. 7.

"Latr. gen. crust. et ins. I. p. 98. n. 1.

"Grösser als Gamm. fossarium, 6 bis 7 Linien lang, von derselben Gestalt, doch an den scharfen..."
1835. MILNE-EDWARDS, H.

After discussing the subject in regard to the Isopoda, from Cymothoa and Anilocra Milne-Edwards passes on to make the following remarks on the Amphipoda:—“Les Crayms ou pour de baleines présentent aussi des différences considérables dans la forme de leur trone et de leurs membres, suivant l’âge auquel on les examine, et ces différences rentrent encore dans la même catégorie que celles dont les Cymothées nous ont fourni les premiers exemples.

“En effet, ce qui contribue le plus à donner aux Crayms adultes l’aspect si particulier qui les distingue, et les éloigner du type normal des Isopodes, est l’aplatissement et la largeur considérable des segments de leur thorax, la forme bizarre de leurs pattes et le grand
développement des vésicules fixées à la base des rudiments des membres thoraciques de la troisième et quatrième paires (Pl. 14, fig. 13). Les jeunes Cyames ont au contraire une forme svelte et élancée. Tous les segments de leur thorax se ressemblent parfaitement entre eux, et représentent des tronçons d’un cylindre; leurs pattes sont grêles, cylindriques, et parfaitement extensibles; enfin les vésicules respiratoires ne sont pas plus développées que chez les Protons, les Chevrolles et les Amphipodes. (Voyez pl. 14, fig. 14).

“II en résulte que les Cyames, lorsqu’ils viennent de naître, diffèrent bien moins des autres Crustacés du même groupe naturel que lorsqu’ils sont déjà parvenus à l’âge adulte. [Ces observations ont été faites sur de très jeunes Cyames ovales (Roussel de Vauzème) extrait au moment même de la poche ovarière de leur mère; les différences ne peuvent donc être attribuées à ce que les petits naissent appartenue à une espèce distincte comme quelques naturalistes à qui j’ai communiqué mes recherches semblent le penser].

“J’ai eu également l’occasion d’examiner quelques jeunes Phronimés. Les adultes, comme on le sait, se font remarquer par la grosseur démesurée de leur tête, par la forme presque conique de leur thorax, par le renflement de l’article basilaire des six premières fausses pattes abdominales, et surtout par le développement considérable des pattes thoraciques de la cinquième paire et par la grosse main didactyle qui termine ces membres, disposition dont les Amphipodes n’offrent pas un second exemple. (Voyez pl. 14, fig. 9). Dans les jeunes Phronimés, ces anomalies n’existent pas encore. La tête est de la grosseur ordinaire. Le thorax est presque aussi large en avant qu’en arrière, et se renferme par le milieu; l’article basilaire des fausses pattes abdominales est grêle et cylindrique; enfin les pattes thoraciques de la cinquième paire ne sont pas plus longues que les pattes voisines, et ne sont pas didactyles; on y remarque seulement un peu d’élargissement dans le pédoncule articulaire, sur le bord inférieur duquel le doigt mobile s’infléchit comme cela a lieu pour les pattes subcheliformes de toutes les Crevettes. (Voyez pl. 14, fig. 10).”

In his own “Amphithoe de Prevost,” he notes the enlargement of the hand of the second gnathopod in the adult. In the young, the head is more voluminous than in the adult, and the lower antennae, instead of being twice as long as the upper, are but little longer; “enfin les pattes mâchoires extérieures sont beaucoup moins chargées.”

1835. Ross, James Clark.

Owen, Sir Richard, born 1804 (Hagen).

Appendix to the narrative of a second voyage in search of a North-West Passage, and of a residence in the Arctic regions during the years 1829, 1830, 1831, 1832, 1833. By Sir John Ross, C.B., &c., &c. Including the Reports of Commander, now Captain, James Clark Ross, R.N., &c., and the discovery of the Northern Magnetic Pole. London, 1833. (Amphipoda, pp. lxxxiii—xcii, partly by Owen.)

Guérin’s Themisto gaucheliadici, from the Falkland Islands, is here recorded as occurring of greater size near the west coast of the Peninsula of Boothia, but it is, Boeck says, the Gammarus (Themisto) libellula of Mandt that is intended. The Gammarus vaga next mentioned is referred by Boeck to Anonyx (Scarcies) vahlii, Kroyer. Among other already known species, Talitrus celeris, Sabine, is renamed Amphithoe celeris, being in fact Onisus aculeatus, Lepechin, now called Rhachotropus aculeatus. The new genus Acanthochiton (Owen, MS.), is thus defined:—“Antenne suberaquales, 4-articulat, articulo ultimo et plurimis segmentis efformato, articulo tertio superiorum brevissimo. Pedes 4-antici, monodactyli, filiformes, articulo ultimo princi paris serrato. Rostrum pro-

Footnote.

Xxx 21
ductum acutum, incurvatum. Oculi parvi." The type species, *Acanthoneus cristatus*, is described and figured. The generic name being preoccupied, is changed by Beeck to *Acanthoneusoma*.

The new genus *Acanthoneusoma* (Owen, MS.), is thus defined:—Antenne inaequalis, superiores dimidio breviores, articulo ultimo e plurimis segmentis efformato, articulis tertii et secundis superiorum equalibus. Pedes 4-anteci, monocactili, filiformes, articulo ultimo primi paris unguiculato. Rostrum productum acutum, undulatum. Oculi parvi.

This generic definition was sharply criticised by Kroyer, who transferred the type species, *Acanthoneusoma hisrix*, to *Amphithoe*. Beeck regards it as identical with *Onices eusipidatus*, Lepechin, and as Owen's generic name was preoccupied, he calls it *Acanthoneus eusipidata*. E. J. Miers would retain it as a distinct species, *Acanthoneus hydrix*, Owen. The *Acanthoneus hydrix* of Buchholz is, I think, clearly a distinct species, as Miers points out, and may receive the name *Acanthoneus buchholzi* in honour of its describer. Owen, in speaking of the rostrum of his species, says, "this part is white, curved over the head, and directed forwards."

The description by Spence Bate, Brit. Mus. Catal., p. 147, corrects this statement, saying, "Cephalon furnished with a minute rostrum. First segment of the pericran having a large central dorsal tooth projecting upwards and forwards on the anterior margin." Buchholz supposes that Kroyer, Bruzelius, and Beeck, have only had young examples to examine, and would so account for the differences between their specimens and his, but Owen says expressly "Plate 9, fig. 4, represents a large-sized specimen of the *Acanthomeus Hystrix*", so that to him, at least, Buchholz's argument will not apply.

---

1829—Guérin-Méneville, F. E.

1844.

[This work was published in livraisons between 1829 and 1844. The Plates containing Amphipoda probably all belong to the early part of 1836. An advertisement in the "Quarante-cinquième livraison. Crustacés. Pl. 35.," says, "La 46° et dernière livraison se composera du Texte descriptif de l'Iconographie et paraîtra fin mars 1838," but the promise was not, it appears, fulfilled till the end of 1843. The specific names, however, being given on the plates, will carry the date 1836.]

In the third order of Crustacea, les Amphipodes "genre CREVETTE (Gammarus Fab.)" stands alone, with various sub-genera. In the description of Pl. 25, fig. 4 is referred to *Pheronima atlantica*, Guérin, 1836. Branchial vesicles are shown as attached to the third, fourth and fifth pereopods. The observation follows, "Nous avons une autre espèce, prise dans l'Océan qui baigne les côtes de l'Amérique, assez loin de l'embouchure de la Plata. Elle ressemble à la précédente, mais la main de la cinquième paire de pattes est beaucoup plus longue et plus grêle, peu renflée vers l'extrémité, avec la griffe simple, mais fortement renflée au milieu et une forte dent au côté interne de la pointe opposée de cette griffe. Cette troisième espèce a, comme on le voit, beaucoup de ressemblance avec la *Pher. solutaria*, mais elle s'en distingue facilement par l'absence de dent au milieu interne du doigt mobile. Nous lui avons donné le nom de *Pheronima solutaria*."
REPORT ON THE AMPHIPODA.

Fig. 5. is referred to “Hyperia Latreillii, Edw.”, with the note that Stras described it under the generic name of Hidula (Mém. du Mus., t. xviii. pl. iv.).

Fig. 6. Hyperia pectestrès, Guér., is thus described, “Très-distincte par la longueur de ses pattes et de son corps. Antennes inférieures un peu moins longues que les supérieures : celles-ci, moins longnes que la tête. Pattes de longueurs très-inégales, grelles avec le premier article ou la lance aussi mince que les articles suivants.—Hab. les côtes du Chili.”

Fig. 7. is of “Theoniéta Gaudichaudii Guér.”, the mandible of which is drawn with a four-jointed palp. Guérin adds a “Nota. M. Kroyer (Greenland amphipoder, p. 63, etc.) a fat courant deux autres espèces de ce genre curieux.”

On Pl. 26, fig. 3 represents “Orchestra Fieberi, Edw.” Fig. 4 is described by the words “Mandibules de l’Orchestia gamarella.” The figure is very like Savigny’s figure of the mandible of Orchestra montagni; and, like that, shows a rudimentary three-jointed palp. Fig. 5. is of Talitrus platycheles, Guér.; Fig. 6. of “Althys arenicola. Leach.”; Fig. 7. of “Gammarus locusta. Latr.,” with the “Nota. Voir la description de plusieurs Gammarus d’Angleterre par M. Johnston (Zool. Journ., 1827, t. iii. p. 175).” Fig. 8 represents “Leuresthes farrina, Savign.”; Fig. 9. “Amphitrite floridea, Savigny.”

On Pl. 27, fig. 1 represents “Corophium longicorne, Fab. Latr. (male)”; Fig. 2, “Corophium longicorne, F. (female).”; Fig. 3. “Jassa polychaeta. Leach.”; Fig. 4. “Corpus tubularis. Say.”; Fig. 5. “Perotypus arenaria. Latr. Hab. les mers d’Europe (copie de Slabber).” Fig. 8. “Typhis foma. Edw.”; Fig. 9. “Le même, juene.”

Figures 1 and 2 Pl. 26, are of “Ione thoracica, Montagu,” male and female. Figures 6, 7, and 10 on Pl. 27, represent respectively “Anomura talpa. Leach.” “Anomura forcularis. Risso.”; “Poronita maculata. Westw.”

In the fourth order, Les Lomodipodes, “Genre CYAME (Cyanus. Latr.)” stands alone with three subgenera. On Pl. 28, fig. 1 represents “Caprella tuberculata. Guér.”, “Hab. l’ile de France.”; the explanation of the figure being followed by the “Nota. Cette espèce est voisine des Caprella acuminata et scapra ; mais elle est bien distincte par sa tête courte, corne, par ses antennes supérieures très-pen plus longues que les inférieures, et par les segments de son corps portant chacun un assez grand nombre de tubercules.” Fig. 1a. “Sa queue vue en dessous,” shows a plen very clearly triarticulate, the terminal joint bearing a pair of wart-like limbs. These figures evidently represent the male sex, and are very different from the figure of “Caprella tuberculata, δ,” in Rate and Westwood, ii, 68, although to some extent resembling the figure they give for the female of that species, but still more resembling, except in regard to the frontal horn, the figure on page 63, which they name “Caprella hystricis,” Kröyer. Fig. 2 is named “Caprella lobata. Latr. (C. lineata? Lin. Edw.), with the “Nota. M. Templeton (Trans. Ent. Soc. vol. 1, p. 191) a décrit et figué plusieurs espèces de ce genre provenant de l’ile Maurice.” Fig. 3. is named “Leptomera policta, Mull.”; Fig. 4. is of “Cyanus ovalis. Roussel de Vauzème.” Numerous details are given, with the acknowledgment, “(figures empruntées au travail de M. Roussel de Vauzème)” It would save some trouble if authors of systematic or general works on a subject would always acknowledge the sources from which their figures are borrowed. Fig. 5. is thus described.—Cyanus Delphini, Guér. 5a. Le même vu en dessous.

Appendice respiratoire et lune ovigère de la femelle.—Hab. Trouvé sur les parties génitales d’un Dauphin, sur les côtes des Antilles.

“Nota. Cette espèce est bien distincte de celles que M. Edwards mentionne, tant par ses formes que par son habitat. Elle est en eau allongée; ses segments thoraciques se touchent sur presque toute leur étendue, à l’exception des derniers qui sont un peu séparés sur les côtés. La grosse pièce des secondes pattes porte au côté interne une fort dent saillante. Les filets branchiaux sont très-courts, inégaux et beaucoup moins longs que les pattes. Les premières articulations des pattes postérieures sont fortement dentées et de formes très-diverses.”
1836. GUÉRIN, F. E.

After briefly reviewing the classification of the Hyperina in the various works of Latreille and Milne-Edwards, Guérin proceeds to define his new genus, *Primno*, as follows:

"Corps allongé, de quatorze segments, non compris la tête. Tête ovale, très bombée, perpendiculaire et terminée en pointe. Deux antennes plus longues que la tête, sublunées, composées de deux articles, dont le premier court et le second effilé vers le bout, et n'étant pas articulé. Pieds de la première paire, les plus courts de tous, à article cylindrique, dépassant la tête de presque toute sa hauteur, et terminés par un petit ongle pointu. Seconds pieds un peu plus longs, avec le premier article large et aplati; les deuxième et troisième très courts, les quatrième et cinquième plus longs et égaux entre eux, et le cinquième terminé par un ongle pointu; troisième et quatrième pieds encore plus longs, simples, à articles cylindriques; cinquièmes pieds de plus du double plus grands que les précédents; le premier article grand, un peu aplati, presque aussi long que les pieds qui précéendent; le second court, armé d'une épine en arrière; le troisième également court, très étroit à la base, renflé en demi lune, et aigu à ses extrémités; quatrième article presque aussi grand que le premier, large et aplati, armé de fortes épines à son côté antérieur; cinquième, grêle, plus long que le quatrième, cylindrique, et un peu courbé, terminé par un ongle assez long, très aigu et un peu courbé; sixièmes pieds beaucoup plus courts, à premier article large et plat; deuxième court, inermes; troisième deux fois plus long; quatrième aussi long que le premier, étroit et armé d'épines en avant; cinquième aussi long que le précédent et terminé par un ongle aigu; septièmes pattes encore plus courtes; à premier article large et aplati, ayant les autres articles cylindriques et grêles, et la griffe du dernier renflée et aronnie, au lieu d'être aiguë comme aux autres pattes. Trois premiers segments de l'abdomen grands et arrondis en arrière, portant chacun une paire de pattes natatoires composées comme dans les Phronèmes; les suivants courts, plus étroits, et donnant attaché à des lunes natatoires simples, larges, un peu lobées au bout, mais n'étant point terminées par deux petits appendices comme dans les Phronèmes.

"Comme on le voit par ces caractères, ce genre est très voisin des Phronèmes, et doit être placé immédiatement après ces Crustacés."

The type species, *Primno macropa* is figured. The derivation of the oddly formed specific name is indicated by the French name "*P. à grands pieds."

The new genus *Hieracomyx* is next described:—"Corps court et massue, composé de treize segments non compris la tête. Tête ovale, très grosse, perpendiculaire, occupée en entier par les yeux; quatre antennes inégales; les supérieures de la longueur de la tête, cachées dans une fossette; les inférieures un peu plus longues; ces quatre antennes composées d'un support plus épais, court, et d'une tige multarticulée. Premier et second segments du thorax réunis, et portant les deux premiers paires de pattes; les deux segments qui suivent égaux entre eux et plus étroits que le premier ou les deux premiers, soudés; cinquième segment plus large et dilaté en arrière et en bas; les deux derniers étroits, cachés en bas par la dilatation du cinquième; pieds de deux premières paires assez courts, simples, égaux entre eux, à articles peu aplatis, troisièmes et quatrièmes terminés par une petite main imparfaitement didactyle, ayant le doigt mobile formée du cinquième article et de l'ongle aigu qui le termine; cinquièmes pieds les plus grands de tous, ayant le premier article très large et aplati, les deux suivants courts et transversaux; le quatrième grand, épaiss, dent au côté antérieur; le cinquième de la longueur du précédent, cylindrique et terminé par un ongle
asszez grand, aigu et un peu courbé; sixièmes pieds plus courts, à premier article aplati, les deux suivants petits, le quatrième renflé, inerme; pieds de la septième paire encore plus courts, ayant le premier article grand, plat, et les suivants cylindriques, moins longs ensemble que le premier, recourbés et cachés sous celui-ci dans le repos; les trois premiers segments de l'abdomen grands, diminuant de grandeur, portant chacun une paire d'appendices natatoires, semblable à ceux des autres genres de la même famille; les trois segments suivants courts, portant chacun une paire de lames plates, ovales, un peu échancrées au bout, mais d'une seule pièce, comme dans le genre précédent. Guérin considers that this genus comes very near his other genus Themisto. He figures the type species Hieraconyx abbreviatus, which Spence Bate gives as Anacyclonema abbreviata, regarding the genus Hieraconyx as representing the male form of Milne-Edwards' Anacyclonema.

The new genus Pronoe is thus described:—Corps allongé, étroit, composé de quatorze segments, en n'y compréhendant pas la tête. Tête grande, occupée par les yeux, arrondie, avancée, ayant le front très bossé, creusé devant pour recevoir les antennes supérieures, avec le tubercule buccal peu saillant. Antennes plus courtes que la tête, plates, paraissant composées de trois articles, dont les deux premiers très courts. Antennes inférieures insérées près de la bouche grêles, cylindriques, sécitées et formées de cinq articles se replayant l'un sur l'autre. Pattes simples et monodactyles, allant en augmentant de longueur depuis les premières jusqu'aux cinquièmes; les quatre premières paires ayant tous leurs articles cylindriques; premier article des trois dernières paires large, aplati et arrondi; sixième paire beaucoup plus courte; septième, composée seulement du premier article et d'un petit tubercule qui semble le rudiment des autres. Les trois premiers segments abdominaux grands, arrondis et portant chacun une paire d'appendices natatoires, conformes comme dans les autres genres. Les trois segments suivants ayant des appendices étroits, plats, allongés et terminés par deux petites lames arrondies au bout; le dernier segment court et triangulaire.

Guérin at first thought that his Pronoe was the young of Typhius, to which it comes very near, especially in regard to the antennes, but he found that it differed markedly in regard to the gnathopods. He figures the type species, Pronoe capito. He also figures and describes in detail his Phronima atlantica, which Claus considers to be the immature female form of Phronima exemplaria, but which Streets upholds as a distinct species. He figures and describes as a new species Oxycephalus oceanicus, though somewhat doubtfully separating it from "Oxycephalus pisatorius," Milne-Edwards, of which species Claus decides that it is the young male.

The new genus Philias is thus described:—"Corps court, comprimé latéralement, composé de quatorze segments, non compris la tête; tête petite, en grande partie cachée dans le premier segment. Yeux saillants. Antennes supérieures grandes, ayant un péduncule renflé et composé de trois articles (la tige est détruite, et il n'en reste que la base. On voit qu'il n'y avait pas de petit filet supérieur comme dans les crevettes). Antennes inférieures trente petites, insérées sous les précédentes, composées de deux articles égaux et d'une courte tige multi-articulée. Quatorze paires de pattes filiformes; simples, monodactyles; les quatre premières paires égales entre elles, plus courtes que les trois dernières, qui sont aussi égales entre elles. Appendices natatoires des trois premiers segments de l'abdomen de forme ordinaire; ceux du quatrième un peu plus petits, mais encore semblables, c'est à dire terminés par deux lames plus longues que la tige qui les supporte, ciliées; ceux du quatrième [cinquième] sont composés d'une tige plate, terminée par deux petites lames ovales et plus courtes, enfin ceux de l'avant-dernier segment ont leur tige plus courte, large et arrondie, et terminée par deux petites lames ovales et un peu pointues. Dernier segment abdominal très court, transversal et un peu arrondi." Of the type species Philias serratus, which is figured, pl. 19, figs. 1-4, he gives the following account, "ce petit Crustacé est long de cinq a six millimètres; tous les segments de son corps ont leur tranche supérieure très saillante, ce
1836. Templeton, Robert.

Under Malacostraca is included the following notice:—

**EDRIOPHTHÁLMA, Gamméridae.**

*Talitrus Latr., Locusta Latr.* Inhabits all our sandy shores.—Orchæsta Leach littèrea Mont. Inhabits all our sandy shores, living under stones and Fæci, and, when disturbed, keeping to a considerable distance.—*Gammarus Latr. Pælex Linn. aquáticus Leach.* Inhabiting our rivers and springs.—G. Locusta Mont. Inhabits the sea along our coasts, never voluntarily leaving the water.—*Corophium Latr. grossipes Linn., longicorne Latr.* Leach. Inhabits Belfast Lough. In the little pools of salt water at the point fields Belfast.” The remaining Edriophtalmæ mentioned are Isopods.

1836. Templeton, Robert.

The *Crustacea* in question were “picked up either at Mauritius or on the way thither.” He first describes:—

**Anisopus dubius.** Pl. XX. fig. 1. Greenish, dotted over with reddish-brown specks. Head large, subquadrangular, carrying 4 antenna, the superior nearly as long as the body, and exceeding in length by about one-fifth part the inferior; the 1st joint is minute, the 2nd large and thick, the 3rd clavate, nearly cylindric, and wanting the little process which characterizes the true Gammaræ, 4th joint multiarticulate, tapering. The inferior antenna has the 2nd and 3rd joints, subequal, much longer than any of those of the superior, and the remaining similar, but of smaller dimensions. Both antenna are spiny or hairy. The thoracic rings are narrow, and extend inferiorly into plates concealing the upper part of the 5 anterior pairs of legs. Those of the abdomen are much larger and end in a 4-articulated tail, with a jointed stylet on each side proceeding from the inferior posterior angle of the ultimate and penultimate articulations. The first pair of legs is extremely minute and terminates in a simple claw, the 2nd much longer, as are the 3 succeeding pairs, and terminates in joints slightly dilated, the last carrying a tolerably strong curved claw. The 3rd pair has the last joint very much dilated, subtriangular, not toothed, but bearing a very strong curved claw; the posterior edge is waved and hairy. The 2 succeeding pairs of legs resemble the 1st pair except in their greater size; but the 6th and 7th pairs, of nearly equal dimensions, exceed all the anterior legs in being both much longer and much more robust, and besides differ in having the coxae very much dilated, and the last joint of each
leaves elongated, surrounded by two blunt teeth, and a large dentate curved claw directed forwards. Immediately behind these legs arises, from the inferior part of each joint, the bifurcate articulated appendages which are called fin-feet; so that all the rings of the body have either true or fin feet or styles articulated to them, in this respect differing from all hitherto noticed genera.

"This species swims with considerable rapidity and has all the habits of our common European marine Gammarus. Its size is about 1/4 of an inch, and its color subject to but little variation, being of a greenish tint more or less brownish in the specimens I have examined. In its generic characters the great and disproportionate length of the 2 last pairs of feet, the fin-feet arising from the succeeding joints, and the appearance presented by the antennae, which are much longer than in the contiguous genera, at once distinguish it. The claws also offer distinctions."

In the above description, Templeton speaks of a minute first joint to the upper antennae, which he very properly does not figure. He speaks of the lower antennae having joints much longer than any of those of the superior; and again his figure contradicts his description. By the extremely minute "first pair of legs," he evidently means the maxillipeds, what he calls the second and third pairs being the two pairs of gnathopods. The third pereopods are missing both from the figure and the description. It is curious that Templeton should have thought his genus distinguished by having appendages to all the rings of the body, since few genera of Amphipods are without this characteristic, unless the telson be counted as one of the rings. Milne-Edwards introduced the genus between Icos and Ampithoe, adopting Templeton's error as to the gnathopods, and not noticing his other mistakes, unless obliquely in the words, "l'abdomen ne parait offrir rien de particulier." Spence Bate, in the Brit. Mus. Catal., p. 245 (Anisopus dubius, p. 145, by error in the index), describes Templeton's species as Ampithoe dubia, adding that "this description is taken from Templeton's figure, which is not well drawn," and that "if the telson (which is not figured nor described) should be found to be formed into a hook, then it belongs to Sunamphithoe." As a matter of fact, fig. 7, on Plate xii, of the Catalogue does not fairly represent Templeton's figure, and since the generic distinction which separates Sunamphithoe from Ampithoe is no longer the hooked telson, but the distal widening of the fifth joint in the hinder pereopods, which Templeton expressly describes and very clearly figures, the name Anisopus would have priority over Sunamphithoe, had it not been preoccupied among the Decapod Crustacea by de Haan, and also among Coleoptera, in 1835.

The next species is described as follows:—

"Traumalea depilis. Plate XX, fig. 2. Erythrecephalus melanophthalimus? Tilesius, New Ann. Wetteransch. i. p. 6, pl. xxi. a. fig. 5."

"Body hyaline, with a few dark specks, especially along the edges of the abdominal plates or rings. The head is quadrangular, not large; the eyes deeply imbedded in it; front retracted inferiorly, from about its middle arise the superior antennae, which are short and tumid; 1st joints short, forming together a truncated cone on which rests the elongate spindle-shaped 4th joint. The inferior antennae arise from the inferior part of the frontal surface; they are much smaller than the superior, composed of 4 joints, of which the 1st is small and obconic, the remainder in length subequal, the last conic. The body swells out to about the 6th ring, when it again becomes gradually reduced in size and ends in a bifurcate articulated tail. There are only 6 legs apparent, the 2 first pairs being very short and apparently without claws, the 4 posterior pairs of about equal length, tapering, and with
slender slightly curved claws. From the abdominal joints proceed bifurcate articulated appendages, but, as well as the whole animal, apparently devoid of hairs.

"This minute species swims but badly, having none of the celerity of motion so conspicuous among the *Gammari*, to which it bears resemblance in its form. It differs from every genus I am acquainted with, in the antennae, in the relative dimensions of the legs, the elongate and undulated form of the tarsal joints, and in the claws. I confess my inability to allot it to its proper place among the minute *Crustacea*, the differences being in fact more conspicuous than qualities by which its affinities to any single genus can be traced. It was found off Port Natal, in the summer of 1835, in lat. 37° S. and 21° E., while I was searching for *Zoea* in the sea-water. It is about 1/4th of an inch in length."

In 1838 Milne-Edwards suggested that this species might belong to his genus *Vibilia*. In the Hist. des Crust., 1840, he leaves it unnoticed. Spence Bate, Brit. Mus. Catal., p. 304, calls it *Vibilia depilis*, remarking that he has little doubt that Templeton’s "figure is an imperfect representation of *Vibilia*, and probably the young of some known species."

The next Amphipod described is:—

"*Cerapus* (Say) additus. Plate XX. fig. 5."

Templeton does not happen to include in the description and figures any of the distinctive marks on which S. I. Smith has founded his subfamily Cerapina with its single genus *Cerapus*, Say. In extracting his specimen from its tube, he seems to have left three pairs of the pereopods in the tube, and to have forced back one pair to an apparent attachment with the second segment of the pleon. There is, however, no reason for withdrawing the species from the genus *Cerapus*, Say, in which Templeton has placed it, its transfer to *Ceropellas* by Milne-Edwards having been based on obvious errors in the original description, and an undue importance attached to the number of articulations in the antennary flagella. Templeton's remarks appended to his description of the animal are worth quoting. "The entire animal is about 1/4th of an inch long, exclusive of the antenna, and it presents some peculiarities, with one exception, unique in this family. It has formed for itself or seized upon a little membraneous tube, nearly 1/4th of an inch long, which does not resemble the case of *Tubularia*, but seems composed of a series of rings, and resembles in texture the papyritious covering of the pendulous wasp's-nests. It is perfectly cylindrical, of a brown colour, and opaque. When disturbed, the little animal retires within this tube, the tips of the antenna alone appearing, with which it continues to investigate its neighbourhood; and whenever the feeling of perfect security prevails, it comes out as far as the second or third ring from the head, the antenna being perpetually in motion, extended to the right or left, or as if lashing the objects about it. When it wishes to change its place it seizes with its claws the little fragments of sea-weed about it, and dragging, urges itself forward. I have never seen it dash itself through the water by any mode similar to that of the *Gammari*; and I should infer that the tube was its natural place of residence from the want of legs or fin-feet at the middle rings, in which it differs from *C. tubularia* of Say, that author figuring a regular succession of both. I have observed the tail slightly protruded, and the members which are sketched as attached to adjoining rings used as feelers. While watching it, which I did for some hours, I was exceedingly surprised and amused to find it disappearing from one end of the tube, and reappearing like magic at the other, having doubled itself up towards its belly in the passage, but with such quickness, considering the narrow calibre of its mansion, that I could hardly credit my eyes but that it had two heads, and indeed, a gentleman who was in the pavilion with me at the time could not be persuaded to the contrary. The animal, however, scarcely remained a second at this extremity, but shot back to the one it had formerly occupied; and during the time I watched it I never saw it remain permanently at it, or rather I should say for a longer period than a second, or a second and a half at furthest. The maxillae resemble those of *Scolopendra*, but are very
minute, and I believe the smaller palpi arise from them or a very closely adjoining part, but vision is so indistinct in so small an object as to make me hesitate in affirming this. The circulation of the blood was distinctly visible in the antennae, and the globules, unlike those I had hitherto examined, were round, and of comparatively large dimensions. From the upper part of the head a spine, with a very dilated base, extends forwards to between the roots of the superior antennae. The eyes were black, with a pale encircling ring. The head brown, dotted with white, especially behind; and the antennae pale, annulated imperfectly with reddish brown."

Templeton further describes "Cuprella (Lam.) scaura. Plate XX. fig. 6. and "Cuprella (Lam.) nodosa. Plate XXI. fig. 7."

*Cuprella scaura*, from Mauritius, in Mayer's opinion perhaps includes *Cuprella attenuata*, Dana, and undoubtedly includes *Cuprella nodosa*, also from Mauritius, *Cuprella attenuata* being the male, *Cuprella nodosa* the form of the female and young. Spence Bate, Brit. Mus. Catal., pp. 355, 357, gives the length of both forms as half an inch, whereas the original from which he is quoting gives for the length of *Cuprella scaura*, "from the tips of the antennae to the claw of the hind leg," about one inch, and states that *Cuprella nodosa* "is about 1/4th of an inch long."

1837. **BENNETT, FREDERICK DEBELL.**

The account of this paper says, p. 42, "it appears that the sperm Whale is not like the *Balaena mysticetus*, constantly found with *Barnacles* and other parasites adhering to its skin, a circumstance accounted for by Mr Bennett from the former species inhabiting deep water, while the latter frequents soundings, and is also much more sluggish in its movements. One species of *Barnacle*, the *Oliva Cuvieri*, is sometimes found attached in a single cluster to the lips or lower jaw of the *Cachalot*, and a few small *Oniscii* occasionally adhere to the skin; in its blubber also numerous cysts of a species of *Cysticercus* are met with." Lütken considers that the *Oniscii* here mentioned are probably *Cyprini*.  

1837. **BURMEISTER, HERMANN.**

Burmeister's first principal group in the Animal Kingdom contains the Gastrozoa with four Classes. The second group consists of the Arthrozoa, beginning with Class five, Vermes. Class six, the Crustacea, is divided into the following orders, Pseudoccephala, Aspidostomrea, Thoracostraca, Arthrostraca. The Arthrostraca, comprising the Amphipoda and Isopoda, are thus defined, p. 567:—

"Vierthe Ordnung. Arthrostraca. Malacostraca ecirophiithalma, Leach. Der Kopf ist frei abgesondert, trägt 2 Paar Fühler, die äusseren ohne Schuppe am Grunde, 1 Paar ungestellter zusammengesetzter Augen mit facettirter Hornhaut, seltener 2-4 einfache Augen, 1 Paar Kiefer und 3 Paare accessorischer Mundtheile. Brustkasten gegliedert, 4-7 ringelig, jeder Ring mit 1 Paar einfacher, selten scheerenförmiger Füsse. Hinterleib 1, 3-6 gliedrig, oder fehlt ganz, im letzteren Falle ohne, gewöhnlich mit Flossen am Ende und Flossensäumen an seiner Unterfläche. Die Jungen haben die Form der Alten, doch öfters fehlt ihnen das"
THE VOYAGE OF H.M.S. CHALLENGER.

letzte Fusspaar, welches sich jedoch bald entwickelt; die Weibchen tragen die Eier an der Brust unter Schuppen, bis die Jungen ausgekrochen sind, ja selbst diese bestehen darin ihre Ausbildung, bis das letzte Fusspaar fertig ist."

In defining the "Flohkrebs. Amphipoda," he says "die Kiefer gewöhnlich mit einem 3gliedrigen Taster." He makes of them two divisions:—"A. Mit grossem 6gliedrigem Hinterleib, woran die aus den letzten Flossensäumen gebildete 5appige Schwanzflosse," containing the two families Gammarina and Hyperina, and "B. Mit verkürzten Hinterleib und einfachen Augen," containing the two families, Lernaeopoda and Pyganomidae. Kroyer finds much fault with him for including the second subdivision in the Amphipoda, but with regard to the Lernaeopoda Burmeister's view has prevailed. His name Arcitostrica has been adopted by authors of eminence for the group to which he applied it. His arrangement of the first two families is as follows:—

"Fam. Gammarina. Das letzte Paar der accessorischen Mundtheile bedeckt die vorhergehenden völlig und schliesst den Mund; der Kopf ist klein, aber die Füßer sind lang. Alle schwimmen behende, vorzüglich durch Schlagen des Hinterleibes und seiner Flossen.

"a. Saltatoria. Leib stark seitlich zusammen gedrückt; die vier ersten Fusspaare stehen nach vorn, und werden von einer Platte ihrer Ringe am Grade bedeckt; Hinterleib gebogen. Alle haben 4 Fühler.

"a. Kiefer ohne Taster, innere Füßer kürzer als die äusseren.

"Gatt. : Talitrus, Orchestia (2tes Fusspaar gross zum Rauben geschickte. O. littoralis, Nordsee).

"b. Kiefer mit Taster, innere Füßer länger als die äusseren.

"aa. 2 Vorderfäße ohne Auszeichnung.

"Gatt. : Lysianassa, Decamnia.

"ββ. 2 Vorderste Fusspaare sind Raubfäße.

"γγ. 2 vorderste Füße scheerenförmig. Gatt. : Lencodora.

"b. Ambulatoria. Leib flachrund, die 4 ersten Brustringe ohne Seitenplatten, daher die Füße bis zum Grade frei sind. Hinterleib grade. Augen klein, oft kaum zu bemerken.

"a. Untere oder äussere Füßer lang, fadenförmig.

"β. Dieselben Fühler sind fuss-förmig und haben statt der Geißel ein einfaches Glied.

"aa. Zwei Geißel an den oberen inneren Fühler.

"Gatt. : Unciola.

"ββ. Eine Geißel am oberen Fühlerpaar.

"Gatt. : Coropus, Podocerus (mit Raubfüssen am 2ten Paar), Corophium (ohne Raubfüssen).

"a. Alle vier Fühler an der STirn eingelenkt.

"a. Die 3 letzten Fusspaare gleichförmig, zum Rudern geschickt.

"β. Manche der 3 letzten Fusspaare sind Scheeren.

"DieGatt. Dactylocera und Anchylomera haben schildförmige Grundglieder an den 3 hinteren Fusspaaren, und die erste am sechsten eine Scheere; die Gatt. Phormina hat am 6ten eine Scheere, keine unteren Fühler und keine schildförmigen Grundglieder.

"b. Das untere Fühler paar sitzt an der hinteren Seite des Kopfes und ist geknickt.
“Mit langem glattem Kopf:Gatt, Oxyechinus; mit kurzem dickem: Typhis (erstes Glied des 5ten und 6ten Fusspaars gross, schildförmig, nach vorn gerichtet)."

In defining the Lamaniopa, he assigned them "2 einfachen Augen," "Kiefer ohne Taster," and says "Hinterleib fehlt, oder Iogiesdirg." He briefly arranges them thus:—

"a. Leib flach gedrückt, mit grossen Krallenflossen, wovon das 3te und 4te Paar in wustformige Kiemenblasen verändert sind.

"b. Leib lang gestreckt, linienförmig; Beine schlank, dünn, gleichförmig; obere Fühler mit Geissel.

"Gatt: Capella, Proton, Leptomera."

The Pycnogonida follow, with Nymphon grossipes and Pycnogonum balsamarum.

1837. Rathke, Martin Heineich, born 1793, died 1860 (Hagen).

This includes references to Amphithoe and Gammarus (Faxon).

1837. Rathke, M. H.

Rathke here describes and partially figures a species under the name of Orchestia littorea, which Spence Bate identifies with Orchestia mediterranea, Costa, but Rathke himself in a note refers to pl. 11, fig. 7 of Savigny’s Descript. de l’Egypte, as giving a capital representation of his species. But this Orchestia montagni is identified by Spence Bate with Orchestia littorea, Montagu. A comparison of Rathke’s figure with Savigny’s makes it tolerably clear that Rathke did not commit an error in his Note, and since Savigny’s species cannot be Orchestia mediterranea and by its long sloping palm and the comparatively short final joint to the shaft of the lower antennae is possibly quite distinct from Orchestia littorea, it will be best to retain Orchestia montagni, Savigny, and refer Rathke’s Orchestia littorea to it. His Gammarus gracilis is identified by Spence Bate and Boeck with Gammarus marinus, Leach. The name of his new genus Amathia being pre-occupied was altered by Bate and Westwood to Amathilia. He thus defines it:—"Thorax subcylindraceus, abdomen compressum. Antennae quater quinqueales; superioribus inferioribus paulo breviore; carunculis ex articulis tribus atque flagello composita; superioribus cum rami parvo accessorio juxta flagellum basin. Oculi magni, reniformes. Pedes quatuordecim; duo corna paria antica chelis monodiacyelis complanatioribus, subequalibus. Stylorum abdominalium paria tria. Abdominis appendiculis terminalibus simplex, erecta, lamelliformia."

His new species Amathia caudata, Bate and Westwood say, "from his description and figure, agrees so closely with A. Sahlinii of Leach, that we should certainly have considered them as identical had not Rathke (1843) stated that they were distinct." An author’s statement, however, in defence of his own species need not be taken as invariably conclusive.

The new genus Hyale is defined as follows:—"Corpus elongatum compressum. Antennae inferioribus aliquid am longiores; carunculæ et tribus articulis atque

On this genus Spencer Bate, B. M. Catal., p. 87, remarks, "Dana has arranged this genus in his subfamily Lysianassinae. Not having seen a specimen, I adopt the same arrangement; but judging from the figure of the author, I should be inclined to classify it near to Nicea of Nicolet, from which the female appears to differ only in the posterior pair of pleopods having two branches—a feature that the author has not alluded to in the description of the animal, although exhibited in the figure. It is this character, together with the absence of any mention whether the mandibles are furnished with an appendage or not, that has precluded my placing it among the Orchestidae."

Axel Boeck in 1870 united Allorchestes, Dana, and Nicea, Nicolet, as synonyms to Hyale, Rathke. In this identification I myself (1876) and Wrzesińskiowski (1879) have agreed with him. Faxon, Crustacea of the Lake Titicaca, 1876, takes a different view, which, to make the subject intelligible, must be given in full. The genus Allorchestes, he says, "differ from Nicea, Nicolet (as limited by Bate and Heller) in having the telson single instead of double or cleft. The fourth segment of the palpus of the maxillipeds is well developed, as in Nicea and Gammaraus, and, as in these genera, is commonly unguliferous. Neither Dana, in describing Allorchestes, nor Nicolet, in his description of Nicea (published in the same year), mentioned the form of the telson. The two names were therefore synonyms. Bate, in a list of British Amphipoda, published in 1856 in the Report of the British Association for the Advancement of Science, indicates, without describing, two genera, Allorchestes, Dana, and Galanthis, gen. nov., which, as appears from his subsequent description, were based upon the trivial character of a different length of the first and second antennae, and a differently formed telson, Dana's name, Allorchestes, being restricted to those species in which the first antennae are (at least) as long as the peduncle of the second antennae and the telson entire, and his own name Galanthis including the species with the two pairs of antennae subequal and short, and the telson cleft or double. In 1861 he suppressed the name Galanthis in favor of Nicolet's Nicea. The proportion of the antennae and the form of the telson brought together by Bate in his generic diagnoses are not in reality always concomitant, and Heller for the first time properly distinguished the two genera by the character of the telson alone. Grube (1866) adopts the relative length of the two pairs of antennae (at most a specific character) as the generic distinction. All his species of Allorchestes have a double telson, and should be transferred to Nicea.

"Boeck (1872) apparently misled by the fact that Bate carelessly describes Nicea Nilssonii with an entire telson, and places it under Allorchestes, would unite the two genera, giving as a generic character 'appendix caudalis brevis, crassa et fiss.' He furthermore considers both Allorchestes and Nicea synonymous with Rathke's older Hyale, the type of which, H. pontica, was carefully described and figured with the posterior caudal styles two-branched. Boeck has not had access to Rathke's type, as far as I can learn; but in a specimen from the Mediterranean 'which is doubtless Rathke's species,' he finds the last pair of saltatorial appendages one-branched. This assumption of identity, it seems to me, cannot outweigh the careful description and illustration of the founder of the genus, unless confirmed by examination of the type of Hyale Pontica.

"In 1874 Professor S. I. Smith described a new amphipodous genus, Hyalella, from the fresh waters of the United States, differing from 'Hyale' in having a styliform fifth segment to the palpus of the maxillipeds and an entire telson. The so-called fifth segment may perhaps be more correctly regarded as a movable spine, like those seen both lateral and terminal on the caudal styles, or like the unguis which tips the dactylopodite of the thoracic legs. However this may be, it is quite as well developed in several species of
"Hyale" (Nicola), and is not therefore a generic character. *Hyalella* is then a synonym of *Allorcliestes.*

To the second paragraph of this quotation is appended this note: "§ Doubtless a large number of the species placed under *Allorcliestes* by Bate in his Catalogue of the Amphipoda in the British Museum have in reality a divided telson. In fact, it would seem that the telson is cleft in most of the marine forms, and such probably formed the bulk of Dana's original genus *Allorcliestes.* The only types of Dana's species that I can discover are two specimens of *A. media* in the Museum of Comparative Zoology. In these the telson is cleft to the base. This, however, will not affect the synonymy as given above."

There are, however, some considerations which Mr. Faxon does not appear to have taken into account. He says that *Hyale pontica* was carefully described and figured with the posterior caudal stylets two-branched (zur Fauna der Krym, p. 87, pl. v. figs. 20-28, 1836), but no allusion to this feature is made in the generic character by Rathke (though Spence Bate introduces it in his Catalogue), and in the description of the species Rathke's words are:—

"die Sprungbeine sind nur kurz und schwach; das erste Paar ist am längsten, jedoch kürzer als das hinterste Paar der Afterbeine, das zweite ist noch kürzer, und das letzte am kleinsten: an den beiden ersten Paaren sind die Äeste ungefähr so lang, als die Wurzelglieder, an den letzten aber bilden die Äeste nur zwei sehr kleine warzenförmige Vorsprüinge des Wurzelgliedes." Here we find that in the first and second uropods the rami are about as long as the peduncles (not much shorter as the B. M. Catalogue makes out), but on the last pair the rami form only two very small wart-like processes of the peduncle. Possibly this means *only two to each peduncle,* but I think that it more probably means *only two* for the pair of peduncles. It is true that on Pl. v., Fig. 21, representing "das hinterste Sprungbein," shows two rami to one peduncle, but this plate is signed "W. Pape del.," not as on other plates in the same memoir, "Rathke del." This takes something from the force of Mr. Faxon's expression, "the careful description and illustration of the founder of the genus." Nevertheless with only these facts in view I should accept Mr. Faxon's ruling. But in his later work, B. z. Fauna Norwegens, pp. 81–83, Rathke describes, under the name "*Amphithoe Precostii,* M. Edwards," a species of which he says "the pleopods of the sixth pair are very small, and do not end with two rami, but each consists only of two joints, tolerably thick in proportion to their length, of which the terminal joint is smaller than the basal, and bears at the end some small spines. The back is quite smooth throughout." He further says, "this animal is very nearly related to an Amphipod which I found in the Black Sea and described under the name *Hyale Pontica,* but is distinguished from it chiefly by the want of a telson." At the end of his book, p. 264, he has made up his mind that the species is new and names it *Amphithoe nissoni.* He thought it a question (p. 83) whether this species and *Hyale pontica* ought not to form a new genus, on the ground that the second gnathopods were so different from those of the Amphithoe species as then accepted. His ascribing to *Amphithoe nissoni* the want of a telson was of course due only to an oversight or an accidental defect in his specimen, but he says nothing of distinguishing it from *Hyale pontica* by the difference of the last uropods. *Amphithoe nissoni* is transferred by Spence Bate to the genus *Allorcliestes,* while *Amphithoe Precostus* of Milne-Edwards is assigned to *Nicora,* although when he saw the type specimen he considered it "synonymous with *Nissoni* of Rathke, but unfortunately omitted to observe the character of the telson," B. M. C., p. 53. Now if *Hyale pontica* really has two rami to the peduncle in the last uropods, that one little extra wart will cut it off from the family of the *Orchestidae,* in which the last uropods are uni-branched. Yet there is nothing else to distinguish it from that family. Its antennae, its gnathopods in both sexes, its general shape both of the body at large and the pleon in particular, will identify it with the *Orchestidae.* Its habitat among stones and mussels on the beach, its colouring, clear bottle-green shading into brown, its

REPORT ON THE AMPHIPODA. 173
size, 3-6 lines, all coincide with the position in the system which Boeck has assigned to it. My own drawings of Hyale (Nicea) lubbockiana, Ann. and Mag. Nat. Hist. for May 1876, made years before I was acquainted with Rathke's work are in close agreement with those by W. Pape on Rathke's plate v. As in the Annals for November 1879, I identified Allorchestes imbricatus, Sp. Bate, with Nicea lubbockiana of the same author, so now, after seeing the strongly imbricated figure in Rathke's work, I am inclined to identify both with Rathke's Hyale postica.

From Mr. Faxon's own observations, that in the type of Allorchestes media, Dana, the telson is cleft to the base, and that in fact the telson is probably cleft in most of the marine forms, which would be the bulk of Dana's genus, I think it is unreasonable to give the name Allorchestes to species with an entire telson. But Nicea, which has been assigned to the species with a double or cleft telson, cannot claim priority over Allorchestes. They are in fact both synonyms of Hyale. For the species with an entire telson there will then be left the name Hyale, originated by S. L. Smith in 1874. See also note on Brandt, 1881.

One other new Amphipod is described by Rathke from the Crimea under the name Amphithoe picta. Of this Spence Bate remarks, "I can detect no specific distinction between this species and A. littorina of our own shores." Nevertheless he retains the species, giving the description of it from Milne-Edwards instead of from Rathke. But Milne-Edwards describes the first and second gnathopods as "presque égales, mais assez larges," whereas Rathke himself says, "Das erste und zweite Beinpaar sind gleich lang und haben auch ziemlich gleich grosse, in Verhältniss zum ganzen Körper aber nur kleine Hände," and in his Latin description, "pedum duobus paribus anticus subaequalibus, chelis eorum minimis. In the British species or variety, "Amphithoe littorina, Spence Bate," the size of the gnathopode is very variable, so that Milne-Edwards' account may perhaps be unintentionally accurate. Rathke found his specimens "in the bay of Balaklava, where it habitually lodges under stones, and resembles Gammarus in its mode of life."

1838. Milne-Edwards, H.

The history of the Crustacea, the Eighth Class, occupies from page 154 to page 498 of this volume. Of the sub-class, Crustacés maxillés, the second legion, Edriophtalmes, contains the three Orders, Amphipodes, Leiomopodes, Isopodes. At p. 256 the editor remarks that most authors have wrongly assigned as a character to the Isopoda, the absence of a palpiform appendage from the mandibles; he divides the Isopoda into three families, Cloportidiens, Cymothoaidiens, Idoteidiens, in the second of which he places Typhis. However, at p. 285, a note signed "E" states that "les Typhis appartiennent à l'ordre des Amphipodes, et à la famille des Hypéridiens," and refers to the "article Typhis du Dictionnaire classique d'histoire naturelle, t. 16, p. 449." "Espèce 1. Typhis ovoides. Risso. Hist. nat. des crust. p. 122, pl. 2, fig. 9," is followed by references to Desmarest and Latreille and to "le typhis ferus" and "le typhis repax" [rapax], both of Milne-Edwards, but so given as to appear more like synonyms of ovoides, than separate species for which they are no doubt intended.

On les Caprellines, pages 293–299, an editorial note says, "Cette division correspond à l'ordre
des Lémiptodes et se distingue facilement des autres Édriophthalmes par l’état rudimentaire de l’abdomen qui est réduit à un simple tubercule. Elle se subdivise en deux petites familles naturelles : les Caprelloïdies ou Lémiptodes filiformes et les Cyamoidiennes ou Lémiptodes ovulaires.” In the first of these subdivisions, Lémiptodes, with the species rubra and pedata, still holds the place which belongs to Proto ventricosa, O. F. M., Proto pedata being added from Desmarest to the synonymy of Lémiptodes pedata. Caprella has the species scolopendroides of Dallus, and phasmina of Montagu, with references to additional species described by Latreille, Leach, Desmarest and Templeton. Under Cyamus, with the “Espèce. Cyane de la balaine. Cyamus celi,” Cyamus ovalis, Roussel de Vauzème is also given, seemingly as a synonym. Latreille’s unpublished East Indian species is mentioned, and the observation made that, “suivant M. Roussel de Vauzème, on aurait confondu sous le nom de Cyamus celi, trois espèces de Cyamus qui vivent toutes sur la balaine ; mais ce naturaliste ne paraît pas avoir fait assez d’attention aux changements de forme que l’âge ancien chez ces animaux.” (Voyez Ann. des Sc. nat. 2° série. 1. 2.)”

On the Amphipods, pages 299-317, a note points out that there are six pairs of abdominal feet, instead of five as stated in the text, and where Lamarck says of the Amphipods, “c’est toujours sur le côté qu’ils se posent,” a note observes that “plusieurs amphipodes qui ne lui étaient pas connus, n’ont pas le corps comprimé et nagent dans la position ordinaire.” The editor observes that the Amphipods form two natural families:

“1° Les Crévettiniens qui ont le corps grêle et allongé ; la tête petite et les pattes-mâchoires recourvant toute la bonne et formant une espèce de livre inférieure terminée par quatre grandes lames cornées et deux longues tiges palpiformes et qui ne sont pas parasites.

“Genres Crêvette, Talitres, Corophie, etc.”

“2° Les Hyperiniens qui sont plus ou moins parasites et ont eu général le corps grêle et bombé ; la tête forte et les pattes-mâchoires très petites, recourvant seulement la base des autres appendices buccaux, terminées par trois lames cornées et dépourvues de tiges palpiformes ou n’en présentent que des vestiges.

“Genres Hypérée, Phronime, Tiphis (p. 285), etc.”

On the species of Phronima, he remarks that they have seven thoracic rings, each with a pair of feet, the fifth of which ends in a dissected hand; that they have also seven abdominal rings, the fifth and sixth more or less coalescent, and the seventh laminar. He thinks that Phronima atlanticus, Guérin, may be only the young of Phronima solenaria. Hyperia, Latreille, is given with three species, latreillii, cyanus and pelagica. The last of these he identifies with Say’s Lanceola pelagica; the first with Hidella orbignyi, Straus, and also with“Onciscus medusarum?” Othon Fabricius, and “Magnum, Strom, Sandnor,” both which he subsequently transferred to Metocopus Medusarum, Kröyer. “Hyperia Suerii” is likewise here a synonym of Latroilletti, but later on under the name Lesueurii, Milne-Edwards speaks of it as a distinct species. “Phronima Reynaudi,” M.-Edw.; “Lestrigoun Fabre,” M.-Edw.; Daiva Gabertii, M.-Edw.; Thermisto Gauchicaultii, Guérin; Dactylocorea, Latreille, and the species Dactylocorea Nicomai, M.-Edw.; Hieracogyne abbreviata, Guérin; Priamo macronyx, Guérin; Anchylothera Bissevallii, M.-Edw.; Anchylothera Huntingi, M.-Edw.; Pronoe capitato, Guérin; Ozycephalus piscatorius, M.-Edw.; Ozycephalus oceanicus, Guérin; and Vibilia Peronii, M.-Edw.; have met with remark in earlier notes. On Dactylocorea the observation is made that Phronima solenaria, Risso, “parait appartenir aussi à ce genre, comme l’a très bien remarqué Latreille (Régne anim. t. 4. p. 117).” On Vibilia the remark is made that Templeton’s Phronima depilis “parait devoir appartenir à ce genre.”

To the account of the genus Gaumarrus is added the note, “les Crévettres forment le type d’une tribu particulière de la famille des Crévetiniers que nous avons désignés sous le nom des Crévetiniers sanctuaire, et que l’on reconnaît facilement au mode d’organisation de la partie postérieure de l’abdomen. Ce groupe renferme aussi les Talitres et quelques genres.
nouveaux." In the species of *Gammarus* from the earlier edition, number 6, the *Pherusa
fucicola* of Leach, is given as "Crevette fucicola, *Gammarus pherusa*," the last word
probably by a slip. We are told to add a great number of species described or figured by
various authors. The notes remark that in all these crustaceas the upper antenna have a
peduncle of three joints with a multiarticulate lash, and that the peduncle of the lower
antenna has four joints. *Doramide*, Leach, is referred with hesitation to the "division
des Amphithoës." Of *Leucithoë* the only species well known is said to be the *Lygesta furcata*
of Savigny, but the *Gammarus articulatus* of Montagu "paraît être aussi un Leucothèque."
Leach's genera *Melita* and *Moera* (Miers) are rejected. "Les Phérases doivent être réunies
aux Amphithoës dont elles ne diffèrent que par un peu moins d'élargissement dans les mains."
*Amphithoë*, Leach, distinguished from *Gammarus* by the absence from the upper antenna
of an accessory flagellum, is accepted.

In the text of this oddly arranged work the following remarks occur as if part of the original
edition, though the references show that they are not so:—"Nous avons donné le nom
générique d'Iseia à des Amphipodes qui sont très voisins des Crevettes, mais qui ont toutes
pl. 29, fig. 11).

"Dans notre genre Lysionasse il n'est au contraire aucune patte qui ait ce mode d'organisation
(voyez le *Lysianassus costae*.) Edwards, Ann. des Sc. nat. t. 20, pl. 10, fig. 17.

"Le genre Philias de M. Guérin ne diffère du précédent que par l'absence du filet multiarticulé
accessoire des antennes supérieures. (Esp. le *Philias servatus*, Guérin, Mag. de Zool. cl. vii,
pl. 19.)"

To *Talitrus* Lamarck had assigned "bouche comme dans les Crevettes." A note here says
"excepté que les mandibules ne portent que des vestiges d'une tige paliforme. This
statement probably rests not on original observation but on Savigny's figure of the mandible
of *Orchestia montagni*, or on Guérin's figure of the mandible of *Talitrus platycheles*, 1835,
since in 1840 Milne-Edwards says of *Talitrus*, "les mandibules (fig. 3) ne présentent que
des vestiges d'un appendice paliforme, ou en manquent même complètement. His figure
shows no trace of a palp. Nevertheless it may be true that in some of the Orchestidae
there is a rudiment of it. Such at least I fancy that I have discerned in *Hyatella inermis,*
S. I. Smith. *Talitrus* in Lamarck has three species, *turnata, gammarillus, carinatus.* A
note to the second points out the difference of *Orchestia* from *Talitrus* and that to *Orchestia*
should be referred Savigny's figures 7 and 8 on Plate 11 of his great work, "*Orchestia
Fischerii, M. Edw.*," etc. A note on the third, which is Fabricius' species, referred by Leach
to *Atylus*, says, "le genre Atyle doit prendre place dans la tribu des Corophioides ou
Crevettiniens marcheurs et se distingue par ses antennes non podiformes, et ses mains de la
seconde paire très petites et à griffes simples."

*Corophium* is regarded as type of a tribe called here *Crevettiniens-marcheurs*, distinguished from
the *santens* by slender body, small epimera, tail not formed for leaping, and distinguished from
other genera of the same division by pediform lower antenna, upper antenna without
accessory flagellum, second gnathopods neither didactyle nor peduncle.

*Arona* and *Podocerus* of Leach are distinguished from *Corophium* "en ce que leurs quatre pattes
antérieures sont terminées par une grosse main subcheliforme," but it is rightly observed
that they are distinguished from one another only by trifling characters. "Le genre
*Unciata* de Say," the editor remarks, "doit prendre place auprès des genres précédents,
mais s'en distingue par l'existence de deux tigelles multiarticulées à l'extrémité des antennes
supérieures." Say's *Unciata* is of course intended. Say's *Ceramus* is mentioned with the
type species *tabularis* and Templeton's *abitus*. It is then observed in conclusion:—
"Enfin, notre genre *Erichthonie* établit le passage entre ces Crustacés et les Leucothèes; la
conformation générale du corps est la même que chez les précédents, mais les antennes ne
REPORT ON THE AMPHIPODA.

177

sont pas présiformes et les pattes de la seconde paire sont terminées par une longue main imperfectement didactyle dont la griffe est biarticulée. (Voyez Ann. des Sc. nat. t. 20, p. 382, et Hist. nat. des Crust. pl. 29. fig. 12)."

1838. COSTA, ORONZIO GABRIEL, and COSTA, ACHILLE.

Fauna del Regno di Napoli. Crostacci.

Preface, pp. 1-4, dated May 15, 1838, briefly notices what had been already done for Italian Crustacea, and proposes to follow Latreille's last classification of the Crustacea in his *Familles Naturelles du R. Anim.*

In this paper Latreille's classification is given.

1838. KROYER, HENRIK NIKOL, born 1799, died 1870 (G. O. Sars).

The introductory observations note that Latreille and Milne-Edwards agreed in making twenty-four genera of Amphipods, but of this number had only thirteen in common. Burmeister's inclusion of the Leptomipods and Pycnogonids in the order of Amphipoda is disapproved, and Milne-Edwards' definition and division of that order held to be the most satisfactory in the then existing knowledge of the subject.

The first species described is called "Lysianassa Vahlii Rhedt," with the remark emphasized in regard to the second gnathopods, that the sixth joint or finger is altogether wanting, a statement which, nevertheless, requires corroboration. Kroyer assigns the species to Reinhardt, whose manuscript name for it he adopts, but it had, in fact, been previously described by Owen under the preoccupied name Gammoros vagr; Kroyer presently changed the name to Anonyx vahlii; Boeck in 1870 made it Socarnes vahlii, but, as his Socarnes cannot fairly be distinguished from Ephydipphe, White, the name will be Ephydipphe vahlii, Kroyer (sp.). The next two species, figured and described respectively as "Lysianassa Lugens Riedt" and "Lysianassa appendiculata Kn.," are now regarded as the female and male of Cancer vagr, Phipps, in the genus Anonyx, and will therefore stand under the name Anonyx vagr, Phipps (sp.). In describing Lysianassa appendiculata, Kroyer calls attention to "small appendages, with which the flagella are furnished: the flagellum of the upper antennae along its lower edge, that of the lower antenna along its upper edge. I know," he says, "no other hitherto described Amphipod, in which anything of the kind is found, except in the Gammarus cratae described by Milne-Edwards." These are the appendages since called calceoli. He also here observes that the number of joints in the antennae increases with age, thus early giving a warning against the separation of species simply on the ground of differences in the length of the antennary flagellum. He then proceeds to remark that the three species just described were referred to Lysianassa as the only one among existing genera capable of receiving them, but that even that would require re-defining to include them with propriety. The monstrous size
of the peduncle of the upper antennae, and the want of a finger and other peculiarities in the second gnathopods, were peculiarities so marked in the three species that he proposes a new genus for them, thus defined:—"*Anonyx*: pedunculus antennarum superiorum crassissimus, ovalis; inferriorum multo gracilior, cylindricus; (oculi magni); pedes primi parvis brevioribus, parenou instructi magno; pedes secundii parvis al longis, gracilissimi, magno carinentes (quinguearticulati), ejusque vice ad finem articulari quinto multis cavitisque praediti setis." To this generic character, he says, may also be added, that the head in all the species is tolerably small, and partially concealed by the first side-plates, a rostrum projects in the middle in a little blunt point, formed by the small lateral excavations for the insertion of the antenna, while the trunk is pretty strongly compressed, though dorsally rounded. Though not considering the mouth-organs of use for generic characters, he mentions that the mandibles are strong, furnished along the inner edge with three dental tubercles (Tandkander), meaning, to judge by the figure, a divided tooth at the tip of the cutting edge and a small molar tubercle; the upper rim shows near the outer angle a tolerably deep incision; the palps are tolerably short. The second maxillae have the lower lobe (inner plate) very small, furnished at the extremity with some long, plumose seta. The maxillipeds have the palps long, the inner terminal plates narrow, linear. A footnote to the words "oculi magni" explains that a species otherwise in agreement with the genus need not be excluded merely on account of its having small eyes.

He next describes "*Gammarus Sabini Leach*, commonly known now as *Acanthilla sabini*, but in my view having a claim to the title *Acanthilla homeri*, J.C. Fabr. He expresses surprise that it should have escaped the notice of [Otto] Fabricius, and calls attention to the very considerable differences between the young and adults, and the necessity for naturalists to take such variations into account if they would avoid the groundless multiplication of species. The next species described and figured, *Gammarus loricatus Sab.,* has by Spence Bate been named *Gammaruscaudatus loricatus*, Sabine. The new species figured and described as *Gammarus pinguis* is now called *Acanthilla pinguis*. "*Gammarus Longula*, Montagu," is judged to be the commonest of all the Greenland Amphipods, and to be undoubtedly identical with *O. Fabricinius* Osciens pulex (n. 231 pag. 254). The suggestion is offered that it may be identical with *Cancer magus* and *Gammarus magus* in the English travels, dating "from Phipp's time." "*Amphithoe carinata* Rhdt. (Tab. II, fig. 6)," is next described. This, which is the *Gammarus carinatus* of Fabricius, now bears the name *Atylus carinatus* given it by Leach. "*Amphithoe Hystrix* (Acanthosoma Hystrix Owen). Tab. II, fig. 6 [7])," next described, has been identified by Boeck with Lepechin's species, under the name *Acanthone caspita*, but the distribution of the species, according to the accounts of Lepechin, Krøyer and Boeck, makes the identification doubtful. In describing the flagellum of the upper antennae, Krøyer remarks that, with exception of the four first joints, which are all furnished with hairs at the end of the lower edge, of the remainder, as a rule, only every alternate one exhibits hairs. Consequently, he says, those joints without hairs easily escape observation and cause discrepancies in counting the total number of joints. From the alternation just mentioned and from the considerable length of individual flagellum-joints in young individuals, he argues that the increased number of these joints in the adults results, not from the budding forth of new joints, but from the subdivision of the old ones. His description of the species in brief is—"*Amphithoe Hystrix*: fronc tu rostrata; antennae superiores dividitius inferiores partem non sequuntur; oculi orbicularius, convexus; corpus parum compressus; annulus thoracis, tribusque abdomenis anteriorebus series aculeorum quingue praeceptibus; primo thoracis annulo prae certeris aculeato, coroa gerenti praequoque et al caput prominens; epimeris fovei solito minus appressis, pleurostern in aculeos posterioris; mandibls lincaribus, angula praditae minutis; appendicis caudatibus minoribus posticis
aliquantum communis." This is followed by a sharp criticism of the generic character
given by Owen for Acanthosoma. "Amphithoe Serrata Kr. (Oniscus serratus, Fabr. Fn. 
gr. n. 237), (Tab. II, fig. 8)" is now Acanthosoma serratum. Kroyer changed serratus 
to serra to avoid displacing Amphithoe serrata, Say. "Amphithoe panopha Kr. (Tab. II, 
fig. 9)" has since been called Plestes panope. "Amphithoe bicuspid Rhdt. (Tab. II, 
fig. 10)," has been referred successively to Paramphithoe, Amphithoeis, Phronima, and 
Phlossos, and is restored by G. O. Sars in 1882 to Paramphithoe. "Amphithoe incrusta 
Rhdt. (Tab. III, fig. 11) (Oniscus Cancl. Fabr. Fn. gr. n. 233)," together with "Amphi-
thoe semiremata Rhdt. (Tab. III, fig. 12), (Oniscus abyssinus Fabr. Fn. gr. n. 236)," 
has been already mentioned in the note on Otto Fabricius, 1780, as now bearing the name 
Postogena incrusta, Kroyer. "Amphihtoe lacusculus Kr. (Tab. III, fig. 13)," is now 
called Calliphtoe lacusculus. "Ischyrocerus angipes Kr. (Tab. III, fig. 14)," is now 
known as Podocerus angipes, Kroyer, though not without the admission that it may be 
identical with the earlier Podocerus cylindricus, Say.

The new genus Ischyrocerus is thus defined:—"Ischyrocerus magni instructe palpis 
gyrum ultimis articulis oblongis, fere truncatis; antennae pediformes; pedunculus 
(s; pars basalis) antecurvarum multo longior flagello (s; parte terminali), quod perpuscil 
modo gaudet articulatus; antennae inferiores flagello appendiculari brevi, uni-
articulato ornatae; pedes primi parvis minutis post calidi, manumque generant; pedes 
secundi parvis naviculi, manum portentose in aditus magnitudinis arnulat; reliqui pedes solito 
forme more conformati; pedes sparsi quarti, quinti & sexti pari saluteri; articulis 
basalis sexti parvis articulis terminalibus triplo vel quadruplo longior; annulis abdominales 
tres anterores annulis thoracis breviores; epimeri mediocris magnitudinis." The name 
Ischyrocerus is a synonym of the earlier Podocerus.

"Medites Medusarum Kr. (Tab. III, fig. 15). (Oniscus Medusarum Fabr. Fn. gr. n. 232)," 
was transferred by Boeck to Dana's genus Tauria, the name Medusarum being pre-occupied. 
Boeillius, however, argues that the species cannot properly be separated from Hyperia, 
and the specific name medusarum being pre-occupied in that genus, he calls the present species 
"Hyperia Kroeyeri." But if G. O. Sars, 1882, be right in identifying Tauria abyssum, 
Boeck, with the so-called Tauria medusarum, the species will by the law of priority become 
Hyperia abyssum. The genus Medusarum is thus defined by Kroyer:—"Pedes primi et 
secundi parvis religiosis permutando breviores, sol calidi, manuque armati cheliformi. 
Articulus horum pedum quartus seu forma praedilis est triangularis, manum efficit, a cujus 
margine inferiori procellis pollici bicurticulatis anterior et doijus posterior. Primus politius 
articulus (s. quintus pedis) magnus, conicus; secundus nareus est pusillus. Digitus conicus, 
pollie abiguallatibus brevior. Margo utriusque pollicis artiuli posterior, manumque digitii 
anterior per totam longitudinem serrati. Ulterius cum gener Hyperia fermre convenit.

"Themisto articula Kr. (Themisto Gaedichaudhi Ross). (Tab. IV, fig. 16)," and "Themisto 
crasicornis Kr. (Tab. IV, fig. 17)," are by Boeck both made synonyms of Themisto 
libellula, Mandt. Kroyer himself felt he had grounds for believing that his Themisto 
articula was not identical with "Themisto Gaedichaudhi Grueris," but that it might well be 
so with "Ross's Themisto Gaedichaudhi.

"Lestrigonus exculus Kr. (Tab. IV, fig. 18)," is considered by Boeck and others to be the male 
of Hyperia medusarum, O. F. Müller. F. H. Streete would keep the genus Lestrigonus 
distinct from Hyperia. "Hyperia obliqua Kr. (Tab. IV, fig. 19)," is also held to be 
a synonym of Hyperia medusarum, O. F. M.

The second part of this work is concerned with Crustacea outside the order of Amphipoda. 
In the third part Kroyer reviews the Greenland Crustacea in general, naming, among the 
fifty-eight species which, he says, had come under his own observation, the Amphipods 
already discussed, which are numbered from 11 to 31 in the series. Under number 38 he
saying, "Caprella septentrionalis (Squilla lobata Fabr. Fn. gr. n. 225) not only differs very considerably from the Caprella quadripodia (Capr. linearis Latr.) which occurs with us, in the form of the second pair of hands, etc., but, so far as I can judge, is also distinct from all known European species. It seems frequent in the Greenland Sea, but is not mentioned by Sabine and Ross." He subsequently figures and describes Caprella septentrionalis, Kr., in the Nat. Tidsskr., pp. 590-596, Tab. VIII, fig. 10-19, without reference to Squilla lobata of O. Fabricius. Under number 29 he says, "Cyanus Ceti (Oniscus Ceti Fabr. Fn. gr. n. 230), is sent from northern and southern districts."

Of the species recorded by O. Fabricius, of which Kroyer personally knew nothing, he thinks that "Oniscus arenarius (Fn. gr. n. 231)" may be a Gammarus or Amphipod, and "Oniscus strombionus (Fn. gr. n. 235)" an Orchestia, as supposed by Milne-Edwards. He then mentions from English authors "Amphithoe Edwardeii (Talitrus Edwardeii Tab. 2. fig. 1-4)" "Amphithoe cristata (Acanthonotus cristatus, Owen. App. to the Voy. of Ross tab. B. fig. 8-12)," which he says seems to stand pretty near to Amphithoe serrae, and "Hyperea Cyanes (Talitrus Cyanes Tab. 1, Fig. 12-18)," all which have been already discussed. In a note he expresses disappointment that Owen should have left Cancer boreas, Cancer amputa and Cancer uagax of Phipps without elucidation.

In the ten orders of Crustacea, which Kroyer here admits, he reckons that the Arctic species number 68, or, taking the number of all then known Crustacea to be 1500, the Arctic species furnish a proportion of about 1 to 22. In these 68, 26, he says, are Amphipods, giving the large proportion of 26 out of a total of 99 then known from the world at large. The total is arrived at by the combination of his own list with that furnished by Milne-Edwards. It should be observed that two species of Lemipoda are here not included in the number of the Amphipoda.

Lastly, Kroyer calls attention to the tendency in the genera Gammarus and Amphipod, as he accepted them, to develop sharp and angular forms, with horn-like processes and spines, the more conspicuously the higher the latitude. As examples he adduces "Gammarus borealis, Gammarus Sabini, Amphithoe Edwardeii, Amphithoe Hystrix, Amphithoe Cristata, which all extend very far within the Polar zone."

1838. KROYER, H. N.

This is stated by the author to be chiefly an epitome of his previous work on the Amphipoda of Greenland with very few alterations. For the three species assigned in that work to Lysianassa, he now gives the name Anonyx. After the description of Amphithoe serrae, Kr., the epitome breaks off with the notice, "continuabitur."

1839. ANDRZEJOWSKI, ANT.

In the "État de la Collection en 1833," the "Crustacés" comprise only our Amphipod, "Gammarus Pulex." For "Année 1838," under the same heading the following Amphipods
are named; "Orchestra littorea Leach. Gammarus Pulex Fabr. ind. Gammarus marinus Leach. Odessa. Gammarus stagnalis Nob. K." "ind" signifie "indigène de ces Gouvernements." "K" stands for "Kiefer." To Gammarus stagnalis, a note is given as follows—Celui-ci diffère du précédent par ses yeux elliptiques reniformes, bien plus grands en raison de la tête que ceux du G. Pulex, malgré que l’animal lui-même ne le surpasse pas par sa taille. Les appendices de la queue surpassent en longueur les deux derniers articles de la queue, tandis qu’ils sont plus courts dans le G. Pulex. On peut les définir ainsi; G. Pulex oculus oblongus exiguis, appendicibus caudalibus duobus articulis ultimis caudae brevioribus. G. stagnalis oculis reniformibus magnis, appendicibus, duos ultimos articulos caudae superantibus. The characters given are insufficient for specific distinction. It is therefore of little importance that the name Gammarus stagnalis is preoccupied as a synonym for a non-Amphipod Crustacean, Branchipus stagnalis.

1839. PHILIPPI, RUDOLPH AMANDUS, born September 14, 1808 (Hagen).

The earliest known description of this singular, mischievous, common, and, since Philippi’s paper, often-described Amphipod is as follows:—"Das Thier ist, einschliesslich Fühler und Schwanzanhänge 4 1/2" lang und ohne dieselben 2 3/4" lang, und gegen 2" breit. Der Kopf ist am schlanksten und so lang als die zwei folgenden Segmente, der Körper wird vom Kopf an allmählich breiter ohne sich jedoch bedeutend von der linealischen Form zu entfernen. Die Augen sind klein und rund; die oben Fühler von nüssiger Länge, borstenförmig, siebengliedrig. Die unteren Fühler sind andehalb mal so lang und bestehen aus 6 Gliedern; die beiden ersten Glieder sind sehr kurz, die übrigen nehmen allmählich an Länge zu, werden platter und die letzten sind dicht gewimpert, so dass sie eher ein Organ zum Schwimmen als zum Tasten zu sein scheinen. Die Brustsegmente sind gleich lang und haben ihre Seitensteile nur sehr wenig entwickelt. Der Schwanz oder Abdomen ist fünfgliedrig; die beiden ersten Glieder sind den Brustsegmenten ähnlich, das dritte Glied trägt auf der Mitte des Rückens ein langes gekrummtes Horn, welches ganz dem der Sphinx-räuen gleicht, und jederseits noch 2 kleine Spitzen. Das vierte Glied ist andehalbmal so lang als breit, unten ziemlich flach, oben concur mit kleinen Höckerchen besetzt, an den Seitenrändern gewimpert. Zwei kleine Höckerchen in der Mitte des hinteren Randes zeichnen sich besonders aus. Dieses Glied trägt jederseits zwei Paar sonderbare Anhängsel, die an seinem Grade eingelenkt sind. Die obere Anhänge sind senkrecht aufgerichtet und bestehen aus 3 länglichen abgerundeten Lappen, die alle mit langen Haaren dicht gewimpert sind, und von denen der vorderste der grösste, der hintere der kleinste ist. Das seitliche Paar Anhänge entspricht volkommen einem der Schwanzanhängen der Gammarinen und besteht aus einem Stiel, der zwei kleine spitze Blättchen trägt. Das fünfte Glied ist sehr kurz, zeigt unten in einer Spalte den After oben in der Mitte und an seinem Grade (oder am hinteren Rande des 4ten Gliedes) eingelenkt ein ovales Blättchen und an seinem Ende eine ungeheure Zange, die beinahe andehalbmal so lang als die beiden letzten Schwanzglieder ist. Ihre beiden Blätter sind flach gedrückt, etwas divergiren, gegen das Ende verschmälernt und lahnförmig gebogen, und haben gerillte Ränder. Die 14 Füsse nehmen von vorn nach hinten an Länge zu, jedoch nicht bedeutend. Die beiden ersten tragen am Ende eine ungebogene Klaue und der Tarsus ist breit mit einem divergirenden Zahn. Das erste Fusspaar ist weit breiter als
THE VOYAGE OF H.M.S. CHALLENGER.

das zweite. Die folgenden Füße enden mit einer langen graden nur an der Spitze schwach hakenförmig gebogenen Klause, die drei hinten haben nur ein kleines blattartiges Hüftglied. Die Kiemen an ihrem Grunde habe ich nicht gesehen, desto deutlicher die 3 Paar falscher Abdominalfüße, die aus einem beiförmigen, lamellenartigen Grundglied und zwei gegliederten und gewimperten Borsten bestehn; so dass über die Ordnung der Crustaceen, zu welcher das Thierchen gehört, kein Zweifel sein kann. Die Kauwerkzeuge schienen mir aus einer ausgerundeten Oberlippe, einem Paar mit 2gliedrigen Palpen versehenen Mandibeln, drei (?) oder vier (?) Paar lamellenartiger Maxillen, und 2 sechshügeligen Kaußüssen zu bestehn."

1839. Rathke, Heinrich.

This paper on the development of Mysis vulgaris is illustrated throughout by reference to corresponding facts in regard to the Isopoda and Amphipoda.

1839. Wiegmann, Arend Friedrich August, born 1802, died 1841 (Hagen).

"In a little Leptomera from the Skagerak," Wiegmann observed that the blood corpuscles were not round or roundish, but "elongate, thin at either end, fusiform." In the gnathopods and other limbs he observed "two active currents, the one arterial, descending, on the hinder side of the legs, the other ascending, on their front side. Each passes through the whole extent of the limb, till at the end of the foot the descending bends round into the ascending."

1840. Bennett, F. D.

To this work Lütken refers for mention of Whale-lice (Larvula ceti) on the Cachalot, p. 169, a Cetacean on which Roussel was unable to find any Cypamus. On a Dolphin, larger than the common Dolphin (Delphinus delphis), and which in the spaces between the teeth in both jaws had cavities to receive the teeth from the opposite jaw, "some Ousti adhered to the body," p. 237. In reference to "the Blackfish of South-Sea Whalers," he says, "a few whale-lice (Larvula ceti) adhere to the skin of this Cetacean," p. 234. See Lütken, 1873, p. 14 (242).
1840. COSTA, O. G. and COSTA, A.

1840. LUCAS, HIPPOLYTE.

Histoire Naturelle des Crustacés, des Arachnides et des Myriapodes. Paris, M. DOCC XL.

In the account of the orders Lernoesipodi and Amphipodi, pages 219 to 240, no original information appears to be given. There is a full account of Cyamus, taken from Roussel de Vauzeme. Of the Lernoesipodi filiformes the genera mentioned are Leptomeria, Naupreilia, Caprellia. In the definition of Leptoneca, the legs "ne paroissent pas tous pourvis d'appendices en forme de sac vsciculeux a leur base, ou mme n'en ayant pas du tout." Of the species, Leptoneca ventricosa, he says, "Cette espce prsente un appendice en forme de lobe a tous les pieds, les deux premiers excepts. M. Latreille lui rapporte aussi l'espce reprsentee par Slabber, Micros., tab. 10, fig. 2, et le Cancer Putatus, Montagu. Transact. Linnae. t. xi, pl. 2, fig. 6, qui en a tous les pieds pourvis, mais ceux de la premire et des trois dernires paires." Proto ventricosa, O. F. M., has in fact only three pairs of branchiae, though Slabber figures it with six pairs. Naupreilia is here as usual without a species.

In the account of the Amphipodi the first mentioned is Orchestia littoralis, with references to Leach in the Edinb. Encycl, and the Linncean Transactions, in both of which he remarks that his Talitrus litoralis is the female of Talitrus locusta. Of Orchestia littoralis he makes no mention. The name Gammarus flavidillosus, M.-Edw., is used for the Squilla pulex
of Degéer, while *Gammarus roeselii*, Cervais, is entered without reference to Roessel. The genera assigned to the first family, Crévétines, are *Orchestra, Talitrus, Lysianassa, Gammarus*, *Amphithoe, Philus*, "Isca," *Lenothoe*. To the second family, Podocérides, are assigned *Erichthoneis, Atlys, Uncido, Ceropus, Podocerus, Corophium*. On "Corophia longicorne" d' Orbigny's observations are as usual quoted. To the third family, Hygréines, are assigned the genera, "Vibilia, Hyperia, Phorcus, Lestrigon, Daira, Themisto, Hieraconyx, Daetylecerus, Asychilomera, Phorinia, Primano, Tiphis, Pronoe, Oxycephalus." The descriptions of Guérin's genera are given with great fulness. To each of the species "Vibilia Peronii," M.-Edw., "Phorcus Reganii," M.-Edw., "Lestrigon Fabret," M.-Edw., "Daira Gabertii," M.-Edw., the remark is attached, "Cette espèce est encore inédite," as though the species were still undescribed, but it is obvious that, when a new genus is established for a single species, the characters of the genus are for the time those of the species also. Part of Plate 17 and the whole of Plate 18 are devoted to figures of Amphipoda, but the figures are not original. The names of *Coropus tubularis* and *Corophium longicorne* are interchanged on Plate 18.

This volume opens with the Edriophilthalmes of Leach as second legion of the subclass "Crustacés maxillés." To mark them off from other Crustacean, Milne-Edwards points out that they have the body divided into three very distinct parts, head, thorax, and abdomen, the rings of the two latter being almost always distinct and free to move; they have no carapace, no movable peduncle to the eyes, although like the Polophilthalmes they have the mouth armed with mandibles and maxillo, and the thoracic limbs all or almost all in the form of ambulatory feet. They do not, however, breathe by branchiae properly so called but by the help of a portion of the locomotive limbs, wholly or in part modified for the purpose; "tantôt c'est l'appendice failléiforme des pôtes thoraciques qui affecte la forme d'une grande vésicule membraneuse à texture délicate, et qui devient ainsi propre à servir d'instrument à la respiration." In the small number of species in which the inner structure is known, "le foie est remplacé par trois paires de canaux biliaires, le cœur a la forme d'un vaisseau dorsal situé tantôt dans le thorax, tantôt dans l'abdomen, et les organes génitaux se rapprochent, par leur structure, de ce qui se voit chez les Insectes." They form, he says, three natural classes thus distinguished:—

```
<table>
<thead>
<tr>
<th>Edriophilthalmes ayant,</th>
<th>Des vésicules branchiales sous le thorax.</th>
</tr>
</thead>
<tbody>
<tr>
<td>l'abdomen bien développé et peuplé de cinq ou six paires de membres.</td>
<td>Membres abdominaux des cinq premières paires hétéromorphes et servant à la locomotion.</td>

```
In his general description of the Amphipod structure, Milne-Edwards notes that the mandibles are "pouvrnes, en général, d'une tige palpiforme," that the dorsal arch in the thoracic segments is generally "composé de trois pièces bien distinctes, savoir : un tergum et deux épines," that at the base of most of the thoracic limbs there is on the inner side "une grande vésicule membraneuse qui semble être le représentant de la branche externe des pates-mâchoires et des pates ordinaires chez certains Isopodiformes, et qui présente ici tous les caractères d'un organe de respiration." The females, he continues, carry their eggs under the thorax, and often have flabelliform appendages fixed to the base of the feet to serve this purpose, but at other times their fructations are discharged by the respiratory vesicles. He does not, however, here specify any instances to justify the last observation, but subsequently he applies it to the genus Hyperia and the genus Paronima, asserting that in the latter genus there are five pairs of branchial vesicles, not three pairs only as commonly supposed. He says that the Amphipoda are all aquatic—a statement, which, in the light of later discoveries, requires some modification. He divides the order into two groups or families in the following manner:

"Pates-mâchoires très grandes recouvrant toute la bouche et formant une espèce de levre sternale impaire terminée par quatre grandes lames cornées et deux tiges palpiformes très-longues. . . . Famille des Crevettines.

"Pates-mâchoires ne recouvrant que la base des appendices précédents, et formant une espèce de levre sternale impaire terminée par trois lames cornées, et dépourvue de tiges palpiformes ou n'en ayant que des vestiges, . . . . . . . . . Famille des Hypérides."

The Crevettines he divides into the Tribu des Sauteurs with twelve genera, and the Tribu des Marcheurs with seven genera. The first Tribe contains two groups, the first of which, comprising only Talitrus and Orchestia, "essentiellement artéioles, ne présentent an plus que des vestiges d'une tige palpiforme aux mandibules." The remaining ten genera form the second group, which live habitually in the water and have a very long mandibular palp.

In the description of genera and species under Talitrus, Latr., he gives the species, 1. salitator, named from the Syquilla saltatrix of Klein rather than from Oniscus locusta of Pallus, or Cancer locusta, Limé; 2. Beauonanae, M.-Edw.; 3. brevicornis, n. s., from New Zealand; 4. platycheles, Guérin; 5. "Crepidii, (Audouin), Saviyuy.

Under Orchestia, Leach, "§ I. Espèces dont les pates de la sixième paire sont à peu près de même grandeur que celles de la septième, ou un peu plus petites," he includes the species, 1. littorea, Leach, with references to Baster, Herbst, Montagu, &c., and the observation that Oniscus gammarellus of Pallus and Oniscus stroemianus of Otto Fabricius and Talitrus gryllus of Esch, all seem to belong to this division of the genus Orchestia; 2. "Montagui," Audouin; 3. "Butula," n. s., "espèce très voisine de l'Orchestie sauteuse, mais dont les pates de la septième paire sont étroites et de même forme que celles de la paire précédente. Habite la mer Rouge," where as Sp. Bate suggests, he has probably written sauteuse by mistake for littorala or littorea. 4. "Debaysert, Audouin; 5. longicornis, Say's Talitrus longicornis; 6. "Chilenais," n. s., which Dana and Spence Bate call Chilisens; 7. "Oeguana," M.-Edw., called Talorchestia Quoyana by Dana and Spence Bate.

"§ 2. Espèces dont les pates de la sixième paire sont beaucoup plus grandes que celles de la septième paire" has the species 8. "Fischerii," M.-Edw., figured pl. 29. fig. 4. In the genus Lysianassæ he places the species, 1. "Costa," M.-Edw.; 2. lagea, answering to "Lysianassa lagea vel Amone lagea, Kiroyer;" 3. "Vahlii," Kiroyer's Amone Vahlil;
4. appendiculata, answering to "Lysianassa appendiculata vel Anonyx appendiculatus, Krøyer;" 5. atlantica, for his own Gammarus atlanticus; with the concluding observation that Cancer ampulla, Phipps, and the imperfectly known Cancer magus, Phipps, appear also to belong to this genus.

He forms the new genus Alihrotus with the one species "Chausseicar," to receive Lysianassa chausseicar, Milne-Edwards, and defines it thus:—"Les Alihrotus, que nous avions d'abord réunies aux Lysianasses, s'en distinguent par la longueur considérable des antennes et la forme grêle de celles de la première paire, qui ressemblent tout-à-fait à celles des Crevettes, et par la conformation des pates des deux premières paires qui sont grandes, fortes et propres à la marche et à fouir; elles ont à peu près la même forme et se terminent par un grand article plat et allongé, dont le sommet est armé d'un ongle gros, conique, et à peine flexible. Du reste, ces animaux ne diffèrent pas notablement des Crevettes." To this genus Spence Bate in the Brit. Mus. Catal., p. 86, adds "Anonyx littoralis, Krøyer, Voy. en Scand. pl. 13. f. 1.," but without reference to Kroyer's own account of it, Nat. Tidssk. 2. R. 1. B. 1844, pp. 621-629, which describes the first joint of the upper antennae as of the thickness usual in the genus Anonyx, and the second gnathopod as nearly filiform. Boeck includes Anonyx littoralis, Kroyer, and two other species in a new genus Onesimus, to which he appends Alihrotus as a doubtful synonym.

Milne-Edwards next gives Philus, Guérin, with its one species, serratus, Guérin. Acanthonotus, "Owen et J. C. Ross," receives the species (1) cristatus, Owen; (2) Nordmannii, n. s., thus described:—"Front d'épouvant de rostre, mais formant au-dessus de la base des antennes inférieures, une grande protubérance qui loge les yeux, et qui porte à son extrémité les antennes supérieures (à peu près comme chez les Ischyroceres). Antennes très-grêles et assez longues; le pédoncule de celles de la paire [supérieure] très-court, et le filet terminal long, mais ne dépassant que de peu le pédoncule des antennes inférieures. Thorax et abdome arrondis et sans dents ni épines en dessous. Pièces épimériennes des quatre premiers anneaux extrêmement grandes. Pates de la première paire ayant leur pénultième article clargi en dessous, près de sa base, et la griffe assez longue, de façon à ressembler à une petite main très-imparfaite. Pates de la seconde paire filiformes et sans trace d'une main préhensile. Pates de la troisième et de la quatrième paire ayant leur troisième article très-grand, et clargi, les deux suivants très-petits et le dernier très-long, mais grêle et styliforme. Pates des trois dernières paires courtes, mais ayant leur premier article très-grand et presque aussi large que long. Fausses pates de la dernière paire beaucoup plus saillantes que celles des deux paires précédentes, et pourvues de deux lames lancéolées de même longueur. Abdome terminé par deux lames sublancéolées dont le bord interne est droit. Longueur environ 5 lignes. Habite les côtes de la Crimée." This species appears to be still unidentified. It does not appear among the Mediterranean species in the recent work by Victor Carus. In the Brit. Mus. Catal., Spence Bate re-names it Protonemea nordmannii. Kroyer, Nat. Tidssk., 4 Rd. 1842, p. 161. n., had already expressed his belief that the species could not be retained in the genus Acanthonotus, but without proposing to place it in the genus Protonemea, which he had just instituted, loc. cit., p. 154, and since to that genus he assigns "Epimera sat brevis," while to Acanthonotus nordmannii Milne-Edwards assigns "Pièces épimériennes des quatre premiers anneaux extrêmement grandes," the union of this species to that genus is hardly likely to stand. The difficulty of such union is augmented by the statement in Boeck, De Skand. og Arkt. Amph. p. 576, that "Pedes secondi parsi parvi, manu non instructi subcheliformi" in Kroyer's generic definition is a slip of the pen for "Pedes primi parsi." Milne-Edwards considers rightly that Amphibius serru, Kroyer, ought to be placed in the genus Acanthonotus, and wrongly that Onesimus cicala of Otho Fabricius is probably the same species; he thinks farther that Gammarus spinosus, Montagu, the type of Leach's
genus *Dexamine*, may well also be an *Acanthomunus*, but that further information is needed about it.

After describing the genus *Isca*, with its type species, *Isca montagni*, Milne-Edwards, which is figured pl. 29, fig. 11, he passes to *Antipeus*, with its single species *dubius*, Templeton, for which see Note on Templeton, 1836.

Accepting the distinction of *Amphitoe* from *Gammarus* as convenient and in general use, though depending only on the absence of the accessory flagellum from the upper antenna of the former, Milne-Edwards unites under this name the "*Amptieus*; *Phorusa* and *Dexamine* of Leach. On the other hand ho divides and subdivides his own *Amphitoe* as follows:—

§ 1. Espèces dont le dos est arondi et dépouvré de grandes dents médianes.

1. *Thorax et abdomen dépouvré d'ériques.*

2. *Antennes superieures au moins aussi longues que les antennes inferieures,* with the species

4. *indica,* M.-Edw.; 5. *picta,* Rathke; 6. *Gaudichaudii,* n. s., from Brazil, in which he emphasises the peculiarity "Hanche des pates de la troisième et quatrième paire oucelaire (au lieu d'être presque linéaire comme d'ordinaire);" 7. *Filosa,* Savigny, from which he thinks that "l'Amphitoe de Ramond, et l'Amphitoe des vareces," as he names *Phorosa fuscicola,* Leach, scarcely differ. He gives notes on *Gammarus obtusatus,* Montagu, for which he had already proposed the name *Amphitoe obtusata*; on the Amphitoe rouge, that is, the *Gammarus rubricatus* of Montagu, or *Amphitoe rubricata* of Leach; and lastly on the Amphitoe dentelé, Say's fresh-water *Amphitoe dentata.*

"aa. Antennes superieures moins longues que les inferieures.*

"aa*. Mains des deux prenieres paires a peu pres de meme grandeur," with the species

"aa**. Mains des pates de la seconde paire plus de deux fois aussi grous que celles des pates anterieures," with the species 14. *Precordii,* M.-Edw.; 15. *pelagica,* M.-Edw.; 16. *Gaimardii,* n. s., which Dana transferred to *Allorchestes Gaimardii,* and for which Spencer Bate adopts the name *Allorchestes Guimardii,* making *Allorchestes compressa,* Dana, a synonym of it; 17. *podura,* with *Hyale podura,* Rathke, for a synonym.

"AA. Cdté du thorax ou le dessus de l'abdomen, garnis d'ériques ou de petites dents.*

"AA**. Des éries sur les planes.*

18. *cancellata,* the *Oniscus cancellus* of Pallas.

"AA***. Planes dépouvrés d'ériques.*

§ 2. Espèces dont le dos est plus ou moins carreié en dessus et armé vers sa partie postérieure de grandes dents médianes comprimées et dirigées en arrière.

B. Front dépouvré de rostre.*

25. "Pamopla," Kröyer; 26. "Carinata," Kröyer, followed by the concluding observation that Say's *Amphitoe serrata* "a le dos dentelé comme les espèces précédentes, mais paraît s'en distinguer par l'existence de trois éries saillantes situées à égale distance l'une de l'autre sur le bord inférieur de chacune des mains."

*CREVETTE.* *Gammarus, Fabricius,* is thus subdivided:—

§ 1. Espèces dont les yeux sont orbiculaires, râlesiformes ou linéaires.

A. Bord postérieur des trois premiers segmens de l'abdomen droit et ne se prolongeant pas de manière à former une grosse épine ou dent médiane.

“AA. Bord postérieur du troisième anneau de l’abeillon, et en général celui des deux anneaux précédents se prolongeant en arrière de manière à former sur la ligne médiane une grosse dent.”

“§ 2. Espèces dont les yeux sont circulaires.

“B. B. Griffe des secondes pates s’intercalissant sur la face interne de la main,” containing only the species, 23. *Dugesii*, M.-Edw., with the note, “cette espèce présente tous les caractères assignés par M. Leach à son genre *Melita*,” and followed by the well-grounded suspicion that *Gammarus palmatus*, Montagu, may be the same species.

*Ischyrocerus*, Krüyer, has the one species, *angulipes*, Krüyer.

*Leucothoe*, Leach, has only the species *furcata*, Savigny, but the description of this is followed by the observation that “le *Gammarus articulatus* de Montagu, d’après lequel Leach a établi le genre *Leucothoe* ressemble beaucoup à l’espèce précédente, mais est trop mal connu pour que nous puissions y assigner des caractères; Leach dit à la vérité que les antennes ne sont formées que de trois articles, ce qui le ferait distinguer facilement, mais il me paraît peu probable que cette observation soit exacte.”

In the “Tribu des Crevettes marcheuses,” with slender, semi-cylindrical bodies, not laterally compressed, with narrow side-plates, lower antennae generally pediform, the palps of the maxillipeds little developed, and the pleon not formed for leaping, he places *Eriothoeus*, M.-Edw., with the one species *difformis*, M.-Edw., and the remark that, “*le Gammarus spinicarpus* de Müller se rapproche beaucoup des Eriothoëes, mais devra probablement constituer un genre particulier;” *Cerapus*, Say, with the species 1. *tubularis*, Say; 2. *pelagicus*, Leach, to comprise *Cancer falcatus*, Montagu, and *Jassa pelagica*, Leach. The new genus *Cerapodina* is thus explained;—“Nous rangerons sous ce nom générique
REPORT ON THE AMPHIPODA.

189

un petit Crustacé qui a été décrit dernièrement par M. Templeton, et qui ressemble beaucoup aux Cérapiodes, tant par son organisation que par ses moeurs, mais qui s'en distingue par la conformation des antennes, dont les deux paires se terminent par un filet multi-articulé. Il est aussi à noter que la tête est ici confondue avec le premier anneau du thorax, et que les quatrième, cinquième et sixième anneaux paraissent être dépouvrus de pates." The single species is Cerapoda aubleti, the Cerapus aubletii of Templeton, which must retain its name, the new genus being only founded on obvious errors in Templeton's description.

The next genus given is Podocerus, Leach, with the species, 1. variegatus, Leach; 2. pulchellus, Leach; followed by an observation on the Podocerus cylindricus of Say. The genus Corophium, Latreille, receives the species, 1. longicornu, with the usual synonymy ; 2. "Bouveli," M.-Edw. Atylus, Leach, has the one species carinatus for the Gammarus carinatus of Fabricius. Uneida, Say, has the single species, irrorata, Say.

The Famille des Hypériques is divided into three tribes. The first, the Tribu des Hypériques gannaroides "characterised by the smallness of the head and the compressed form of the body," includes a single genus, Vibilia, M.-Edw., with Dactyllocere, Latreille, for a synonym, and with one species, Veroni, M.-Edw., Pl. 30, fig. 1.

In the second division, the Tribu des Hypériques ordinaires, "le corps est large et renflé; la tête est très-grosse ; les antennes de la première paire sont subéies et pointues; enfin celles de la seconde paire sont styliformes et ne peuvent se replier sur elles-mêmes comme chez les Typhles, etc." The genera and species included are as follows:— Hyperia, Latreille, identified with Dancer & Montagu, Lanceola, Say, Hella, Straus, and containing the species, 1. "Latreillii," M.-Edw., pl. 30, fig. 16; 2. obavia, Kröyer; 3. Gaulichaudii, n. s., from Chili, redescribed in the Brit. Mus. Catal., p. 289, and figured as "Lestrigonus Gaulichaudii," with the remark that "it closely resembles L. exulans, but may be at once recognized by the distinct armature on the propoda of the gnathopoda." After the numbered species of Hyperia, Milne-Edwards observes that "Hyperia Lesueurii," Latr., seems to differ from the two preceding species by having two little triangular horizontal plates, instead of the single plate at the distal end of the abdomen; that Say's Lanceola pellagica agrees essentially with Hyperia, but is distinguished from the other species by having the sixth pair of legs much longer than the rest; and lastly, that Gammarus galba of Montagu probably belongs to this genus. Metocerus, Kröyer, has the one species, "Metocerus," O. Fabr., followed by the remarks on Talitrus cyanus, Sabine, already quoted in note on Sabine, 1821. Phorcus, M.-Edw., has its one species, formerly spelled Reynaudii, but here Raymouardii, M.-Edw.

Tyro is a new genus instituted to receive Hyperia cornigera, M.-Edw., and is thus explained:—"Dans cette petite division générique, la forme générale du corps est la même que chez les Hypériques si ce n'est que la tête est tronquée antérieurement. Les antennes inférieures sont extrêmement petites comme dans les genres précédents, mais celles de la première paire sont plus longues que le corps, et composées de deux articles dont un basiliaire très-court, et l'autre terminal styliforme, gros et excessivement long. Aucune des pates n'est préhensile, mais leur longeur est très-inégale; celles de la cinquième paire sont beaucoup plus longues que les autres, et quoique assez fortes, ont leurs deux derniers articles filiformes; les pates de la septième paire sont très-petites et si grèles qu'elles ne paraissent pas être propres à la locomotion. Quant à l'abdomen, sa conformation est semblable à celle des Hypériques, si ce n'est que les fausses pates des trois dernières paires sont très-grêles, et ne présentent pas à leur extrémité deux lames distinctes." It has been pointed out by Bovallius, 1886, that this genus anticipates Clypronias, Dana.

Primus, Guérin, is given with the species macrops, Guérin. Lestrigonous, M.-Edw., has the species "Fabricii," M.-Edw., figured pl. 30, fig. 18., the description being followed by the remark that Lestrigonous exulans of Kröyer seems to be intermediate between the preceding

*Phrosina* of Riso, not Latreille, with *Dactyloera*, Latreille, for a synonym, is next described. A note says, "dans l'espèce que j'ai examinée il n'existait aucun vestige d'appendices palpi-formes insérés aux mandibules; mais dans la figure que M. Costa a donnée de ce genre, on voit de chaque côté de la bouche un petit appendice séparé qui paraissait être un palpe mandibulaire, et qui est considéré par ce naturaliste comme une seconde paire d'antennes; il serait possible que ces appendices ne fussent autre chose que les pièces terminales des pâtes mâchoires devenues plus saillantes que d'ordinaire." To this genus is assigned the species "*Phrosina Nicteonis,*" M.-Edw., previously called *Dactyloera Nicteonis,* the description being followed by the remark that "La *Phrosine* semi-lunaire, à en juger par la figure très-détaille qu'en a donnée M. Costa, diffère de l'espèce précédente par l'absence d'une grosse dent à l'angle antéro-inférieur du penultième article des pâtes antérieures, par la forme plus acuminée des lames nataleores qui représentent les trois dernières paires de fausses pâtes, et par quelques autres caractères." In the synonymy of the species he gives "*Pisicool bispinosa* L. Rafinesque," — *Phrosine semiluna*; Riso,—Desmarest, Consid. p. 259.—Costa, Fauna, Crust. pl. iv. fig. 1–5.

To *Phronima*, Latreille, he assigns the species, 1. *sedentaria*, Forskal; 2. "*Atlantica*, Guérin, and adds, in regard to *Phronima costos*, Riso, that it is probably the same, although in the figure, given by Riso and copied by Desmarest, the third segment of the abdomen, probably by error of the draughtsman, is without false feet. He thinks that if Rafinesque's *Sperchias* were better known, it would perhaps come near to *Phronima*.

The Tribu des *Hypérines anormales* is characterized by "un mode de conformation des antennes inférieures qui est très-remarquable; ces organes, au lieu d'avoir la forme d'une tige cylindrique ou d'un stylet peu flexible, et de faire saillie au-devant de la tête, s'inserent à la face inférieure de celle-ci, sur les côtés de la bouche, et se replient trois ou quatre fois sur eux-mêmes en zigzag." "Voyez Pl. 30, fig. 10."

To this tribe he assigns the following genera and species:—

*Typhis*, Riso, with the species, 1. *ferus*, M.-Edw.; 2. *rapax*, M.-Edw.; 3. *ovicis*, Riso. He also says "le genre Oioni de M. Cooce ne paraît pas différer de celui dont nous fussions ici l'historie; mais les figures qu'il en a données sont trop grossières pour que nous puissions assigner des caractères aux espèces dont il fait mention." He thinks further that the *Cancer gurneanus monocaulus* of Montagu ought probably to be referred to *Typhis*, but this is now known to be an erroneous supposition.

*Pronos*, Guérin, has the single species, *capito*, Guérin.

*Oxycephalus*, M.-Edw., has the species, 1. *pisator*, M.-Edw., figured Pl. 30. fig. 10; 2. *oceanicus*, Guérin; 3. *armatus*, n. s., "Tête aussi longue que tout le reste du corps, terminée par un rostre styliforme très-long, renflée au milieu dans le point occupé par les yeux, puis rétrécie dans une étendue assez considérable, et renflée de nouveau à son extrémité postérieure, où se trouve la bouche. Antennes de la première-paire très-petites et terminées par une lamelle ovale; celles de la seconde paire extrêmement longues et grêles. Paires des deux premières paires extrêmement petites; le premier article de celles des cinquième et sixième paires étroit et semblable à celui des paires précédentes. Les papes de la septième paire paraissent manquer complétement, mais il existe, au point où elles devraient s'insérer, une
REPORT ON THE AMPHIPODA.

191

lamelle membraneuse semblable à celle fixée près de la base des pates précédentes. Portion postérieure de l'abdomen très-étroite; le sixième segment, cylindrique, et terminé par un stylet impair aussi long que le corps. Les fausses pates des trois dernières paires très-grêles, très-longues, et terminées chacune par deux stylets. Longueur, environ 1 pouce." This under the name *Rhaleosoma armatum* became the type of the new genus *Rhaleosoma*, Adams and White, 1848.

The Ordre des Leomodipodes or Leomiodes is still described as being without mandibular palp. It is divided as usual into two families. The Famille des Crustacés, on Leomodipodes filiformes, contains the following genera and species:— *Caprella*, Lamarck, with the species, 1. *linearis*, answering to " *Cancer linearis*? Lin. Syst. nat.,” etc.; 2. *acuminifera*, Leach, pl. 33, fig. 1, including *Puce de mer orangense*, Quenouil; 3. *saurae*, Templeton; 4. *notosa*, Templeton; 5. *oeliferus*, for which inaccurately Desmarest is given as the authority, and *Caprella atomus*, Leach, as a synonym; 6. *phasma*, Montagu; the description of which is followed by the remarks that *Caprella tuberculata*, Guérin, Iconogr. Crust. Pl. 28. fig. 1, resembles the preceding species by the existence of a cephalic horn, but is distinguished by having a great number of blunt tubercles all along the back, and by the form of the legs of the three last pairs, of which the penultimate joint is widened and armed with a large tooth on its inner edge; " *Caprella mantis*, Latreille, Nouv. Dict. d'Hist. nat.,” he says, is very imperfectly known; *Cancer filiformis*, Linn., Ann. Acad. t. 6, p. 415, et syst. nat. t. 1, pars 5, p. 2933, probably, he thinks, belongs to this genus.

*Naupridia*, Latreille, with no described species.

*Leptomena*, Latreille, with the species, 1. *pedata*, Müller, and 2. *ventricosa*, Müller, which are, as Milne-Edwards suspected, the male and female of the same species properly called *Proto ventricosa*. That *proto*, Leach, is the same as *Leptomena* is recognised by Milne-Edwards, though he does not give *Proto* its rightful precedence.

In the Famille des Leomodipodes ovalaires on Cyamiens he places the single genus *Cyamus*, giving Lamarck, instead of Latreille, as the earliest authority for the name. The species he recognises are, 1. *erraticus*, Roussel de Vauzème, in the synonymy of which he erroneously groups together the various names applied to species of *Cyamus* in writings earlier than R. de Vauzème's treatise; 2. *ortes*, R. de V.; 3. *gracilis*, R. de V., with the concluding observation that "le *Cyamus Delphini* de M. Guérin (Iconographie, Crust. Pl. 28, fig. 5) parait differer des especes precedentes par la brieveté des appendices branchiaux, et par la maniere dont les divers anneaux du thorax se toucheant latéralement."

184. MILNE-EDWARDS (Editor).

Les Crustacés. Le Règne Animal distribué d'après son organisation, pour servir de base à l'histoire naturelle des animaux, et d'introduction à l'anatomie comparée par Georges Cuvier. Edition accompagnée de planches gravées, ... par une réunion de disciples de Cuvier. Paris, Fortin, Masson et Cie, Libraires, successeurs de Crochard. (No date is given in the work itself; I understand from Mr. G. K. Fortescue of the British Museum that it appeared in *Livraisons* between 1836 and 1849; it is sometimes called the Crochard Edition, or the Illustrated Edition.)

Pages 165–188 refer to the Amphipoda.

The Amphipoda, pl. 58 to 61, include under "des Crevettes (Gammarus, Fab.)," *Phronima, Latr.; Hyperia, Latr.; Phrosome, Risso; Dactylocoera, Latr.; Ione,* ("mais uniquement d'après une figure de Montagu, *Oniscus thoracicus*, Trans. linn. soc. x. iii., 3, 4"); *Orchestra,
Leach; Talitrus, Latr.; Astylus, Leach; Gammarus, Latr.; Melita, Leach; Marx, Leach; Amphiloe, Leach; Pherusa, Leach; Decaunine, Leach; Lencsothoe, Leach; Coropus, Say; Podocerus, Leach; Javaa, Leach; Corophium, Latr.; Pterygoeca, Latr.; Apseudes, Leach; (Eupheus, Risso); Typhlus, Risso; Ancusa, Risso; (Gnathia, Leach); Pranica, Leach. These form the third order. The fourth order, Lepadipoda, pl. 63, includes under "De Cyane (Cyanus, Latr.)," Leptomera, Latr. (Proto, Leach); Naupedia, Latr.; Caprella, Lanck; and for "des cyanes proprement dits," Cyamus, Latr., (Larvata, Leach).

The only part of this work which is of any independent value as regards the Amphipoda is the group of fine plates.

As to "Dactylocera Sicensis, Edw.," pl. 58, fig. 2, the editor says, "Cette espèce ne me paraît pas différer de celle désignée par M. Risso sous le nom de Phrosina semilibata, et citée par M. Latreille comme genre de son genre Dactylocère; cependant elle ne présente pas les caractères assignés par notre auteur à ce même genre."

On "Jone thoracicus, Latr.," pl. 59, fig. 1, he says, "il suffit de comparer ces figures d'une part avec celles des Talitres et des autres Amphipodes proprement dits, et de l'autre part avec celles des Cymothées, etc. (Pl. 55), pour se convaincre que ce n'est pas ici la place naturelle du genre Jone; dans la classification adoptée dans mon Histoire Naturelle des Cuscutés, ces parasites sont rangés dans une division particulière de l'ordre des Isopodes à la suite des Cymothéciens."

Bate and Westwood, i. p. 10. n., consider that the representation of Talitrus solitarius, Edw., pl. 58, fig. 2.a., has in reality been taken from Talitrus boreometrus, Edw.

The mandible of Orchestia littorea, pl. 59, fig. 2.d., seems to show a rudiment of a palp, but unjointed.

"Orchestia Quoyiana," Edw., pl. 59, fig. 4, is clearly depicted.

"Gammarus Dyanesii," Edw., pl. 60, fig. 3, has the remark, "Cette espèce offre un exemple de la forme des mâles de la deuxième paire, qui est caractéristique du genre Melita de Leach. Genre qui ne paraît pas devoir être adopté." It is in fact a synonym of Melita palmata, Montagu, the type-species of Leach's genus.

"Pl. 60. Fig. 4. Gammarus brevicaudatus, Edw. Individu mâle. Ici la main de la deuxième paire offre les particularités de forme propres au genre Marx de Leach. "Fig. 4. a. Patte de la seconde paire chez la femelle, conforme de la manière que chez les Crostévès ordinaires." These are the two sexes of Gammatella brevicaudata. Ou fig. 5. Melita palmata, Leach, he says, "Ce genre, comme nous venons de le dire, ne paraît pas être admissible." Fig. 6. "Amphileos Marionis," Edw., is identified by Spencer Bate with Decaunine spinosa, Montagu.

Pl. 61. fig. 4, "Podocerus variegatus, Leach," "d'après l'individu décrit par Leach et conservé dans le Muséum Britannique," has the last peron-segment and the first of the pleon dorsally produced backwards in a very marked tooth-like process.

Pl. 62 bis, is devoted to Typhlus oxoides, Risso, and Typhlus jerus, Edw.; pl. 63 to Caprella linearis, Leptomera ventricosa, and to Cyamus oralis, Roussel de Vauzème.

1841. Delie Chiaje:

Descrizione e notomia degli animali invertebrati della Sicilia citeriore. Napoli, 1841. 5 vols. folio.

Bate and Westwood, ii. p. 27, refer to plate xxiii. of this work as containing a figure of Delicarum papillomae, Delie Chiaje, with Pharamia sedentaria inside it. Claus, 1862, makes a similar reference. Bate and Westwood, loc. cit., also refer to Otto, "Nova Acta," xi. p. 313, and Otto is referred to by Claus likewise.
1841. Eichwald, Eduard von, born July 4, 1795 (Hagen).

Fauna Caspio-causasia nonnullis observationibus novis illustravit Eduardus Eichwald. Cum Tabul. lithograph. XL. Petropoli, mcccclxii.

At page 225, under "Crustata," he says, "Inter caspium maris et nigri insulas e Crustatorum classe similis quaque ac inter Pisces intercedit differentia; in hoc scilicet propter maris communionem aliis mediterraneis alia deprehenduntur genera aliaque prorsus species, quam in illo; sic ad Ponti insulas pertinent inter alia complura Pagurus Diogenis Riss., Pisidius longicornis Leach., Xanthia viridissima Riss., . . . alique; porro Orchestia littorea Leach., Gammarus hoestus Leach. alique, Asthix dein et Hyale, duo Amphipodum genera nova, Amphilobus, Idhix . . . multaque alia, a col. Rathke fusus descripta et a caspio mari plane aliana; alia denique in utroque mari offenduntur, quibus potissimum Asthix pertinent." For the "duo Amphipodum genera nova," he refers to Rathke, "zur Fauna der Kreya, 1837," so that for Asthix we should probably read Amathix. His own descriptions of Amphipoda are as follows:

"Gammarus Caspium Pall. Reise durch Russland I. Petersb. 1801, pag. 477.

"Segnenta caudalis in dorso nuemornata, postrema duo stylo dorsoali multo notata et appendice utrinque cylindracea bifurea, interjerto insuper medio foliolo lineari, primi parvis pedibus minutissi, secundo et tertio cheliferis, reliquis retractum versis.

"Hab. in caspio mari, ad ostium Rhymni una cum Gammarus palicus Fabr., ad insequentem fortasse speciem referendo.

"Gammarus Hemorrhaphes m. Tab. xxvii. Fig. 7. a. b. c.

"E fusco-viridis, segmentorum singularum postico margine externo laterali purpuro-sanguineo.

"Hab. in mari nigro; in caspio adesse quoque videtur.

"Corpus vic 4 lin. longum; antennis ac pedibus omnibus et appendicibus caudalis ciliatis.

"Inter antennas capit parvo infrafixas macro compressus nullus, quo itaque recedit a Gam. cancillio Pall., (Spiegel. Zool. Fasc. IX. Berol. 1772 Tab. III, fig. 18.) cui in ceteris quoad antennas similiumus; priores tres articuli (pedunculus) superiorum antennarum G. hemorrhaphes breves, articuli vero flagelli multo minores, minimi, numerosissimi; priores dein articuli duo inferiorum antennarum multo longiores, saltum duplo longiores illis superiorum, at minus numerosi articuli flagelli inferiorum idemque ha multo breviores superioribus, licet paululum crassiores iis, non ut in Gam. hoestus Pall. antennae superioris multo breviores inferioribus. Gammarus hoestus, a col. Rathke descriptus (l. c. 373) fortasse ad haec pertinet speciem, exceptis tamen antennis, quas superiores parum tantum longiores dixit inferioribus.

"Oculi viridi-nigri, semilunares.

"Squamae segmentorum pectoralis laterales sive laminae ab his segmentis direcempes pedesque contgentes volumine conspicio notabiles; quarta lamina omnium reliquarum latissima, maxima, post cam tres alia minima, quasi rudimentaria; numeros carum in universum illi pedem respondet, ut itaque septem segmenta pectoralia laminae ibidem laterales adundant et a media parte disjunctas monstrant; reliqua abdomina segmenta genuina simillima.

"Cauda sensim latitudine crescens, postrema duo segmenta exigua aculeis in dorso predita ultimunumque sussum conversa spina apicali. Sub hac cauda extrema parte subtus infixo spiri pedes breviores, apice biliidi versusque anteriore elongati ali.

"Pedes pectorales 7, antici duo tarsis latioribus instructi, tarso secundi pedum paris (l. c. b.) latiore, longiore, quam ille prioris (l. c. a.) subtusque hispido-acutulus; primi quoque parvis pedum tarsus hispidus, ut minus aculeatus, reliquorum instar; omnemque reliqui tertii instar (l. c. c.) pedes hispiduli; in Gammarus hoestus duo pedes antici tarsi subqualiter latius longisquae instructi; tales quoque in nostro balthico.

(Zool. Chall. Ext.—Part lxvii.—1887.)

Report on the invertebrata of Massachusetts, comprising the Mollusca, Crustacea, Annelida, and Radiata. Published agreeably to an order of the Legislature, by the Commissioners on the zoological and botanical survey of the State. Cambridge, 1841.

The Crustacea occupy pages 321-341. At page 333 the account of the “Amphipoda” begins, followed by that of the “Lemipoda.” The following notes are given:

“Genus Orchæstia, Leach. O. longicornis. Tælitrus longicornis, Say; Trans. Acad. Nat. Sc., i. 384. This appears to be the same as Cancer gæmarus saltator of Montagu (Trans. Lin. Soc., ix. 94, tab. 4, f. 3,) which is given as synonymous with Tælitrus locusta of Lamarck, Pennant, and others. But it is not Gæmarus locusta of Montagu.

“Two or three other species of Orchæstia, and one of Amphipoda, remain undetermined.

“Genus Hypæra, Latr. H. galba. Gæmarus galba, Montagu; Lin. Trans., xi. pl. 2, f. 2. The following are doubtless synonyms: Oniscus mechiæærum, O. Fabr.; Fæna Gerv., 275. Hypæra Suerii, Latr. Hypæra Latréillii, Milne-Edw.; Ann. des Sc. Nat., xx. 388, pl. 11, f. 1-7. This curious animal is found in the pouches of the Modus or Sun-fish as they are commonly called. Whether they make this their home, or whether they become entrapped there or not, it would be difficult to determine. They seem, however, to be quite at their ease in this situation.

“Another animal with long, many-jointed antennæ, was found in company with the above, which belongs either to the same genus, or to the genus Hieraconyx.

“Lemipoda. Genus Cyamus, Latr. C. cetti, Latr.; Gen., i. 60. Desm.; Conséd., 280, pl. 4, f. 4. Edwards; Ann. des Sc. Nat., 2d Series, iii. 328, pl. 64, f. 13, 14. Oniscus cetti, Lin.; Mulh. Lartëndæ cetti, Leach. The whale-louse may be properly enumerated among our Crustacea, as it is found on the whales which are occasionally caught on our coast. It varies in form, according to its degree of development.

“Genus Carphæstia, Lam. I have observed two species of this curious genus, neither of which can I refer to any described species. One of them is very delicate, about half an inch long, with no spines upon any part, that I can discover, and having its back thinly dotted with dark green.
"The other is an inch in length, entirely crimson except its black eyes. The head is blunt, the lower antenna ciliated and extending to the second segment, and the upper ones to the third segment; first two segments nearly as long as the three next, and about one-third of the whole length; on the middle of the first is a spine; two last segments short and heart-shaped. Hands having a long curved finger; an imperfect thumb on the second pair of legs; a tubercle at the base of the ovate carpus, and a small spine at the middle. This might be called C. sanguinea, from its colour, which it retains in spirit.

"These curious animals are found among clusters of zoophytes and delicate sea-weeds. Their mode of walking is like that of some caterpillars, who bring the tail forward to the head and then thrust the body forward its whole length to prepare for another step."

Mayer, 1882, considers that the descriptions of Caprella sanguinea given by Gould and Stimpson leave the species indeterminate.

1841. Koch, C. L. See Note on Koch, 1835.

The pages 363–368 of this volume by the same author, though mentioned in Boeck’s list, do not refer to the Amphipoda. Under the title above given, Section IV. is "On the Structure and Habits of the Caprellid; with descriptions of some new Species."

Goodsir gives a short account of the circulation of the blood in the Caprella, describes the ovaries, and in regard to the process of exuviation says that the skin "burst behind the head in a transverse direction, and also down the mesial line of the abdominal surface." He speaks of their being little known, owing "firstly, to their pelagic habitats," and further on says, "they are in general local in their habitats, frequenting corallines which are found in deep water." As a matter of fact, the Caprellids have a very extensive distribution, and may be found in great profusion between tide-marks. The species which he describes and figures are:—

Caprella spinosa, of which he says, "this species differs from the Caprella Phasma of Colonel Montagu in having five spines on the first thoracic segment, and from the segments being considerably longer. The third joint of the superior antennæ is very much longer, and the first pair of feet are also minute and slender, differing in so far from those of Phasma, which are strong and powerful. The inferior edge of the last joint of the second pair of feet is also armed with two strong spines, whereas in Phasma there is only one strong spine." It is nevertheless identified by Mayer with Protella phasma without hesitation, in accordance with the opinions of Bate and Westwood, and of Boeck.

Caprella tuberculata, the full description of which is followed by the remark, "This species is apt to be confounded with the Caprella acanthifera of Leach, but may be distinguished from it by the double fringe of spines on the lower edge of the inferior antennæ; the superior antennæ are also much shorter than those of the acanthifera."

Caprella loricata, of which he says, "this species may be distinguished from Caprella linearis, with which it is most apt to be confounded, by its greater comparative size, the structure of the antennæ; by the shortness of the post-occipital segment; the situation of the swelling on the first thoracic segment, which is at the posterior edge, whereas in the linearis it is at the
anterior; the femoral joint of the second pair of legs is not clavate in the linearis, and is also quite straight."

*Cuprella linearis*, after describing which he says, "this appears to be the *Cuprella linearis* of authors; there are some marks of difference, but they are trivial, and not sufficient to authorize any new specific distinctions."

Of these last three species, Mayer remarks, "Goodsir's species *C. levis* and *C. tuberculata*, were referred by Boek to *C. linearis* and *C. septentrionalis*; the second was referred by Rate to *C. acanthifera*; I refer them both to *C. linearis*, that is, to *C. lobata*, Kröyer, var. α and var. γ, leaving it on the other hand undecided, whether Goodsir's *C. linearis* has anything in common with the Linnean species." In a note Mayer observes that Goodsir rightly distinguished his *Cuprella tuberculata* from *Cuprella acanthifera*, Leach, by the double fringe of spines on the lower edge of the inferior antennæ. The name *Cuprella tuberculata* was preoccupied by Guérin, whose species is most probably distinct from Goodsir's.

Fauna of New Zealand.

List of the Anulose Animals hitherto recorded as found in New Zealand, with the Descriptions of some New Species by Messrs. Adam White and Edward Doubleday, Assistants in the Zoological Department of the British Museum.

In the "Class Crustacea" only 29 species are here included, with only 2 Amphipods, "Talitrus brevicornis, M. Edw. Hist. Nat. des Crust. iii. p. 15," and "Orchestia Quoyana, M. Edw. iii. p. 19."

1842. Guérin-Ménéville, F. E.

The giant Amphipod here described is closely allied to one which was among the first prizes of the Challenger dredgings, and which, owing to the comparatively scanty supply of literature available on board, was considered to be of a new genus, receiving the title *Thalassocellus pellicida*. Guérin says:—

"La famille des Hypérides se compose aujourd'hui de 15 genres, tous formés avec des Crustacés de petite taille. En voici un que l'on peut regarder comme un géant dans sa famille, car il est cinque ou six fois plus grand que les plus grandes espèces connues. Ce genre devra être placé entre nos *Themisto* et les *Daira* de M. Edwards, dans le groupe formé avec les Hypérides qui n'ont qu'une paire d'antennes; voici ses caractères essentiels:—

"Genre *Cystisoma*—Deux antennes seulement, composées de trois articles. Pattes des première et seconde paires terminées par une petite pince à doigt mobile un peu plus long que le doigt immobile, terminé par un petit ongle articulé à son extrémité. Les autres pattes allongées, grêles, aplatis; les troisième et quatrième augmentant graduellement de longueur. Pattes des quatrième cinquième et sixième paires munies à leur base d'une large
plaque respiratoire arrondie et aplatie. Les trois premiers segments de la queue ayant chacun en dessous une paire de fausses pattes assez grandes, formées d’une tige terminée par deux lames. Quatrième et cinquième segments plus petits, munis chacun, en arrière, d’une paire de fausses pattes allongées, portant au côté externe une petite lame articulée et formant une large nageoire postérieure. Corps très globuleux, vide en dedans comme une vessie, allant ensuite en diminuant jusqu’à l’extrémité postérieure, tète fort grosse et presque entièrement occupée par les yeux."

"Comme on peut le voir par l’exposé de ces caractères, ce genre se distingue des Doria, dont il est voisin, par les pattes très-imparfaites, et des Themisto par l’absence des antennes inférieures. On ne peut non plus le confondre avec les Primus, car ceux-ci n’ont pas les pattes antérieures terminées en pince.

"Cystisoma Neptunus. (Voy. notre pl. 1, fig. 1.) Tête et corps vides, gonflés comme une vessie, Tête plus large que le Thorax, ayant de chaque côté et un peu inférieurement une rangée d’épines partant de l’insertion des antennes en avant, et se terminant au bord postérieur près de la bouche; une seconde rangée très-courte, formée de petites épines, de chaque côté de la bouche en dessous. Thorax formé de six segments apparents; le premier et le second réunis, portant les deux premières paires de pattes: segments du thorax ouvrant au milieu, en dessous, une carène assez aiguë avec deux petites épines, et présentant de chaque côté au premier segment, et au bord postérieur seulement aux autres, une ligne transversale de petits tubercules. Segments abdominaux également caréné au milieu. Pattes armées de petites dents sur leur innombrable internes.—Long. 9 cent. (3 pouces 4 lignes), Larg. de la tête, 2 cent. 1/2.—Hab. le grand océan indien. Ce précieux Crustacé nous a été donné par M. Petit de la Saussure."

Guérin’s species is called Themisto Neptunus by Bovallius, 1886, but it should in my opinion be named Cystisoma spinosum, J. C. Fabr. See Notes on Fabricius, 1775, and Bovallius, 1886.

1842. Kroyer, H. N.

Kroyer, who had himself visited Spitzbergen and the north of Norway, and likewise for a time resided within the tropics, here brings forward arguments against the application to the Amphipoda of the supposed law in zoological geography, that animal life is more vigorously developed progressively from the Poles to the equator. He finds it inapplicable to these Crustacea and some other inhabitants of the sea, whether we regard variety of forms, numbers of individuals, the size they attain, or the brilliance of their colouring. He says, “on a glass bottle, with a little Amphipod, not an inch long, which was sent to the Royal Museum, the sender has written, ‘with this Crustacean Godthaab Bay was filled to such an extent on the 11th of July 1841, that in several places it was impossible to see through the water.’ The small creatures, which are known to fishermen under the name of Tangtalker, and which likewise belong to the Amphipods, are so numerous off Greenland, that in a single night they can consume the largest seal, so that nothing but the skeleton remains.” He then gives Holbøll’s often-quoted experience of landing up masses of this abundant and voracious species of Anonyx, by means of bait in an open basket. The Crustacean from Godthaab Bay he names Themisto arcticus, Kr. Where species are common to Spitzbergen, Greenland and the coast of Norway, he finds that they diminish in size the further south they are found. Caprella septentrionalis, he
says, is the largest species of its genus. He further illustrates his point by reference to the considerable size of the northern Amphipods. "Anonyx lagena, Amphitro Edvardissi, Gammarus Sabini, Gammarus Locusta and above all Gammarus loricatus, of which," he says, "1 possess an individual from Spitzbergen, of a length of more than two inches."

On the whole, he concludes that the colder seas may be regarded as the true and proper home of the Amphipoda.

He proceeds to define several new genera as follows:

1. Opis:—"Pedes primiti paris tellis armati portentoss magnitudinis. Reliquam cum genero Anonyx conveniunt." The type species is given as Opis Echerchiti Holm. The generic name being preoccupied has been changed to Opies by Boeck.  

2. Stegopera:—"Epimera insignis magnitudinis, loricam efficientiam, subj qua latent membra. Caput maximum, quasi proboscidium, epimeris omne horum fere lacinis, caudis, ut videtur, desitutum. Antennae breves (capitis altitudine non longiores); superiores pedunculo crassissimo, flagello appendiculato ulnino, unarticulato; inferiores subappendiculares. Mandibula pulpe instructa brevissimo, crasso, unarticulato, dentato, parum mobili; pedes maxillares quaedam pedunculati; labrum maximum. Pedes primiti et secundi pars unibus subheleboliformibus destituti. Pedes quinti pars pedibus tertii quartique paris structuram et direcione similis." Spence Bate corrected the error of attributing a palp to the mandibles, as indeed Kroyer had himself done tacitly in the figures of Stegopera inflata, in the Voyage en Scandinavie, &c. The type species, Stegopera inflata, as also pointed out by Spence Bate, is the same as Cancer ampuUa, Philps.  

3. Phoxus:—"Caput pergmuum (quaerit ferme longitudinis animalis partem efficienti), triangulare, depressum, antice productum et acuminatum. Antennae supericiei capitis inferiori adfixae, alterum par anteriorum, alterum posteriorum, nitrunque validum, pedunculo crassissimo. Antennae anteriorioribus perbreves (capite breviore), flagello appendiculato insolite magnitudinis ornate; pedunculus flagellis longior. Antennae posterioriorum pars unibus longiores. Mandibulae sat magna, pulpo longissimo. Pedes primiti et secundi pars unibus subheleboliformis armati valida; pedes tertii quartoque paris manibus subheleboliformi, cujus palman praebeat articulus tertius quaritusque juncti, unguem quintum sextusque; sextum pedum par ceteris multo longius. Flagellum pedem fere filiforme. Epimera pergmu, margine inferiori setis sat longis instructa. Appendix candalis laminis constans dianus." For this genus Kroyer says Captain Holboll had proposed the unuitable name Spinifer, distinguishing two species, Spinifer spinosissimae and Spinifer flagelliformis, which Kroyer unites in his type species Phoxus holbiU. The other new species, given as "Phoxus plumosus Holb." Kroyer afterwards thought should form a new genus, an opinion acted on by Boeck, who, ever ready to make new genera, instituted the genus Harpina, a preoccupied name, which he changed into Harpinia. J. Sp. Schmiiiler, 1884, calls attention to the fact that in Boeck, 1876, fig. 1 on pl. viii., does not represent Harpina plumosa, though it is so named.  

6. *Protonemeda*—"Annuli thoracii latiores quam altares, dorso subdepresso. Antennae superiores pedunculo elongato (flagello param breviori) instructae, flagelloque appendiculati multiarticulati. Antenne inferiores pediformes, pedunculo longissime, flagelloque ter ad minus longitudine superante. Pedes secundi parvis, manu non instructi subcheliformi. Pedes tertii quartique paris sat magni; articulis corum quintus sextusque quasi in unguen longissimum sunt coali, qui cum articulo terto quartoqve manum quodammodo efficiere videtur prehensilem. Epimera sat brevia. Pedes spurii quarti, quinti et sexti paries saltatorii." In this description Boeck notices that the expression, "pedes secundi parvis, manu non instructi subcheliformi," is a slip of the pen for "pedes primi parvis et," which has led subsequent authors astray. The type species is *Protonemeda fasciata*, Kr.

8. *Photis*—"Corpus sa latum, compressum. Antenne subpediformes (a.; elongate, sat validæ, pedunculo flagellis parviarticulinatis multo longiori), flagello appendiculati destituita. Pedes primi et secundi paris sat breves, validi, manu subcheliformi armati robusta. Pis quinti paris recurvatus, inversus, ungve rudimentari. Epimera per magna; quinquies paria anteriore ad marginem inferiorem setis sat longis instructa; quanta cadem est ac quarten altitudine, postice profundus excissum. Lamina terminalis inferior pedis saltatorii tertii paries rudimentaris." Boeck points out that this genus is omitted from the British Museum Catalogue. The type species is *Photis Rehikarti*, Kr.

10. *Lafayustus*—"Caput depressuum, latius quam longius, rostratum. Antenne sat breves,
THE VOYAGE OF H.M.S. CHALLENGER.

subulate, valde (superiores validissimae), eadem formae pedunculi et flagelli longitudine, subrostr in eodem plano postice, alterum par anterius alterum posterius. Oeuli in superficie capitis dorsoi siti. Mandibulae angustiores, acuminate, palpo intractae; lamina maxillariori exterior nullis divisia articulis; pedes maxillares palpo bibractulato. Thorax latus, depressus. Pes primi paris gracilimins, manu lineari, ungue elongato; pes secundi paris brevis, validus, manu quadrata, ungue sublaminari apice setoso. Reliqua decem pedes validi, subcheliformes, eadem formae longitudine. Epimeris medioequis magnitudinis, quantum par in acumen inferne productum. Pedes natatorii elongati, pedes saltatorii debiles. The type species is "Lafontius Starlitis, Kr.," at the time the species was constituted the only one of the Gammarina known to be parasitic.

Under the heading “new species of known genera,” Kroyer here alters Milne-Edwards’ definition of Lencothoë, Leach, to embrace two new species which he describes, Lencothoë crypeta, Kr., from Greenland, and Lencothoë glacialis, Kr., from Spitzbergen. These, he thinks, if refused admission to Lencothoë, would require, not simply one, but two new genera for their reception. He rightly observes that every genus founded on a single species must be liable to modification in its form to include subsequent discoveries. His own two species are now included in Boeck’s genus Metopa, of which Lencothoë crypeta is the type. He describes Gammarus dentatus, n. s., by Sp. Bate named Megapodes dentata, and by Boeck transferred to Melita dentata. He reluctantly admits the separation of Acanthonotus, Owen, from Amphithoe, excluding from it Acanthonotus normannii, Milne-Edwards, which Spence Bate gives as Prodomoidea normannii. Kroyer adds a new species Acanthonotus inflatus, very near to Oulacus scutellus, O. Fabr., but “with back rounded, not dentate.” These two by Boeck are named Acanthonotoma inflatus and Acanthonotoma scutellus respectively, Owen’s generic name and White’s alternative for it, Vertamnus, being both pre-occupied. Kroyer next re-describes Ischyrocerus longipes, adding a new species Ischyrocerus inflatus, both of which belong to the older Podocerus of Leach, and Ischyrocerus longipes in Bate’s opinion certainly, in Boeck’s doubtfully, being a synonym of Podocerus cylindricus, Say. The new species “Podocerus Leachi” here described was afterwards called “Cerapus Leachi” by Spence Bate, and Cerapus differens by Boeck. To this last S. I. Smith restores its original name Eriothoicus differens, Milne-Edwards. Kroyer notices that the male of his species is an Eriothoicus, for which reason he makes that genus yield as a synonym to Podocerus. In the genus Anonyx he notes that his Anonyx appendiculatus is only the male of Anonyx lugena. He has also discovered, he says, that in this genus the males are distinguished from the females in that the antenna, besides being considerably longer in the lower pair, are furnished with a number of small appendages, which seem to act as suckers (Sugeskaaler), by which probably the male holds the female fast. These had been already noticed by Milne-Edwards in 1830 on his Gammarus ornatus. They have since, at Stimpson’s suggestion, been called calceolus; it is now known that they are not in all species confined to the male sex, or to the lower antenna, and as they are sometimes found in both sexes, Kroyer’s explanation of their use is thought untenable. He finds a similar distinction between the sexes in his new genus Opis, Phoros and Ampelisca, considers that Amphithoe ornata and Amphithoe inermis should on this ground be considered male and female of the same species. These are united by Boeck under the name Pontogeneia inermis. He attributes his discovery indirectly to Captain Holboll, his suspicions being aroused by the great number of the species to which Holboll gave names. Of these Kroyer paired “An. scutelator” with its female “An. Krögeri,” “An. velatus” with “An. ornatus,” “An. Eriothoicus” with “An. longus spec.,” names of undescribed species which do not re-appear. In a note he expresses a regret that Milne-Edwards did not retain Allibrotus chausicus in the genus Lysianassa and transfer Lysianassa costar to the genus Anonyx.
1843. Kroyer, H. N.

After remarking on various mistakes and improvements made by his predecessors in the classification of the Læmodipoda, Kroyer gives his own opinion that they ought not to constitute a separate order, but to be united with the Amphipoda, as a family of that order. This had been already done by Barmeister, but as he at the same time united the Pycnogonida to the Amphipoda, Kroyer thinks that his systematic arrangement was not well grounded. Kroyer points out that the Læmodipoda no less than the Amphipoda have seven segments to the peræon (Brystringe), the first being always distinguished from the head by a more or less obvious line of demarcation; the mandibles, though sometimes without a pally, in some species have a large, three-jointed one; the eyes are not, as Barmeister states, simple, but “consist, as in the Amphipoda, of a number of small pyriform lenses, ensheathed in pigment and covered by a common cornea;” the want

(Zool. Chull. Exp.—Part LXVII.—1887.) XXX 26
of side-plates (epimera) only carries a little further the reduction observed in some Amphipoda, especially *Gammarina gressoria*. Where the action of the pleon keeps up a fresh supply of water to the branchie, Kröyer thinks that the side-plates covering the branchie may attain their fullest development without interfering with respiration, but that in the Leomodipoda, there being no pleon to fulfil this office, the branchie have to be left free. The absence of a pleon he connects with their mode of life, which leads them to cling and climb, and only very rarely to swim. Important as this mark of difference is, Kröyer urges that its weight is much diminished by the discovery of two new genera of Leomodipoda, in one of which the pleon, though small, has five segments, in the other only two, but in both is furnished with two pairs of jointed limbs. Thus, he considers, a transition is established to those Amphipoda, such as *Corophium*, in which the pleon is less strongly developed. He mentions that the genus *Cerapodina* wants feet on some of the segments of the peracon in common with the Leomodipoda, but that argument only rests on the faulty description of *Cerapodina*. He considers that the Leomodipoda, as a family or division of the Amphipoda, come nearest the *Gammarina gressoria*, referring to the pediform antennae among other marks of resemblance. He characterizes the family as follows:—"Pleon rudimentary or only little developed. No Epimera. The first of the seven peracon-segments united with the head along an oblique line, its pair of feet projecting under the maxillipeds. Feet generally wanting on the third and fourth peracon-segments. All the feet are in general claspers, that is to say, furnished with hand and movable finger. Only two or three pairs of branchial vesicles (on the second and third [3rd and 4th], or on the second, third and fourth peracon-segments). Antennae more or less pediform, the upper always larger and stronger than the lower. Eyes very small, circular." Of the family he makes two subdivisions:—"Caprellina. Form generally very elongate, thin, cylindrical. Branchial-plates bladder-like. The lower antennae of moderate size, and the feet of moderate strength. Often a palp on the mandibles. *Cyamus*. Form generally very flat and broad. Branchial-plates very large, sword- or saber-shaped, sometimes bipartite, in the males furnished with special appendages at the base. The lower antennae rudimentary. Feet extraordinarily developed. Mandibles without palp."

The general form, he says, has ceased to be a striking distinction between the two subdivisions, since the discovery of a thin *Cyamus* in *Cyamus gravile*, and a stout *Caprella* in *Caprella dilatata*. To the *Caprella* he assigns four genera, 1. *Leptomera*, Latr.; 2. *Cerocaps*, Kr.; 3. *Æginita*, Kr.; 4. *Caprella*, Lam. All these he defines; the two new ones as follows:—

Latreille’s *Nauphela* (*Nauphela* in Milne-Edwards) is dismissed by Kröyer as founded on a misconception, and the identity of *Proto*, Leach, with *Leptomera*, Latreille, being pointed out, the claim of *Proto* to priority is vindicated. Why Kröyer himself does not adopt it is not explained.

"*Caprella* Januarii Kr. (Tab. VI. fig. 14–20)" from Rio-Janeiro, is described with much detail. This species is identified by Spence Bate with the earlier *Caprella equilibra*, Say. Mayer agrees with Spence Bate, and points out that Kröyer, usually so exact, does
REPORT ON THE AMPHIPODA.

203

not mention the ventral median spine on the second pereion-segment of the male. Kroyer calls attention to the great difference between the adult males and females, especially shown in this, but existing also in other, species of Caprella.

"Ceratop Haalstedt Kr. (Tab. VI. fig. 1–13)," from South Greenland, is described in detail. It is still the only known species of the genus. In regard to the quinque-articulate pleon, in a note Kroyer says, "it is possible, as in itself not improbable, that the pleon consists of six rings, in that the ring which I have treated as the fifth, is perhaps composed of two pretty closely united."

"Egina longicornis Kr. (Tab. VII. Fig. 1–12)," also from Greenland, is next described.

At page 585 begins the description of "Caprella dilatata Kr. (Tab. VIII. fig. 1–9)," from Rio Janeiro. Mayer identifies it with the earlier Caprella acutifrons, Latreille. "Caprella septentrionalis Kr. (Tab. VIII. fig. 10–19)," already alluded to in previous papers, is here fully described, without the reference to "Squilla lobata Fabr. Fn. Gr. n. 225," given in Grønl. Amph. It is said to be the commonest of the Caprellina in Greenland.

For "Caprella lobata Mull. (Tab. VII. fig. 24–28)" Kroyer gives the references

"Zoologia danica, fasc. II", pag. 21: Squilla quadrilobata.

"Müller, Palaearctic Crustacea, fasc. III", pag. 58: Gammarus quadrilobatus.

"Linné, Systema naturae, edit. XII", pag. 1056: Cancer linearis?"

Pallas, Spicil. zool. IX. 78: Oniscus scolopendroides?

"Zool. danica tab. 56 fig. 1–5 a" and tab. 114 fig. 11–12 ?"

These are followed by a full description, winding up with the discrimination of three varieties as follows: "var. a. superficies dorsalis annulii thoracici qvinti, sexti, septimiqve aculeis destituta; var. b. superficies dorsalis annulii thoracici qvinti, sexti, septimiqve aculeis destituta; laminae branchialae suborbiculares. var. c. caput annulatas thoracis secundus, tertius quadrato-aculeis nodis evolutis minuttissimis prædesta." Mayer assigns the species, with varieties a and b, to the name Caprella linearis (Linn.) Bate. var. β, he thinks may belong to Kroyer's Caprella septentrionalis, though that itself, he supposes, may be but a variety of Caprella linearis.

"Caprella Hydrie Kr. (Tab. VIII. fig. 20–26)," of which the largest specimen was only about 3" long, is regarded by Mayer as, with little doubt, a young form of Caprella acanthifera, Leach, and quite distinct from the Caprella hydrie of Bate and Westwood.

"Leptomera pedestis" Abildg. (Tab. VII. fig. 13–23), receives a full description, preceded by the following references and synonyms:

"Müller's Prodromus, n. 2960: Squilla ventricosa (Quannen).

"Dana, Consid. a. les Crustacés pag. 276: Leptomera ventricosa (F)."

"— — — — — — — Proton pedatum (F & F).

"Latreille i Cuvier's Règne anim. I", ed. IV, pag. 128: Naupedia?"

"Zool. dan. tab. 56 fig. 1–3 (F) og tab. 101 fig. 1–2 (F)."

Kroyer notices the incorrectness of the view propounded by Eschscholtz, 1830, that Leptomera rubra, Lam., might be regarded as a synonym of Caprella scolopendroides, Lam. He recognises the priority of the name ventricosa, but rejects it for the insufficient reason that its meaning is only suitable to the female. Mayer reinstates it, in the title Proto ventricosa, O. F. Müller.
1843. Rathke, M. H.

On pages 60–63, Rathke describes *Liriöpe pygmaea* as type of a new Amphipod genus. The name *Liriöpe* had been already used for a genus of Medusae by Lesson, and Dana recognized that the creatures described by Rathke were not Amphipods. A full account is given in the British Sessile Eyed Crustaceans, vol. ii. pp. 257, etc., of what is known of these strange animals, and of the nomenclature, under the genus *Cryptothiria*, among the Bopyride.

Of the genuine Amphipods, Rathke’s *Gammarus anomalus* n. sp. (Tab. IV. Fig. 7.) is by Spence Bate and Boeck named *Microdomus anomalus*. *Gammarus sundecallii* n. sp. (Tab. III. Fig. 2.) was redescribed by Bate and Westwood as “*Liriöpe Schedtiandra,*” by myself as “*Liriöpe Normalis,*” and by Hoek as *Cheirocratus brevicornis*, its name finally being *Cheirocratus sundecallii*. *Gammarus pocilurus* n. sp. (Tab. IV. Fig. 2.) and *Gammarus kroeyeri* n. sp. (Tab. IV. Fig. 1.) are alike identified with *Gammarus marinus*, Leach, both by Sp. Bate and Boeck. Of *Gammarus sabini*, Leach, Rathke gives a new description in order to distinguish it from his own nearly-related species, *Amathilla carinata*, from the Crimea, and *Gammarus angulosus*, n. sp. (Tab. III. Fig. 3.) from Norway. Nevertheless, it is not an absolutely untenable opinion that these three species are in reality identical. That his *Gammarus angulosus* is not the young of *Gammarus sabini*, Rathke thinks is proved by two circumstances, first, that he had seen several specimens of it with eggs, and secondly, that the young of *Gammarus sabini* of the same size (4 to 4½ lines) have already the same shape as the old. But the female may be very much smaller than the male, as in *Melita palma* and other species, and Rathke’s observation as to the young of *Gammarus sabini* does not agree with the experience of some other observers. Bate and Westwood unite *Gammarus angulosus* with *Amathilla sabini*, and would do the same to *Amathilla carinata*, but for the (insufficient) reason that Rathke himself says that it is different.

Rathke’s *Gammarus zebra* n. sp. (Tab. III. Fig. 4.) is identified by Spence Bate with the female of *Podocerus cylindricus*, Say, which Bock accepts as a synonym only with a ¹⁄₄, placing the species under *Podocerus* (*Ischyrocercus*) anguipes of Krüyer. *Amphithoë tenicornis*, n. sp. (Tab. IV. Fig. 3.), is named *Doramine tenicornis* by Spence Bate, who notices the improbability of Rathke’s statement that the species has no telson, and observes that “certainly Rathke’s *tenicornis* is very closely allied to, if not identical with Montagu’s *spinosus.*” Of the latter species Boeck makes it a synonym, *Amphithoë podoceroides*, n. sp. (Tab. IV. Fig. 4.) which Sp. Bate transferred to his genus *Simamphithoë*, is retransferred by Boeck to *Amphithoë* and made to supersede *Amphithoë littorina*, Sp. Bate. In my opinion *Cancer Gammarus rubricatus*, Montagu, is the same as *Amphithoë littorina*, in which case the name will stand as *Amphithoë rubricata*. *Amphithoë proximilis*, M. Edwards? (Tab. IV. Fig. 5.), is said to have no telson. At p. 264c it is established as a distinct species, with the name, “*Amphithoë Nilsoni*”; it has already been discussed in the note on Rathke’s earlier work, 1837. *Amphithoë norvegica*, n. sp. (Tab. IV. Fig. 6.), is now placed in the genus *Calligopsis* (see Sp. Bate and A. Boeck). Of the new genus *Iphimedia*, the following definition is given:—“Antennae superiores inferioribus breviores : illarum pedunculii tribus, harum e quatuor articulis compositus: omnium flagellum teue, multiarticulatum. Pedes secundii paris manibus subplicibus, primi paris, illis minores, chelis instructi, quarum pollex ex uno tantum articulo constat: reliqui pedes illi Gammarorum similis. Pedes spurii in duos ramos minusve complanatos divisi.” Spence Bate objects to this definition that the hands of the
second gnathopods are not simple, but subchelate, as Rathke's figure represents them. This is only a question of terminology, as may be seen from Rathke's specific description, "An dem zweiten Beinpaare (K) kommen nur Anleitungen von Händen vor, indem das letzte Glied derselben kaum etwas breiter, als das vorletzte, übrigens aber ziemlich lang, tafelartig dünne und mit seinem hinteren unteren Winkel so hervorspringend ist, dass es hier einen platten, breiten und abgerundeten Fortsatz bildet, der ungefähr halb so lang erscheint, als die dicht vor ihm eingelenkte Klause." The type species, to which this description applies, is named Iphimedia obesa (Tab. III. Fig. 1). Kroyer afterwards described the same species as Microcheles armata, and Dana, altering the definition, included in the genus species which have nothing to do with it.

Podocerus capillatus, n. sp. (Tab. IV. Fig. 8) is said by Rathke to come near Podocerus variegatus, Leach, but to be adequately distinguished from it. In this view Bate and Westwood agree with him. Bruzelius named it Jassa capillata. Böeck considers it the same as Podocerus variegatus, which was the type of Leach's genus Podocerus, but he rejects Leach's genus Jassa as synonymous with his Podocerus. Jassa of Bruzelius he alters into Janassa, because after Leach's time Jassa was used for a fish. He then enters Podocerus capillatus, Rathke, as a synonym of Janassa variegata, Leach. But surely, when a genus is retained, the type species must continue to belong to it, and if Janassa variegata really differs generically from the other species of Podocerus, Janassa must be called Podocerus, and the other species by some other name. The muddle that will ensue may best be avoided by re-uniting Janassa to Podocerus, from which it is separated only by fine-drawn distinctions. Podocerus calcaratus, n. sp. (Tab. IV. Fig. 94) Böeck unites to Podocerus falcatus, Montagu. The Caprella phantasma, Lanneck, Caprella acuminifera, Leach; and Caprella soleopendaloides, Lam. (C. linearius, Latr.) all belong to Caprella linearius. Leptomera pedata, Lam. (Proto pedatum, Desmar.) corresponds to Proto ventricosa, O. F. M.

1843. Kraus, Ferdinand.

The only Amphipods noticed are Orchestia botella, Milne-Edwards, Gammarus palus, Fabr., Cymamus erraticus, Roussel de Vauzème, and Cymamus ovalis of the same author. Litten notices that the identification by Kraus of Cymamus erraticus with Cymamus ovalis is erroneous.

1844. Costa, Oronzio Gabriele.

In the second Legion, Edrofalki, Order 3, Amphipodi, are given Orchestia littorea, and Gammarus fasciatus, a new species which is figured Tav. i. f. 3, but not described, except in so far as two.
THE VOYAGE OF H.M.S. CHALLENGER.

varieties are thus mentioned. "Var. a, corallinus. Var. b, vidaceus." In Order 4, Lernoesi-
podi, are given Caprella phaeno, Caprella linearis, Caprella acutifrons. Anconus jugiito-
larius and Prenza coronata are now placed in the 5th Order, Isopodi.

To judge by the figure Costa's Gammarus fasciatus must belong to the Mera and Melita group. It is not mentioned in the Brit. Mus. Catalogue, and is quite distinct from the earlier Gammarus fasciatus, Say, which is there described and figured. The three last segments of the pleon and the three first of the pleon are dorsally produced backwards into small teeth, the fourth and fifth of the pleon into large ones. The side-plates of the pleon are represented as low and all nearly alike. The lower hinder angle in the first three segments of the pleon is produced sharply backwards. The upper antenna have a long peduncle, the first joint long, the second still longer, the third not very short. No secondary appendage is shown. The second gnathopod has a large hand, with bidentate palm. The fourth pereopod is rather longer than the fifth. The first joints are but slightly dilated. The branches of the third uropod extend far beyond those of the second and third. In spite of some differences it seems tolerably clear that this is the Cercobacus orcesfipes of Achille Costa, said by him to have been "found by Prof. O. G. Costa in the Gulf of Tarentum," though he gives no reference to Gammarus fasciatus. Since the same Gammarus fasciatus lapsus as pre-occupied by Say, and since Cercobacus is recognised by Heller as identical with Mera, O. G. Costa's species will become a synonym of Mera orcesfipes, A. Costa.

1844. De Kay, James E.

Zoology of New-York, or the New-York Fauna; comprising detailed descriptions of all the animals hitherto observed within the state of New-York, with brief notices of those occasionally found near its borders, and accompanied by appropriate illustrations. Part VI. Crustacea. Albany, 1844.

The Crustacea belonging to "Order III. Amphipoda," and "Order IV. Lernipoda," are described on pages 35 to 41. In the preliminary list of works consulted, no mention is made of Rafinesque, on whose incursions, had he seen them, this author might have thrown much light. De Kay includes in his definition of the Amphipoda the old statement not universally applicable, that the mandibles are furnished with a palp. Of the species which he figures his descriptions are probably independent, though only one of the species is new. For Orchesla longisieruis, Say, "Pl. IX. fig. 28 & 28a. Female," he says:—"Eyes oval. Lower antenna longer than the body; the third joint, under the legs, armed with series of short spines, the fourth joint, with about thirty articulations, minutely spinous beneath. Second pair of feet with the hands dilated, oval, smooth, with two obscure spines on the anterior margin; one at the lower angle, and the other more elevated in the middle; the thumb much curved, acute at its tip, which rests on the interval between the two tubercles (see fig. 28, A.). The two posterior pairs of feet longest. Upper pair of antennae short, not extending beyond the second joint of the lower pair. Length, 0.5-1.0. These small crustaceans are well-known under the name of Sand-flea or Beach-flea, occurring along the shores of Long island, digging holes in the sand in which they conceal themselves, and living upon dead animal substances. They furnish an abundant supply of food to the numerous birds along that coast."
Of *Orchestia gracilis*, Bos. pl. vii. fig. 19, he says:— "Lower antennae much shorter than the body, slightly hairy, but not rugose upon the third peduncular joint; last article with about twenty-five articulations. Anterior pair of feet with a prominent obtuse tubercle on the antepenultimate joint; penultimate joint dilated into an obtuse tubercle at the inner tip to receive the thumb. Palm convex so as to receive the thumb without an interval, as long as the lower edge of the hand. Length, 0.5-0.6. Habit of the preceding, and abundant along the sandy beaches above the influence of the tide."

Of *Talitrus quadrifilus*, pl. ix. fig. 27, he gives the following description:— "Head compressed, eyes obliquely oval. Lower antennae shorter than the body, and only reaching as far back as the fourth segment, slightly hairy and somewhat rugose on the third joint. Upper antennae very short, scarcely exceeding the second joint of the lower ones. Body compressed. Tail with three appendices terminating in four spines, each furnished with a series of rigid setae. All the feet armed with a slender acute claw. Color, dark brown; eyes blackish brown. Length, 0.3-0.5. This species also passes under the name of *Beach-flea*, and is frequently found concealed under stones and sea-weed."

Of *Gammarus minutus*, Say, pl. ix. fig. 29, he says:— "Body incurved, subcompressed. Upper antennae longest, with the setae short, attaining the tip of the second articulation of the terminal joint, which has about twelve articulations. Eyes reniform. Color. Body whitish, with a few pale fulvous spots on the sides. In dried specimens, the color becomes reddish, and the lateral spots, more particularly towards the tail, are bright red. Length, 0.15-0.3. This species is common in most of our fresh-water streams, and may often be detected under stones and pieces of wood. It is extremely active, and is popularly known under the name of *Fresh-water Shrimp.*"

As "extra-limital" species, he gives brief accounts of *Gammarus macronatus*, Say; *G. fasciatus*, Say; *G. locusta*, Montagu; *G. appendiculatus*, Say; *Amphithoe serrata*, Say; *A. delata*, Say; *A. punctata*, Say. His account of *Cerapus* is as follows:— "Genus *Cerapus*, Say. Antennae very large and robust, nearly equal; the upper of four joints, the lower or lateral ones of five. Anterior pair of feet small, monodactyl; the second pair with a broad palm and a two-jointed thumb. Head distinct, ending in a small rostrum. "C. tubularis." (Id. [Say, Journ. Acad. Nat. Sc.], p. 49. C. oblites, Templeton, Tr. Ent. Soc. Lond. Vol. i, pl. 20, fig. 5. See Pl. 10, fig. 43 of this work.) Head with a macronate carina before, hand and first joint of the thumb with one or two obtuse teeth; eyes oval, black. Color. Body above blackish, with irregular paler spots; antennae and feet white; joints tipped with blackish; two hind pair of feet and tail white. Inhabiting a membranous tube open at both ends. Length, 0.25. *Sea-beach, Egg Harbor, New Jersey.*" This is followed by an account of Say's *Leptodactylus denticus*, of Say's *Unicola irrorata*, and of *Hyperia*, Latreille, to which he assigns "Hyperia latreillii." (Nat. Am. Nat. Vol. 20, p. 388. Say, *Lanecola pelagica*, Ac. Sc. Vol. 1, p. 318. **Gould** loc. cit. p. 335.) Anterior pair of feet shortest; third, fourth, and seventh equal; fifth longer; sixth longer than the thorax. This species is probably the same noticed by Dr. Gould under the name of *H. galla*, Mont., as occurring in the pouches of *Medusa*—*,* on the coast of Massachusetts. Mr. Say's specimen was obtained from the Gulf stream." Lastly he describes Say's *Podocerus oglesbyi*. Under *Lepidopoda* he figures, plate vi. fig. 14, and describes *Cyamus exilis*, which, he says, "is usually found attached to the bodies of whales along our coast, and occasionally on tunnies and other large marine animals. It varies much in form according to its degree of development, and this has given rise to several nominal species, which have not yet been sufficiently examined." In the description he speaks of the second and third pairs of feet as "replaced by slender appendices, at the bases of which are the branchial vesicles." As "extra-limital," he notices *Cyamus abbreviatus*, Say. In the genus *Caprella* he describes Say's species, *Caprella geometrica*, and as "extra-limital," notices the two species mentioned by Gould in 1841, and *Caprella equilibra*, Say.

The two orders, Amphipodes and Lamalipodes, are defined at page 382. The tribes, families and genera pertaining to them are named, and to Cymene is subjoined the remark, "Je suis porté à croire qu'il faudrait rapprocher de ce groupe les Pycnogonides."

1844. Tellkampf, Theodor G.

On pages 321, 322, is given the description of "Triura cavernicola. (Fig. 18.) Crustacea. Malacostraca," with "Character. 10 Fusspaare, von denen die vorderen 2 Paare in Palpen verwandelt sind. Drei Schwanzspitzen." Without the remainder of the description, the copy of Tellkampf's fig. 18 will suffice to show that this creature cannot belong to the Amphipoda, as suggested by Schiodte, and afterwards by Böck. Dana, Choristopoda, p. 306, says in a note, "Genus Triura, Tellkampf, Rhora forsan allinis."

It is mentioned, but not described in the Archiv für Anatomie, Physiologie und wissenschaftliche Medizin, herausgegeben von Dr. Johannes Müller, Berlin, 1844, p. 383.

1844. Thompson, William, died Feb. 17, 1852 (Hagen).

REPORT ON THE AMPHIPODA.

County Down, 1834, Mr. Hyndman and W. T.,” There is nothing else about Amphipoda. On “Pycnogonum balanarium, Fabr.,” he observes, “Pyc, balanarium must on our coast be content with a smaller victim than a whale, and condescends to suck the juices of an Arcticia.”

1844. ZADDACH, ERNST GUSTAV, died June 5, 1881 (Friedländer, Nature novitates).

Synopses crustaceorum Prussicorum prodromus. Regiononti, 1844.

Under the heading “Crustacea, adhue in provincia nostra Borussia reperta,” Zaddach enumerates seven Amphipods. These he names 1. Talitrus saltator, M.-Edw., which is better called Talitrus beasta; 2. Gammarus beasta, Fabr. (l), his doubt being occasioned by differences which he found in his specimens from the description by Milne-Edwards; 3. Gammarus fluetalitis, M.-Edw., which is Gammarus palaez, De Geger; 4. “Gammarus Vogesi,” M.-Edw., which has been identified with Melita palmata; 5. “Amphitoe Rathyi, nov. spec.” which, in Zaddach’s opinion, “maxime affinis est Amphitoe norvegas,” Rathke, and by Boeck is identified with the neighbouring species Callipus lacustris, Krayer; 6. Leptocheirus pilosus, n. g. et sp.; and 7. Corophium longicorne, Latr.

The new genus Leptocheirus is thus defined:

“Inter Amphipoda, quae in maris balticis littoribus habitant animalia reperta sunt, quae, concesso genera Amphiopodum notus a Milne Edwod constiitutis discernenda esse, nulli generi aliae descripto adnumerari possunt, sed in novum genus, quod Leptocheirun nanunpari propono, coliunda sunt. Genus eunum Amphitoe secundum illum scriptorem pedibus duorum primorum parium cheliferis, ceterorum non prehensilibus, et antennis superioribus inferiororum truncis longioribus simplicique flagello instructis inigni est. Hae autem animalia, quae num describamus, eunum genere Amphitoe antennarum quidem structura cteoronomicque partim formis omnino conveniunt, pedum autem secundci pars constructionae ab his different et generi Talitro similiora sunt. Hi enim chelis vacui nec ad comprehendas [comprehendendas] res apti nec ad graditudem sunt habiles, sed debiles compressique a lateribus et contrastet ceterisque pedibus occulti reperintur. Nc autem fines hujus novi generis augstiores claim, hae singulares pedum constructione non respecta, quesque Amphipoda saltatoria pedibus primit tantum pars cheliferis, ceteris non prehensilibus et antennis superioribus flagello auxiliario vacui inter se congruant, generi Leptocheiro adnumeranda esse potu.”

In the description of the type species, Zaddach very plainly says, “Mandibularum palpö e tribus articularis constant, articularis pene inter se equalibus, ultimo pilosi,” so that Boeck, De Skand. og. ark. Amph., p. 548, seems under some misapprehension when he says, “Müller visite i 1848 (Arch. f. Naturgesch. xiv. p. 62), at Zaddach havde overset, at Kindhakkermere eres forsynede med en Palpe, ligesom han ikke havde bemærket, at de øvre Fale have en Bisvebe.” That the upper antennae have a minute accessory flagellum is in fact remarked by Muller. Boeck retains the name Leptocheirus, though affirming that it is pre-occupied for an insect, but the earlier name alluded to is spelled Leptocheiro if Scudder may be trusted on the point.

1845. GOODSIE, HARRY D. S.

At p. 75 he describes “Amphitoe pelagica. Pl. VII. fig. 1. A. with peduncle of superior antennae about half the length of the inferior antennae, being almost the same length as the first three.

(zool. chal. exp.—part lxvii.—1887.) XXX 27
THE VOYAGE OF H.M.S. CHALLENGER.

joints of the peduncle of the lower antennæ. First pair of legs small, second pair with the wrist very much enlarged, and the claw sickle-shaped and moveable, inferior edge having a small tooth with a slight notch on either side of it near the distal extremity; claw as long as the wrist, and tapering very gradually to a point." The figure shows that by "wrist" in the above description the large ovate hand of the second gnathopod is intended. The antennæ are slender, the lower only about half the length of the upper. The right number of legs are shown, but there are distinctly nine peraeon-segments figured. The uropods and telson are small. The Brit. Mus. Catalogue certifies that Goodrich's species is identical with *Amphithoe pelagica*, Milne Edwards.

1845. Kroyer, Henrik.

After a detailed account of the new species, *Podalirius typicus*, the new genus *Podalirius* is thus described:—

"*Pod. typicus*: fuscescet, pilosus, capite thoracique inermibus. Long. 2". Hab. in Asteraceantibus rubente.

"Fig. prima tab. IIIae exhibit anuulum thoracicum quintum eum pede rudimentario et vesicula branchiali (l) rudimentaria."

P. Mayer vindicates Kroyer's accuracy in the above account against various succeeding writers. The rudimentary branchia (l) is, however, he says, as Kroyer himself suspected, only a sexual appendage (die weiblichen Geschlechtsklappen) of the female. Mayer adds that the lower antennæ are without "Ruderhaare," and that in *Podalirius krøyeri*, Haller, there are traces of the first and second peraeopods.

Kroyer next describes *Orchestia granulicornis*, n. s., from Valparaiso, figured Tab. 1. fig. 2. a–u, and accidentally misnamed *Orchestia longicornis* on the plate. This species is omitted from the Brit. Mus. Catal. It evidently belongs to *Hyale*. The next species, *Orchestia nitrosensis*, n. s., is identified by Boeck with *Hyale nilssonii*, Rathke, Kroyer himself having suspected that this and the preceding species were separated from *Orchestia* by their longer upper antennæ, and the unguis of the maxillipeds. *Orchestia platensis*, n. s., tab. ii. fig. 2. a–i, from Mont VIDEO, though retained by Spence Bate as a separate species, has in his opinion nothing but locality to distinguish it from *Orchestia gryllus*, Bosc, a North American species. *Talitrus tripusculus*, n. s. 2, tab. ii. fig. 2. a–e, is identified by Boeck as the female of *Orchestia gnamarellus*. It is omitted from the Brit. Mus. Catal. *Gammarus anisochir*, n. s., tab. ii. fig. 1. a–p, from Rio Janeiro, was transferred to *Mera* by Dana, who thought it very near *Mera astipes*; by Spence Bate it was referred to *Melita*. Kroyer himself was inclined to make it the type of a new genus, *Anisochir*, but he was restrained by finding that the female was a true *Gammarus*, and the male only distinguished from that genus by having the second gnathopod on the left side strongly chelate. He considered it very near to, though clearly distinct from, *Gammarus appendiculatus*, Say. Kroyer here takes the opportunity of criticising Milne-Edwards' division of the *Gammarus* by the shape of the eyes as very artificial and perhaps untrustworthy. The absence of the accessory flagellum on the upper antennæ, which separates *Amphithoe* from *Gammarus*, he considers a comparatively
REPORT ON THE AMPHIPODA.

trivial character. The want of a second ramus on the third uropods, or its quite rudimentary condition, he thinks may be of considerable importance, considering the relation of these uropods to the frequent springing movements of the Gammari, and that on this account not only his species **aniokhir**, but also **Milne-Edwards**, *deniatus*, Kroyer, *brevicostatus*, Milne-Edwards, might form a separate genus. The first three have since been transferred to *Melita*, the last to *Gammarella*.

Kroyer next describes *Aora typica*, n. s., tab. iii., fig. 3, a–i, the new genus *Aora* being described as follows:—

There seems no doubt that Kroyer was misled by a lateral view of the telson into supposing it bifid; his description of the "hand" in the first and second peraeopods is rightly rejected by Boeck; Kerguelen specimens of an *Aora*, very closely allied to Kroyer's species, exhibit the characters of the lower lip which he describes, but the marginal hooks are not so large as those which he figures, and the appendages which Schelde has designated "manubral processes," though more than usually produced, scarcely suggest the epithet subedeliforni.

As largest of the South American Amphipods he had met with, Kroyer describes from Valparaiso, *Amphithoe femorata*, n. s. (Tab. iii. fig. 4, a–i–j), 9½" long, the antennae not included, intermediate between *Amphithoe* and *Pholis*, and suited, Kroyer thinks, to be the type of a new genus, when the Amphipoda come to be thoroughly revised. It agrees, he observes, with all that Milne-Edwards says of his "**Amphithoe Gaudichaudii**" from the Brazil, except in the conial ramus of the third uropods assigned to that species. But one of Kroyer's own figures shows that also in *Amphithoe femorata*, from a certain point of view, these rami may appear to be conical. Kroyer thus defines the species:—"**Forma robusta**, dorso rotundato, fronte, thorace et abdomen incrustasa. **Antenna superiores** dimidium animalis longitudinem superantes, pedunculo valido, flagello setiformi; **secundus** pedunculi articulis primo parum modo brevior, multo vero gracilior; tertius articulis eum articulis flagelli et longitudine et erasitudine fere congruen. **Ocelli** suborbiculares, minutii. **Antenna inferiores** subpediformes, superioribus tertia fere parte breviores, flagello dimidium pedunculi longitudinem sequente, utrinqueque equis articulum longitudinalis suadente (quinta parte). *Podes thoracici* primi et secundi paris feminei manu fere rectangulae, equis margo inferior sat profunda sed angustissima praedita est incausa ad ungueum excipiantum. *Podes primi* maris ut femine; secundii vero pedis manus examinata, incausa caret. *Podes tertii et quarti* paris articulo primo maximo, valde dilatato, laminiari; ungve parum mobilii. *Quintum par* robustissimum, femore (v: articulo primo) latior quam longo; ungve prehensili (ut et sextum par septimunque). **Epinura magna**, marginis inferioris piloso; epinuma quintum postice profunde et angulariter excisum ad femur quinti pedis excipiantum, quum supra dorum protrudatur. *Podes abdominalis* sexti paris robustissimum, stylis brevissimis; exteriori sublongiori, subconico, inferiori biahamato et spinossimo; interiori suborbiculari. **Appendix caudalis** unica constat lamina triangulare, setis marginis posterioris quatuor."
This species is omitted from the Brit. Mus. Catal., 1862.
At p. 403 (see Index and p. 476) a new species, as Kroyer supposed, is introduced under
the name Caprella longispina, which he soon after transferred to the genus Sagina. Amphipectes
rotundata (for which see Note on Liljeberg, 1862) is also according to the Index, mentioned
on p. 403; Amphipectes ahooko abomonaculata is said to be mentioned on the same page, and
the genus Sagina on p. 402, but these two pages I have not seen.
In the Continuation, the description of Ampipoda begins at p. 476 with Sagina longispina, Kr.;
this he found necessary to remove from Caprella, in which he had previously placed it,
by reason of the mandibles having palps. He doubted whether it ought not to become the
type of a new genus, since he found rudimentary branches on the fifth peraeon-segment, and
the pleon tri-articulate, without any trace of limbs or appendage. Mayer considers that the
supposed branches were the external sexual organs of a female specimen, and agrees with
Spence Rattray in identifying this species with Protella phaenusa, Montagu.
The new genus "Siphonocetes, novum Ampipodum genus, ad Gammariina gressoria referendum," is thus described:
"Antennas superioribus multi breviore, subpediformes, flagello brevi, punciarticulato;
antennas inferioribus pediformes. Oculi haud conspicui. Mandibula angulo antico-interiori
profunde bifurcato, tuberculato molari dentisculato, palpo brevi unicaarticulato. Labium
superius profunde bisdivum vel duobus compositum laminis ovatis; labium inferioris bisdivum,
lateraliter productum et acuminatum. Maxillae bilaminares, forma vulgaris. Pedes
maxillares palpo brevi quasiarticulato. Pedes thoracici primi et secundi parvis validissimis,
manu instructis subcheliformi. Pedes tertii et quarti paris articulo primo latissimo, laminari;
articulo quarto oblongo, laminari, manum præbente, cujus unguis effectur articulo quvinto
subconico articulatoque sexto acutarii. Pedes quinti sextique paris minutissimis sed robusti,
recruciati, articulo primo clavato, ungvo furcato. Pedes septimi paris graciles, recurvati,
articulo primo laminari, unguem minuvissimo, furcare. Pedes abdominalis primi, secundi et
tertii paris natatorii, breves, validissimi, parte basali latissima, rhomboidali; pedes quarti
quintique paris saltatorii; pes abdominalis sexti paris natatorii, unico instructis lamina
terminali."
"Animal tubum inhabitat, e lapillis fragumtisque concharam formatum."
The type-species is described under the name of Siphonocetes typicus, Tab. vii. fig. 4, a-f.
Boeck thinks that Kroyer has been led to describe the upper lip erroneously, by confusing
it with the lower lip. Boeck also says that Kroyer's figure of the last uropods is incorrect,
as he draws them with two small nails, though in fact there is but one, the prolongation of
the peduncle on the inner side giving the appearance of a second. In the present work the
last uropod is not figured, Boeck must therefore be referring to the Voy. en Scand., pl.
xx. fig. 1., in forgetfulness that Kroyer has here described the uropod in question just as
Boeck himself does, but with the additional observation that, "Den fremspringende Vinkel
er invigt ved en skmaa stribe afset fra den ovrige Roddeed, og kunde mankere saaledes antyde
den ikke fuldt sordrede indre svammeplade." It is this appearance, not a second ramus,
that is shown in the Voy. en Scand., pl. xx. fig. 1 u. Kroyer places the genus nearer to
Corophium than to Cerataspus, and is followed in this view by Dana and Boeck.
He next describes Glauconome longispis, n. s., Tab. vii. fig. 2, a-c, as type of a new genus,
Glauconome, which he considers near to Ischyrocerus, these two genera in his opinion uniting
the Gammariina saltatoria and Gammariina gressoria. He thus defines Glauconome:
"Antennas subpediformes; superioris flagello ornatæ appendiculati perparvo; Oculi minutii,
parum distincti. Mandibulae apex in duos fissos ramos, qui dentibus sunt armati coniis;
tuberculato molari dentibus confertissimis instructis. Labium superioris breve, depressum,
latissimum, margine anteriori medio inciso; labium inferioris quatern compositum laminis
setosis. Labium maxilloidea pedum maxillarium dentibus armato validis; unguis palpi apice
setosus. Pedes primi parvis robustissimis, manu subcheliformi; pedes secundi parvis gracilib, manu carens subcheliformi; pedes tertii quattuor parvis pergracilib; pedes quinti, sexti septimique parvis gracilib, femoribus parum dilatatis. Pedes abdominales primi, secundi et tertii parvis natatorii, breves sed robustissimi; pedes abdominales quarti septimique parvis saltatorii, validi; pedes sexti parvis rudiamentariis, natatorii. Epimera minima, fere evanescientia."

In the description of the species *Glaucomeone leucopis*, Kroyer says, "*Sjette Par Bugfudder* meget smaa og plompe; *Boederen* omtrent to Gange saa lang som den ydre Endeplade, meget bred, i Enden skraa afdæksen i Retningen indad og bagtil; den ydre Endeplade regelmaessigt oval, væbnet i Enden med fem eller sex temmelig lange Borster; den indre Endeplade er endeel mindre end den ydre, stumpt konisk, ligefades foresyet med et Par Borster." Boeck does not notice this detailed description, but refers to the figure in the Voy. en Scand., as erroneously giving these uropods with two branches, instead of a single branch and a produced peduncle. S. I. Smith, 1880, on the ground that Boeck had access to Kroyer's types, accepts his correction of Kroyer, and identifies *Glaucomeone leucopis* with *Uncia leucopis*, Say. It should, however, be observed that Kroyer's description is extremely precise, and that the figure, Voy. en Scand., pl. 19, fig. 1, which agrees with it, was not drawn by Kroyer himself, if we may trust the signature "C. Thoram del." at the foot of the plate. In any case, as S. I. Smith observes, the name *Glaucomeone* is preoccupied, but whether it should be identified with *Uncia* may still perhaps remain a little doubtful.

*Eusirius cuspidatus*, n. s., figured pl. vii. fig. 1, a-d, is next described as type of a new genus near to *Gammarnus* and *Amphithea*, and with some approach to *Lencothoe*. The genus *Eusirius* is described as follows:—

This genus is placed by Boeck in his subfamily *Lencothoe*. *Dolichia spinosissima*, u. s., Tab. vii, fig. 1, a–k, is described as type of a new genus intermediate between the *Gammarina* and *Caprellina*. The genus is thus defined:—

THE VOYAGE OF H.M.S. CHALLENGER.

To receive this genus Dana instituted the family Dulichiidae, in 1849. *Stegoecephalus inflatus*, Kroyer, is next described in detail. This is now known as *Stegoecephalus ampulla*, Phipps, 1774.

*Pontoporia femorata*, Kroyer, is here next described in detail, but without any reference to the curious dorsal process which is represented in the Voy. en Scand. pl. 23, figs. 2a, 2y., on the observation of which Brancus established a new species, *Pontoporia farrigera*, which, according to G. O. Sars, is not distinct from *Pontoporia femorata*.

Descriptions are next given of *Lewidhoe glacialis*, Kroyer, Tab. vi. fig. 2, a-f, *Lewidhoe clypeata*, Kroyer, Tab. vi. fig. 3, a-g, "Phoecus Holboelli Kr." and *Phoecus plumosus*, Kr., now known respectively as *Melopa glacialis*, *Melopa clypeata*, *Phoecus holboelli* and *Harpiaria plumosa*. Kroyer himself was inclined to regard the two latter as generically distinct. Of both species he notes that he has never found the maxillipeds united to the head, but always to the first peraeon-segment.

Pages 578–637 are devoted to the genus *Anonyx*. Kroyer first discusses and describes at great length what he calls "*Anonyx Ampulla*, Phipps," combining with it "*Cancer magnus*, Phipps!?" his own "*Anonyx Lagenus* (Hannen)," *Anonyx appendiculatus* (Hannen), and other synonyms. The species which he here describes, which he figures in the Voy. en Scand., pl. 13, fig. 2, a–z, and which does in fact include the species of *Anonyx* just mentioned, is now known as *Anonyx magnus*, Phipps, while the *Cancer ampulla* of Phipps, figured here pl. vii. fig. 3, a–g, and in the Voy. en Scand., pl. 20, fig. 2, a–t., as *Stegocephalus inflatus*, Kr., is now known as *Stegoecephalus ampulla*, Phipps.

A full description is next given of "*Anonyx Vabilii* Kr." which Milne-Edwards had transferred to *Lysianassa*, and which Boeck calls *Scarnes calbi*.

*Anonyx gulonus*, n. s., is described, with a note that "Fabricius's *Oniusus Cicala* seems in many, if not in all, respects to come very near to it, and is obviously in any case an *Anonyx*.

*Anonyx itloralis*, n. s., is next described. This was made by Boeck type of a new genus *Oniunus*, which he thinks possibly a synonym of Milne-Edwards' *Alihrotus*, to which Spence Bate had previously referred the *Anonyx itloralis* of Kroyer.

A species, to the young and sexes of which Captain Hulbell had given three separate manuscript names, *velatus*, *orantes*, and *brocipes*, is next described as *Anonyx plautus*, n. s. This also is placed by Boeck in his genus *Oniunus*. Figures of the various species above mentioned are given in the Voy. en Scand.

No Amphipoda are mentioned in this report, so far as I can perceive. It was perhaps included in Boeck's list under some misapprehension.

1846. Dana, James Dwight, born February 12, 1813 (S. I. Smith).

1846. Kroyer, Henrik.

In this continuation Kroyer first describes "Amönx Edwardsii," n. s. ? This is transferred by Boeck to Orestinus, and distinguished from the species called "Amönx Edwardsii, Kr.,” in the Brit. Mus. Cath., p. 73.

"Amönx Holbéli,” n. s., next described, is made by Boeck the type of a new genus, Hippomedon.

The next species, Amönx lurvidus, n. s., is made by Boeck the type of another new genus, Aristius.

Amönx minutus, n. s., is transferred by Boeck to his genus Orchestène.

Amönx nanus, n. s., is made by Boeck the type of a new genus, Tryphosa.

Figures are given of these five species in the Voy. en Scand.

From the species of Amönx, Kroyer passes on to the nearly related form Opis, since called Opis, and now describes in detail under the name “Opis typica, Kr.” what he had previously described in brief as "Opis Eschrichtii Holb. He explains that Holboll had given the name "Amönx Eschrichtii” and three other names to what were only varieties, sexual or otherwise, of a single species; Kroyer himself therefore thought proper to unite them under the name Opis typica. But the name “Opis Eschrichtii” already published
must take precedence. The Brit. Mus. Catal. gives them as two separate species, though Kr0yer's descriptions are identical, so far as the shorter one extends.

Remarks on the habits of animals belonging to the genera Anonyx and Opis are quoted from Holboll. These are followed by an account of Microcheles armata, supposed to be a new species and type of a new genus Microcheles, thus defined:—

"Primul secundumque pothum thoracicorum par exilia, linearia, elitis armata minutissimis. Manolitas perva, apice bifurcata, non vero dentata; palpo triarticulata; tuberculo mohari proprio nullo, ante palpum vero corpore instructa claviformi, dentata. Labium inferior quatuor constans laminis fere aequilibus, cornibusque lateribus sat maginis. Pedes maxillares laminis maxillaribus maginis, palpo brevi, triarticulato (ungue destituto). Epliure magna; paria quatuor anteriora inferius in angularum acutum producta. Pedes ab laminis saltatorii elongati, gracilesque. Antennas forma fere vulgari, superiores flagello appendiculare destituta."

The species, Microcheles armata, is figured in the Voy. en Scand., pl. 11 B, fig. 2, a–c. It was subsequently identified by Liljeborg with the earlier Aplinolita obesa of Rathke, so that both the generic and specific names used by Kr0yer take rank as synonyms. Amphitlioe alboncnculata, here described as new, is by Boeck identified with Amphitlioe puber-ceroides, Rathke, and is therefore probably not more than a colour variety of Amphitlioe rubricata, Montag.

Next, "Amphitlioe Edvardsi" is described, under the name which Owen gave to the "Taliafus Edvardsi" of Sabine, which is identical with Oniscus aculeatus, Lepechin. See Note on Lepechin, 1780.

Lastly, Acanthonotus tricuspis, n. s., is described, pages 115–123. This species was afterwards by Boeck made the type of his genus Cleipndes. The species included in this continuation are all figured in the Voy. en Scand. For the benefit of any one unacquainted with the alphabetical order used in the Scandinavian languages, it may be pointed out that in the Indices to Kr0yer's papers, the diphthong æ and the symbol Œ follow the letter æ.

18461 Kr0yer, Henrik.

The reputed date of publication is 1846, for the Atlas of Crustacés. It consists of plates for which no text was ever published, and is attributed by repute to Kr0yer. W. Thomson, in 1847, refers to the plates as Kr0yer's. Brandt, in 1851, compliments Kr0yer on figures of Anonyx in this Atlas, "Livr. 37–41 auf. Pl. 13–18 meisterhaft von ihm dargestellt." The beautiful figures agree with the elaborate descriptions which Kr0yer gave from time to time in his Naturhistorisk Tidsskrift, but the plates which appeared occasionally in that magazine have none of the artistic pretensions of those in the Voyages. As Kr0yer's own name nowhere appears in the present work, it may be presumed that he was not the draughtsman, but the editor, who supplied the dissections and supervised the delineations. The Amphipoda figured are named as follows:—Pl. 10. Amphitlioe edwardsi, Sab.; Amphitlioe patchella, Kr. sp. n. Pl. 11. Amphitlioe eucriata, Kr.; Amphitlioe porphyra, Kr. Pl. 11 B. Amphitlioe alboncnculata, Kr. nov. Sp.; Microcheles armata, Kr. nov. gen. et Sp. Pl. 13. Anonyme Vittatus, Kr. Nov. Sp.; Anonyme ampulla, Phipps. Pl. 14. Anonyme vallii, Kr. 5 et 7; Anonyme vulgus, Kr. nov. sp. Pl. 15. Anonyme holzoll, Kr. nov. sp.; Anonyme pl酗ns, Kr. nov. Sp. Pl. 16. Anonyme edwardsi, Kr. nov. sp.; Anonyme tnnditns, Kr. nov. sp. Pl. 17. Opis typicus, Kr.; Anonyme nanus, Kr. nov. sp. Pl. 18. Acanthonotus tricuspis, Kr. nov. sp.; Anonyme uranthis,

REPORT ON THE AMPHIPODA.

Kr. nov. sp. Pl. 19. Glanconum leucops, Kr. nov. sp.; Eusirius crusgulatus, Kr. nov. gen.sp.;
Ægina (?) longispina, Kr. nov. sp. Pl. 20. Siphonocetes typicus, Kr. nov.gen. et sp.;
Stegosephalus infulatus, Kr. Pl. 22. Donichia spinossima, Kröyer; Lencodohc elyptaca,
Kr.; Lencodohc glacialis, Kr. Pl. 23. Amphilisa [Ampelisa] gaimardi, Kr. nov. sp.;
lobata (lobata), Müll. §, ? et Var. All these are described in the Naturh. Tidskr. except
Amphilisii pitchella (which Bruzelius assigned to Paramphiloë), and Boeck transferred to
Phaenex, Sp. Bate), and "Ampelisa Gaimardi" (which Boeck in 1870 transferred to a
separate genus, as Biphis gaimardi).

Plates 10, 11, 11 B, 18, are inscribed "C. L. Petersen del.," the others "C. Thornam del.," except
pl. 23, of which the draughtsman is not mentioned.

1846. MÜLLER, FRIEDRICH.

T. x. Fig. A–C.

This species Axel Boeck (De Skand. og Arkt. Amph. p. 52) proposed to refer to the genus
Crangonyx, Sp. Bate, but Aug. Wrzesiowski, after detailed comparison of Müller's descrip-
tion of Gammarus ambulans with his own species, decides that Müller's species must stand
as Gaphana ambulans in the new genus along with Gaphana polonica. The points which
distinguish Gaphana polonica from Gaphana ambulans are perhaps due rather to age than to
difference of species. Müller gives the following diagnosis of his species:—"Gammarus
ambulans, fronte inerui, oculis subrotundis, antennis superioribus inferiores excedentibus,
flagello auxiliari minimo biarticulato instructis, dorso levii, pedibus aprioris parvis septi
simplexiis, conieis, perexiguis, appendicibus caudae duabus, brevibus, cylindricis, apice
spinulosis. Long. 2", antennar. attributed 0.8"."n

1847. ALLMAN, GEORGE J.

Biological Contributions. No. II. On Chelura terebrans, Philippi, an
Amphipodous Crustacean destructive to submarine timber-works. The Annals and
pp. 361–370. Plates XIII. XIV.

The characters of the genus, of which Philippi gave no detached summary, are thus drawn out:
short and more slender than the inferior, and consisting of a peduncular portion which
supports two unequally developed rami; inferior antennæ large, not divisible into a distinct
peduncle and rami. Mandibles strong, palpigerous, furnished with a narial tubele and
transverse ridges. First pair of maxillæ strong, pyramidal, palpigerous; second pair
lamelliform. Maxillary feet large, bearing a palp-like stem, and united at their origin so as
constitute a great opercular lip covering all the other organs of the mouth. Thorax
composed of seven distinct segments with the spineræ distinct and moderately developed.
First two pairs of thoracic feet didactyle, five remaining pairs terminated by a small
unopposable claw. First three segments of abdomen each bearing a pair of binamous
natatory feet, remainder of abdomen consisting of one very large trunk supporting anteriorly
a pair of large foliaceous lobed appendages and a pair of cylindrical false feet, and terminated

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

XXX 28
posteriorly by two lamellar leaping organs and an intermediate leaf-like lobe." Reference is made in a note to the researches of Erichson (Entomographia) which would displace the use of the terms thorax and abdomen as applied by carcinological writers. In the specific description, he says that the superior antennae "consist of a peduncular portion which is composed of three hirsute articulations, the last of which supports two rami of very unequal development," remarking in a note that "this condition of the superior antennae is not described by Philippi." He mentions the name destructor, which he had given to his Irish specimens, before becoming acquainted with Philippi's account, in case after-investigation should show the Irish form to be in fact distinct from the Adriatic species. In describing the appendages of the terminal segment of the abdomen, he says "the appendages of the third pair constitute a sort of tail, by which the body is prolonged backwards; they are borne upon the posterior extremity of the segment, and consist each of a very large leaf-like lamina supported on a short basal joint;" adding in a note that, "it is these basal joints of the two caudal appendages which Philippi seems to have mistaken for a fifth abdominal segment, with the anus in a fissure on the back."

He considers that "the families of the Amphipodous Crustacea may be analytically arranged as follows:--

Family.

"Fourth and fifth abdominal segments confluent. Abdominal appendages of the fourth and fifth pair very different in form (heteromorphous). . . . CHELURIDE.

"Fourth and fifth abdominal segments distinct. Abdominal appendages of the fourth and fifth pair nearly similar in form (isomorphous). . . . GammariIDE.

Mouth concealed by the maxillary feet. . . . Gammaride.

Mouth not concealed by the maxillary feet. . . . Hyperide."

1847. BRANDT, JOHANN FRIEDRICH, born 1802 (Hagen).

This paper, though earlier published, was originally read after the more full account published in the Mémo. de l'Ac. imp. de St. Pétersbourg, 1849. See note under that date. Brandt thinks that the want of the breathing appendages, which could scarcely have escaped so acute an observer as Steller, had they been as strikingly developed as in Cyamus, points to an affinity between "Sirenoeyamus?" and Leptomers.

1847. FREY, Heinrich, and Leuckart, Rudolph.

Beiträge zur Kenntniss wirbelloser Thiere mit besonderer Berücksichtigung der Fauna des norddeutschen Meeres. Von Dr. Heinrich Frey and Dr. Rudolph Leuckart. Mit zwei Kupfertschink. Braunschweig, 1847.

Pages 100-109 are "Über den Bau der Caprellen." The authors object to Kreyer's proposal to make the order of Leoniidipoda a family among the Amphipoda. They refer to Naturh.
REPORT ON THE AMPHIPODA.  

To the Amphipoda they attribute seven instead of five pairs of lateral slits in the heart, although three would have been sufficient for the Caprella as well as the (other) Amphipoda. They consider that the so-called branchiae in the Caprella are not sufficient to discharge the whole function of respiration, and that probably the legs and antennae take a share in it.

Pages 136-168, “Verzeichniss der zur Fauna Helgelands gehörigen wirbellosen Seetiere,” are due to Dr. Leuckart alone. Among the Arthropoda, Crustacea Malacostraca, he enumerates the following Amphipoda: — “Talitrus saltator (Montag.) Milne Edw.—Orchestra littorea Leaeh.—O. sp. dub.—Gammarus leonsta Fabr.—G. elongatus n. sp.—G. Sabini Leaeh.—G. angulosus Rathke.—Melita palmata (Mont.) Leaeh.—Iphimedia ocean Rathke [Kollik.]—Amphithoe podoceroides Rathke.—A. gibba n. sp.—Podoerns capitatus Rathke.—P. calcaratus Rathke.—Metaurus medusarum Kröy.” — “Caprella linearis (Lin.) Latr.—Podalirius typicus Kröy.”

The doubtful Orchestra, which he thinks may be “Orchestra Botte,” Milne-Edwards, is obviously, as Boeck observes, only a young Orchestra (littora) gammarellus. The Gammarus elongatus, n. sp., not mentioned in the Brit. Mus. Catalog., is a little doubtfully united by Boeck with Macro longimanus (Leach) Thompson. In describing Melita palmata, Leuckart suggests that Gammarus elongatus, Milne-Edwards, is the same species, a view adopted by subsequent authors. He says that Ampithoe gibba, n. sp., “is distinguished from the nearly related A. norvegica Rathke and A. Rathkii Zadd., by the fact that the second, third and fourth segments of the postabdomen in the front half are narrowed, while projecting (bucket-formed) in a hump in the hinder half, giving the part of the body in question a peculiar appearance.”

None the less, or one might say, all the more, Boeck identifies it with Callopinus lariceus, Kröyer. Leuckart recognises that Podoerina has a minute accessory appendage on the upper antennae. He agrees with Kröyer in supposing that the fifth peron-senegment of Podalirius typicus has a (third) pair of branchiae, misled, Mayer says, by “die weiblichen Geschlechtsklappen.”

Among works consulted, Leuckart mentions “Köllicker (Beiträge zur Kenntniss der Samenflüssigkeit wirbelloser Thiere. Berlin 1841).” In this treatise perhaps would be found a reason for the addition of Kollicker’s name to Rathke’s as an authority for Iphimedia ocean.

Sinonimia moderna delle specie registrate nell'opera intitolata: Descrizione de' Crostacei, de' Testacei e de' Pesci che abitano le lagune e golfo veneto rappresentati in figure, a chiaro-scuro ed a colori Dall' Abate Stefano Chierighini Ven. Clodiense applicata per commissione governativa dal Dr. Gio. Domenico Nardo. Venezia, 1847.

Nardo says that Chierighini's work occupies twelve volumes, nine of plates, and three of text. The index to the Crustacea is in the first volume, and the figures of them are in the second. The portion applying to the Amphipoda, with Nardo's synonymy, is given as follows:—

"Sp. 59, f. 75. Can. Saletus, Ch. volg. Saletto de' Mar. Orchestia ?

"Macrourus, articularis, testa perpendiculariter subtruncata, fronte mucronato; pedibus decem abscis manibus.

"Trovato ne'l fondi fangosi del mare.

"Sp. 60, f. 76–79. Can. Algernis, Ch. . . . . Lasgta algernis, Ch., Nardo. an. n. g. Miss.

"Macrourus, thorace rostrata, manibus duabus adactylis, pedibus decem, extremitate cauda trihila.

"Trovato copiosamente in laguna, nidulato sulle foglie della zoster alla maniera delle Frigane.

"Sp. 61, f. 80. Can. linearis, L. . . . . Caprella, n, sp?.

"Sp. 81 [61], f. 81–82. Can. Varietas linearis, Ch. . . . . Caprella, n, sp?"

For a little additional light on these species, see Note on Nardo, 1869.

1847. Schiødt, Jørgen Christian, born April 20, 1815, died April 21, 1884 (R. Bergh).

Boeck says that in this paper, page 81, Schiødt gives a short diagnosis of Gammarus stygius [? stygius], which later became type of the genus Niphargus.

1847. Thompson, William.

He observes that Chelura terebrans, Philippi, was known to Leach, who had labelled specimens as Neorutes vesicoides, a name adopted by White in his "List," etc., 1847. Both Neorutes and Chelura, he observes, are preoccupied as generic names. The habits of the species are discussed, and its powers of surviving out of sea-water. Scudder only gives two uses of Chelura, viz., " Chelura Phil. Crust. 1839. A," and " Chelura Hope. Lep. 1840. A."
1847. Thompson, William.

In the order Amphipoda he mentions the following:— 6. *Orchestra* (sp.), Bangor, Co. Down, 1835, W. T.; distinct from *O. littorea.* 7. *Amphithoe fuscicola*, Leach (sp.), with a reference to *Pherusa fuscicola*, Leach. 8. *Amphithoe rubricata*, Mont. (sp.). 9. *Amphithoe*, sp. Bangor, Co. Down, 1835, W. T.; distinct from the preceding and *A. obtusata*, on comparison with the specimens in the British Museum. 10. *Gammarus marinus*, Leach. 11. *Gammarus canopus*, Leach. 12. *Gammarus longimanus*, Leach (sp.). *Mecora longimanus*, Leach MSS. 13. *Gammarus punctatus*, Johnst. Zool. Journ. vol. iii. pp. 177, 490. I found in a case formed by itself among the branches of *Corallina officinalis* growing in pools between tide-marks at Springvale, Co. Down, in July 1846. The species was determined by comparison of mine with those from Berwick presented by Dr. Johnson to the British Museum. 14. *Opis typica*, Kroyer. 15. *Ammonyx* (Kroyer) sp. It is distinct, he says, from the species described by Kroyer, and "although a proper description cannot (on account of the state of my eyes) be drawn up, some idea may be given of this Ammonyx—which is well worthy of the name of elegans)—by the following note:—length of body 6 lines; of upper antennae 1 line; of lower antennae 4 lines; general colour yellowish pink; eyes red; lateral or abdominal plates adorned with scarlet stellate markings, of which there are five or six on those nearest the head; they become gradually fewer on those towards the tail, so that not more than one appears on the hinder plates. These markings render it very beautiful. My *Ammonyx* is distinct from a British species (locity unknown) in the collection of the British Museum. 16. *Ammonyx, genus,* or rather a form between it and *Stegosephalas*, Kroyer, was dredged from a depth of twenty-three fathoms (shelly sand) in Belfast Bay in Oct. 1846 by Mr. Hyndman. 17. *Cerapus falcatus*, Mont. (sp.), Linn. Trans. vol. ix. t. 5. f. 2. *Jassa pelagica*, Leach. " 18. *Hyperia galba*, Mont. (sp.). 19. *Hyperia Latreillii*, Edw. 20. *Lestrigonus*, sp.

In the "Order Lebbeolipoda" he mentions "21. *Caprella lobata*, Mull.," Kroyer, Voy. Scand. et Lapw. Crust. pl. 25. f. 3rd, dredged Oct. 1839." The note says, "36 presents a very different form, but is considered a variety only." 22. *Caprella tuberculata*, Goodsr. Edin. New Phil. Journ. vol. xiiii. p. 188, pl. 23. f. 6. specimens taken with the last. Guérin in his Iconographie, &c. pl. 28. f. 1. represents a species which he calls by this name; it is from the Mauritius (Texte Description Crust. p. 24)." 23. *Caprella acuminifera*, Leach. 24. *Erigona longispina*, Kroyer, Voy. Scand. &c. Crust. pl. 19. f. 3. (described in Kroyer's 'Natuurhist. Tidenk.' 1st liinde, 5th hefte, 1845, p. 476). A single individual of this very fine, large and spinous form was taken with the two first-noticed *Caprella*. My specimen differs only from that represented by Kroyer in having one or two more spines retrally on the body; it is wholly red like his, and has retained this colour in spirits to the present time. Goodsr's *Caprella spinosa* (Edin. New Phil. Journ. vol. xiiii. p. 187. pl. 3. f. 1) approaches very near to this species, if it be not the same; it is described as "having the whole body of a pale white colour."

1847. White, Adam.

The book is anonymous, but the introduction, pp. iii.–viii., signed John Edward Gray, says: "Great care has been taken by Mr. Adam White in the determination of the species, the
THE VOYAGE OF H.M.S. CHALLENGER.

verification of the synonyms, and in arranging them into generic groups, in accordance with the present state of the science." Since, then, the work is due to Mr. Adam White, it is difficult to appreciate the fairness of omitting his name from the title-page. He divides the Malacostraca Eriophthalamata into two orders, Amphipoda and Leechipoda, the former containing the two families, the Gammaride and Hyperide; the latter the two families, the Caprellide and Gymipoda. In the Gammaride, after Talitrus locusta and Orchestia hirta, come the following entries.

"Orchestia megagrothalamus. Scamballa meg., Leach, MSS. a-b- ?

In the Brit. Mus. Catal., 1862, Orchestia trigonochiriinae, Leach MS. B.M., is figured and described as a new species; Orchestia tristensis is identified with Orchestia platensis, Kröyer, 1845, from Monte Video; Orchestia megagrothalamus is figured and described; and Orchestia quoyana is transferred, in agreement with Dana, to Talorchestia.

The list continues with Lysianassa Costa; Dexamipe spinosa; "Dexamipe carina-spinosa. Cancer carina-spinus, Tarrton, Mont. Lisa Trans. xi. 4. 1. a. Isle of Wight," for which see Note on Tarrton, 1802. Seven species are assigned to Amphlethiaceae; namely, A. rubricea; A. fuscus, with Pherus fuscus, Leach, for a synonym; A. obtusata, Mela obtusata, Leach; "Amphlethio viridis. Elamis viridis, Leach, MSS. a. Sicily." "Amphlethio punctata, Say, Journ. Acad. Sc. Phil. i. 383. a. U. States (Great Egg Harbour). Presented by Thomas Say, Esq.;" "Amphlethio truncata, Spinola, a-e. Italy. Presented by M. Spinola," afterwards figured and described by Spencer Bate in the Brit. Mus. Catal. as Morea truncata, with the remark, "this species may be Gammarus crassimanns of Viviani, 'Phosphor. Maris,' etc. p. 10. t. 2, figs. 7 and 8; but not having seen that work I hesitate to do more than suggest the possibility;" and lastly, Amphlethio Edvardsi, Ross, Sabine's Talitrus Edvardsi, from Spitzbergen, for which see Note on Oniscus acidentis, Leach, 1780.

 report on the amphipoda.

223

“After the Gaumari the list gives “Vertumnus, Leach. Vertumnus Cranchii, Leach, MSS. a—d. Falmouth. From the collection of Dr. Leach,” since identified by Boeck with Epimeria cornigera, Fabricius, 1779. After Lysanassa articulata, Montagu’s Devonshire species, “Leucothoe — a, b. Mediterranean (Genoa),” is given. Then come Cerapus pulchatus, Edw., identified with Jassa pel., Leach; and Cerapus falcatus, as a name for “Cancer (Gammarus) falcatus, Mont.,” and “Cerapus falcatus p., Edw. Crust. iii. 61. (not Jassa pel., Leach).” These are followed by Podocerus variolatus, Leach, and Podocerus pulchellus (=Jassa pulchella, Leach), all the last four in White’s list being now recognised as forms of a single species. Corophium longicornne, Latr., is given with various authorities, and the synonym “Gammarus longi., Fabr. Ent. Syst. ii. 516. R o e m e r. Gen. Ins. t. 33. f. 6. Astacus linearis, Pennant, Brit. Zool. iv. 17, t. 16, f. 31. Oniscus volutator, Pullus, Spic. Zool. ix. 59 f. 4, f. 9.” Next is “Nemertes, Leach. Nemertes sessiloides, Leach. a—d. Britain. From the collection of Dr. Leach,” identified by W. Thomson, 1847, with Chircura teres, Spix, 1839. Astacus carinatus, Fabr., and Uncia irrorata, Say, presented by Say, conclude the Gaumariad.

The Hyperiadea are represented by “Hyperia Latreillii,” Edw., with “Hiella Orbignii, Strauss,” for a synonym; by Hyperia galba, with the synonyms “Cancer (Gammarus) galba, Mont.,” and “Callianira. g. Leach, m. n.;” by Meocerus eganer, Edw., with the synonyms “Talitrus Cy., Sabine,” and “Hyperia Cy. Edw.,” the whole of which group is united into a single species by Boeck as Hyperia Medusurus, O. F. Müller, 1776. Before Meocerus eganer, the list gives Metoecus medusurus, Krøyer, with the synonym Oniscus Met. O. Fabr., for which see Note on Krøyer, 1838. The next species is thus entered, “Primno, Guerin. Primno Guerinii. a. Atlantic Ocean (8. Lat. 8° E. Long. 46°). Congo Expedition.” No notice is taken of this species in the Brit. Mus. Catalogue, where Guérin’s type-species, Primno macrops, is figured and described. The list next gives Phronima solandri, Forsk., and Phronima atlantica, Guerin; concluding the Hyperiadea with “Typhis monoculosis. Cancer (Gammarus) m., Montagu, Linn. Trans. ii. [xi.]. 2. f. 3. a. South coast of Devon,
From the collection of Col. Montagu, and "Typhis— a-c. Norfolk (Cromer.)" Since the Typhis monocalaboides is in point of fact the Gannarid, Stenothec monocalaboides, the Typhis from Cromer has but a doubtful claim to that generic title.

To the family Cyamidae are assigned five species of Cyamus, 1. Cyamus crassus, Rouse. with the synonyms Ophicera c., L.; Spallia c., Degoeq; Cyamus c. Latr.; Panope c., Leach; Larvula c., Leach; 2. Cyamus crassus, Rouse; 3. Cyamus gracilis, Rouse; all these three being said to come from British Seas. No. 4 is mysteriously represented by "Cyamus— a.—." No. 5 is Cyamus abbreviatus, Say, from North America. Presented by Say.

1847. White, Adam.

In the "Order Amphipoda, Family Gammaridæ," White thus describes his genus Ephippiphora:—

"Head rather large; antennæ distant from each other, the upper pair with the basal joints very thick and conic, inserted in a deep notch in front of head; two setæ at the end of each, the outer the thicker. Lower pair of the antennæ with the basal joint somewhat elongated and furnished with hairs.

"Body much compressed, the lateral appendages on the first eight joints very large, and nearly concealing the legs; the appendage of the fourth joint much dilated behind at the end; eighth to eleventh joints slightly keeled on the back; appendages of the last three joints of abdomen longish, with short spines on the edge behind.

"A genus allied to Orchestia and Talitrus."

"Ephippiphora Kroyeri, White, List. p. 130.

"The body is very highly polished, the edges of the segments behind somewhat tinged with yellow; the legs and caudal appendages slightly brownish."

"Hab. Van Diemen's Land.

"Named as a small compliment to the very eminent Danish naturalist, whose researches among the less studied orders of Crustacea are so well developed in his published but not easily accessible works. I regret that, excepting a few foliated plates of the large 'Voyage en
REPORT ON THE AMPHIPODA.

Islanda,' &c., I had not seen any part of them when I prepared the 'List of Crustacea in the British Museum.'"

The account of the upper antennæ shows that White is wrong in allying his new genus to the Orchestidea; in Bœck's opinion his own Scaræus may possibly be a synonym of White's Epilippines.

1848. Adams, Arthur, and White, Adam.

On page 63 is given "Rhabdosoma, Adams & White. Oxycephalus, M.-Edw. We regret that the state of the only specimen in the British Museum is such that we cannot give the generic character with that detail which we should wish. It is founded on the third species of Professor Milne-Edwards, indeed Mr. White has the authority of that eminent Crustaceologist that it is his very species; it is so different from the Oxycephalus pescator, M. Edwards (Crust. III. p. 100 t. 30. f. 10), that we have traced the figure of Oxycephalus pescator, and added it below that of the Oxycephalus armatus to show the difference. Someday it may be proved to be a sexual character, when of course our name will sink, but as yet we know of no such discrepancies in the sexes of those Crustacea.

"The head is as long as the rest of the body, and ends in a very long beak; from the state of our specimen we cannot describe this, but indicate it on the plate from a drawing made at the time of capture. The immense length of the body and beak would sufficiently mark this generic form. The first two pairs of legs are shown in the figure, which must serve till we can procure further specimens, when we hope to give ample details of this very singular crustacean, and to analyze its characters at length. It forms a singularly interesting link between the Amphipoda and Lernaeida, as it were, the two; we should like to have this form examined particularly by Prof. M. Edwards or Dr. Kreyer.

"Rhabdosoma armatum, Adams and White. (Tab. XIII. Fig. 7.) Oxycephalus armatus, M.-Edw. Crust. III. p. 101. pl. 30. f. 10, copied. (Tab. XIII. Fig. 8.)

"The specimen described by Professor Milne Edwards was found by MM. Quoy and Gaimard in the Ocean between Amboina and Van Dieman's Land, and is now in the Paris Museum. Ours was taken during a calm, floating on the surface of the South Atlantic Ocean."

1848. Leydig, Franz.

In his Treatise "Ueber Amphipoden und Isopoden," 1878, page 229, note 2, Leydig says that he had already in 1848 described and figured the segmentation-process of Gammarus; but he does not say that the account was published, though this would seem to be implied by the context.

1848. Milne-Edwards, H.

This note, at page 398, records the finding of an amphipod, with a body 9 cm. long and 3 cm. high, by M. D'Orbigny, who took it from the stomach of a fish caught off Cape Horn. Supposing it to be new, Milne-Edwards names it "Lysianassa Megallanica."

It has since been identified with Mandle's Gammarus Gryllus, and named Eurytomes Gryllus.

(zool. chal. exp.—part lxxv.—1887.)

Müller notices that the genera *Talitrus* and *Orchestia* belong to the warmer seas, and seem to be wanting in the Arctic waters, the proper home of the typical *Gammarus*. From this point of view he thinks the discovery of two new species from the Baltic not without interest. He does not consider the presence of the large second hands in *Orchestia* sufficient for a generic distinction from *Talitrus*, while in the two new species, as in *Orchestia platensis*, Kroyer, the males belong to *Orchestia*, the females to *Talitrus*. *Orchestia euchore* is fully described and figured, but it is, as Böeck says, not to be distinguished from *Orchestia gammarides*. Müller says that the mandibles are without any trace of a palp, as if he had given special attention to that point. He recognizes the great likeness between *Orchestia grapsus* and *Orchestia deshayesi*, Audouin. In conclusion he says, "Orchestia platensis, Euchore et Gryphus inter se convenient:

"Antennis sup. capitis longitudinalen haud aut vix superavitibus; manubilalis palpi ne vestigio quilibet gaudentibus: maxillarum paris I lamina interna angusta setis pinnatis curvatis duabus instructa; palpi pedem maxillarum articulo ultimo brevi lato rotundato; pedibus II paris in $^\diamond$ manu validis instructis, in $^\heartsuit$ debilibus, ungue exiguo articuli V$^{i}$ foliaco- dilatati, eujus margini anteriori inseritur, apicem hand superante praeditis; branchiis I parae angustis elongatis flexuosis; pedibus saltatoribus paris ultimis exiguis conicis, stylo terminali unico donatis; laminae caudali unica crassiuscula, spinis ornata.

"Differunt:

"Orchestia platensis, Kr. Antennis superioribus caput longitudinaline equantibus aut vix superavitibus; antennis inf. vix tertianum corporis partem longitudinalis equantibus, pedunculo flagellum 14 articulatum parum excedente; odulis ellipticis; primi pedis articulo quinto apicem versus in $^\diamond$ dilatato, haud dilatato in $^\heartsuit$, ungue valido inermi; manu pedis secundii in $^\diamond$ lata ovali; pedis septimi articulo quarto in $^\diamond$ incrassato, in $^\heartsuit$ gracili, lamina caudali truncata; longitudinaline lineari 6.

"Orchestia Euchore F. Müll. Antennis superioribus caput, inferioribus tertianum corporis partem, lorum pedunculo flagellum 18 articulatum longitudinalis equantibus; odulis rotundis; primi pedis articulo quinto apicem versus in $^\diamond$ dilatato, haud dilatato in $^\heartsuit$, ungue valido spinulis duabus in margine interiore armato; manu pedis secundii in $^\diamond$ ovali; pedis septimi articulo quarto in $^\diamond$ incrassato, in $^\heartsuit$ gracili; laminae caudali emarginata; long. 5".

"Orchestia Gryphus F. Müll. Antennis sup. capite brevioribus; inferioribus in $^\diamond$ dimidiam, in $^\heartsuit$ quinquam (I) corporis partem longitudinalis equantibus, flagello 20 articulato pedunculi dimidiam subsequente; odulis rotundis; primi pedis articulo quinto uie in $^\diamond$, uie in $^\heartsuit$ dilatato, ungue valido spinula unica in margine interiore armato; manu pedis secundii lata, incisa profunda in ramos duos divisa, anteriorem longiorum latiorum, posteriorem acuminatum; pedis septimi articulo quarto in utroque sexu gracili; laminae caudali emarginata; long. 4.""

Another notice, headed "Bemerkungen zu Zaddach's Synopsis Crustaceorum Borassicorum prodromus," states that *Leptocheirus pilosus*, Zaddach, has in fact a very rudimentary, one-jointed accessory flagellum on the upper antennae, which had escaped the notice of the author of the genus *Leptocheirus*, when the absence of an accessory flagellum was made part of the generic character.
1848. Siebold, Carl Theodor Ernst von, born 1804, died April 7, 1885 (Friedländer, Nature novitates).

Lehrbuch der vergleichenden Anatomic der wirbellosen Thiere. Berlin. 1848.

1849. Brandt, Johann Friedrich.

After quoting Steller's account, Novi Comment. Petropoli. t. ii. pp. 298, 324, and 330, and considering how far it agrees or disagrees with the genus Cyamus, Brandt continues, "Ad stabilisdum tamen differentiam genericam aliorum Sireniorum ordinis animalium pedicularum cognitio adhae optanda videtur. Qua de causa pro tempore parasitum Rhytine dubitante (sicuti signum interrogationis indicat) genere Cyamorum quidem insecurius, sed in parentesi nomen hypotheticum Sirenocyanum interrogatianis signo addito pariter exhibinimus antequam, qua sequitur, descriptionem ejus in ordinem systematicum redactam ponimus.

"Cyamus (?) num genus proprium Sirenocyanus (?) Rhytina.

"Pedes mandibulares biarticulati, extremitate acutissimi et elavati. Pedum thoracicorum sex paria. Pedes thoracali annulo inserti chelis similes, biarticulati. Appendices respiratorii a Stelleri non descriptae. (An characteres generis Sirenocyanus!).

"Characteres specifici.

"Corpus dimidiam plerumque uneiam longum, diaphanum.—Color candidus aut subflavus." If the creature was correctly observed by Steller, the genuine Cyami, Brandt says, differ from it:— "Pedibus mandibularibus [maxillaribus] 5-articulatis, pedum corporis geninorum paribus quinis, omnibus quinque-articulatis, necnon appendicibus respiratorius in secundo et tertio corporis annulo pedum loco conspicius." He thinks that the Rhytina's parasite may have been allied to the Leptomerca rather than the Cyami, and contemplates the possibility of finding other Sirenocya still living on other Sirenia.
1849. **Caspary, Robert.**

In the full and fairly accurate description which Caspary gives, he obviously falls into error when he says that the intestinal canal (der Darm) runs from the head to the tenth segment in which it opens, the tenth segment in his reckoning being the second of the pleon. Of the last three peripods he says that “das Thier streckt sie über den Rücken hinaus, und Fig. XIX. zeigt und kriecht, auf dem Rücken liegend, öfters auf ihnen.” I think it may be safely said that the creature much more usually crawls with the ventral side downwards, the extremities of these peripods being extended upwards out of use.

Bate and Westwood are inclined to think “*Nipharyx Kochianus*” Sp. Bate, identical with the specimens “described and figured by Caspary and Hossius, referred to in the synonymus under *N. aquilex*.” But their *Nipharyx Kochianus* is expressly distinguished from *Nipharyx aquilex* by its second and third pleon segments having the infero-posterior angle acute. Caspary’s figure agrees with their *Nipharyx aquilex* in having that part rounded.

1849. **Dana, James D.**

The tribe of Amphipoda here includes the subtribe Gammaracea and Hyperiacea, the former of which consists of six groups or families.

Fam. II. **Gammaridae**. Subfam. I. Lysianassinae, with the genera thus grouped:—

Fam. VI. Dulichidae. *Dulichia*, Kroyer.

Fr. Müller having in 1848 denied the propriety of separating the *Orchestia* and *Talitri*, Dana remarks, “There is however a wide difference between the species having a styliform joint terminating the second pair of legs and those with a hand however minute or obsolescent. The only safe course appears to the writer to consist in drawing the line between species having a finger or claw however small or large, closing upon the fifth joint, and those species having an extended finger or claw not closing up.”

The new genus *Allorchestes*, identical with *Niera*, Nicolet, published in the same year 1849, and probably the same as *Hyale*, Rathke, 1837, is thus defined:—“Pedes primi secundique
subcheliformes. Antennae superiores breviores, basi inferiorum longiores. Maxillipèdes ad apicem unguiculati," with the following note, "The species of this genus have the aspect of many Amphithoe, and have probably been hitherto referred to that genus. They have the very short posterior styles of the Orthocera, and resemble them in habit and in the absence of a palpus to the mandible; while they differ in having the superior antennae longest and in the stout spine or claw terminating the maxillipèdes. The writer has dissected the mouth of nearly a dozen species of Allorchestes." The italicized word *longest* is no doubt only a slip for *longer.*

The subfamily *Lyciasmessu,* which includes *Uristes* in its second, and *Stenia* in its third division, is defined as having "Antennae superiores ad basin crassae. Epimera granulata. Pedes sex postici non prehensiles."

The new genus *Uristes* has for its characters "Pedes primi subcheliformes, secundi non subcheliformes; reliqui non prehensiles;" "Antenne sup. non appendiculata. Pedes secundi vergiformes; tertii quartique brevissimi." As pointed out by Spencer Fave, it is probably only founded on a misconception.

The new genus *Stenia* is characterised by "Pedes primi secundique subcheliformes, reliqui non prehensiles;" "Antenne sup. non appendiculata." This genus Dana subsequently dropped, as not distinct from *Aunoya,* Krøyer.

The new genus *Clypeoma* is placed among those Corophiæ which have "Digitii nulli 2-articulati," and further defined as having "Antenne longae, flagello crasso rigidoque, obsolétæ articulato." "Antenne styiformes, rectæ. Pedes filiformes, non prehensiles, sex postici prolongi." Boralliæ, 1885, identifies this genus with *Tyro, Milne-Edwards,* 1840.

The new genus *Uristes* is defined simply by the words "Pedes toti vergiformes, nulli prehensiles," Its companion in the *Ilidæ,* *Pterygoëma,* Latreille, "Pedes postici suballevati," is a synonym of *Lepidactylis,* Say (Hauslorus, P.L.S. Müller), which Dana places among the Gammarinæ.

Dana observes in his notes that *Mesu* and *Molita* are separated by Leach, and *Amathia* by Rathke, from the genus *Gammarus,* that *Amphithoe* includes the *Dorarima* and *Pherusa* of Leach, that *Ensieur* of Krøyer is not sufficiently distinct even for a subgenus, that *Krøyer's Microchæ,* Rathke’s *Iphiniella,* and Owen's *Acanthosoma* are near *Amphithoe,* that *Siphonocree* of Krøyer differs from *Podocree* only in having the posterior legs longer than the four preceding, and that *Glauconine* of Krøyer has the hands and antennae of *Uristes.*

This letter from Liljeborg to Lovén is mentioned in Boeck's list, but I cannot find that it contains any information about the Amphipoda, or any mention of Crustacea, except the bare fact, p. 32, that at Tromsö in Norway he had observed some which he had not at the time of writing determined.

1849. Lucas, II.

In the "Première Classe.—Crustacés. Troisième ordre, les Amphipodes. Première Famille, les Crevettines. Première Tribu, les Crevettines sautantes," he gives the following species,
THE VOYAGE OF H.M.S. CHALLENGER.

Occasional notes are made upon the various species. The new ones are described and figured. "Orchestia Perieri," pl. 5, fig. 1, called in the Brit. Mus. Catal., "Allorchestes Perieri," now becomes Hyale perieri. Lysianassa longicornis, pl. 5, fig. 2, "Long. 10 millim, larg. 3 1/2 à 4 millim.," is thus defined, "antennis primis sat elongatis, primo articulo infra fortiter spinoso; secondis elongatissimis; pedibus spinosis, posteriorum primis articulis subtiliter denticulatis." Besides the very pronounced spine at the lower distal end of the first joint of the peduncle of the upper antenna, we learn that "leur filet accessoire est assez court." "Les yeux sont très-grands et reniformes." The telson is "assez fortement creusé en cuiller et terminé en pointe arrondie postérieurement. Les styles terminaux des fausses pattes des trois dernières paires sont assez allongés." The highly useful information is also given that, "La première et la seconde paire de pattes ne présentent rien de remarquable." The figure 26 shows the upper antenna with a thick first joint having infero-distally a small process and a long spine, the second joint not much shorter than the first, and two a half times as long as the third. Spence Bate adopts the name for a British species, to which he does not assign any spine on the upper antenna, and of which he says (Brit. Sess. Crust. i, p. 88), "the central tail-piece exhibits no peculiar character." According to G. O. Sars, 1882, Lysianassa longicornis, Sp. Bate, is the male of Anonyx cleaveri, Sp. Bate, and is renamed "Orchomène Batei," G. O. Sars, although the first gnathopods as figured and described by Bate and Westwood do not agree with the definition of the genus Orchomène. Heller in 1866 gives a fresh description and figures of Lysianassa longicornis, Lucas, with a long process instead of a spine on the upper antenna. By the antenna this species approaches Costa's genus Ichnopus.

"Amphithoe Vaillantii," pl. 5, fig. 3, "Long. 12 à 17 millim. larg. 3 à 4 millim.," is thus defined: "flavescens, subtiliter viridi punctata; antennis equilibus, fortiter ciliatis; pedibus primi parvis brevibus, secundi parvis elongatissimis, penultimo articulo valde eximantani, ad basin spinâ instructo; corpore levigato." In regard to this species see Note on Prof. Catta, 1876.

"Vibilia Jeangerardii," pl. 5, fig. 4, "Long. 10 millim. larg. 3 millim.," is thus defined: "rubro subtiliter laxeque maculata; antennis primi parvis levigatis, antîci obtusâ truncatis, secundii parvis brevibus; pedibus levigatis, penultimo articulo paulisper arcuato; septimo segmento abdoninis supra trilobato, penultimo antîci transversim depressi." It is near "Vibilia Peronii," M.-Edw., but differs from it "par la tête, qui, à son sommet, est moins acuminé; le dernier article des antennes supérieures est aussi plus allongé et surtout beaucoup plus obtusément tronqué à sa partie inférieure que dans la V. Peronii." Moreover in Vibilia Jeangerardii the lower antenna, he says, are a little more than half as long as the upper, while in the other species they are much longer than the upper antenna.

Caprella tabida, pl. 5, fig. 6, is identified by Mayer with Caprella artifrons, Latreille.
REPORT ON THE AMPHIPODA.

Historia física y política de Chile segun documentos adquiridos en esta republica durante doce años de residencia en ella y publicada bajo los auspicios del supremo gobierno por Claudio Gay ciudadano chileno. Zoología. Tomo tercero. Paris, MDCCXLI.

The Crustacea occupy pages 115 to 318 of this third volume. In the first division, “Crustaceos mexilados,” the “Amphipodos” and “Larcomelipodos” are respectively the third and fourth orders. The Amphipods, pages 226 to 249, include the two subdivisions, “Gamaranos” and “Hiperineas.” In the former, Talitrus chilensis, n. s., is established on a damaged specimen with the definition, “T. antennis brevissimis; pedibus anterioribus gracilibus; corpore supra leví, ad latera rugoso.” A new genus follows, thus described:—

“Orchestoidea.—Orchestoidea. Antennae superiores minúsculas, inferiores [inferioribus] multo breviores; articulo primo latu, quadririformi, fortiter depresso; secundo gracili, cylindricō; tercio secundo breviori, gracili, ciliato, tipilla brevisima, quinque articulata terminante. Antennae inferiores maxime, crassissimae; articulo ultimo pedunculi elongato; penultimo ultimo crassiori, tegillae breviores. Oculi magni. Palpus pedum maxillarium externum quadriradiatus, parum elongatus, crassus; articulo primo brevissimo; tercio quadririformi, apice truncato, in medio fortiter emarginato, quartoequ, angusto brevi, tuberoso. Mandíbula robusta, fortiter dentulata, palpo usque. Pedes primi pars tarsi styliforata terminati; secundii pars subbiliformes maxima crassissima, oralis; segmenta angulati.”

The fuller description concludes with the observation, “los apéndices de los anillos abdominales son cortos y bifidos; el último segmento es muy corto y repentinamente replegado por bajo, lo que da á la extremidad posterior del cuerpo un aspecto truncado,” to which he appends the remark by way of note, “la forma de las antenas y la del cuerpo de estos Crustaceos representan á los Talitros, mientras que la disposición de sus patas del segundo por los incorpora á las Orquesias: pero las pata-quitadas externas y sobre todo la forma de los tallos palpiformes los separan completamente, siendo intermediarios de ambos géneros, con quienes tienen muchas relaciones.” The type species, Orchestidea tuberculata, pl. 2, fig. 4, is defined as “O. flavescens; corpore tuberculato; articulo primo pedunculi antennarum externarum crustulato; fronte in media breviter angulato; pedibus villosis.” Nothing is said about the female.

He then describes Orchestia chilensis, M.-Edw.; Orchestia brevicornis, n. s.; “Orchestia Gayi,” n. s.; Amphitoe chilensis, n. s., pl. 2, fig. 5; “Amphitoe Gayi,” n. s., pl. 2, fig. 6. The new genus Nicca is thus defined:—“Antennae superiores exstis breviores. Caput crassum. Oculi oculi, obtusum dispositi. Pedes breves, primi et secundi pars subbiliformes; maxilae brevissimas. Mandibula brevisima, bilobata, multidentata, non palpagna. Labium sternale maximum.” To the general description he adds that he has formed this genus upon a specimen which has various affinities with Amphithoe, but differs in the absence of the mandibular palp and the relative length of the antennae, bringing it near to Talitrus, and above all by the considerable development of the beakel portion and the form of the maxillipeds; its dilated (rechoncho) body resembles that of Talitrus. The type species, “Nicca Lucasii,” pl. 2, fig. 7, is defined “N. obscure fuscus-virescens; corpore brevi, crasso, curvato, concavo; pedibus maxillariis externis fortiter tuberculatis.”

He next gives Gammarus chilensis, n. s.

This is followed by what Nicolet supposed to be a new genus, Latoria, thus defined:—

“Antennae superiores graciles, elongati, articulo secundo pedunculi primo longiores, cylindricī, tercio brevi, bifidolato. Antennae inferiores pedunculo elongatissimo, tipilla brevisima.
Caput breve, anterius truncatum. Oculi parvi. Mandibulas palpigenae, palpi triarticulatae, articulo primo brevi, secundo tertiique elongatis, cylindraceis, fortiter ciliatis. Pedes maxillares externi palpis quinque articulatis; articulo ultimo unguiformi. Pedes quattuor primorum parum prehensiles; Pedes primi parvis longiores, robusti, palpo spiniformi infra munitii; digitus elongato, cylindraceo, unguiculato, terminali."

The type-species, Lalaria longitarsis, pl. 2, fig. 8, is defined: "L. fasciaca; pedibus posterioribus longis pilis vestitis; pedibus anterioribus ciliatis."

Ozyephalus, M.-Edw., he thus defines: "Caput maximun, depressum, elongatissimum, anterius acutum. Antennae superiores crasse, fractae, capite breviores, capitis retculo inecertae; antennae inferiores graciles, cylindraceae, alaeque, thorace longiores. Oculi maximi. Pedes primi et secundi parum dilatati; segmentis [sequentibus] elongatissimae, graciles, subdilatati. Pedes sextis parvis et brevissimis, vel nulli. Segmenta primo secundo tertioque abdominis magnis, pedunculo appendicibus natatoriarum crassissimi; segmenta quarto et quinto brevissimae; sextum elongatissimum, appendicibus styliformibus, acutissimae, elongatissimae, terminali." A misprint here and there seems to have affected the Latinity of this passage. One species of this genus, the author says, pertains to Chili, namely, Ozyephalus oceanicus, Guerin, thus defined: "O. antennis superioribus ovatis, articulo parculo, acuto, terminatis; antennis inferioribus parvis, quinque articulatis; articulis ciliatis."

In Order IV, "Lomodiopodes," the "Caprellanas" contain the genus Caprella, which Nicolet assigns to Leach. He concludes the description of this genus with the words, "abdomen rudimentario, teniendo cerca de su base un par de appendices estiliformes y biarticulados," adding a note, "Conocemos tres especies de este género, é ignoramos por qué motivo el Sr. Milne-Edwards niega á las patas del segundo par las vijigullas branquiales, puesto que la C. longicornis las tiene, y muy aparentes."

Caprella longicornis, n. s., pl. 4. fig. 3, is thus defined and described: "C. fusca; capite elongato, antice globoso, postice cylindrico; antennis superioribus setiformibus, longissimis; antennis inferioribus brevilibus; pedibus parvis secundis tanto angustis, elongatis, antice dilatatis, postice subcylindrico."

"Cabeza una vez y media mas larga que el primer articulo del tórax, con su parte anterior globosa y in espinas, ocupado el tercio de su longitud; los otros dos tercios son cilíndricos, mucho mas pequeños y tan gruesos como la mitad anterior del primer segmento torácico; antenas superiores muy largas, fuertes en la base y disminuyendo insensiblemente de grosor hasta la extremidad del tallo multiarticulado; las inferiores son muy cortas, delgadas y filiformes; las patas del primer par están adheridas à la pas inferior de la parte globosa de la cabeza, cerca de la boca, son cortas, delgadas, y concluyen en una mano subglobosa; las del segundo par, al contrario, son muy largas y las termina una mano que ocupa la mitad de su total longitud, estrecha, levemente arqueada, repentinamente dilatada en el tercio anterior y subcylíndrica cerca de su base; el segmento torácico á que estas patas se hallan adheridas es
irregularmente triangulariforme, y su ángulo anterior, que es el más largo, sostiene la cabeza; en el posterior está inserto el segmento siguiente; las patas ocupan el ángulo inferior, que tiene además dos vejiguitas branquiales adaptadas a la base de las patas; los dos segmentos que siguen son, como el resto del cuerpo, subellítricos, llevando cada uno dos vejiguitas branquiales; las patas del primero de los tres últimos pares son muy cortas y rudimentarias, y las de los otros dos prolongadas y subquilliformes, con el penúltimo artículo dentellado en el lado interno; dos filetes espiniformes por bajo del abdomen.—Color moreno amarillento claro.—Longitud, 8 mm.

_Caprella brevicollis_, n. s., pl. 4. fig. 4, is defined:
“C. fisca; capite brevi, subgloboso; antennis medioverticalibus; pedibus secundli pars antice ovatis, subglobosis.” It was taken with the preceding form.

_Caprella spinifrons_, n. s., is thus defined:
“C. capite brevi, anticse subglobosse; fronte spinose; antennis superiormbus longis pilis ciliatis; manibus secundli parvis magnis, elongatis, tutus forterior emarginatis.” This species was founded on a damaged specimen.

In the “Cianianos,” the genus _Cyamus_ is described. The name of Lamarck is attached to it, as though he were the originator of the name. The species _Cyamus gracilis_, Roussel de Vauzøró, figured on pl. 4. fig. 7, is defined with the words:—“C. cinereo-viresces; corpus elongato, subfusiformi; appendicibus brannquilibus elongatis, cylindraceis, simplicibus, ad basin obturcularibus.”

The Atlas containing the figures referred to in these descriptions is dated 1854.

The new species, _Talitrus chilensis_, _Orchestia brevicollis_, _Orchestia gayi_, _Amphitoe gayi_, _Gammarus chilensis_, _Caprella brevicollis_, and _Caprella spinifrons_, are not included in the list of the Brit. Mus. Catal., 1862. _Caprella longicollis_ is figured and described in that work, but as Mayer has pointed out, the species is by an error assigned to Lucas, and its habitat given as Algeria instead of Chili.

For the genus _Nicra_ see Note on Rathke, 1837. The genus _Lentaria_ is a synonym of _Aora_, Krøyer, 1845, and the species _Lentaria longitarsis_ is identified by Spence Bate with Krøyer’s _Aora typica_. _Caprella brevicollis_ is considered by Mayer to include the female and young forms of _Caprella longicollis_, and, as _Caprellina longicollis_, the species becomes the type of a new genus founded by G. M. Thomson in 1879. This genus I propose to name _Caprellina_, since _Caprellina_ is preoccupied as the name of the group to which the genus belongs. _Caprella spinifrons_ is left indeterminate by Mayer.

1849—Schiødt, J. G.
1851.

Specimen faunae subterraneae, 1849. m. 4 Tafeln. Aus den Abhandl. der Copenhagenener Akademie der Wissenschaften. 5te Reihe. Bd. II. (Appears to be the same work as the above. See also Entom. Soc. Trans. I. 1850-51, pp. 134-157.)

Schiødt comments first on the slow growth of knowledge in regard to the subterranean fauna.

In his historical review he mentions Tellkampf’s _Triura cavernicola_, which, he says, “seems to belong to the order of Amphipoda,” an obvious error in which he is followed by Boeck. At page 26, he institutes the new genus _Niphargus_, with this definition:—

_200L. CHALL. EXP.—PART LXVII.—1887._

XXX 30
"Ordo Amphipoda.—Familia Gammarii.

The type species he names Niphargus stygianus, which is figured on Pl. III. In the course of a full description, he thus distinguishes the sexes, "lamina basilis ultimi pedum parvis duplo longior segmento. Stylus ejus interior in m a r e sextam decimam in f e m i n a vero septimam styli exterioris partem sequens longitudine, apice spinulis preditis duabus setisque pennata singula. Stylus exterior cylindricus; articulus primum laminam basalem in f e m i n a duplo, in m a r e autem triplo superans longitudinem, fasciculis ornatis utrinque spinulam brevissimum in mari obsoletioribus; fasciulis lateris exterioris e binis compositis spinulis setisque pennata singula; articulus secundus in f e m i n a dimidium articuli primi partem complens fere longitudinem, lateribus apiceque fasciculis preditis setularum; in m a r e longitudine fere articuli primi, glaber, levissimus, apice solo fasciculato."

He concludes with the statements:—"Commoratur in locis depressioribus specus Adelsbergensis et Lanc, aqua repleta stilllicidio abundante sedimentoque tectis fundi crystallo. Agillime salit, captu difficilissim; territus latebrass fundi velocissime petit."

Schiodte next describes with great fulness, and figures, Koch's Pherusa alba. As Pherusa was more than once preoccupied, he gives a new generic name, Titanethes, in "Ordo Isopoda.—Familia Oeni. — Tribus Orchestidus," the species becoming Titanethes albus. It is perhaps owing to Koch's use of the name Pherusa, earlier employed among Amphipods, that Schiodte's Titanethes has itself been spoken of as an Amphipod genus.

1850. BATE, CHARLES SPENCE, born March 16, 1819 (C. S. B.).

Notes on the boring of Marine Animals. In Notices and Abstracts of Communications to the British Association for the Advancement of Science, at the Birmingham Meeting, September 1849. pp. 73-75. London, 1850.

This paper, though mentioned in Boeck's list, does not refer to Amphipoda. Of Crustacea only Panopeus is mentioned.

Another paper by Spence Bate, in which no Amphipoda are mentioned, is likewise included in Boeck's list, "On some Crustacea dredged by Mr. Darce in Shetland, Ann. Nat. Hist. X. 1852, pp. 356-357."

1850. DANA, JAMES D.

Dana here says:—"In a synopsis of the genera of Gammaracea, in this Journal, volume viii. p. 135, three genera of Orchestidae are mentioned, Talitrus, Orchestia and Allorchestes. We here add a fourth; and for the purpose of giving a fuller comparative view of the four, and correcting a misprinted word, we insert the generic characters for the group."
REPORT ON THE AMPHIPODA.

“Pedes primi non cheliformes nec subcheliformes, articulo styliformi confecti; secundi sepe subcheliformes, manu sive parvulâ et debili sive nullâ. Antennæ superiores basi inferiorum breviores. . . . Talitrus (Laureille).

1850. De Haan, Willem, born February 7, 1801, died April 15, 1855 (Hagen).

During the publication of this fine work M. de Haan was stricken down with a grievous illness which confined him to his bed for years, but did not prevent his courageously completing the publication (Herklotz).

The only Amphipod dealt with is "Caprella Krügeri," of which the author only had a dried specimen to describe, hence, Mayer says, in spite of the good figure, it cannot be determined with certainty, though he believes it to be synonymous with Caprella squillibra, Say.

1850. Hosius, A.

He complains that Gervais and Milne-Edwards, in attempting to distinguish Gammarus fluviatilis vel röselii from Gammarus pulex, disagree with one another, though both dealing with specimens from the neighbourhood of Paris. He assigns Gammarus pulex to Degeer and Gammarus fluviatilis to Rösel, but as he has never met with this latter species in rivers, he thinks that the name Gammarus röselii given it by Gervais ought to stand. He enters into a detailed comparison between these two species and the blind Gammarus puteanus of Koch. In regard to habitat, Hosius says that Gammarus puteanus is confined to wells, that he has only found Gammarus röselii in still or weakly flowing deep waters, but Gammarus pulex in strongly flowing, shallow, brooks, often only an inch deep. In Milne-Edwards’ Manual, he says, we must cross out Gammarus pulex, put Gammarus pulex, Degeer, in place of Gammarus fluviatilis, and lastly insert Gammarus röselii, Gervais (or Gammarus fluviatilis, Rösel), and Gammarus puteanus, Koch.

1850. Liljeborg, V.

In a letter to Hr. Lovén, Liljeborg mentions that in Russian Lapland he had observed among other Crustacea, Gammarus locusta, Mont., Krøy.; “Amorce Edwardeii, Krøy.”; Caprella
lobata (Muell.), Krøy. In the neighbourhood of Tromsø, he mentions "Gammarus locusta Mont., Krøy. Varieties: Antenne superiori inferioribus longiores, et curum pedunculis articulum penultimum ped. antenn. infer. coccidentes. Pardalisa cuspidata Krøy.—Leucothoe norvegica n. sp. L. elypeata Krøy. sat aaffinis. Antenne superiori inferioribus longiores, flagello pedunculo longiore, articulo primo secundum superane, et art. tertio minimo; flagillum antenn. infer. ultimo pedunculi articulo brevis vel anguale; manus pedum secundi paris maxima, dilatata, apice vero acuminato, aculeoque marginis posterioris terminali calidissimo et unguis equo; epimera quarti annulli thoracici maxima, latitudine vero alituidine parum majore.—Anonyx ampulla (Phipps), Krøy.—Caprella lobata (Muell.), Krøy." Both by Spence Bate and Boeck Leucothoe norvegica is considered as probably identical with Leucothoe elypeata, Krøyer, 1812, becoming in that case Metopa elypeata. Bate and Westwood in their Appendix, vol. ii. p. 500, retain it as a distinct species, Montagna norvegica. Krøyer's Leucothoe elypeata they think may be the female of Montagna pollexiana, Spence Bate. Any one who has seen the figure of the hand of the second gnathopod of Leucothoe norvegica given by Liljeborg in the K. V. A. Handl., 1851, will be convinced that he has anticipated Bate's Montagna pollexiana, with which also his description minutely agrees. If this be a variety only of Metopa elypeata, as Boeck supposes, it is at any rate a very striking one. For the present it may stand as Metopa norvegica, Liljeborg, with Leucothoe norvegica, Liljeborg, Montagna pollexiana, Sp. Bate, and Montagna norvegica, Sp. Bate, and Bate and Westwood, for its synonyms.

1850. NATALE, GIUSEPPE DE.

Descrizione zoologica d'una nuova specie di plojaria e di alcuni crostacemi del porto di Messina con poche considerazioni generali sulla natura delle appendici aculeiformi delle piante e degli animali. Messina, 1850.

After describing the insect, Tav. 1. fig. 1, which he names "Plojaria Ambigua," n. s., at page 8 de Natale begins the following account of Cheirocrisita mesemensis:—"Il genere Cheirocrisita (Tav. 1. fig. 2.) formato dal Prof. Cocco, sopra certi Crostacei del nostro porto, ci son parecchi anni, merita di essere illustrato come singolarissimo per le forme esterne.

"La famiglia dell' Iperidi, tra i Crostaci Amphipodi, distinta da molti e razionali caratteri da quella dei Gammaridi; come si sa, può divisioni in tre sottofamiglie. La prima, che si potr dir degli Iperidi Gammaroidei, distinguendo bene dalle due altre; perchè sempre presenta nei suoi generi un piccel capo, un corpo compresso, con gambe polpiformi rudimentali ai piedi massicelli. Anzi, indipendentemente dagli altri caratteri, si potrebbe, come principale, assegnare la piccolezza relativo del capo per distinguergli dalle due sottofamiglie seguenti le quali, tranne il solo Oxyephalus, ci presentano un capo grosso ed enorme. Ma di queste due la prima, che si disse dall' Edwards Iperini Normali, presenta le antenne del secondo pajo stiliformi, non ripiegabili su di sè; ed in ciò distinta dalla terza sottofamiglia detta dell' Iperini Anormali, le cui antenne ripiegabili su di sè costituir potranno di tre a quattro frature.

"In quest' ultima sottofamiglia, che potrebbe dirsi dei Tiñini, perchè il genere Typhis ne è il tipo, vanno fiori classati tre generi; cioè: Pronoe, Typhis ed Oxyephalus. Distinti i due primi dal terzo ad un capo corto, arrotondato, e portante le antenne del primo pajo alla sua fascia anteriore, mentre il terzo ha un capo lunghiissimo, e puntuto cole antenne del primo pajo inserite sulla sua fascia inferiore. Distinto il Typhis dalla Pronoe, poichè questa non presenta, come il primo, i piedi del secondo pajo presili, ed il primo articolo dei piedi delle due ultime paja dileipeforme grandissimi. Dalla Typhis, non si conoce nè quale che l'unica
T. Ovoides che, come vedremo in appresso contrariamente al parere di M. Edwards, differisce assai assai dall’Orio Zanclaus del Prof. Cocco. La Pronoe, e l’Oxycephalus sono esotici a noi.

Fra questi tre generi, che sinoora comprendono la sottofamiglia degli Amphipodi, Iperidi, Tifini, deve oramai intercalarsi un quarto, scoperto da parecchi anni dal Prof. Cocco, e da lui chiamato Cheiropristis. Di esso daremo la descrizione ed il disegno sopra individui soggetti ad osservazione microscopica.

Tra i tre generi Iperini menzionati, più al Typhis rassomiglia il Cheiropristis. Com’esso, infatti, ha un capo corto e grosso, le antenne ripiegabili in fratture e le anche dilatate. Ma se ne distingue per importanti caratteri.

"I Typhis distinguonansi eminentemente per una specialità di struttura delle anche delle due ultime paja, che larghissime sono, e clipeiformi in modo che formano come due valve, le quali, riunite ed approssimate in mezzo, l’animale ripiegando i piedi, e la coda al di sotto, chiudono inferiormente il corpo, e gli danno la forma d’uno sferoide. La estremità posteriore della coda è senza appendici.

Il Cheiropristis però non presenta per nulla questa straordinaria dilatazione delle anche delle due ultime paja di piedi, le quali se non dilatate, sono incapaci ad occultare il corpo come fra due valve; la sua coda ha delle appendici; ma come il Typhis presenta i piedi del secondo pajo prensili, ma un pochino diversamente conformati.

Esso ha un capo corto, ma largo, verticale, ribattuto sul corpo, più largo arrotondato in sopra,
più stretto, con alcune smarginature sulla faccia inferiore. Le antenne, situate sul mezzo
della sua faccia anteriore, sono inserite sopra due peduncoli cortissimi che si toccano alla
base. Da ciascun peduncolo corrono infuori due altri articoli, di cui il secondo più lungo, e
come che si biforquesse, caccia le due antenne, composte di un gran numero di articoli
ripiegabili con fratture o no. Le inferiori sono sempre più corto delle superiori. Gli occhi
son posti obliquamente ai lati del capo; son triangolari, coll’ apice del triangolo in alto, e
coll’ angolo esterno della base che tocca il margine esterno del capo. Sotto il margine
inferiore del capo, e cominciando d’avanti in dietro, stanno due palpi mascellari gracilissimi,
corti, filiformi, sporgenti in avanti, con tre articoli distinti. Dietro questi si osservano due
steli palpiformi, cortissimi, ad un’ articolo poco distinto, e dietro di questi i piedi mascellari
lunghe, filiformi, di tre articoli di cui l’ultimo, appena visibile, curvato a gancetto sul
penultimo. Esistono sette paja di piedi diversi tutti di forma, come sette sono gli anelli
oracici che li portano.—Il primo e secondo articolo del primo pajo son cortissimi e gracili,
ma il terzo è lungo, dilatato, arcuato, e porta dietro due o tre pezzi corti interarticolari,
l’ultimo articolo terminato da due robusti denti uno in avanti, e più lungo del precedente.
I piedi poi del secondo pajo son di diversissima conformazione. Il loro primo articolo è
lungo, largo, ad orli angolosi, laminare; al suo orlo articolare inferiore presenta una forte
smarginatura in cui si annuda un articolo stretto e gracile; questo porta un terzo articolo
largo quasi quanto il primo, ma dentato a secco sul suo orlo posteriore; un quarto articolo si
attacca a quest’ ultimo, mobilissimo, e si può piegare sul taglio di esso posteriore in modo da
dar a questo articolo terminale l’apparenza d’una mano subcheliforme.

"Il terzo pajo di piedi contrasta col precedente per la sua asimmetria. È gracile, cortissimo, filiforme,
con tre articoli appena distinti di cui l’ultimo a punta si finisce. Il quarto pajo ci presenta
uno sviluppo molto cospicuo, come i due seguenti; in esso infatti, il primo articolo è
allungato sebbene un po’ stretto; porta in giù di esso altri due articoli, di cui l’ultimo più
grande dà inserzione al terminale che è edentuto, arcuato e piegato a gancetto su di quello.
I primi articoli dei piedi del quint o e sesto pajo sono più larghi e forti, ma quel del sesto
più di quel del quinto; anchedue dietro esseri articolati con parecchi anelli picciolini,
esilissimi, terminansi con uno che è arcuato e piegato pure a gancetto sul penultimo. Il
settimo pajo di piedi addimostra ad un solo articolo cortissimo, e visibile appena.
L’addome in vero è pochissimo sviluppato, con due soli articoli di cui uno rudimentale, e se
le molte analogie che legano il Cheiropristis ai Tifidi non si oppongono, noi, con ragioni
evidenti, lo porremmo per quest’ ultimo carattere tra i Ciandini nei Lembridedi. La coda
terminasi per una natatoja mediana triangolare terminata a punta, frangita di cigli lamellosi
agli orli, e di due altre natatoje di forme subromboidale ai fianchi.

"Il corpo è tozzo; è largo e corto, altissimo il torace, onde la larghezza si comprende due volte e
mezzo nella lunghezza totale. Alto uniformemente dal capo fino agli ultimi anelli toracici,
esso si restringe notevolmente verso la coda, i cui anelli non han la metà dell’altezza del
torace.

"Data così la descrizione generica del Cheiropristis, i caratteri suoi specifici potrebbero formolarsi
così brevemente.

"Cheiropristis Messanensis. (Cocco) Corpore antice tereti, superius rosso, albicante inferius,
seppuntiore quam alto. Antennis superioribus longissimis, inferioribus ultra earum dimi-
diam porrectis; laminae caudae lateralis, subrhomboidales, media triangulares uncinata.

"Anco ai Typhis si rassomiglia il Cheiropristis per l’abitudine che ha di contrarre i piedi sotto
il torace, in modo che, in tutti gli individui che se ne prendono non comparisce di essi che il
solo torace al di fuori, e non o che con la più gran pazienza del mondo che si arriva a
svolgere i lor piedi senza romperli. È lungo da tre a quattro linee. In certi giorni
dell’andato Decembre il mare ne gittò infiniti lungo la spiaggia presso al nostro porto; ma,
d’allora in poi sono scomparsi."
It will be seen in the note on Cocco, 1832, that in that year Cocco mentions a species which he calls *Cheiropristis Hieron*, but I can nowhere find allusion to any description of either the genus or the species, and am at length forced to conclude that Cocco never published any. In this case *Cheiropristis messanensis* should be cited with de Natale's name both for genus and species. It is not easy to see what de Natale means by saying that the posterior extremity of the tail is without appendages in *Typhis*, while he affirms that in *Cheiropristis* the tail has appendages. *Typhis* has in fact three pairs of uropods, whereas he represents his *Cheiropristis messanensis* with only one pair. His statement that the abdomen of *Cheiropristis* has only two joints, of which one is rudimentary, can scarcely be trusted, and indeed does not agree with the figure, in which at least two fully-developed pleon segments are shown and a third not obscurely indicated. In the B. M. Catal., p. 325, under *Anchylyomera sledentaria*, the *Phronima sledentaria* of Costa, Spence Bate say, "I am inclined to think that *Cheiropristis Messanensis* of Cocco belongs to this genus and probably to this species." In agreement with this opinion I consider the species to be *Anchylyomera messanensis*, de Natale, in the subfamily Phrosininae. In comparing de Natale's description with others relating to species in the same genus, allowance must be made for the fact that he obviously took only a lateral view of his specimen, without dissection. In such a view, I know from experience that the broad fourth joint in the large third pereopods of *Anchylyomera* may appear narrow, and that a telson in reality rounded may seem to be lanceolate. His attempt to disentangle the limbs without breaking them, may well excite the commiseration which he invites, since he had evidently not thought of the expedient of separating them from the body of the animal.

Of *Orlo zonaleus*, Cocco, de Natale says that Milne-Edwards judged inconsiderately in saying that it did not appear to differ from *Typhis*. Besides the characters here derived from a single damaged specimen in spirit, he gives a fuller account in the appendix.

He institutes a new genus to receive "*Ornitthoramphus Coccol*," figured Tav. 1. fig. 3. This, though he calls it a new Crustacean, had been long before described by Cocco as "*Orlo Ornithoramphus*" with some doubt whether it should not be put in a separate genus. Of the necessity of this de Natale was convinced, but was somewhat doubtful whether it might not belong rather to the Isopoda than to the Amphipoda *Hyperina*. He describes it thus:

"Esso si presenta d'una forma allungata e rotondetta. Il capo, convesso all'orlo superiore, finisce in avanti a modo di becco d'uccello; appareanza tanto più curiosa, in quanto che portà alla latà della sporgenza rostriforme, un soleo che simula una specie di comissura. Gli occhi son piccolissimi, quasi invisibili, e segnati solo da due punti netti per ciascun lato del capo. I palpi mascellari ganci assiali ad articolii indistinti. I piedi mascellari con un'articolazione grossa e primitiva, che portà in fine i due filiformi articolii lunghissimi, fratti e piegati su di sè in un soleo longitudinalmente inferiore del capo; una strizzatura separa il capo dal collo. Dal primo anello toracico, mediameramente, son eranie che prendessero inserzione i piedi mascellari, che son corti, tozzi, robusti, ineuguali, ad articolii stratti e corti, di cui l'ultimo porta una vera mano cheliforme. Simile chela termina pure i piedi teracici del primo pae, di cui il primo articolio è lungo, stretto, lineare; ma l'ultimo robusto, dilatato e terminato da mobile gancetto. Tutte le altre sei pae di piedi segmenti, in generale, tranno una varia lunghezza di esse, e degli articolii che le costituiscono, sono identiche. Il lor primo articolio è dilatato, foliaceo, diafano; i segmenti stratti, allungati simili a palpi, frangiati di peli agli orli. Il primo pae tra esse è il più lungo, quindi vanno gradatamente decrescendo di lunghezza, fin l'ultimo che è cortissimo e con tre soli articolii lineari. I sette anelli toracici son quasi simili, della stessa altezza del capo. L'addome si compone di tre anelli ben conformati e distinti, ma l'ultimo porta inferiormente due lamelle vibratili, diafane, che si piegano l'una sull'altra come valvole.—Queste lamelle
saran, come negli Isopodi, una metamorfosi degli ultimi falsi piedi addominali? Questa domanda che sino non abbiamo potuto risolvere, a causa del piccolo numero d'individui che si vennero fra le mani, ci impedirà di determinare il posto che dovrà occupare l'Orrithocharmus nella serie Carcinologica.—Manca l'addome di qualche traccia di falsi piedi; ma la coda però si termina per un potente ed allungato articolo, che porta ai fianchi due lamelle filiformi a mo' di stilletto, che sono le lame nuotatrici laterali. Più indietro, ed in sotto, stanno da ciascun lato due lamelle triangolari, mobili, divaricabili tra esse; finisce la coda in un pezzo quadrilatere terminali. Avendone rinvenuto uno, ancora vivente, gettato sulla spiaggia, al veder le lamelle terminali dell'addome vibrar fortemente, mi corsi in mezzo d'aver per le mani un'Isopoda. Questa idea mi venne confermata, qualor osservandolo al microscopio non mi fu dato osservar traccia alcuna delle vescicole branchiformi, respiratorie che caratterizzano eminentemente gli Amphipodi. Per altro, la total mancanza di falsi piedi addominali, lo allontana da tutti gli' Isopodi; e se le lamelle vibratile si volessero considerare come trasformazione di tali piedi, conserverrebbe costituirsi, tra gli' Isopodi, una famiglia a parte, in cui essi solo si comprendesse."

He finds it has great analogy with the Sphaeromidae, but other points tend towards placing it with the Typhide.

"I caratteri specifici potranno così brevemente formularsi. Orrithocharmus Coccio. Corpore hyalinio, pellucido; capite subrotundato, rostro brevissimo, teretissimo, longitudinalit altitudinis quinquiplana fere equante; capite longiore altitudine corporis. Oculis minimis; lamine capite lateralius, anterioribus styliformibus valde elongatis.

Having obtained five fresh specimens, de Natale was able to add an "appendice all' Orio zancleus." In this he says, "Ecco descritto con le più rilevanti differenze, che dal Typhis, lo distinguono—

"Ha un corpo tasso, breve, raccolto; un capo grosso, con un muso ottuso, e due enormi occhi triangolari, laterali, con l'apice in alto—Manca di qualunque traccia d'addome superiori che nei Typhis costantemente esistono inserito a capo al muso—Egli è vero che potrebbe supporre, essersi tali appendici perdute e rotte; come avviene di sovente nel descritto Cheiropristis, ed in altri moltissimi; ma poichè tra tutti gli'individui da me, e dal Prof. Cocchi osservati, non ne è stato mai alcuno, che ne avesse offerto traccia; così ci è quasi certo di poter concludere che esse manchino affatto—Le antenne inferiori giseciono, come i palpi, bifratte, ampiate, ripiegate in un ampio incavo sottocefaUco—I piedi delle due prime paga toraciche terminansi a chiara didattila, larga, dentata; ma gli articoli basali del primo pejo son lineari, mentre quelli del secondo pejo sono strettamente contorti, e dilatati—Quelli delle due paga sequenti son gracili ambulatori terminansi da valida uguetta—Di simil guisa terminansi i piedi del 5° e 6° pejo; ma il lor articoles basali è dilatato, folaceo, applicato sui piedi anteriori nel riposo—Ma questa dilatazione è un rudimento in paragone a quella, che si vede nei Typhis, in cui può occorlar sovr' essa la coda, e l'addome internamente. I piedi del 7° pejo sono rudimentali. Il torace alto quanto il capo non è rigonfio come nei Typhis; in questi, i tre primi anelli addominali son grandi, ma son piegodini nell'Orio. In quelli i falsi piedi han largo il peduncolo, le cui lame terminali son allungate striate a traverso, dentellate agli orli—Nell'Orio cioèm pedunculo porta quattro laminette stiliformi, acute, non rigide, né striate, né dentellate. Il 4°, 5°, 6° anello addominale costituiscono nel Typhis una coda bruscamente ripiegata in giù, con tre altre paga di falsi piedi, e due lamelle terminali. Nell'Orio i sudetti anelli più bassi del tronco, non son piegati in giù, ma orizzontali, con nessuna traccia di falsi piedi, ma con sei paga d'appendici nuotatrici, laterali, oltre il pezzo stiliforme terminali—

"I caratteri specifici dell'Orio Zancleus saranno.

"Orio Zancleus (Cocco)—Gryseo-Lutescente, punctis nigricantibus adspersis; altitudine longitudinalis quartum, et ultra equante; oculis triangularibus nigris; lamine capite lateralius lanceolatis.—
"Negli Amphipodi Iperini Anormali si raccolgieranno adunque i generi Typhis, Orio, Pronoe, Cheiropristis, Oxycerophalus, ed Ornitoramphus—La diversità generica tra questi due ultimi potrà dedursi da che l'Oxycerophalus presenta: occhi enormi, due paja d'antenna, sei anelli con sei paja di falsi piedi addominali; l'Ornitramphus mostra: occhi microscopici, antenne nulle, tre anelli addominali senza traccia di falsi piedi, ma con lamelle vibratili branchiformi, onde è che meglio starebbe tra gli Isopodi—I caratteri della famiglia, come furono stabiliti dall'Edwards per comprendere la Pronoe, il Typhis, e l'Oxycerophalus, son da modificare or che se ne trovano intercalati altri tre generi. Essi saranno: capo grosso, antenne or patenti, or occulte in una smarginatura sottocefalica, ma sempre ripiegabili in frature.—Così la famiglia de'Tiñi, verrà distinta da quella degli Iperini Gammaroidi e Vibilidi a capo costantemente piegolino—e dagli Iperini Ordinari ad antenne superiori subuliformi, ed alle inferiori non ripiegabili in frature."

It may be presumed that in the account of Ornitoramphus Cocco, by the terms 'i piedi masculari con un articolo basiale grosso e piriforme,' and 'i piede masculari, che son corti' etc., de Natale intends respectively the second pair of antennae and the first gnathopods. "I piedi masculari," may be either the first antennae or the mandibular-palps. The species should be compared with that called Oxycerophalus typoides, by Claus, in 1879. This species, from Zanzibar and from the harbour of Massina, has "Kopf kugelig aufgetrieben, mit sehr tiefer Antennengrube und spitzen, ziemlich kurzem Schnabel. Nackengegend stark verengert. Die vorderen Antennen des Männchens gross, mit stumpfen Zahnfortsatz an dem sehr gestreckten Schaft. Zweites Antennenpaar sehr lang, mit stark ausgebogenen Gliedern und kurzem Endgliede. Greifhand der vorderen Beinpaare mit ungezähnten, in eine lange Spitze ausgezogenen Rand." Other particulars are given, concluding with "Das Caudalkopfsegment mehr als zweimal so lang wie die kurze Schwanzplatte. Letztes Uropodenpaar sehr kurz." It is clear from de Natale's figure that he has fallen into a misapprehension in regard to the "microscopically small" eyes, as he indicates their very considerable extent.

In the account of Orio zanclus, de Natale denies the presence of upper antennae, but fig. 3 on plate ii., here reproduced in fig. 26, evidently represents this species, though the fact is not stated in the text, and in this figure three antennae appear. Claus gives the following account of Eupronoe maculata, n. s., from Zanzibar:—"Körper gestreckt, 10–12 mm. lang, mit grossen ramifizirten Pigmentfeelen. Kopf ziemlich lang und vorn merklich verschmälerst. Der proximale eingekrümmte Abschnitt am Femoralgliede des vorderen Beinpaares so lang als der nachfolgende verbreiterte Theil. Scheerenfortsatz am Carpus des zweiten Beinpaares so lang als das Metacarpalglied. Distalier Theil des Femoralgliedes keulenförmig angesehellen. Carpalglied des ersten Beinpaares ohne Fortsatz. Femoralplatte des siebenten Beinpaares viel kürzer als die des vorausgehenden Beinpaares. Schwanzplatte trigonal am hinteren Ende verjüngt, lanzet-förmig zugespiitzt." In Eupronoe armata, n. s. (Pronoe brunnæ, Dana, he gives, "Körper mässig gestreckt, punktirt, circa 7–8 mm. lang, mit grossem, gerundetem Kopf." A female Eupronoe, 4 mm. long, from Lagos, which is, he says, extremely near the preceding species, "entbehrt der kreisförmigen Einkrümmung an den vorderen Gnathopoden." From these accounts it seems possible that Cocco's Orio may have anticipated Claus's Eupronoe, but there are many difficulties in the comparison.

(Zool. Chall. Exp.—Part LXXI.—1887.)
1850. Natale, Giuseppe de.

This paper is mentioned in Bock's list. I was unable to obtain a sight of it until too late for an abstract to be inserted here. See appendix to the Bibliography.

1850. Steenstrup, Johannes Japetus Smith, born March 8, 1813 (J. J. S. S.).

The Cyamus sp. n.1 of this paper was afterwards described by Lütken under the name Cyamus globiceps. Lütken, 1873, page 48 (276), assigns Steenstrup's paper to the Forening for 1843; Bock gives it as above.

1850. White, Adam.

The Introduction assigns this Catalogue to Mr. Adam White. The title shows the limitation of its scope compared with the "List of the specimens of Crustacea," drawn up by the same author in 1847. The nomenclature is somewhat varied, and numerous synonyms are here given for the terms adopted. The class Crustacea is adopted from Brissi, 1756; Subdivision I. Crust. Maxilloba, from Latreille, 1825; I. Edriphthalma, from Leach, 1814–1815; I. Amphipoda, from Latreille. In this is placed Tribe I. Gammartera, containing Fam. I. Orchestidae; Fam. II. Gammariidae; Fam. III. Podoceridae; Fam. IV. Cherididae; and Tribe 4 [2]. Hyperita, containing Fam. I. Phronimadse; Fam. II. Typhidae. Order IV. Laxinodipeda, Latreille, contains Fam. I. Caprellidae; Fam. II. Cyamidae.

Naturally, many species in the former list do not occur in this which is confined to British Animals. Among the Gammaridae the additions are, Opis typica, Kroyer's Sea-Screw, from Ireland; Anomura albus, British Coast; Anomura, sp., Thompson, from Ireland; Amphihoe punctata, Johnston's Coast-Screw, referred to "Gammarus punctatus, Johnston, Zool. Journ. iii. p. 177; Thomp. (W.) Ann. Nat. Hist. xx. p. 243," but without any explanation of its relations to Amphihoe punctata, Say, mentioned in the earlier list. This is followed by Amphihoe dubia, referred to "Gammarus dubius, Johnston, Zool. Journ. iii. p. 178." In place of "Vertumnum Crackii" of the earlier list, the following entry is made:—

"Acanthopterus.
"Vertumnum, Leach, MSS. White (1847).
"I. Acanthopterus (Vertumnum) Testudo. Cranch's Sea-Screw.

REPORT ON THE AMPHIPODA.

"Vertumnus Crunchii, Leach, MSS.; White, List of Crust. in Brit. Mus. p. 89 (1847)."

To the genus Gammarus, White now adds, Gammarus subterraneus, Leach, which he suspects may be "Gammarus palus, var. jun."; Gammarus carinatus, the Keel'd Coast-Screw, "Johnston, Zool. Journ. iv. p. 52;" Gammarus maculatus, the Spotked Coast-Screw, Johnston, Zool. Journ. iii. p. 176; while Gammarus campylophus, Leach, is now given as Gammarus camplago, the Bent-eyed Coast-Screw. In the Podoceridae, "Jassa, Leach, Ed. Enc. vii. p. 433 (1814 or 1815)," receives the two species in the earlier list assigned to Cercopes. To the well-known Cercopes, is applied the English title of "Long-haired Mud-Liver." The Family Chelura is occupied by Chelura aterrimus, "Sea Woodborer," Philippi's names for the genus and species being rightly preferred to the older MSS. names, Newvermescoidea, Leach.

To the family Typhicidae is added Typhus nolens, for "Gammarus nolens, Johnston, Zool. Journ. iii. p. 179."

Lastly Proto pedata becomes Proto pedale, Müller's Spectre Shrimp.

In the family Cyamidae, the species are given as "1. Cyamus ceti. Common Whale-louse, including in the synonymy Cyamus eraticus, Roussel de Vanzemo, with Oziwes ceti, Linn., etc., etc.; 2. Cyamus ocellis. Oval whale-louse, and 3. Cyamus gracilis, Slender Whale-louse." A concluding observation says, "Here by many authors are placed Nymphon, Pycnogonum, and their allies."

Most of the species are designated by English names similar in character to those which have been quoted.

1850. WHITE, ADAM.

After describing Potamobates serratus and Gonboloclylus cultrifer, n. s., which are figured on Pls. XV. and XVI, White says, "On the same plate with G. cultrifer is figured an Amphipod, which may be the species figured by Colonel Montagu in the ninth Volume of the 'Linnean Transactions,' t. 5. f. 5, under the name of Oziwes testudo. I have named this on the plate Acanthonotus testudo; it belongs to Prof. Owen's genus Acanthonotus; in the British Museum it bears Dr. Leach's manuscript name, Vertumnus Crunchii. The head is produced and pointed between the antennae, and instead of the small number of segments assigned by Colonel Montagu to his Oziwes, there is the normal number of the various genera of Amphipoda."

It was afterwards recognised that this species has nothing to do with Montagu's Oziwes testudo, and that it does not belong to Owen's genus Acanthonotus, but to the neighbouring genus, Epimeria, of Costa, being in fact Epimeria corniger, Fabr.

1851. BATE, C. SPENCE.

The species Belica arenaria here figured and described was subsequently named Suctator arenarius, but in the meantime Dana had recognised it as belonging to Say's genus-
Leptidactylus, and S. I. Smith has identified it with Leptidactylus styliacus, Say, which is the same as Oniscus arenarius of Slabber, for which P. L. S. Müller proposed the generic name Haustorius. The genus Boëlia is thus defined:—"Back broad, round and smooth. Upper antennae forked. Lower antennae ciliated, having the second joint flattened. First pair of feet simple; second and third pairs didactyle, remainder simple. The three anterior pairs of feet much smaller than the rest; the lateral appendage to each annular segment, together with the joints of the three last pairs of feet, largely developed, so as to appear like scales. Natatory feet arranged in double parallel pairs." I may mention that this creature is very common in stretches of sand round the British coasts, and very vivacious in appearance when burrowing into the sand. While it is alive in sea-water, the circulation can, under the microscope, be very distinctly seen in the broad plates of the hinder pereopods.

"Amphithoe Moggridgei" here described and figured as new, was in the Brit. Mus. Catal., 1862, referred to Anathilla (Cancer) carino-spinosa, Turton, but in the same year, 1862, in the "British sessil-eyed Crustacea," it was identified with Anathilla sabint, Leach, the Anathilla homav, Fab., of this Report.

1851. Brandt, J. F.

After reviewing earlier opinions on the distinctions between Talitrus and Orchestia, and the agreement of the two in regard to the second gnathopods of the females, he points out that in many other classes generic distinctions have been drawn from the peculiarities of a single sex, but that, apart from this, there is a real though somewhat fine distinction between Talitrus and Orchestia in regard to the first gnathopods. He therefore defines these as follows, recognising that "Der zweifelhafte, vielleicht keinen echten Talitrus darstellende T. Cloquetii ist dabei ausgeschlossen":—"Genus Talitrus Bosc. e. p. Talitrus Leach, Latr. M. Edw. Dana. Pedum primi paris ultimus articulus in mare et femina subconicus, hau cristiformis vel subcheliformis, ungue elongato, parum flexili ipius articuli marginem inferiorum longe superaute armatus.—Pedum secundi paris ultimus articulus in utroque sex ungue obsoleto, marginis ipius inferiorie breviores instructus.—Antenne superiores basi seu pedunculo inferiorium breviores. Maxillipedes apice obtusi.

Talitrus cloquetii, if rightly represented in the Description de l’Égypte should, he thinks, form an intermediate genus (eine eigene Mittelgattung) between Talitrus and Orchestia, for which he proposes the name, Talitrochestia? He would then follow Guérin in making three sections of the genus Talitrus, thus arranged:—

"Spec. 2. Talitrus Brunneolobii M. Edw.;" "Spec. 3. Talitrus brevicornis M. Edw.;"
"Spec. 4. Talitrus tripudians Krüyer."
REPORT ON THE AMPHIPODA.

In further remarks on this last species, of the correct figuring of which he is with some reason rather suspicious, he considers that his proposed new genus or subgenus agrees with *Orchestia fem.* by the structure of the first gnathopods, but by the relations of the second gnathopods not entirely either with *Orchestia* or with *Talitrus*, except that in "T. Cloquetii" the first gnathopod appears shorter than the second (as in *Orchestia max.*); a circumstance, he says, which led Guérin to make it the type of his Section C.

The genus *Orchestia* is arranged by Brandt as follows:—

1. Pedum sextum et septimum par longitudine fere aequales vel septimum paullo longius.

10. "Sectio II. Antennae superiores pedunculo inferiorum longiores. (Subgen. *Alorchestina* nov),"

12. Die als Subgenus *Alorchestina* aufgestellte Gruppe sind Orchesten, welche in dem anscheinlichen Längeverhältnisse der oberen Fühler zu den unter sich derGattung *Alorchestes* anreihen und sich nur durch den Mangel der spitzen Krallen an den Maxillarfüssen davon unterscheiden. Dass *O. nigrisemis* kein *Alorchestes* sei, geht aus Kröyer's Mittheilung hervor, denn er bezeichnet darin den *ulimum pedum maxillarium articulums* als *conicum.* Von *O. Pereiri* ist die Gestalt der Maxillarfüße leider weder beschrieben, noch abgebildet, so dass sie möglicherweise ein echter *Alorchestes* sein könnte. Uebrigens nähert sich *O. nigrisemis* wegen des *ulimum articulums pedum maxillarium conicum* auch mehr der Gattung *Alorchestes* als die in der *Sectio I.* angeführten Orchestien.

"Orchestia ad alia genera spectantes." “Spec. 1. Orchestia grandicornis Kröyer . . . = Allorchestes grandicornis;" “Spec. 2. Orchestia longicornis M. Edw.," with Talitrus longicornis, Say, and Scambalia longicornis, Leach, Mss. This species, he thinks, is closely allied to, if not identical with, his own Megalorchestes californianus.

This portion of Brandt's paper concludes with remarks on Orchestia glythys, for which the name Scambalia Sayana, Leach's Mss., is given in the List of Crust. Brit. Mus. 1847.

The remainder of the paper, pages 310–313, treats of "Megalorchestia" as the only genus in which the Amphipoden aus der Gruppe der Orchestiden." This new genus, he says, to some extent by the form of the first gnathopods inclines towards Talitrus, by the second gnathopods more to Orchestia, by the maxillipeds to Allorchestes, from which last it is again removed by the very short upper antennae. For the name he says, "Ich bezeichhe sie nach Maassgabe der Größe der ihr zum Grunde liegenden Art als Megalorchestia." This genus is a synonym of Orchestoidea, Nicolet, 1849. Brandt defines it thus:—

"Pedum primi pars inferior articulis etiam in maribus spicis angustatis (Tab. 1. fig. 12).—Pedum secundi pars ultimus articulorum marium semper maximus, cheliformis. Pedum maxillarium articulatum ultimum angustatum, spicis unguiculatis. Antennae superiores pedunculo inferiorium breviores." The type-species, Megalorchestia californiana, is described and figured with much detail. The telson is described as "lamina caudalis simplex cordata in medio dorso longitudinaliter impressa." The plate shows numerous details.

Talitrus longicornis, Say, the O. (Scambalia) longicornis of Leach's Mss. is discussed as offering "? Spec. 2. Megalorchestia longicornis."

In regard to Talitrus eleganti, see Note on Saviguy, 1825; the subgenus Talitrochaeta, resting only on the obscure figure of that otherwise undescribed species, has never met with acceptance. Of Orchestia ochotensis, Spencer Bate in the Brit. Mus. Catal., p. 369, says, "this species appears to differ but little from Dana's figure of O. Pleiergii." For Orchestia nitrostenis, see Note on Kroyer, 1845.

1851. Brandt, F.

The Amphipoda occupy pages 130–144 (54–68) and 511 (74). They are placed in the Subclassis Crustacea Maxillata, Legio Edriothalama, and embrace two sections, the Gammaridea and Leomodiopoda. The new species Orchestia ochotensis is described and figured, figs. 18–26, and placed near to "Orchestia Betta," provisionally so-named, from the Black Sea. (See the preceding Note.) Brandt reports, as taken by Wonesenski in the Sea of Okotsk, Anonyx ampulla, Phipps, accepting this designation and a long list of synonyms from Kroyer, 1845, for numerous specimens which he had himself examined. On the authority of a letter from Lichtenstein, he adds to the synonymy "Gammarus Grylles" Lichenst. sp. M.S. Mandt, but as he also specially refers to the Atlas of the Voy. en. Scand. (Livr. 37) Pl. 13, fig. 2 a-c, there cannot be any doubt that the species intended is Cancer (Anonyx) angus, Phipps. He also reports numerous well-preserved specimens of "Anonyx Edwardsi," Kroyer, as having been taken by Wonesenski, along with one of the preceding species, out of the stomach of a whale captured in the Bay of Motschigmanok. In the genus Gammarus he takes Section 1. A. a. Milne-Edwards, with "the inner branch of the third uropod as large as, or at least more than half as large as, the outer," to include "Spec. 1. Gammarus buenosi?" from the river Dacha in the Sea of Okotsk; "Spec. 2. Gammarus pulex, De Geer," taken in the basin of the hot-springs of Natschik,
REPORT ON THE AMPHIPODA. 247

and "Spec. 3. Gammarus sitchensis" n. s., fig. 28, a-c., from the Island of Sitcha, intermediate between Gammarus braculata and Gammarus palus and fasciatus, Say. This Boeck unites to Gammarus braculata, in regard to which species Brandt makes vigorous efforts to disentangle the confusions of the earlier writers. Under B with " the inner branch of the third uropod not even, or at most, a quarter as long as the outer, and often only rudimentary, he places " Spec. 4. Gammarus sitchensis," n. s., fig. 29, a-c., from Atcha and Unalschka; " Spec. 5. Gammarus braculatus," n. s., fig. 30, a-c., from Ayan on the sea of Okotsk; " Spec. 6. Gammarus ochotensis," n. s., fig. 31, a-c., from the same seas, and " Spec. 7. Gammarus longirostris," n. s., fig. 32, a-c., allied to Gammarus dentatus, Kroyer, with which Spence Bate was inclined to unite it, while under the name of Melita dentata, Kroyer, Boeck actually does so.

Among the Lammalipoda Brandt gives, from Nichte Bay in the Sea of Okotsk, Caprella affinis, n. s., like Caprella binervis, Johnston (1835), but differing from it in the greater size of the hands of the first gnathopods, which are more than half the size of those of the second gnathopods, and in the much longer, untoothed, penultimate joint of the hinder pair of feet, which appears longer than the two preceding joints. Caprella nitchensis, n. s., he compares with Caprella binervis, Müller (Kroyer, Voy. en Scand. pl. 25. fig. 3). Mayer does not find himself able to identify either of these two unfigured, briefly described species, or even to decide whether they belong to the genus Caprella at all.

Spence Bate in his B. M. Catalogue founds a new genus, Braultia, for a species which he refers to as " Gammarus latissimus, Brault, Voyage de Middendorf," with " Hab. (Arctic Asia) Voyage de Middendorf." The figures and description were taken by Sp. Bate from specimens which Professor Brandt had sent to the Museum at Paris, but the species Gammarus latissimus was instituted by Gerstfeldt in 1858, and was found by Maack in the Angara at Irkutsk.

1851. COSTA, ACHILLE.

March. Fauna del Regno di Napoli.

Genere Callisoma; Callisoma, (Costa).

The genus Callisoma, named in 1840 by O. G. Costa, is now described:—" Generis characteres essentiales. Antennae superiores capite paulo longiores, validissimae, subulate, pedunculo crassissimo, biarticulae: inferioris graciles, longissulce. Polles quatuor anti graciles hand cheliformes, secundl longiores. Epinota articulari quatuor thornicellis clupeiformia, inferne postice producta. Characteres naturales. Corpus compressum, brevissimurn, et late subovatum. Antennae superiores breves, capite idem ac inferiorium pedunculo paulo longiores; pedunculi articulo primo crassissimo, duobus sequentibus longitundine et crassitie decrescentibus; setis duobus pluri-articulatis, seta primaria caras subulate, pedunculo breviore; secundaria minuta gracili. Polles primi parisi graciles, main simplis unguiculata terminati; secundl anteriorioribus far similis at longiores: trium parium posticorum articulo primo
THE VOYAGE OF H.M.S. CHALLENGER.

dilatato scutiformi. Epicera satis lata: quarti articuli majora, inferne postice distincte producta, illa articuli quinti circum-dantia."

"Callisoma punctata, O. G. Costa," is described and figured. The short definition is:

"C. corpore dimidio fere longituninis alto, epimeris articuli quarti thoracis postice ad illorum quinti angulum infero-posteriorum usque prodnetis; carnes, maculis punctiformibus crebris ordinatis rubro-sanguineis pictus; oculis nigris, antennis pedibusque pallidis.—Long. lin. 3½; alt. max. lin. 1 4/10."

"Callisoma Hopei" is also described and figured, being distinguished from Callisoma punctatum chiefly by the absence of the dendritic spots, and by the different development and shape of the side-plates. The genus Lysianassa, Milne-Edwards, and the type species Lysianassa costa, Milne-Edwards, are described.

1851. Hope, Frederick William, born January 30, 1797, died April 15, 1862 (J. O. Westwood).

Costa, Achille.

Catalogo dei Crostacei Italiani e di molti altri del Mediterraneo per Fr. Gugl. Hope. Napoli, 1851. 48 pages. 1 Plate.

Though A. Costa’s name does not appear on the title page the work appears to be at least as much due to him as to the Rev. F. W. Hope.

The Catalogue differs so strikingly from most catalogues of Amphipoda that I give the Amphipodian portion in full.

As genera incerta sedis are given Hexona and Zuphea of Risso, with their respective species
Parasitica and Sparicola. An addendum is given Genere Amphithionotus, Guttatus,
A. Costa, Napoli.

Among the Aecilidae, Leach, are placed Apestes, Leach (Euphausia, Risso), with the species
liquoisus, Risso; Tanae cavolinii, Edw.; Otiska penicillata, Risso. The Pranizidae, Hope,
contain eleven species of Praniza, and Ananaeus fornicarius, Risso.

The first Amphipod species described, and the only one figured, is "Callisoma Hopei, A. Costa,"
fig. 2. This is considered by Bock as the type species of Costa's genus Callisoma; but
the description says "Secunda haec generis Callisoma species facile a C. punctato distinguitur corpore minus aequatus; colore roseo vel subflavoscente immaculato; epimeris quarti articuli thoracis inferne postice ad illorum Quinti articuli medium marginis inferioris, neque ad angulum infero-posteriorum neque productis. Long. lin. 2." The Callisoma punctatum

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)
from which it is here distinguished was named Callisoma punctata by O. G. Costa in 1840, but not described till 1851 (see preceding Note). It must be considered the type of the genus, as Spence Bate suggests, Brit. Mus. Catal., p. 84, note, though he had not been able to find the description of it. Costa's species Gammarus montanus from Lago del Matese, and Gammarus longicaudatus from the drinking water of Naples, are given here for the first time. They are not mentioned in the B. M. Catalogue, from which Amphithoe longispines and Amphithoe gracilis are also omitted. All these four are described at length in Costa's R. s. Crost. Ann. d. R. d. Napoli.

The genus Amphithomonotus, A. Costa, is thus defined:—"Illis ex Amphithois species constitutam est hoc genus, quæ dorum vel omnino carinatum et sphoenum, vel saltum quibusdam abdominis articulis si non et thoracis postice in spinam vel dentum productis habent; ex quo peculiarem habitatm praebent. Amph. marionis, Edw.; panoplos, Kroyer; carinatus, ejusd. et quæ sequuntur ad hunc genus pertinent." The type species, Amphithomonotus acanthophthalmus, A Costa, which is here said to be "affinis Amph. marionis," was afterwards, under the name Amphithomonotus marionis, by Costa himself made a synonym of "Amphithoës marionis, Edw.," and must, as Boeck says, be included along with that species in the synonymy of Dorsanvis spinosa. The next species, given as Acanthonotus guttatus, A. Costa, and said to be very near to Amphithoe carinata, is evidently meant for Amphithomonotus guttatus, as given in the addendum above mentioned. Costa in his subsequent work does not notice this, but silently transfers the species to his genus Notropis, which Spence Bate and Boeck agree in referring to the genus Atylus, Leach, and also agree in misspelling Notropis, though Costa gives the derivation versus, back, and ventris, feet. The species guttatus is omitted from the B. M. Catalogue. Since both the species, acanthophthalmus and guttatus, belonged to genera already established, the genus Amphithomonotus, created to receive them, must be considered to have perished at its birth.

The genus Epimeria, A. Costa, is thus defined:—"Hoc genus, Amphithoës et Amphithonotis maxime affine, epimeris quarti et quinti articuli thoracis elatis, ceteris valde majoribus, simul elypeeum sequies inferne emarginatum formanribus, dignoecundum. Dorsum fere ut in Amphithonotis."

Of this genus, Spence Bate remarks that it apparently "differs in nothing from Acanthonotus of Owen, of which probably it is a synonym." Boeck does not accept this view, but identifies both the type species, Epimeria tricristata, A. Costa, and Acanthonotus coccii, Bate and Westwood, with Gammarus corniger, Fabricius, 1779, under the name Epimeria corniger. The Brit. Mus. Catal., in rendering the above generic definition, says, "Coxe of the first and second pairs of pereiopods long, the rest considerably broader," but Costa's meaning is that the coxae or side-plates of the second and third pairs of pereopods are prominent, very much larger than the rest.

In Hope's Catalogue it may be observed that he inserts Ostro ornithorhynchus, Coceo, as well as Ornithorhynchus coccii, Natale, although de Natale clearly explains that his species is the same as Coceo's. As to the genus Carcinococcus and the species assigned to it, de Natale, 1850, says, "Finalmente il mio Carcinococcus arriva tra gli Stomatopodi Unicornziate, Eritini—Dedicandone la specie al mio Maestro il Prof. Costa de Napoli—ho voluto foggirane il nome suo Carcinococcus; da quello dell' illustre Prof. Coceo, ad imitazione di Carlo Luciano Bonaparte che sopra uno Scopelino scoperto dal Ch. Istituto di Messina foggio il suo Icthiococcus—al cui specie Ornatii, e Perezii sono proprie del nostro porto. Hence these three species are here quite out of place. Leucathoe parthenogena Costa subsequently withdrew. His later Corophium achenopuma and Viblius species probably answer to Ambonites achenopuma and Elasmococcus spicilus. There are several other genera and species named, of which I can give no account. Some of them are perhaps described in de Natale's letter to Achille Costa, of which I extremely regret that I have never been able to obtain or see a copy. (See Appendix.)
1851. LILJEBORG, WIILHELM.

At page 311 he mentions having observed "vid Solnottskaja i Ryska Lappland," among the Crustacea, "Gammarus locusta, Mont., Kröy.;" "Anisgyrus Edwardsii, Kröy.;" "Caprella lobata (Muell.); Kröy."

At page 346 occurs the heading, "Förteckning öfver de af mig i trakten af Tromsö i Norge observerade Daggiojur, Fostlar etc." Among the Tromsöi Crustacea are the following Amphipoda:

- "Gammarus locusta, Mont.; Kröy. Varietas: Antennae superiores inferioribus longiores, et carum pedunculi articulum penultimum pedunc. antenn. infer. excedentem.—Parablissus cuspidatus, Kröy.—Pontoporia femorata, Kröy.—Amphithoe albomaculata, Kröy.—Anisgyrus ampulla (Philp.); Kröy.—Ischyrocerus minutus, n. sp. Antenna superiores inferioribus insigniter longiores, flagello ultimam pedunculi articulum sequente, circiter 6-articulato, articulus elongatus, flagello appendiculari vix dimidiam primi articuli flagelli proprii longitudinem sequant; ultimam pedunculi antennarum inferiorum articulum flagellum eire. 5-articulatum sequans; manus primi et secundi pedum parum fere equeales, subapertura forma minima. Tantummodo specimen unum, feminam oviheram, circ. 4 mm. longum e profundo magno aequat.—Lencithoe norvegica, n. sp. (Tab. xx. fig. 4)." For the description, see Note on Liljeborg, 1850. Ischyrocerus minutus is identified by Bock with Podocerus antennae, Kröy, but it is more probably the same as the species described by Sars in 1882 as Podocerus minutus, n. s.

After some Isopods, Liljeborg also mentions "Caprella lobata (Muell.); Kröy."

1851. LILJEBORG, WILHELM.

Of the hundred and six species collected by v. Dueben, numbers 34 to 70 belong to the Amphipoda. Many are merely named. On a few, notes are given as follows:—

"34. Orchestia litorea, M. E.—Femina a mari tam diversa forma pedum secundi paris, ut illa formam typicam generis Talitri M. E. et hic canem formam gen. Orchestie efferit videatur. Femina Talitris tridentanti Kr. sat similis est; forma pedum secundi paris prornus cadem est, longitudino vero pedum quarum et quintae paris diversa, quam ha pedes hisdem secundi paris longiores.

"42. Anisgyrus norvegicus n. sp.—A. planus Kr. sat. affinis, diversus tamen: antennae superioribus feminae et maris fore equeales, flagello circ. 14-articulato, flagello appendiculari 5-articulato, artic. primo eternis viu longior; antennae inferioribus antennae insigniter diversae—maris plus quam duplo—longiores; epimerrio quarto postice profundo situato, epimerrio quinto mediocrii, subquadrate, antecedentibus humilior. Preferre inter se similis." This in 1855 he identifies with Anisgyrus galbus, Kröy.

"51. Amphithoe Pansilipüs M. E.—Omnino ei similis, oculi vero non visible.
THE VOYAGE OF H.M.S. CHALLENGER.

57. *Gammarus Dubeclii* n. sp.—Antecedenti [*Gammarus locusta*, Fabr.] simulimus, tamen distinctus: maguaidine minori; antennis magis hispidis, superioribus longioribus; flagello appendiculari breviore circuit. 5-articulato; tuberulis segmenti 4: i, 5: i et 6: i abdominis pilis longis; manum pedum spuriousum ultimorum insiguiet inequalibus, interiore tertia parte minore &c. Haud infrequens videtur, quam multa adsiit specimina. Apud omnia ratio illa inter ramos pedum spuriousum ultimorum plane constat." This in 1854 he makes a synonym of *Gammarus locusta*.

59. *Gammarus Sundevalli*, H. Rathke. Femina mari dissimilis nauibus ped. 1: i et 2: i paris minuis fere equalibus." This is now known as *Cheirocratus sundevalli*.

60. *Gammarus assimilis*, n. sp.—Precedenti simulimus, praequie diversus: pedibus maris secundis paris longiores [longioribus], manu elongata, fere rectangulata, infra pone unguem oblique truncata et tridentata, antice et postice equaliter, non dense, pilosa. Inter feminam et marum dissimilitudo eadem ac precedentis." This is now called *Cheirocratus assimilis*.

64. *Gammarus Zebra*, H. Rathke.—Generi Ischyroceri, Kr. potius adnumerandus.*

65. *Ischyrocerus anguipe*, Kr.

66. L. (Podocerus) calcaratus (H. Rathke) Sine dubio cadae species ac antecedens, eujus calcis manus pedum secundis paris non evolutum, sed tantum tuberulo minuto indicatum.*

68. Leucothoe—? Sine dubio junioris *L. clypeata*, Kr. Femina ovifera minuta: antennis superioribus inferioribus brevioribus; manus pedum secundi paris mediori, ovata, margine posteriore medio uni-dentata; praetera *L. clypeata* similis. Apud quidam specimina minitisima, sed tamen ovifa, ovis solammodo paneis majoribus, antenne fere eadem longitudine sunt, manus pedum secundi paris vero codem modo formata." This is now known as *Melops clypeata*.

Under "Loemodipoda (amphipoda)," he gives

70. *Caprella lobata* (Müll.); Kr.—Admodum variabilis. Aculei partium superiorum corporis nullum distinctionem specificum praestare videantur. Feminae plurunum supra sunt aculeate, carnane amnui thoracici et manus breviore." This may belong to variet of Krayer's *Caprella lobata*, which Mayer puts, with the other varieties, under *Caprella linearis* (Linne) Batse.

1851. Peters, Wilhelm Carl Hartwig, born 1815 (Hagen).

Specimen academicum inaugurale, continens annotationes de quibusdam crustaceis indigenis, quod ... publico ac solemni examini submittit Leonardus Alexander Johannes Burgersdijk, e pago Alphen Batavus, ad diem xix. m. Junii a. MDCCLII. Lugduni-Batavorum.

Burgersdijk is at great pains to discriminate *Gammarus pulex* from Rüel's species which Gervais named *Gammarus rosei*. It will be useful to see in juxtaposition the synonymy, as he has drawn it up for each species.
**REPORT ON THE AMPHIPODA.**

“*Gammarus pulex*

"*Squilla pulex*, de Gere, Mém. VII, p. 525, Tab. 33 (excl. synon.).

"*Gammarus pulex*, Lat., Régne anim. IV, p. 120 (excl. citat. Linnaeus).

"*Gammarus pulex*, Desmarest, Consid., p. 266, Tab. 45, fig. 8, 8a (excl. synon.).

"*Gammarus pulex*, Zetten, Comment. fig. A, C seqq. (excl. synon.).

"*Gammarus fluviatilis et pulex*, Milne Edwards, Crust. III, p. 45 et 48 (pro parte et excl. synon.).

"*Gammarus aquaticus*, Leach, Linn. Trans. XI. 359."

Zenker's varieties of *Gammarus pulex*, *longicaudatus* and *brachicaudatus*, Burgersdijk says he has found mixed together (promiscue). After giving his reasons in full for the synonymy to *Gammarus pulex*, he adds, "Neque Linneum neque Fabricium citavi, quia plures species confundebant, sic in Linnei Syst. Nat. Ed. XII, Cancer pulex, testo synonymia, constat. Gammarum Roeselli, Gammarum hunc puleum, et Orbis specieu, Gammarum Roeselli eiam sub nomine Canaris locustae militat; in Fabrici Ent. Syst. II, pag. 516 sub Gammarus locusta et puleus similis est confusio." From want of materials he refrains from discussing *Gammarus pulex*, Koch, called by Gervais *Gammarus pulex minutus*, and concludes the subject with the remark, "si tribus hisce speciebus, G. Roeselli, pulex, pulex additur G. ambulans Fr. Müller (Wieg. Arch. 1846, I, pag. 296), nullam omisit e speciebus aequae dulcis, quae hucusque in Europa reporta sunt." Here however he reckons without the *Gammarus* (*Niphargus*) *pungens* from the warm springs in Italy, of which we find notice in Ray.

A short chapter is given on *Gammarus locusta*, for which he cites as authorities Leach, Desmarest, Kréyer, Milne-Edwards and Zaddach. He thinks that Guérin's figure in the Iconographie, Crust. Tab. 26, probably represents *locusta*, but points out that the upper antennae in fig. 7 are shorter, in fig. 7a much longer, than the lower. Nor does he include in the synonymy Montagu's *Cancer* (*Gammarus*) *locusta*, since it has the upper antennae much shorter than the lower.

“*Gammarus Roeselli* Gerv.

"*Squilla fluviatilis*, Roesel, III, Tab. 62.

"*Cancer locusta*, L., Sulzer, Insect., fig. 152.

"Croccelles des baieaux, Geoffroy, Insect. II, pag. 667, Tab. 21, fig. 6.

"Gammarrellus pulex*, Herbst, Krabben und Krebse, II, pag. 132, Tab. 36, fig. 4, 5.

"Gammarus pulex*, Latreille, Hist. nat. des Crust. et des Ins., VI, pag. 316, Tab. 57, fig. 1.

"Gammarus Roeselli, Gervais, l. l.

"Gammarus Roeselli, Hosius, l. l."

(In reference to this list he notes that Sulzer's and Geoffroy's figures are copied from Roesel's figure.)

In "Class Crustacea, Subclass C. mandibulata," Couch gives definitions of the two genera Caprella and Proto. In the first he describes 1. Caprella phasma, Montagu's Cancer phasma; 2. "C. Acanthifera," for which he gives "C. Acanthifera, Johnston, Mag. Nat. History, Vol. vi., p. 46, fig. 7a.—Vol. viii. fig. 70, p. 671.,” as his authority; 3. "C. Pennantii," with references to "Cancer Atimus, Stew. Elem., Vol. ii., p. 317; Astacus Atimus, Pennant, Brit. Zool., Vol. iv., pl. 13, fig. 2;" 4. "C. Linearis," with reference to Cancer linearis, Linn., Cancer lobata, Stewart, Caprella linearis, Johnston: "the head is obtuse, and the species the shortest and stoutest of any found in our seas, with no spine along the whole of the dorsal surface." C. spinulata (Couch), is thus described:—"Long and slender; the head is larger than the next articulation, and without a spine; the occipital articulation with a spine near its posterior margin, and there is one on the next ring above the branchial; there are two on the third, one above the branchial, one near its posterior margin, and one on the centre of each of the others. Superior antennae as long as the body, basal joint small, the second about four times as long as wide, the third long and slender and slightly enlarged towards its distal extremity, the last multi-articulate and ciliated; the inferior antenna much smaller than the others; at the lower part of the head two pedipalpi, small and bifid at their extremities. The hand very large, moveable joint long, slender, and hooked, and at its point, when bent, touches a spine on the hand." Mayer thinks these characters would suit C. acanthifera, but recognises the uncertainty. The "occipital articulation with a spine" is a little suggestive of Aeginella spinosa, Boeck. Lastly, he describes Proto pellatus, without naming any authority.

1852. Dana, James D.

This paper contains only Dana's own new species. In "Subtribus I. Gammaeacea. Familia I. Orchestidea. Polypus mandibulatus" obsoletus. Corpus compressum, operculis lateris. Styli canales duo postei breviores,” he gives genus I. Talitrus, Latreille, "Pedes primi styli formae, secundi vel non subelliformes vel manu debilissimae confecti. Antennas praebebas inferiores breviores,” with the species Novi-Zelandiae, gracilis, ornatus; genus II. Talitronus, Dana, "Pedes secundi manu valido prehensili confecti. Alias Talitro similis,” with the species insculptus which he afterwards identified with Orchestidea tuberculata, Nicolet, as an Orchestidea, dropping both his own genus Talitronus and Orchestidea of Nicolet; genus III. Orchestidea, Leach, with the species ephrica, tenalis, rectispina, spinipalma, rectipalma, obtota, dispar, octobrachium, serrulata; genus IV. Alborcheotes, Dana, with the species compressa, rectipalma, hieripalma, gracilis, perscula, hamata, australis, brevicrurae, Novi-Zelandiae, intrepida, orientalis, and Alborcheotes grandis."
In "Familia II. Gammaridae. 

Forsan genus hic description Erichthonio disceptat et novum. Hoc credente, genus Pyctilus (a πτιλος, pugil) in manuscriptis auctore institutum est," with the species Erichthonius (Pyctilus) macrocallus and Erichthonius (Pyctilus) pygmar.

"Familia IV. Iciliidae. Corpus valde compressum, latum, vix lineare, abdomine articulato normali, valde inflexo. Pedes plerumque lati expansi in tota Aranei. Antenna quattuor flagelli confectae, non pediformes. Antennula grossa. Genus Icillus. Antennae elongatae, secundae longiores. Pedes non prehensiles, toti vergiformes, apicem magunulati. Styli caudales sex furcati." This genus receives the single species, Icillus ovatus, of which the specific name was afterwards changed without notice into the better Latin Ovatus. In regard to his Amphitoe brevis, in which the second gnathopod is large in the male but small in the female, Dana adds to his description the remark, "Microchelai, generi non vero, ut mihi videtur, femina A. brevispelia forsan pertinet."
1852. Dana, James Dwight.

"The term Choristopoda, applied to the Tetradecapoda, alludes to the subdivision of the thorax into segments, each devoted to a separate pair of legs; this is a prominent peculiarity of the species, distinguishing them from all the Podophthalmia, and with rare exceptions from the Entomostraca."

"The Amphipoda are uniformly characterized by having—

"1. The three posterior pairs of thoracic legs thrown backward and more or less obliquely forward, and constituting one series, while the four anterior pairs are thrown forward and outward, in another series; this arrangement may be represented by the figures 4:3, (or 2+2:3, as the four pairs of the first series are often in two sets of two pairs each).

"2. The branchial appendages thoracic.

"3. The abdominal members in two sets, the three anterior pairs subnatatory, the three posterior styliform—an arrangement represented by the figures 3:3."

From these he distinguishes the Isopoda, and places Arcturus, Tanais, &c., in an intermediate group or tribe called Anisopoda.

"The Amphipoda contain two prominent divisions, distinguished by the organs of the mouth, the eyes and general habit, the Gammarus and Hyperia sections, as laid down by Edwards. The addition of the Lemipoda to the Amphipoda introduces a third division. The sections are hence:

"Subtribus III. Hyperidea.—Maxillipedes abbreviati, lamellati, operculiformes. Caput grande, oculorum cornis pleurumque tectum. Appendices abdominales ac in Gammarides, latins lamellati.

"The Caprellidea have the habit of certain of the Anisopoda, and their short abdomen calls to mind the Isopoda. They therefore properly stand first among the Amphipoda.

On subtribe II. Gammaridea, he remarks:—"[Among the Gammaridea, the author finds that the posterior caudal styles offer important characters for distinguishing natural groups or genera, and upon this ground, some new genera have been recognized among the Corophiide and Gammaridae, and others that have been rejected are sustained. Thus Iphimelus is distinct from Amphithoe, Macro and Derochote from Gammarus, etc.]." He then gives Fam. 1. Durlichidea, G. 1. Dulichia, Kröyer. Fam. II. Cheleidea, G. 1. Chele, Philip. Fam. III. Corophiide. Subfam. 1. Clydoniine.—"Styli caudales sex simplices, subulati. Clyphonia, Dana, Amer. J. Sci. [2], viii, 140.

"2. Styli caudales tritii minuti, cir costi, simplices, tritique ramo exatus non praeclari

\textbf{G. 6.} Podocerus, Leach.—"Pedes 1mii 2dique subchelati, 2dis validioribus. Antenne superiores breviores, non appendiculati. \textit{[An maris digitus 2dis interdum 2-articulatus Kröyer teste.]} In a note he observes, "Jassa of Leach may without inconvenience be united to \textit{Podocerus}, as there is no essential generic difference between them."

The same remark has been applied by later writers to the next genus, \textbf{G. 7.} Cylrophium, Dana, "Pedes 1mii 2dique subchelati, 2dis validioribus. Antenne superiores breviores, appendiculat useful." \textbf{B.} Digitus 2dis 2-articulatus." \textbf{G. 8.} Cylrophus, Say. — "Antenne pediformes, subvisae, flagellis earentes. Pedes 1mii 2dique prehensiles, 1mii parvi, 2dis manu bene confectis. Styli canales 3ii bicorni, ramis subervis, longusulcis. \textit{Tubum membranaceum inhabitat}.

\textit{in which definition the account of the third uropods is rather to be remarked than accepted.} \textbf{G. 9.} "Cylrophus, Edw. (Cylrophus, Templeton)\textit{.}

\textbf{G. 10.} Eribolithus, Edw.

\textbf{Subfam. 3.} Eribolithinae. — "Antenne non pediformes nec subpediformes, flagellis sat longis basique sat brevi instructae. Styli canales ac in \textit{Corophium}.

\textbf{G. 1.} Eribolithus, Dana. Pedes toti unguiculati et tenues, 4 anteci longi, non prehensiles, eiliati, 10 postici fere similis. Antenne superiores breviores non appendiculat useful." \textbf{G. 2.} Pterygocera, Latr.

\textbf{Fam. IV.} Orchestidae, is introduced with the note:—"The author gives a different arrangement of the species of Orchestidae from that published in this Journal, [2], viii, 135 and ix, 295, and rejects the genus Talitronus, there instituted. He follows Fr. Müller (Archiv f. Nat., 1848, 53) in considering the Talitri and Orchestes as forming a single genus, his recent investigations confirming this view. The Gammaridae also are rearranged." He then gives

"G. 1. Orchestes.—Maxillipeses non uninuculati. Antenne 1mæ basi 2parum breviores. Epimerae 5tis 4tis parviores breviores."

\textbf{Subgen. 1.} Talitrus.—"Pedes 1mii maris feminae manu non instructi."

\textbf{Subgen. 2.} Talorchestia, D.—"Pedes 1mii maris ac in Talites, feminae manu parvulæ instructi."

\textbf{Subgen. 3.} Orchestia.—"Pedes 1mii maris feminae manu plus minus instructi.

\textbf{G. 2.} Allorchestes, Dana.—"Maxillipeses uninuculati. Antenne 1mæ minus, basi 2parum longiores. Epimerae 5tis 4tis susparsa multo breviores." On the three subgenera see the following note. In the proposed arrangement the older name \textit{Talitrus} should have been assigned to the genus, rather than \textit{Orchestia.}

\textbf{Fam. V.} Gammaridae, contains—

\textbf{Subfam. 1.} Stegocephalinae. \textbf{G. 1.} Stegocephalus, Kröyer.

\textbf{Subfam. 3.} Lencothoinae.—"Antenne superiores basi plus minus graciles. Maxillipeses elongati, angusti, articulo longo magnisiformi confecti, lamellis internis percoeleis. \textit{Mandibulae sive palpigerse sive non palpigerse, processu molari carentes.}\textit{An semper?} Epimerae magnæ." \textbf{G. 1.} Stenotroph, Dana, "Epimerae permagna, \textit{4tis maxima, 5tis parvis.} Pedes 4 anteci subchelati, 2dis validioribus. Antenne superiores longiores, non appendiculati. \textit{Mandibulae non palpigerse, processu molari carentes.} Styli canales 1mii

\textbf{(Zool. Chall. Exp.—Part LVII.—1887.)}

Of "Subfamilies III. Hyperidea," he says, "In the first family of the Hyperidea, (the Hyperidea), neither of the 5 posterior pairs of legs are subchelate, and the antennae are not folded up beneath the head or thorax. In the second (the Phronimidea), one or more of the 3 posterior pairs of legs are subchelate or much enlarged, apparently for grasping in coition, and the antennae are as in the Hyperidea. The third family (the Typhidae), differs from both the preceding in the concealment and folding of the inferior antennae beneath the head or thorax, and in many of the species, the abdomen closes up against the venter."

REPORT ON THE AMPHIPODA.

259

1852. Dana, James Dwight.

Pages 8–12 of Part I. contain preliminary notes on the classification of the Edriophthalmia. In Part II. the pages referring to Amphipoda are from 691—696, 805—1018, 1440—1443, 1518—1524, 1595—1596.

Taking the Edriophthalmia as Subclass II. of the Crustacea, he makes the Choristopoda, or Tetradactepoda, the first order of this subclass, and thus defines it:—"Cephalothorax multi-annulatus, segmentis thoracis numero septem, pare pedum utroque ad segmentum singulum pertinente, segmento anteriori cephalico brevi. Pedes thoracis peditiformes, sepiissime unguiculati. Abdomen paribus appendicibus pluribus infra instructum. Appendices branchiakes sive thoracici sive abdominales.” Of this order he makes three divisions, the Amphipoda, Anisopoda, and Isopoda, rejecting the subdivision of Lernipoda, introduced by Latreille. “The Amphipoda,” he says, “are uniformly characterized by having—"

"1. The three posterior pairs of thoracic legs in one series, and the four anterior pairs in two other series of two pairs each. The branchiæ are thoracic."
"2. The abdominal members in two sets, the three anterior pairs subnatatory, the three posterior styliform."

Of the intermediate Anisopoda, he says, "They have—

1. Like Amphipoda, the three posterior pairs of thoracic legs in one series, and the four anterior in a different series.

2. Like Isopoda, the three posterior pairs of abdominal members are not styliform, only the last having this character."

In discussing the question whether the Amphipoda or Isopoda should rank the higher, he remarks, in favour of the Amphipoda, the position of the branchiae on the thorax, as thoracic branchiae characterize all the higher Crustacea. On the other hand, he considers that they show inferiority, by the elongated abdomen, with natatory appendages below, and by the usually long antennae, both these being Macroural characters. Further, the anterior set of legs includes four pairs, an evidence, he considers, of less concentration of force in the cephalic ganglia; they have a less compact body, are less apt to take to a habitat on dry land, and above all, have often the two "dorsal cords" distinct between the ganglia, while in the Isopods there is but a single cord. This double cord is seen in none of the higher Crustacea.

In Tribe III. the Amphipoda (p. 805), he recognizes two types of structure, one, the Hyperidea, with small, operculiform maxillipeds, large faceted eyes covering most of the large head, the extremity of the abdomen broad and depressed, the natatory abdominal appendages usually oval, lamellate; "in the other type, the outer maxillipeds are elongated and palpiform, the eyes are small, the head of moderate size, the abdomen, when not obsolete, narrow, and the natatory abdominal appendages usually slender. This second type comprises two groups. In one section, the Caprellidea, the abdomen is obsolete. In the other, the Gammaridea, the abdomen is fully developed, with three pairs of natatory appendages, and as many of stylets."

This section embraces the typical Amphipoda, the Gammarii, Talitri, and the like.

His three subtribes, Caprellidea, Gammaridea, and Hyperidea, he divides and subdivides into families and subfamilies, which are defined as follows:—

Subtribe I. Caprellidea. Family I. Caprellidae.—Corpus anguste elongatum, fere filiforme. Antennae 2dae longitudinis mediocres. [Species non parasitica.]

Fam. II. Cyanidae.—Corpus lato depressum. Antennae 2dae rudimentariae. [Species parasitica.]

Fam. II. Cheluridae.—Corpus fere cylindricalum, epimeris mediocribus. Abdomen abnormale, segmentis 4te 5toque coelesit et oblongis, stylos inter se valde dissimilibus.

Fam. V. Gammaridae.—Saltatoriae vel natatoriae, pedibus nullis lateraliiter propriis. Corpus sexpius compressum, raro subdepressum, epimeris sive magnis sive parvis. Styli caudales laxiores, duobus altimis oblongis sexpiusque ultra 2dos non prolongatis, rarissimi. Mandibulae sexpiisse palpigere. Maxillae 1me palpo 2–3-articulato (rarissime 1-articulato) instructe.

Subtribe III. Hyperidea. Fam. I. Hyperidea.—Antennae 2dae exsertae. Abdomen in ventrem se non flectens. Pedes 5ti 6tiqve 7miqve formâ longitudinâque mediocres, 5ti 6tiqve non pererassis nec prehensilibus.
Fam. II. Phronimidae.—Antennae 2nd exsertae. Abdomen in ventrum se non flectens. Pedes 5th 6thique sive crassi sive elongati, saepius prehensiles, quaque 3rd 4thique sepe prehensiles.

Fam. III. Typhidiæ.—Antennae 2nd sub capite thoraceque celatae et saepius replicatae. Abdomen in ventrum sepe se flectens. Pedes 6 postici internum abbreviati, articulo 1no operculariformi, internum longitudinali mediores.

The family Caprellidae is not subdivided by Dana into subfamilies, but he distinguishes three sets of genera in the following manner; 1. _Pedes thoracis numero 14_, containing the genera _Proto_, _Leach_, and _Protella_, Dana. 2. _Pedes thoracis 3rdi 4thique omnino obsoleti_, containing _Caprella_, _Lamarck_, _Aegina_, _Kröyer_, _Cercops_, _Kröyer_. 3. _Pedes 3rdi 4thique obsoleti_, with the single genus _Podatiria_, _Kröyer_.

The family Cyamidae contains but a single genus. So also in the Gammaridea, the families _Dulichidæ_ and _Chelurideæ_ have but one genus apiece.

The family Corophidiæ is subdivided into three subfamilies.

1. Clydoniinae.—Styli caudales:—1mii 2dique slices, subulati.
2. Corophiinae.—Antennae plus minusve pediformes. Styli caudales 1mii 2dique biramci.
3. Icillinae.—Antennae non pediformes nec subpediformes, flagellis sat longis basique sat brevi instructae. Styli caudales ac in Corophiina.

The family Orchestidae contains the genus _Orchestia_ with three subgenera, _Talitrus_, _Taloceras_, and _Orchestia_, and the genus _Allorchestes_, but no subfamilies.

The family Gammaridae contains the following subfamilies:—

5. Pontoporeinæ.—Pedes 3rdi 4thique plus minusve prehensiles; 6 postici non prehensiles.
6. Iseeinæ.—Pedes quattuor vel sex postici subprehensiles.

In the Hyperiæa, the family Hyperidea is subdivided into three subfamilies:—

The family Phronimidae contains three subfamilies:—

1. Phroniminae.—Abdomen versus basi sat gracile. Pedes 5thi magna mammjdactylæ vel monodactylæ confecti, 3rdi 4thi extremitate graciles, non prehensiles. [Antennæ breves.]
2. Phrosininae.—Abdomen versus basi sat crassum. Pedes 5thi prehensiles, monodactylæ; quoque 3rdi 4thique prehensiles. [Antennæ breves.]
3. Phorcinæ.—Pedes 5thi 6thique valde elongati et crassi, sed manu non confecti. [Antennæ breves.]

In regard to the genera into which the subfamilies are distributed many observations are called for. Among the Phronimina, genus 3, _Platophyium_, Dana, has been considered to be the same as genus 4, _Cyrtophyium_, Dana, but Haswell under another name revives the distinction. See Note on Haswell, 1885. Genus 7, _Cratophyium_, Dana, yields to genus 6, _Podocerus_, Leach. Genus 9, _Composita_, Edw., belongs to genus 8, _Ceraphe_, Say. _Pterygopera_,
Lateville, the second genus of the Isciinae, is the same as Lepidactylus, Say, which appears later on as genus 1, of the Poutoporeine.

The genus Orchestia and its three subgenera, Talitrus, Talorchestia, Orchestia, are defined for word as in the previous paper, the definition of Talorchestia, therefore, still being, "Pedes 1mi maenas ac in Talitro, feminae manu parvulæ instruérunt," but, to agree with Dana's other statements, and with the facts of the case, the definition of Talorchestia should evidently read:—"Pedes 1mi feminae ac in Talitro, maenas manu parvulæ instructi. It is probably owing to this misprint that the British Museum Catalogue speaks of the males of this subgenus as Talitri and the females as Orchestia. The three subgenera have since been generally accepted as genera. The whole subject is somewhat involved. The genus Talitrus, Lateville, at its first appearance in Desch. vol. 1, p. 78, is thus defined:—"Quatre antennes simples; les intermédiaires supérieures, et plus courtes que le pédoncule des latérales et inférieures ; dix à quatorze pattes."

"Exemple du genre. Gammastrus hirudina, Fab.—Oniscus gammarellus, Pallas."

In vol. ii. p. 148, a fuller definition is given:—"Quatre antennes simples; les intermédiaires, supérieures, plus courtes que le pédoncule des inférieures. Corps allongé, couvert de pièces crustacées, transverses, presque égaux, et appendiculées sur leur côté. Dix à quatorze pattes; les antérieures terminées par des mains. Des appendices bifides à l’extrémité du corps."

In 1813, Leach carved a new genus out of Talitrus, giving for Talitrus the character "Pedes quator anteci in utroque sexu subequales monodactylis;" for the new genus Orchestia, "Pedicum parum quattuor antica monodactyla, pari secundo manu compressa magna, femineo pari antico monodactylido secundo didactyla." Thus the original definition of Talitrus is set at naught, and those members of the group which have "the anterior feet terminated by hands" are assigned to Orchestia. Milne-Edwards distinguishes the two genera only by the second gnathopods, with a large subcheliform hand in Orchestia, non-prehensile in Talitrus. He takes no notice of the distinction of sex in Orchestia to which Leach refers.

In 1848 Friedrich Müller called attention to the fact that the females have sometimes the characters of one genus, while the males have those of another, the females in certain Orchestes being true Talitri. In Dana's words and according to Dana's definitions, "in one group, the individuals of both sexes are Orchestes; in another, the males are Orchestes and the females Talitri; in a third, both sexes are Talitri.

A further complication is introduced into the group by the genus Orthostoidae, Nicolet, or Talitronus, Dana. In this it appears that the females are Talitri, while the males are Talitri in the first gnathopod and Orchestia in the second. The genus comes therefore nearer to Talorchestia than to Orchestia. Dana's generic name was, according to Dana, published in the same year with Nicolet's, but may yield precedence, since Dana rejected his own genus, and, so far as I can make out, dates the publication from the time when his paper was read, rather than from the time when it was technically published. On p. 1505, among the addenda et corrigenda, he says:—"Orthostoides tuberculata of Nicolet, (loc. cit., Pl. II. f. 1.) is the author's Talitronus insculptus, and the genus Talitronus was instituted and published by the author on July 1, 1849. The name has been since rejected by him for Orchestia insculpta; and as Gay's specific name is the older, it will become Orchestia tuberculata. We suspect that his Talitrus Chilenis is what we have considered the female of the O. insculpta." Megorchestia, Brandt, 1851, is an additional synonym.

The second genus which Dana assigns to the Orchestide, is clearly distinguished from his first genus, Orchestia, in the following manner:—"Allorchestes;—Maxillipedes unguculati. Antennae 1mae minores, basi inferiorum sepiissime longiores. Epimerae 5ae 4tae saepius multo breviores."

Further on, p. 883, he adds to the generic description, "Feet of first and second pairs subchela.
Posterior stylets very short and quite simple, as in *Orchestia*.” He also observes that in some species the carpus of the second pair of legs in males is “produced downwards back of the hand, between the hand and the anterior extremity of the third joint (while in *Orchestia*, the third joint is never separated from the hand by a portion of the carpus, and the carpus is always short, transverse, and is situated wholly above the third joint).”

But while *Allorchestes* is with sufficient clearness distinguished from *Orchestia*, its own position is otherwise involved in some obscurity.

On page 1849, among the addenda et corrigenda, Dana remarks, “The genus *Nicea* of Nicolet (loc. cit.) may possibly be the same with *Allorchestes*; but the essential characteristics are not given, excepting the non-palpigerous character of the mandible. Even if identical, the genus does not antedate the author’s, as the description of *Allorchestes* was first published on July 1st of 1849. The maxillipeds are peculiar in having the surface tuberculate, and the inner lamella is dentate only at apex, and there sparingly.”

Neither Dana, in describing *Allorchestes*, nor Nicolet, in describing *Nicea*, mentions the form of the telson. Hence, in Mr. Faxon’s opinion, the names were synonyms, and he agrees with Spence Bate and Heller in allotting the name *Allorchestes* to the species which have the telson entire, and the name *Nicea* to those in which the telson is divided. As shown in the note on Rathke, 1837, I myself consider it right to assign the name *Hyale* to the latter, and *Hyalela* to the former.

In passing on to the Gammarideae, it should be noticed that, in defining the subfamily Stegogammarinae, Dana follows Krøyer in erroneously assigning a palp to the mandibles. The genus *Urastes* which he places among the Lysianassine is evidently based on misconception, as Spence Bate has neatly pointed out. The description in Dana evidently corresponds with the figure, and of this Spence Bate observes (B. M. Catalogue, p. 89, note), “In the figure, Dana has drawn one of the first pair of periopepods instead of the second pair of gnathopods. The meros always overrides the carpus in the periopepod, and underrides it in the gnathopod.” Dana places *Allbrotes*, Milne-Edwards, among the Gammarineae, but it more probably belongs to the Lysianassine. He separates *Mera*, Leach, from *Melita*, Leach, on the ground that the former has the first antennae appendiculate and the latter not so, whereas in both genera the upper antennae have an accessory flagellum. His three species of *Mera* have been transferred by Spence Bate to *Melita*, and his *Melita tenacirostris* to *Mero*, though with the notice that if the original description of this species, assigning no secondary appendage to the upper antennæ, is to be relied on, a new genus must be formed for its reception, along with *Melita Frenseii*, Savigny-Audouin. Axel Boeck rests the discrimination of the two genera apparently only on these two points, that in *Melita* the third joint of the mandibular-palp is elongate, and the inner branch of the third uropods very small, while in *Mero* the third joint of the mandibular palp is not very long, and the inner branch of the third uropods is nearly as long as the outer.

The genus *Dorothéa*, Dana, and *Pygids*, Dana, are by S. I. Smith made synonyms of *Eri-thoeina*, Milne-Edwards. *Anisopus*, Templeton, which Dana places in his subfamily, Lysina, is doubtless identical with the later genus, *Synamylopous*, but the name *Anisopus* was preoccupied. In his notes Dana observes that *Glauconeuma* of Krøyer has the hands and antennae, and apparently the other characters of *Ureido*, Say; to that genus it has in fact since been united by S. I. Smith. He also remarks that *Bellia* of C. Spence Bate (afterwards named *Salvator*) falls to *Leiocolycatis*, Say.

Among the Hyperidea, the genus *Lestrigoniscus*, M.-Edw., is now generally considered to belong to *Hyperia*, Latr., though Streets keeps it distinct. Dana gives two genera, distinguished from one another and from *Hyperia* by differences in the gnathopods, viz., *Meroerus*, Krøyer, and *Tauria*, Dana. These two Boeck unites as completely synonymous under the name *Tauria*, *Meroerus*, though the older, being preoccupied; but Boralli, 1886, considers
**THE VOYAGE OF H.M.S. CHALLENGER.**

_Tauria,_ Dana, distinct alike from _Hyperia,_ with which Spence Bate united it, and from _Metacuc,_ with which Boeck made it synonymous. _Daira,_ Milne-Edwards, is altered by Dana, on page 1596, to _Dairilia,_ on the ground that _Daira_ was preoccupied. This new form of the name is incorrectly given as _Dairinae_ in the British Museum Catalogue, owing probably to the misprint in Dana's own work, on page 1442. It is given correctly on pages 1519, and 1545 and 1604; Bovallius, 1885, says, "I am quite sure that Dana was wrong in introducing the animals described by him into the genus _Daira_ of Milne-Edwards;" he is of opinion that _Paraphryminia,_ Claus, comes nearest to, if it be not identical with, the _Daira_ of Milne-Edwards. _Synopinae,_ Dana, the single genus of his subfamily Synopinae, must be transferred to the Gammaridea, as Claus has already pointed out. In some of the species of this genus, besides the compound principal eyes to which the generic name refers, there are two small subsidiary groups of ocelli; hence the expression "pigmentum ocellorum unicum" in the generic character is unsuitable.

For the readjustment of the other two families of the Hyperidea see Notes on Claus, 1879.

In treating of the Orchestidae, which he takes as the type of the Amphipoda (p. 849), Dana describes in detail the head and its (theoretical) segments. He considers that the sides and top of the head correspond to the first antennary and ophthalmic annuli, one or both; that the epistome and lateral plates adjoining it represent the sternal and episternal pieces of the second antennary annulus [against which view see Spence Bate, British Assoc. Report, 1885, p. 26]; that the labrum and a lateral piece above the mandible represent the sternal and episternal pieces of the mandibular annulus; that the back piece of the lower part of the head which supports the maxillipeds is the proper episternal of the maxilliped annulus, while the first and second maxillary annuli are represented, unless combined with the maxillipeds at the back of the head.

Pages 1395-1413 contain an interesting essay on the classification of Crustacea. "The fundamental idea," the author says, "which we shall find at the basis of the various distinctions of structure among the species is, the higher centralization of the superior grades, and the less concentrated central forces of the inferior." "This centralization is literally a cephalization of the forces. In the higher groups, the larger part of the whole structure is centred in the head, and contributes to head functions, that is, the functions of the senses and those of the mouth. As we descend, the head loses one part after another, and with every loss of this kind there is a step down in rank. This centralization may be looked for in the nervous cords; but the facts are less intelligibly studied there than in the members, the production and position of which measure the condition of the forces." At the close he criticizes the names Pedophilum and Eriophilum, on the ground that although many stalk-eyed Crustacea may belong to the Pedophilum, there are many sessile-eyed species which cannot be grouped with the Eriophilum. In the classification which follows, pages 1414-1415, he renames his Subclass II., Tetraedropoda, which he thus defines:—"Annuli cephalothoracis cephalici numero septem. Oculi sessiles. Appendices branchiales simplexissimae, sine thoraecis sine abdominales. Cephalothorax multi-annulatus, carapace carinatus, pedibus seriatis instructum. Abdomen appendicibus seriatis instructum, raro obsoletea." The epithet _simpleissima_ applied to the branchial appendages must be qualified in regard to some species of Amphipoda.

The work concludes with an essay on the Geographical Distribution of Crustacea, pages 1451-1592, in which many interesting conclusions are deduced from the facts at Dana's command. When he comes to speak (p. 1581) of the "origin of the geographical distribution of Crustacea," he says, for the origin of the existing distribution of species "two great causes are admitted by all, and the important question is, how far the influence of each extended. The first, is _original local creations_ the second, _migration_." The form of his answer to this question would probably have been different had his book been
written ten or twenty years later, but he fully admits that migration "is an actual fact in nature, interfering much with the simplicity which zoological life in its diffusion would otherwise present to us."

The new species, published either in this work or in the two preceding papers also dated 1852, are as follows,—in Subtribe I. Caprellidea. Fam. I. Caprellidae; Prodo elongatus, identified by Mayer with Prodo ventricosum, O. F. Müller; Procka gracilis, the only addition to the variously-worded definition of Protella being, "pedes utinam subequi"; Caprella robusa, according to Mayer the young of Caprella aetifrons, Latr.; Caprella cornuta, with a variety named obtusirostris; Caprella antennata, which Mayer thinks may be the same as Caprella sena, Templeton; of this a variety is named subdennis; Caprella globiceps, which he thinks may be a variety of Caprella dilatata, Kröyer; the last-named species, which Dana figures and describes, is held by Mayer to be synonymous with Caprella aetifrons, Latr.; Caprella javanica, Kröyer, which Dana figures and describes, is referred by Mayer to Caprella sayilibra, Say; Dana himself suggests that the animal which he figures as the female may be a distinct species, for which in that case he proposes the name Caprella hanaulis; after Caprella globiceps he describes Ægina tenella and Ægina acutula, suggesting that the latter may be the female of the former.

Subtribe II. Gammaridea. Fam. III. Corophiidae. Subfam. I. Clyloninina. Clydonia gracilis; Clydonia longipes, which with the preceding species should, according to Bovallius, be transferred to the genus Typh, M.-Edw., among the Hyperidea; Subfam. 2. Corophiine. Corophius quadriceps, a species, as Dana himself intimates, of doubtful position, and probably immature, since the length is given as "nearly one line;" Platophium brasilianum; Cyrtophium orientale; Cratoophium validum, named by Sp. Bate, in the Brit. Mus. Catal., Pachyurus validus; his Gammarias orientalis he here calls Cratoophium orientale, and Sp. Bate, in the B. M. C. renames it Pachyurus orientalis. Subfam. 3. Icelinina. Icelius ellipticus, which had been originally named Icelius oralis.

Fam. IV. Orchesitidae. Orchestia (Talitrus) novi-xealamis, with the suggestion, since proved correct, by G. M. Thomson, that it may be the female of Talorhodina quoyana, M.-Edw.; Talitrus brevicornis, M. Edw., which he next describes, is, he says, "near the novi-xealamis;" according to the B. M. C. "Dana likewise considers it a true Talitrus, unless it should be the female of Talorhodina Quoyana;" but I do not find this alternative in Dana's own work; his next species Orchestia (Talitrus) insula is has been originally published as Talitrus insula for the male and Talitrus ornatus for the female; in the addenda he calls it Orchestia tuberculata, Nicolet, for which the Brit. Mus. Catal. restores Nicolet's name Orchestioida tuberculata; Orchestia (Talitrus) brasiliensis is named Orchestioida brasiliensis in the B. M. C.; Orchestia (Talitrus) pygellensis is named Orchestioida pygellensis in the B. M. C., but as only the female of this species is described, and the Catalogue states that in Orchestioida "the female is a true Talitrus," it is difficult to see how the determination is arrived at; Orchestia (Talitrus?) scabripes is transferred to Orchestioida in the B. M. C.; Orchestia (Talitrus) gracilis, of which the female had been already published by Dana as Talitrus gracilis, is now Talorhodina gracilis, having in the male "feet of first pair with a small, narrow hand," p. 862; Orchestia (Talitrus?) quoyana, Milne-Edwards, is now accepted without doubt a Talorhodina; in the subgenus Orchestia he places Orchestia scutigera, comparing it with Orchestia chilenis, M.-Edw.; Orchestia capensis; Orchestia chilenis?, Milne-Edwards, the female only, which is accepted in the B. M. C. without a ?; Orchestia nitida; Orchestia serrulata; Orchestia tenus; Orchestia syrticola, a species which G. M. Thomson, 1880, unites with Orchestia novi-xealamis, Sp. Bate, and Orchestia tenus, Dana, describing it as "a strictly terrestrial form, always occurring among dank vegetation, bush soil, etc., and drowning very rapidly in water; extremely common;" Mr. Thomson says, "it is singular that Prof. Dana should have..."
described the male only of O. syphica, for it has been frequently noticed, both by Professor Hutton and myself, that males are extremely rare," but in fact, though the B. M. C. only describes the male, Dana's description is of the female, and the male form of uncertain habitat, of which he appends a description, is left doubtful between Orchestra syphica and Orchestra lenticulus: Orchestra spinipalma: Orchestra tahitensis, taken "at fifteen hundred feet elevation, on the Island of Tahiti, several miles from the sea," must be transferred back to the name Orchestra recticornis under which it was originally published; Orchestra dispar: Orchestra quadrirama: Orchestra laevigatus: Orchestra pikeingii. To the genus Allochoisteria thirteen species are assigned, of which (with one exception) the true generic position remains uncertain, as no information is given as to the telson; the specific names are "I. Caimanovi (Edw.), D."

In place of compresa, Dana, the doubtful correction being accepted as certain in the B. M. C.; Dana says, "the description by Edwards agrees with our specimen in most points, though differing in making the posterior stylets end in two rudimentary branches, instead of one," a critical point on which the B. M. C. gives no information: 2. verticornis, to which Allochoisteria recticornis, Dana, is referred as "female of A. verticornis?" the suggestion being here made that Krøyer's Orchestra graminensis from Valparaiso is an Allochoisteria near to recticornis; 3. kirkbyana: 4. graminis: 5. bunalis, "female?"; 6. australis; 7. boreocornis: 8. novi-zelandiae, the male of which had been originally described as a separate species under the name intertiosa; 9. orientalis: 10. Allochoisteria (B) graminis, called Allochoisteria graminis in the B. M. C., which omits the important observation made by Dana, "the reinforce eye of this species leads me to doubt the correctness of arranging it with the Allochoisteria, and as I made no dissection, I am not sure that its mandible has no palpus, or that its posterior stylets are simple;" 11. medius, changed into medius in the B. M. C.; 12. "Hawaiienisks: 13. "Pugettensis." Since Mr. Faxon has ascertained that in Allochoisteria medius the telson is cleft, this species should, according to Mr. Faxon's view, be called Nicea medius, but, according to my view, Hyale media.

In Fam. V. Gammaride, Subfam. 2. Lysianassine, begins with the species "Lysianassa? Brasiliensis," which from the character of the lower antennæ is no doubt described from a male specimen, but of what genus there is no decisive evidence; the next species Lysianassa nasuta is likewise of doubtful genus; Urostes gigas, as Spence Bate has pointed out, is founded on a confusion, the first periscope having been described as the second gnathopod; the species has not yet been assigned to any definite position, which the description of the mandibles "with a pointed dentate apex," the abdomen ending "in an oblong seventh joint," and "the antepenult segment of abdomen acute behind" ought to find for it; "Amphithoe Fugitiva," having been originally called Stenio magnellanica, must receive the name Amphi- thermus magnellanica; Urothoe rostratus is changed by Boeck into Phoxus rostratus, leaving the next species Urothoe irostratus, as the type of the genus. Subfam. 3. Leucothoeine, contains Stenothoe calclus. In subfam. 4. Gammaride, Dana places Iphilimelia simplex, in the B. M. C. renamed Atlyus simplex: Iphilimelia nolosa, which according to Dana "is allied to the Acanthaster hypervis of Owen;" Iphilimelia fiscicula, which he had previously called Amphithoe fiscicula, and which the B. M. C. renames Atlyus fiscicula: Iphilimelia capensis, of which he says, "this species is very near the Genus Anomias, Edwards, but there is no appendage to the superior antennæ," and which in the B. M. C. is called Atlyus capensis: Iphilimelia pygnettensis, which the B. M. C. sets in a new genus Graatæ, with only one other species, called Graatæ iabericæ, this latter being probably the young of Amalthaea homari, Fabr.; Dana's Iphilimelia pygnettensis should in my opinion be called Pleodes pygnettensis: Edricus novi-zelandiae, in the B. M. C. called Edricus novi-zelandiae, with the appended remark that, "Graatæ Pygnettensis may belong to this genus (certainly not to Iphilimelia)?"; the name is again altered by Thomson and Chilton into Edricus novi-zelandiae; to Amphithoe Dana assigns seven species, rubella, orientalis,
REPORT ON THE AMPHIPODA.

267

Moira described the "Gammarus the named" as Gammarus that M. Meera Miera Miera. The Epimenx furcicornis is resembles Spenoe Gammarus are genus "be antennae it and between new because originally the subeonico, Fuller B. the and and unisocliir; from fuller B. the and Megamiera Gamarella. D"a"a"a. D. Dana's figures, following species which says, "asjKva as". and the mandibular palp has the second joint much shorter than the first, it probably belongs to a distinct genus, perhaps including Gammarus asper, since Dana says of these two, "they are alike in the very slender mandibular palp without a ciliated arrangement of hairs on the apical joint"; Gammarus albicus in the B. M. C. becomes Megamora albida; Gammarus tenax is called Microstomopus tenax in the B. M. C., with the remark appended that "this species closely resembles M. anomalous of the British coast." Gammarus furcicornis, in the B. M. C. Mora furcicornis; Gammarus tenax in the B. M. C. Mora tenax; Gammarus furcicornis, of which Dana makes, and, as it were, in the same breath retracts, the suggestion that it may "be the female of the G. tenax" is called in the B. M. C. "Mora Fuegiensis"; Gammarus quadrimanus, in the B. M. C. Mora quadrimanus; Gammarus brasilianus called "Gammarus Brasilianus" in the B. M. C., although contrary to the definition of the genus Gammaridae, the upper antennae are twice as long as the lower, and the third uropods are evidently regarded as biramous; Gammarus pugilensis the B. M. C. leaves unaltered. Between the last and the following species Dana places a heading, "appendix to the genus Gammarus." This section begins with Gammarus? peruvianus, called in the B. M. C. "Megamora Peruvianus;" this species was originally called by Dana Amphithoe peruvianus, and is here said to be "near the G. brasiliensis in many characters;" Gammarus? pubescens, previously called Amphithoe pubescens, is named in the B. M. C. Gammaridae pubescens, but it is difficult to see on what grounds, since the upper antennae are "almost twice as long as the other pair," and the third uropods are not described; Gammarus? indicus in the B. M. C. is named "Megamora Indica." Melita tenax in the same, doubtfully including what was originally Amphithoe tenax in the male, and Amphithoe (Melita) inaequilabis, female, is in the B. M. C. as Mora tenax in the same, though with some doubt as to the genus, because the species is described as "having no appendage to the superior antenna;" Mora calidus in the B. M. C. is named Melita calidus; Mora setipes, in the B. M. C. Melita setipes, is distinguished by the most trivial characters in the description from the following species Mora antisclir, of which the synonyms given are Gammarus antisclir, Kroyer, and G. (Mora) pilum, Dana, this becoming in the B. M. C. Melita antisclir: Dana's figures, however, of the two species setipes and antisclir suggest the possibility of more considerable differences than those which he mentions in the text. A fuller definition than in the previous paper is then given of the new genus Decoloea.

"Epinoe marginatus, blue subqu? b?bata, 4?e?e b?revoes. Margo frontis lateralis juxta oraculums super c?le saliens. Styli caudales postici simplicissimi, ut longi, cono level. Subcosta, apice paulo recta et quod spicis duabus brevissimis esorit. Antennas superiorum seque longiores, appendiculatae." He adds, "the posterior styli are like those of Pyctius, and unlike those of any of the preceding genera. The cerasus in the legs of the first pair is often as long as the head, and sometimes longer. The two very short spines at the apex of the posterior styli are full half as broad as long."

The new genus Pyctillus is more fully defined as follows—

"Epinoe set breves. Pelta 1 obt 2 setae pedunculis, repleti non pedunculis, secundumum digito 2-articulato, manu 1-articulati. Antennae elongatae, sessilia subus primae aficer. Styli
THE VOYAGE OF H.M.S. CHALLENGER.

caudales postici ac in Dercothoe.” He adds, “the genus is near Erichthionius (Edwards), if not identical with it. The stress which is laid by Milne-Edwards on the rudimentary character of the epimerals of the anterior thoracic segments, and his reference of his species to the Corophiide or gressorial Amphipods, leads us to doubt the identity. The posterior styles have the same form as in Dercothoe, and the form of the head, the projecting eyes, and general habit, are nearly as in that genus. The approximation is so close, that the genera are evidently of one and the same group; we have no evidence in the antennæ, caudal styles, or legs, that the species in every case are gressorial. The antennæ are slender, with long flagella. The epimerals are broader than in some Gammaria. The caudal styles are rather long.” He also says that “a female Pyctilus, bearing eggs, has been observed by the author, which has the same form of hands as is characteristic of the group Erichthionius,” and that “in this genus as well as the preceding, the first joint of the legs of the fifth and sixth pairs is very broad, while that of the seventh is narrow.”

Spence Bate makes Erichthonius and Pyctilus, and inclines to make Dercothoe, synonymous with Cerapus, Say. Boeck puts them all three under that genus, which S. I. Smith has shown to be distinct from them all. S. I. Smith unites Dercothoe and Pyctilus as synonyms of Erichthonius, but still without noticing the breadth of the side-plates in (some at least of) Dana’s species, which, as Dana himself observes, makes the identification with Erichthonius doubtful. In the work of Bate and Westwood, vol. i. p. 453, Dana is supposed to have “founded his genus Pyctilus upon a misconception of the figure of Erichthonius difformis,” but Dana clearly alludes not to the mistake in the figure, but to the express words of the generic account, “l’état rudimentaire des pièces épimériennes des premiers anneaux du thorax,” in the Hist. des Crust., vol. iii. p. 59.

Dana’s species are named Dercothoe cuneiformis, previously Gammarus cuneiformis; Dercothoe speculans, previously “Amphithoe peculans (by mistake for speculans); Dercothoe hirsuticornis, previously Gammarus hirsuticornis; Pyctilus macrodactylus, previously Erichthonius macrodactylus; Pyctilus pugnax, previously Erichthonius pugnax; Pyctilus brasiliensis.

In Family 1. Hyperidea, Subfam. 2. Hyperine, contains Lestrigonius fuscus; Lestrigonius rubescens; Lestrigonius Fabreii? Edwards; all which may perhaps belong to the genus Hyperia; the genus Metacaus, Krüyer, ought, Dana thinks, to be merged in Hyperia, to which he assigns the species Hyperia agilis; Hyperia trigona. The genus Tauria is thus defined:—

“Antennae quatuor breves, basi approximatis. Tarsae nulli subcheliformes nec subprehensiles, nisi ete abbreviatis,” with the type-species, Tauria macrocephala.

The new genus Cylogopus is thus defined:—

“Tauria affinis. Pedes nulli subcheliformes nec subprehensiles, nisi ete abbreviati.” with the type-species Cylogopus naegellanius.

Daira? deltilia, Daira? depressa, Daira nullispina, are at page 1596 transferred to the generic name Dairia (not Dairia, as in the B. M. C. and elsewhere), Dana being preoccupied; but if Bovallius, 1885, is right in assigning Dana’s species, not to Daira, Milne-Edwards, but to Thamypis, Spence Bate, among the Lycelmus, the name Dairia, Dana, will displace Thamypis, by right of priority. The definition given by Dana is as follows:—

“Antennae unius nigra maxima, 2dix erecta. Pedes lati 2dique plus minuscule procarinates: tarsi pedum coliguum breves, Rami stylosum coliguum longi.” It is placed in the second division of the subfamily, which have “Antennae tota breves. Caput oculique procarinatum.”

Subfam. 3. Synopina, contains the single genus Synopis, with the further definition,

“From subalaris. Antennae 4 longae, operta, Linx appendiculata. Pedes 2 antici subcheliformes, procarinat duo verticiformes, quatuor exsertae subprehensiles, digito 2 articulato; reliquorum nigrescent, angustulati.” Claus observes that this genus belongs to the Gammarina,
and Dana himself notices the resemblances. The species assigned are *Synoplia ultramarina*, (with the suggestion that one of the forms figured may be a distinct species to be called *Synoplia gracilis*), and *Synoplia angustifrons*; in the former he speaks of the eye as single, occupying "the whole breadth of the triangular head," but in the latter species he speaks of "the eyes" in the plural. Boavallius, in 1886, makes the "Amphipoda Synopidea" a separate tribe, in which "the first family, Synopidae, is the most closely related to the Gammaridae."

In Family II. *Phronimidae*, Subfam. I. *Phronimius*, contains only *Phronimius atlanticus*, Guérin, not figured, the brief notes indicating that *Phronimia sedentarina*, Forskal, is in question.

Subfam. 2. *Phroniminae*, contains *Ancylyomena purpurea*; *Ancylyomena thyropyros*, "length, one line; specimen probably not mature"; *Themisto antarctica*.

Subfam. 3. *Phorcius*, contains only *Phorcas hyaloeplalus*, on which Dana remarks, "This species has most of the characters mentioned for M. Edwards' *Phorcas Raymovollii*; but, he observes, that the antennae are 'un peu renflées vers le milieu'; while, in this species, the basal portion is stout ellipsoidal. Moreover, he states, that the second thoracic ring is very much developed, and the fifth pair of legs is shorter than the sixth."

In Family III. *Typhidiae*, Subfam. 1. *Typhus*, begins with the genus *Dithyrus*, with the following addition to the definition:

*Ablumen ad ventrem optimo claudens. Caput transversum, pigmentis non grandibus. Antennae 2ae sub capite celebres, breves, non replicatae. Pedes 6 postici coxis latissime eleyeat, parte pedum reliqua obsolete. Pedes 4 antici subcheliformes. Ablumen 5 articulatum, segmento ultimo triangulato."* In the appended remarks Dana says, "the abdomen, unlike that of *Typhus*, is shorter than the thorax." This genus is identified by Claus with *Typhus*, Risso, and as *Typhus* is preoccupied, *Dithyrus* (not *Eutypus*, Claus), takes its place. The species for which Dana instituted the genus is called *Dithyrus fusa*.

The genus *Thyropus* receives the additional definition:

*Ablumen ad ventrem optimo claudens. Caput transversum. Pigmenta oculorum non grandia, quattuor. Antennae 2ae longae, sub thoracis latero celebres, 4-5 replicatae, articulo uno multo breviores quam 2bus. Pedes 6 postici coxis late eleyeat, articulis reliquis paulo abbreviatis."* Remarks are appended to distinguish the genus from *Typhus*, together with the statement that, "this genus includes the *Typhus ferox* of Edwards, Crust., iii. 96." For *ferox*, *ferus* should be read. The type-species is *Thyropus diaphanus*, Claus, Platyscelidea, 1879, considers that *Typhus ferox* probably belongs to his genus *Hemityphus*; on the other three genera he says there can be no doubt, "that Dithyrus and Typhus be Dana lediglich als weibliche Formen zu Thyropus als dem männlichen Typus zu beziehen sind," loc. cit., p. 7, and he gives the heading, "Eutypus=Typhus, Risso, (Thyropus, Dana, Sp. Bate = Dithyrus Dana ?; Platyscelus Sp. Bate ?)," but he further says, "Die Untersuchung einer grossen Anzahl kleinerer und grösserer Thyrididen aus sehr verschiedenen Meeren hat mich davon überzeugt, dass Charakterisierung derGattungen auch nach Bescichtigung der durch die sexualen Verschiedenheiten veranlassten Irrthümer viel specieller gehalten werden muss, und dass in der Edwards'schen Gattung *Typhus*, die Dana'schen *Thyropus*, eine Reihe von Gattungen enthalten sind." p. 9. At p. 17 he suggests that *Thyropus diaphanus*, Dana, may be the same as his own new species, *Tanychelus sphacrona*.

Subfam. 2. *Proneinae*, contains *Pronea brunnea*, which may, in Claus's opinion, be the same as his *Eurypronea armata*, and *Lycusa cruentacea*, as type-species of *Lycusa*, the following addition being made to the definition of that genus:

"Pigmenta oculorum granida. Antennae 2ae sub capite celebres et replicatae et flagello longissimo capite confertes. Pedes 4 antici subcheliformes, reliquis mediores; 2 ultimi breviores; osse posticae angustae. Ablumen in ventrum se non flectens."* Claus, 1879, agrees with Spence Bate that this definition scarcely suffices to distinguish *Lycusa* from *Pronea*, but for independent reasons he considers Dana's genus fully tenable.
In his notes Dana recognizes *Leptocerus*, Latr., as a synonym of *Proto*, Leach. He remarks, p. 839, "it is possible that the *Palacorus Leachii* (Kröyer), should form a distinct genus, as the animal lived in a tube like a Ceranus." At p. 832, he says, "*Glaconome* of Kröyer has the hands and antenna and apparently the other characters of Unciola. Say describes the hands of the second pair in Unciola as adactyle; but they still are probably like those of Glaconome." In a note to *Amonia*, Kröyer, he explains that he omits the genus *Epilippophora*, White, from his synopsis, on account of its insufficient description. As to *Leptochirus pilosus*, Zaddach, he asks, p. 910, "May the form be female only?" In a note on *Iphimedia*, Rathke, D., he says, "*Desmane* of Leach, may perhaps be included here," and "the genus *Hyale* of H. Rathke," he says, "contains no characters in its description by this author, which do not apply equally well to species of Iphimedia."

"*Amphithoe*, Leach, D.," he says, "includes *Pleurum* of Leach." In a note on "Gammamus, Fabr., D.," he mentions *Anatulius*, Rathke, and *Eusurus*, Kröyer, but does not give them a place in the synopsis. The note on *Lepadastylis*, Say, remarks, "here falls Bellia of C. Spencer Bate." In the addenda, p. 1995, he observes, "Page 908:—*Callicoma*, Costa (loc. cit.) appears to be identical with *Lysianassa*;" "Page 910.—*Niphargus* is the name of a new genus near Gammamus, proposed by Schödte;" "Page 913. The genus *Laloria* (L. longitarsis) of Nicolet (loc. cit., Pl. 2, f. 8), is between the Gammarius and Coryphideae, and appears to be identical with *Aor* of Kröyer, which was also from Valparaiso."

1852. Liljeborg, Wilhelm.

Among the Crustacea of this district already noticed by others, Liljeborg mentions "*Caprella linearis*, Latr., Órsted, De regionibus marinis, p. 73." He observes that in *Amphelisca macrocephala* as in "*Amphelisca Gaimardi* Kröyer (Voy. en Scandinavie etc. t. 23, f. 1, a, b)" there are four eyes instead of the two to which the Amphipoda had hitherto been limited. In these four he found no trace of facets, or cones, and concludes therefore that they are simple, as given in the original definition of the genus with a query. In the species which he describes as *Amphelisca Eschrichtii*? Kröy., he found only two eyes, but with creatures that burrow in the mud at considerable depths, he thought the eyes too unimportant to justify a generic distinction depending on their number. However, in 1855, as *Haploops tubicola*, this species became the type of his new genus *Haploops*. Göa's subsequently discovered that *Haploops* agreed with *Amphelisca* in having four eyes. In specimens preserved in spirits the lower pair have a tendency to disappear. Liljeborg was the less inclined to lay stress upon the eyes from noticing that in certain Amphipoda which live at great depths, they are entirely wanting, "as, e.g., in the genus *Stenosephalus*, Kröyer, and probably *Pardalina* and *Elilurus* Kr." As the last of these examples shows, it must not be too easily taken for granted that eyes are wanting, because they have not been detected, in species of Amphipoda, though Liljeborg's conclusion is justified that the possession of two eyes, given by Milne-Edwards as a general character for the order, cannot be attributed to it without reserve.

In the Latin description of "*Amphelisca Eschrichtii*? Kröy.," corresponding as above-mentioned to *Haploops tubicola*, is included a description of the male, which refers to a separate species, called in 1855 *Haploops carinata*. He here remarks that Órsted, "(Naturhist. Tidsskr.
2.A. 2 (ed. 1 band, p. 493,) includes among the Crustacea from Drobak, a species under the name of *Amphelica rotundata* Krøyer, a name which lapses for want of attendant description. *Amphelica macrocephala*, u. sp., is described, this being a species which in 1851 Liljeborg had supposed to be "*Amphelica Eschrichti* Krøyer." *Amphithoe pedunculata*, Rathke, he found much smaller here than on the coasts of Norway. *Amphithoe compressa*, n. s., here described, and thought to be very like *Amphithoe tessellaris*, Rathke, was called *Aligus compressus* by Spencer Bate, and later identified by Boeck with *Aligus serramundicus*, M.-Edw. *Amphithoe pugnax*, n. s., is identified by Boeck with *Photis reinhardti*, Krøyer, 1842. Liljeborg thought it something like *Iphimedia obesa*; Rathke, which, he remarks, had anticipated Krøyer's *Microceles armata*, 1846. In the list of *v. Dueben's Crustaceae*, 1851, he had given "44. *Iphimedia obesa*, H. Rathke. 45. *Microceles armata* Kr." He therefore here observes that the latter had proved to be a young specimen of *Eulicera saginatus*, Kr.

Under *Gammarus boruta* (Lin.), he gives "G. Duebeni Liljeb." as a synonym, and this description, "Oculi reniformes nigr, antennae superiores longiores, flagello appendiculari 5-7 articulato; rami pedum spuriorum ultimorum insignier incurvantes, interior exterior saltem tertia parte minor.—Vulgaris." He describes *Gammarus maculatus*, n. sp., the name being preoccupied by Johnston, and the species being, as Liljeborg afterwards recognised, Montagu's, now known as *Melita obtusata*. *Gammarus longipes*, n. s., which he thinks very like his own *Gammarus assimilis*, 1851, was called *Autonoe longipes* by Bredius.

In "*Hyperia Latreilli* M.-Edw.," he notes that the young differ from the adult in respect to the antennae. An account is appended by S. Lovén of the tubes constructed by *Amphelica eschrichtii*, Krøyer. Several specimens taken on one occasion in their tubes, proved to be all females. The close proximity of the tubes taken on another occasion suggested that the species might be gregarious.

1852. Sutherland, Peter C. White, Adam.

Journal of a voyage in Baffin's Bay and Barrow Straits in the years 1850-1851, performed by H.M. Ships "Lady Franklin" and "Sophia," under the command of Mr. William Penny, in search of the missing crews of H.M. Ships Erebus and Terror. London, 1852.

"In the neighbourhood of Berry Island dredging was frequently attended to," and "the display," he says, "of animal and vegetable life before us, when the dredge was emptied, was really wonderful. Whole heaps of Mollusca, Crustacea, Annelids, and Echinodermata could be seen tumbling out from among masses of sea-weed." Sutherland says that the sea-bottom there is "the habitat of myriads of creatures belonging to the genus *Caprella*, *Cylops*, *Gammarus*, etc." (p. 140). On p. 142 he gives a striking account of the voracity of the Gammarines, naming especially *Gammarus arcticus*. Whether it were a dead seal or a live sucking-fish (*Lepodogaster*), short work was made of their prey.

In the Appendix, vol. ii. pp. 161, 162, he describes, according to Boeck, "*Gammarus magney*, Sab., *Amphithoe pedunculata*, Kr.; *Amphithoe Edwardsii*, Sab., and *Stylocheilus inflatus*, Kr.; a species of *Anodyx*, and lastly *Caprella coccopodes*, n. s., which falls to *Caprella septentrionalis*, Kr." Mayer in 1882 thinks that, judging by the figure, Boeck's view of *Caprella coccopodes* is probably correct.
1853. Burgersdijk, L. A. J.

This work is included in Maitland’s list of authorities, 1875. He refers to it only for one of the localities of Cammarus pulex.

1853. Costa, Achille.

Fauna del Regno di Napoli.

The genus Guerinia, Hope, is described, with the type species Guerinia nicæensis, which is figured.

Phronima, Latreille, is described, and the type species Phir. sedentaria, Forskal, to which Pisitoe lecifrons, Rafinesque, is united as a synonym, while Phronima custos, Risso, though not included in the synonymy, is declared in the “observations” to be also identical with Forskal’s species. The genus Phrosine, Risso, is described, and of Risso’s two species, Phrosine semilunata is fully described and figured, while Phrosine macrophalma, which Costa had not himself seen, is briefly alluded to. Costa would have preferred to name the two respectively cornuta and inermis. He considers Pisitoe bipinnosa, Rafinesque, though inaccurately described, probably the same species as Phrosine semilunata.

1853. Costa, Achille.

This work is obviously due to the pen of Achille Costa, although the new genus, and two out of the three species, are attributed to Hope.

The new genus Guerinia is thus described:—“Genus characteres essentiales. Pedes primi paris validaissimi, prehensiles, manu magna valde uncinata; secundis graciles, band prehensiles, ungue destituti. Antenna superiores bisectae; seta primaria articulo primo maximo. Ocelli magni, reticulati, dorso fere contigui.

In the observations that follow, this Crustacean is regarded as a sort of link between the Amphipoda and the parasitic Isopods, such as Anilocra. By Spenke Rate, in the Brit. Mus. Catalogue, it is placed between Laffaytius and Leplolactys. The type species is named Guerinia nicæensis, and is beyond doubt generically, perhaps also specifically, identical with the later “Triuchizostoma Rouchii,” Emark and Bocck, 1860. Bocck, who had obviously not met with Costa’s paper, fully describes the mouth-organs, and points out that the relations of the genus are with the Hyperidae, Orchestidae and Lysianassae. He places it by itself
REPORT ON THE AMPHIPODA. 273

in the second tribe of the Amphipoda, which he calls Prostomata, subsequently classing them as the first family of his second division, Gammarina. He states that the large finger of the first gnathopod is hinged, not as usually to the anterior, but to the lower hinder, angle of the hand, and directed forwards. That this is not shown in Costa's figure may have arisen from an accidental twisting of the hand in the specimen figured, or perhaps the artist had the unwanted feature before him, but could not believe his own eyes, and took the liberty of correcting nature, or we may argue from the researches mentioned below that Costa's specimen had not reached the age at which the peculiarity is developed. Boeck further differs from Hope by describing and figuring the third joint on the second pereopod as greatly expanded, by representing the first joint of the fifth pereopod in the complete figure as drawn out on the lower hinder angle instead of rounded off, and by describing the telson as split at the point, while in Hope's figure it is rounded and entire. But the figure of the telson in Boeck shows no slit, and the downward produced angle of the first joint of the pereopod is in the text and in a separate figure attributed to the fifth pair of feet, that is, the third pereopod, so that I am inclined to unite the two species in spite of differences which seem to me more likely to be due to inadvertence in the observers than to diversity in nature. This conclusion, independently arrived at, is more or less confirmed by the recent investigations of Boavilius, who, in 1886, describes and figures with great clearness and detail "the adult female" and "the young male" of Boeck's species, placing it in his new tribe of Amphipoda Synquides. He is evidently, like Boeck, unaware of Costa's Guerini, but he throws light upon it by showing that the position of the finger of the first gnathopods is normal in young specimens, and that in these the third joint of the second pereopod is not greatly expanded. On the other hand, he represents the telson as deeply excavated in the young, but in the adult female as having a smoothly rounded termination. "The description of Boeck," he says, "is not quite accurate; it seems that he has taken some characteristics from the adult animal and others from very young ones."

The second species described and figured is "Callisoma Barthelesi, Hope." The differences mentioned, having to do, it seems, exclusively with comparative measurements, are probably not of specific value. The name is not included in the Brit. Mus. Catal., and the species is entered by J. V. C. R. 1886, as "non descripta." The description is as follows:—"C. antennis superioribus capit thoracisque articulo primo simul viis longioribus, seta primaria pedunculo parum breviori, inferioribus thoracios articulis septimi $\frac{1}{2}$, quinto $\frac{2}{3}$ margine ascenantis attingentibus; epimeris quarti pars postice tertia anticae marginis inferi sequentiun non ultra productis; pedibus spuriis abdominalibus fere ex quo terminalis. Long. lin. 3; lat. lin. 1. "Osservazioni. Molto affinità al Callisoma Hopei, A. Cost., dal quale nondimeno dimostre per la fusa unghietta de' piedi anteriori assai più lunga, per le antenne in ambedue i sessi rispettivamente più corte, per gli epimeri del quarto anello un poco men prolongati posteriormente."

The third Crustacean of this paper is "Jura Hopeana," Costa, an Isopod.

1853. COSTA, Achile.

The report on Costa's paper is dated Napoli, 17 Settembre 1853, and signed by Giovanni Gussone, Giovanni Guarini, Benedetto Valpes. The characters of the new genera and species are (Zool. Chall. exp.—Part LXVII.—1887.) xxx 35

1853. Gosse, Philip Henry, born 1780 (Hagen).

At page 367, after describing the chambers in the peduncle of Chrysaora cyclonota, Gosse says, "a little shrimp-like creature, about half an inch in length, with large lustrous green eyes (Hyperia medusas), makes these chambers his residence." "There were three or four specimens on this Chrysaora, and I have found it parasitic on other large Meduse. But there were also on the one I am describing a vast number of minute white specks, which on examination proved to be little Crustacea, and, as I suspect, the larvae of this species. They are not larger than a grain of sand, shaped somewhat like a toad, with the abdomen distinctly separated, narrow, and bent abruptly under, in the manner of the Brachyura. (See Plate xxii. fig. 15.)"

At page 370 (see also page 82), he discusses "The Mantis shrimp." He says "one can never take a living specimen of that beautiful zoophyte Plumularia cristata, without finding its numerous pinnate branches inhabited by curious Crustacea of the genus Caprella." He compares them with the Spider Monkeys of South America, with the tropical genus Mantis among insects, and for mode of progression, to the caterpillars of geometric moths. He has "seen the large red species swim, throwing its body into a double curve like the letter S, with the head bent down, and the hind limbs turned back, the body being in an upright position." He thinks that the capture of prey is helped by the sudden clutchings of the lower antennae. "They consist of four or five stout joints, each of which is armed on its inferior edge with two rows of long stiff curved spines, set as regularly as the teeth of a comb, the rows divergating at a rather wide angle." "The first and second pair of legs," he says, "(but especially the latter), have the last joint but one developed to a great size, while the terminal joint is so formed as to shut down upon it just as the blade of a clasp-knife does upon the handle. Then to add to the efficiency of this instrument of precision, the great joint which represents the haft is armed with a double row of spines set at an angle so as to make a groove, into which the blade falls, and this latter is cut along each side of its edge into fine teeth like those of a file." He finds "several species even on the same small fragment of weed, if it be tolerably well peopled with Plumularia or Peltiellina, some much larger than others, and beautifully mottled with transparent ruby colour on a clear horn, and distinguished by variations in the relative size, in the shape, and in the armature of these formidable weapons; and there is a species larger still, of a dull purplish-red hue. But all have pretty much the same manners, except that the smaller species are more agile." It is obvious that the differences mentioned may only refer to age and sex, instead of being specific, as Gosse supposed, but undoubtedly on the Devonshire coast, Caprella acanthifera, Caprella frentensis and Caprella acutifrons may all be found in very close proximity.
At page 382 he introduces "The Caddis Shrimp," which has its tubes on Chondms crisps, and which he proposes to name "Ceranus Whitle." Rate and Westwood with some hesitation call it Sepiomeetes whitei, Boeck doubtfully places it among the synonyms of Ceranus abditus, Templeton. At present the species remains indeterminate.

1853. Lucas, Hippolyte.

Of Amphipoda he enumerates, pp. 465–466, "Talytjus platycheloi" Guérin; Gammarus fluviatilis, Rosel, which he says, "Habite les sources d'eau douce de Stito, dans les environs de la Canée"; and Gammarus marinus, Leach, which "se plait dans les sources saumâtres de l'Arnegre de Retino."

1853. Quatrefages, A. de.

In a list, "cited almost entire from M. van Beneden, in which are enumerated the various species of invertebrate animals whose phosphorescence has been established," (p. 18), the only Amphipods mentioned are Erythroephalus macropitholimus [melanopitholimus] and Gammarus pulex. At page 183 the remark is made, that "the Talitri, so numerous on our sandy shores," "become luminous by contact with the phosphorescent water," not being phosphorescent in themselves.

1853. Westwood, J. O.

It is mentioned that in April 1853, Mr. Westwood communicated to the Linnean Society the discovery in a well near Maidenhead of Niphargus stygus, Schiödte, an animal hitherto only found in the caverns of Adelsberg. This has been since separated from Schiödte's species under the name Niphargus aquilex.

1854. Nicolet, H.

Atlas de la historia física y politica de Chile por Claudio Gay. Fauna. Paris, MDCCCLIV.

Plates of "Crustáceos," numbered 1, 2, 3, 4, have on 1, 2, and 4 the inscription "H. Nicolet ad nat. del," and on Number 3 "Nicolet del." The figures of Amphipods on Plate 2 are named at the foot of the plate as follows:—" 4 Orchestiidea tuberculata Nic. 5 Amphitoe chilenus
THE VOYAGE OF H.M.S. CHALLENGER.

Nic. 6 A—— Gayi, Nic. 7 Nica Lucasti Nic. 8 Lalaria longitarsus Nic.”
Similarly those on plate 4 are named “4 Caprella longicornis Nic. 5 C—— longicornis Nic. ” “7 Cyamus gracilis Anct.” Anct. is perhaps a misprint for auct., an abbreviation of auctorum, but in the text, vol. 3, p. 296, 1849, Cyamus gracilis is properly referred to Roussel de Vauzème.

1854. Schauroth, von.

At page 560, the 15th article of this paper is headed “Paleocrangon problematica Schloth. Taf. XXII. Fig. 2.” Schlotheim’s specimen of his Trilobites problematæ, Schlotheim says on the authority of Bronn’s Nomenclator, no more to be found. Schlotheim’s collection went into the Berlin Museum, but there Beyrich informed him the specimen no longer existed, and had been in vain searched for by Quenstedt. Schauroth considers that a little fossil from the Zechstein dolomite of Fösenneck is the same species as that which Schlotheim described and figured. It has the exterior “überall chagrinirt und überdiess mit verschiedenen Höckern geziert.” “Das Kopfschild ist von der Seite geschen fast dreieckig und zeigt an der vorderen Seite knoxtige Erhöhungen, welche als Insertionstellen der Fühler, Fresswerkzeuge und selbst der Augen gedeutet werden dürften.” “Das Brustschild ist das grösste von allen Segmenten.” The back is carinate, and the general appearance agrees very nearly with Kirkby’s Proserpentis problematica, but Schauroth seems to have regarded the pleon as the head. He thinks the nearest palæozoic forms are to be found in Gitocrangon and Adelothyxanthus. Identifying it, rashly as I think, with Schlotheim’s species, he says, “Ich schlage vor dieses Geschlecht Paleocrangon (aus παλαῖον und ἡ κραγγων, ähnlich dem Richter’schen Gitocrangon, gebildet) zu nennen, den Körper selbst also Paleocrangon problematica Schloth zu bezeichnen.”

1854. Stimpson, William.

Synopsis of the Marine Invertebrata of grand Manan; or the region about the mouth of the Bay of Fundy, New Brunswick. Smithsonian Contributions to knowledge. (Accepted for publication, January, 1853). Washington, 1854.

The Island of Grand Manan “is more properly an archipelago than an island.” “It is surrounded on all sides by deep-water (a hundred fathoms or more).” Stimpson adopts Dana’s division of the Tetradacapoda into Isopoda, Anisopoda and Amphipoda. In the second division he describes Tenais ilium, n. s. Among the Amphipoda he gives Caprella lobata, Krüyer, which is Caprella linearis, Linn.; Caprella sanguinea, Gould, and Caprella longimana, n. s., both of which in Mayer’s opinion are too briefly described for recognition, though the latter may be Caprella acantihera, Leach. Caprella robusta, n. s., which Spence Bate renamed Caprella stimpsoni, because the name Caprella robusta was preoccupied by Dana, is restored to its original name by Mayer, on the ground that Dana’s Caprella robusta falls to Caprella acanthifera, Latr. Caprella robusta, however, must be considered to have lapse as a synonym. Aegina spinosissima, n. s., is by A. Bocck with a ą, and by Mayer without one, made a synonym of Bocck’s later name Aegina echinata. This identification is disputed by G. O. Sars, 1885. “Caprella spinosissima, Norman,” from the
"Porcupine" Expedition, was given in Sir Wyville Thomson's Depths of the Sea, by mistake (according to Norman in Mayer, Caprelliden, p. 35, note 1) for Caprella spinosissima, Stimpson. Norman, however, in 1886, gives "Caprella spinosissima, Norman - C. horrida, Sars." A specimen supposed to be the female of the species in question was sent by Norman to Mayer, and proved to be in fact an Aegina, which in Mayer's opinion may represent a new species, to which he would in that case assign the name Aegina spinosissima Norman, but that is surely pre-occupied by Stimpson's species. That the specimen figured in the Depths of the Sea is a Caprella, I have satisfied myself by dissection of the mouth organs, and in fact it no doubt falls to the name Caprella horrida, Sars (see Note on G. O. Sars, 1885). Unciola irrorata, Say, is mentioned. Podocerus nitidus, n. s., is described. The new genus Leptothoe, which Spence Bate identifies with Mora of Leach, is thus defined:

"Body linear, segments well separated, epimera very small; superior antennae longest, with a long accessory flagellum; inferior ones subpediform; legs of the first two pairs with subechiniform hands, those of the second pair being largest, with unarticulate fingers. Caudal stylets of the last pair very long, with equal lancedolate rami on short peduncles. This genus differs from Podocerus, Leach, in possessing accessory flagella to the superior antennae; and from Cratophium, Dana, in its long nonarticulate terminal stylets, and in having the superior antennae longest." The type species is "Leptothoe Dana," now called Mora dana. Stimpson's Cerapus rubricornis which "inhabits flexible tubes, of sizes corresponding to that of the individuals, composed of fine mud and some animal cement by which it is agglutinated," is identified by S. I. Smith with Eriodontus dilleronis, Milne-Edwards. His Cerapus fuscicolus is identified by Sp. Bate with Podocerus cylindricus, Say, while Boone doubtfully places both these designations under Podocerus anguipes, Kroeyer. Podocerus cylindricus, however, being the eldest of the names. S. I. Smith gives Podocerus fuscicolus as an independent species, naming Podocerus cylindricus, Say, not Bate, Cerophyllum cylindricum. Stimpson's Cerapus fuscicolus is allowed by Sp. Bate to remain in that genus with a ? It cannot stay in that genus as defined by S. I. Smith, since the figure of the pleon shows that there are at any rate five rami on each side to the appendages, whereas in Cerapus there are only four. Stimpson doubtfully identifies Orchestia grallus, Gould, with Talitrus grallus, Bosc. His Allorchestes littoratis is recognized by S. I. Smith as Hyale littoratis. The tail is said to terminate in an arched lamella, which may be a way of expressing that it is cleft.

Lyniamaeus spiniferus, n. sp., according to Spence Bate, Brit. Mus. Catal., p. 120 (omitted from index), "seems to be closely related to" his genus Phaenal. It is thus described:—"Body smooth and shining, slightly compressed, but rounded above, broadest anteriorly, tumid at the head, and much compressed at the abdomen, which constitutes nearly one-half the length of the body. Epimera not very large. Head rounded, with a prominent down-curving rostrum, and rather large red eyes. Superior antennae two-thirds as long as the inferior ones, thick at their bases, but tapering suddenly after the juncture of the long accessory flagellum, which is nearly one-half the length of the principal one. Inferior antennae with very thick basal articles, and equaling in length two-thirds that of the body, their flagella constituting more than one-half their length. Legs hairy, all terminating in short hooked fingers; those of the first two pairs slender, longer than the rest, with the antepenultimate article in each a little expanded, but scarce sufficiently to form a band. Posterior legs much shorter than usual, and provided along their edges with short spine-like hairs. First three segments of the abdomen serrated above on their posterior edges; last three compressed above into sharp spine-like projections, of which the middle one is the longest. Caudal stylets of the first pair very long and slender, projecting beyond the sharp extremities of the second pair, which are short, while those of the third pair are
THE VOYAGE OF H.M.S. CHALLENGER.

long, with long lanceolate rami projecting beyond the others. The tail terminates in two long spines. Colour wine-yellow; inferior antennæ annulate with reddish. Length, 0.32 inch. Dredged in forty fathoms, on a soft muddy bottom off Long Island, G. M."

It is scarcely necessary to remark that the armature of this species must distinguish it in a striking manner from the Lysianassæ in general. Of his *Anonyx nobilis*, Stimpson says that it most resembles *Anonyx appendiculatus*, Krøyer, but the distinctions he mentions do not suffice to separate the two species, and *Anonyx appendiculatus* itself is not distinct from *Anonyx purpureus*, Pilipi. *Anonyx politus*, n. sp., according to Spence Bate, has nothing in the description to distinguish it from *Anonyx holbælli*. *Anonyx holbælli* of Bate, according to Boeck, = *Anonyx galbus*, Krøyer, from which it may be inferred that *Anonyx politus* is a synonym of *Anonyx galbus*, which is itself probably the same as "*Oniscus Ciceria*," Fabricius. The new species *Anonyx pallidus* and *Anonyx exiguus* are both endorsed by Spence Bate, as also *Stenothoe elypacta* and *Leucothoe grandimans*, although of the latter he observes, "this species closely resembles *Leucothoe articulosa*. The only differences seem to be the small coxae, the length of the dactyls of the first pair of gnathopoda, and the colour of the American species." It may be noted that the dactyls of the first pair of gnathopoda in Stimpson's drawing agrees with that of *Leucothoe* (articulosa) epimécarpa, so that the species must be considered doubtful.

*Oniscus serratus* of Ottho Fabricius is here named *Acanthonotus serratus*, a name which Boeck alters into *Acanthonotozona serratus*. *Amphithotonotus cataphractus*, n. sp., is regarded by Boeck as a type for the genus which he calls *Tritrops*, a preoccupied name, altered by S. I. Smith to *Rhachotrops*. *Amphithotonus*, Costa, had lapsed as a synonym of *Dacentine*.

*Amphithoton* variscus is identified by Spence Bate with *Amphithoton punctata*, Say. *Amphithoton maculata*, Stimpson says, "differs from the last species in being more robust and of a much harder structure; also totally in coloration." As the Amphipoda are sometimes extremely soft just after shedding the skin, one is inclined to believe that Stimpson may have laid too much weight on the texture of the integument, in separating this species from the preceding one. *Iphimedia vulgaris*, which is said to differ from *Amphithoton inermis*, Krøyer, by "its larger eyes and epimera, and much longer caudal styles," is renamed by Sp. Bate *Atylus vulgaris*. *Amphithoton inermis* is taken by Axel Boeck as type of his genus *Pontogeneia*.

The new genus *Monoculosus* is thus defined:—"Body tumid anteriorly; head rostrate, with the eyes so close together as to appear one. Superior antennæ without accessory flagellum; inferior ones subpediform. Legs of the first two pairs with large subcheliform hands, formed of the last two articles of each; the appendent joints having their inferior apices produced into slender thumbs. Legs of the posterior five pairs ungulate, those of the last pair being exceedingly long. Caudal styles all biramous; the rami being equal. Maxillipeds large, elongated, with unguliform terminal articles, and internal lamelle of about one-half their length. Mandibles palpgereous." Stimpson adds, "this genus resembles *Eusiris* in the structure of the hands, and *Eudiceras* in its long posterior feet."

The type species is *Monoculosus demissus*. The next two species mentioned are *Gammarus sabini*, Leach, and *Gammarus macrophthalmus*, n. sp., the latter of which is named by Spence Bate *Gammaroacanthus macrophthalmus*. *Gammarus pulex*, which Stimpson names as equivalent to *Cancer pulex*, Lin., *Oniscus pulex*, Mull., O. F. Fabr., and *Gammarus boreata* of Montagu, Krøyer and Gould, is referred by Spence Bate, who had received specimens from Stimpson, to *Gammarus ornatus*, Milne-Edwards, and later on by Stimpson himself to *Gammarus boreata*, J. C. Fabr. *Gammarus purnulatus*, identified both by Bate and Boeck with *Gammarus dentatus*, Krøyer, is placed by Bate in his genus *Megamere*, by Boeck in the genus *Melita*, Leach.
The new genus Pilbochirius is thus defined:—"Body broad, as in the Corophida; epimera large and strong; much higher than broad. Mandibles with greatly elongated palpi; maxillipeds with their internal lamellae of half their own length. Superior antennae appendiculate, inferior ones subpediform. Legs of the first pair subchelate, very thick and strong throughout their length, in the male; those of the second pair plumose, without hands, but minutely unguiculate; those of the third and fourth pairs small, slender, and tapering, with the last three articles forming a kind of hooked finger, but with no dilated hand; posterior three pairs strongly unguiculate; those of the last pair much the longest. Caudal stylets all biramous, those of the first two pairs with a strong spine projecting from the inferior apex of the peduncle, along with the rami."

"This genus resembles in most characters Leptochirius, Zaddach, and may perhaps prove the same; that name, however, is preoccupied in insects. It has relations with the Pontoperina in its plumose hairs, and somewhat in the structure of the legs of the third and fourth pairs; while it also approaches those genera of the Gammarinae which recall the Corophidae." Since, however, Zaddach's genus was not, as Stimpson spells it, Lepto-

chirius, but Leptocheirus, Böck seems to have done rightly in giving it precedence, so that Pilbochirius pinguis, which Spence Bate has named Pontomedita pinguis, will now stand as Leptocheirus pinguis.

The new genus Pseudophthalanus, or as Stimpson spells it, Pseudophothalus, is thus defined:—

"Body greatly compressed, with large epimera. Head with an irregular deposition of blackish or reddish pigment anteriorly, in which are one or two oval or circular clear spots on each side, without facets. Maxillipeds with five articles, of which the terminal one is oval; internal lamellae with combs of spines at their apices. Mandibles palpigerous. Antennae very slender, the superior ones with their basal articles much thickened, and without accessory flagellae; inferior ones arising much behind the bases of the superior ones. Legs of the first and second pairs sometimes with small subcheliform hands, shorter than the antepenult segment, but often simply unguiculate; those of the third and fourth pairs elongated, tapering, with their second joints very small, the third expanded into a hand; posterior pairs short; last pair with very broad basal joints. Caudal stylets all biramous. Tail terminating in a thin lamella. Epimera and third and fourth pairs of legs with plumose setae along their edges."

This genus had already been described by Kroyer under the name Ampelisca. The briefly described type species, Pseudophthalanus pelagicus, has become, therefore, Ampelisca pelagica. Pseudophthalanus antiqua, according to Böck, is obviously synonymous with Ampelisca tenaecornis, Lilljeborg. Spence Bate describes further from Grand Manan, "Pseudophthalanus ingens, Spence, MS.," which he had received from the author. Being an inch and a half in length, it is well named Ampelisca ingens. Phoxus fusiformis is identified by Spence Bate with Phoxus plumosus, Kroyer, which Böck places in his genus Harpidea. "Phoxus Kroyeri" of Stimpson Spence Bate accepts, renaming his own later "Phoxus Kroyeri," Phoxus simplex. Böck, on the other hand, gives up "Phoxus Kroyeri," Stimpson, as insufficiently described.

1854. WILLIAMS, THOMAS.

On page 294 he discusses Chitina. On page 295 he says, "Every Crustacean is a water-breathing, every Insect an air-breathing animal. To this rule there can be found no real, many
THE VOYAGE OF H.M.S. CHALLENGER.

apparent, exceptions." Of the heart, p. 296, he says, in the Pseudopoda, Isopoda, Amphipoda and Leptodipoda, it is tubular in form, and occupies the mid-region of the dorsum, sends off arteries before, behind, and laterally, and receives the venous blood through lateral venous orifices." "Caprella linearis," is figured, pl. xviii. fig. 6., and portions of Talitrus on pl. xviii., to illustrate the circulatory system and the anatomy of the branchial organs. He remarks, p. 302, of the Amphipodan family, "the thoracic limbs are commonly said to be transformed into branchiae at their bases. The depending edges of the dorsal plates (the epimeral of the tergal arc) are however much more suitably organized than the proximal articulations of the legs. They are penetrated by a very dense system of canals. The epidermis is reduced to an extremely thin and transparent lamina. The component hexagonal cells may be readily observed. The outer or epidermal lamina is united to the opposite parallel lamina by dots of parenchyma. The blood streams in the intermediate passages. These parts therefore correspond in ultimate structure in the most exact manner with leaves of the branchiose of the Crab."

1855. Bartels.

Troschel points out that there are possibilities of mistake in such accounts, the more especially as Bartels was not an eye-witness of what had occurred. The specimens sent belonged to Gammarus pulex, Gervais.

1855. Bate, C. Spence.

The subject of this paper, so far as it concerns the Amphipoda, is discussed at large in the British Association Report by Mr. Spence Bate, for 1855.

1855. Bell, Thomas, born 1792, died 1880 (W. P. Sladen), and Westwood, J. O.

The last of the Arctic Voyages; being a narrative of the expedition in H.M.S. Assistance, under the command of Captain Sir Edward Belcher, C.B., in search of Sir John Franklin, during the years 1852-53-54. With notes on the natural history, by Sir John Richardson, Professor Owen, Thomas Bell, J. W. Salter, and Lovell Reeve. Vol. II. London, 1855.

At page 404 the Amphipoda begin, and contain mention of "Gammarus Sabini, Leach;" "Gammarus borealis, Sabine;" "Gammarus boreus, Sabine;" "Gammarus Kroyeri (n. s.), Plate XXXIV. fig. 4. Antennae superioribus inferioribus diltilio longioribus, abdominis segmentis quatuor anterioribus in media, secundo et tertio ad angulum inferiorem posticum, in dense productis," the English description being followed by the remark that
"This species has a very close resemblance to Amphitoe bicuspis of Kroeyer. It is however a true Gammarus, as the accessory filament of the superior antennae does exist, although extremely small. \textit{Hab. Wellington Channel, in thirty-five fathoms.} The name was preoccupied by Rathke, in 1813, and the species is identified by Boeck with Melita dentata, Kroeyer, 1842. This is followed by \textit{Lycianassa lagena, Kroy.} and \textit{Amphitoe bicuspis, Kroy.}; \textit{Amphitoe Jurini} (Kroy.), a specimen in a broken state occurs, which may probably be of this species, given in the Brit. Mus. Catal. as a synonym of \textit{Phersona fuscicolor, Leach}; \textit{Acanthoassa hystrix, Owen;} \textit{Stegoecephalus} (Kroy.) \textit{Amphulla} (Phipps), Plate XXXV., fig. 1, which is re-figured by Westwood, \textit{the figures hitherto published} by Phipps and Herbst (copying from Phipps) being \textit{exceedingly imperfect and incorrect.} Those in Kroeyer’s great work had probably not come under the author’s notice.

At page 407 the Lemodiopoda contain \textit{Caprella spinifera (n. s.), Plate XXXV., fig. 2. Segmentis omnibus corporis spinis armatis.} Figure 2e shows the mandible with its long three-jointed palp, which transfers this species to the genus \textit{Ejima.} In the explanation of the plate it is thus given \textit{‘2e, ‘palpigerous mandibles?’} \textit{‘2h, terminal segments of the body seen from above,’} is followed by \textit{‘2i, the same seen sideways, showing a pair of short exarticulate filaments attached to the last leg-bearing segment, and a pair of similar appendages, accompanied by a pair of larger two-jointed ones, attached to the minute terminal representative of the abdomen.’} This species is identified by Spence Bate with \textit{Ejima spiniosissima}, Stimpson, 1854.

Mr. Bell concludes by saying, \textit{‘For the elaborate anatomical details of the plates, and for the greater part of the description of them which I have adopted, I have to acknowledge my obligation to Mr. Westwood.’}

1855. Dana, James Dwight.

Most of the drawings for this magnificent work were, the author states, made during the years 1838–1842, in the course of the cruise of the expedition. It is greatly to be regretted that the portions of the text and the sets of plates relating to the different groups of Crustacea cannot be separately procured. As it is, the work is rare, expensive, and unwieldy to handle, alike difficult for the carcinologist to get or to do without.

After the engraving, but before the colouring, of the plates, a large part of the original drawings were destroyed by fire in Philadelphia. The loss occasioned by this catastrophe is not likely to be soon repaired.

With the exception of \textit{Phronima atlantica}, Gnérin, Dana here figures all the species of Amphipoda which he describes as brought home by the expedition.

1855. Gosse, P. H.

At page 30, in the \textit{‘Order Eupipiophilma. Fam. Cyamiol. Genus Cyamus (Fabr.),’} Mr. Gosse introduces \textit{‘C. Thompsoni (niihi).} Plate III. fig. 11. Body about \textdegree\textperthousand of an (Zool. Chal. Exp.—Part LVII.—1887.) XXX.36
inch in length. Five pairs of feet equally developed; all five-jointed; all with the penultimate joint large and ovate. Third and fourth segments each furnished with a single small oval appendage.” “It was attached to one of two specimens of Hyperidea bidens, the capture of which in Portland Roads was recorded in the ‘Annals of Nat. Hist.’ for November 1854.” This species has since been made the type of a new genus, Platycyamus, Litke. See Note on Litke, 1873.

At page 307, in the “Fam. Copephidae,” Unciola irrorata, Say, is recorded from Weymouth.

1855. Gosse, P. H.

In “Subkingdom III. Annulosa,” Gosse places “Class IV. Crustacea.” These are divided into two sections:—

“Mouth prolonged into a sucker, . . . . . . . . Thelastia.
“Mouth armed with jaws, . . . . . . . . . . Dactiia.”

The first section includes the Pycnogonidae and other families. “Section II. Dactiia,” is divided into three orders, Ectonoostraca, Etrighiophtha, Podophthalma. The Etrighiophtha are distinguished from the other two by the following characters:—“The modified legs performing the office of gills; eyes sessile, immovable; thoracic feet for walking, usually seven pairs; no carapace.” It is thus subdivided:—

“Abdomen a rudimentary tubercle, without distinct members. Branchial vesicles suspended from the thorax, . . . . . . . . Lernedipoda.

“Abdomen well developed, and provided with five or six pairs of members.
“Branchial vesicles almost always absent from the thorax. First five pairs of abdominal members almost of the same form, unsuited to locomotion, and apparently serving as gills, . . . Isopoda.

“Branchial vesicles under thorax. First five pairs of abdominal members diversely formed, and serving for locomotion, . Amphipoda.”

To “Suborder I.—Lernedipoda,” he assigns “Caprella (Lamk.). Body lengthened, slender, cylindrical; both pairs of antennae well-developed; feet long, but wanting on the second and third segments of the thorax,” with the species linearis (fig. 223), tenuis, acuminifera, acutifrons, plana, tuberculata, lobata, acanthifera, longispina; “Leptomerea (Castrin). As Caprella, but all the segments of the thorax furnished with feet,” with the species pedata (fig. 224); and “Cymus (Lamk.),” with the species erraticus, ovalis, gracilis, Thompsoni (fig. 225). His “Li. pedata” can be recognised from the figure as Proto ventricosa, but the figure of C. linearis is useless. No authorities are mentioned for the species, nor are any descriptions given.

“Sub-order III. Amphipoda” is thus subdivided:—

“Fourth and fifth abdominal segments united; fourth and fifth abdominal appendages dissimilar, . . . . . . . . . . . . . Cheirurae.

“Abdominal segments distinct; abdominal appendages similar.
“Foot-jaws covering only the bases of the preceding appendages, and forming a lip with three plates, but deprived of palps, . Hyperiacea.

“Foot-jaws very large, covering the whole mouth, and forming a lip terminated by four great horny plates and two very long palps, . Gammuracea.”

In the first Tribe, the Cheirurae, stands, as might be expected, only Cheirura terebrans, Philippi (fig. 290). In “Tribe II. Hyperiacea,” he places “Hyperia (Lat.). Second pair of antennae style-shaped and unfolded; body inflated. H. Latreille. Fig. 251; n. s. [H.] galba,” and, “Typhis (Risso). Second antennae folding on themselves so as to form three
or four elbows; first joint of fifth and sixth feet forming great oval plates, concealing all
the others. T. monocolooides. Fig. 252; mag. ½. [T.] nobena." Figure 252 is not a
Typhus, but probably the Cancer Gammarus monocolooides of Montagu, now called Stenothoe
monocolooides. It should be noticed that the letters a. s. after Fig. 251, do not mean new
species, but natural size.

Tribe III. Gammarinae," are thus subdivided:—

Body depressed; epimera very small or obsolete; abdomen straight, normal;
three last pairs of false feet tipped with swimming-plates; antennae foot-
shaped,

"Body much compressed; epimera very large, scale-like, and encasing the
bases of the first four pairs of feet, posterior extremity formed for leaping.
" Superior antennae longer than the footstalk of the inferior, and
much longer than the head; mandibles carrying long palps;
antenna lash-like,

"Superior antennae much shorter than footstalk of inferior, and
scarcely longer than head; mandibles without palps.

" Family I. Corophiidae, contains 1. "Cerapus (Say). Second feet fanged; fang two-jointed;
all the antennae without many-jointed lashes at the tip. C. pelagicus. [C.] falcatus. C.
Whitei. Fig. 253; mag. ½; 2. "Podocerus (Leach). First and second feet fanged; fang
one-jointed; inferior antennae without lashes. P. variegatus. [P.] pulchellus. Fig. 254;
mag. ½; 3. "Corophium (Lutr.). Second feet not fanged; inferior antennae without
lashes. C. longicornis. Fig. 255; mag. ½; 4. "Uricola (Say). First and second feet
fanged; all the antennae tipped with many-jointed lashes; superior pair furnished with a
minute appendage at the base of the lash. U. irrorata. Fig. 256; mag. ½.

The small figure of Cerapus whitei seems to show a second gnathopod with a dilated wrist
and narrow hand quite unlike the small cup-shaped wrist and dilated oval hand depicted for
Cerapus whitei in "A Naturalist's Rambles on the Devonshire Coast," but the figure in
this work is too small to build any argument upon. The generic description, it should be
observed, says "fang two-jointed."

" Family II. Gammaridae," contains Gammarus (Fahr.), with the species locusta (Fig. 257),
marinus, camptotopes, pules, grossimanus, longimanus, Crenchii, punctatus, carinatus,
maculatus; Amphithoe (Leach), with the species punctatus, fuscus, obtusata, Moggridgei,
rubrincata (Fig. 258), dubia, spinosa (Fig. 256), carina-spinosa (this and spinosa being
bracketed as " = Decumine (Leach);" Leuothoe (Leach), with the species articulosa
(Fig. 259); Acanthothoe (Owen), with the species testudo; Anonyx (Kröyer), with the
species altius (Fig. 261) and elegans; Opis (Kröyer), with the species typica (Fig. 262).

" Family III. Orchestidae," contains Talitrus (Lutr.), with the species locusta (Fig. 263);
Subator (Bate), with the species arenarius (Fig. 264); and Orchestia (Leach), with the
species littorea (Fig. 265) and Deshayesii.

As "Genera apparently intermediate between the Edriothenia and Polophthalma," he places
the Family Cuma, containing the genera Cuma (M.-Edw.), Alatuna (Goodier); Bodotria
(Goodier).

1855. Leydig, Franz.

Zum feineren Bau der Arthropoden. Archiv für Anat. und Physiol. Jahrgang,

See Note on Leydig, 1878. Pages 444, 445, 452 of this work are mentioned in the references.
1855. LILJEBORG, W.

This is an appendix to the contribution of 1852. Attention is called to the neglect of the sexual characteristics in the Amphipoda, a better acquaintance with which would probably necessitate some changes in the established genera and species. As marks of the female, Liljeborg notes relatively larger epimera, more or less developed ovaerial appendages by the side of the branchiae, smaller antennæ and gnathopods, and often the presence of eggs in the pouch. Under the heading "Crustacea marina ad Kullaberg in Scania mense Julii 1852 collecta," he records, with full descriptions of the new species, *Amphidea beccigata*, n. s.; *Amphidea tenuicornis*, u. s.; "Gammarus Sabini," Leach; *Gammarus angulosus*, H. Rathke; *Gammarus pocellurus*, H. Rathke; *Gammarus erythrophthalmus*, n. s.; *Gammarus macrourus*, n. s.; *Leucodex hircus* (Montagu), with a long description, an account of its differences from *Leucodex furina* (Savigny), and a concluding observation that Kröyer's *Leucodex chryptostoma* and *glacialis* as well as *Leucodex norvegica* Liljeborg can scarcely be included in this genus; *Ichyrophorus minutus*, Liljeborg, with a description, and a discussion of its relationship to *Ichyrophorus anguis*, Kröyer, and *Ichyrophorus latipes*, Kröyer, which are both, he says, several times larger than *Ichyrophorus minutus*; *Erithonius difformis*, M. Edwards, with a long description, and a discussion of the relationship of *Erithonius to Pidocerus*, etc.; *Leuotechus sturionis*, Kröyer, with a description; *Caprella hibata* (O. F. Müller); *Leptomera pedata* (Abildgaard).

*Gammarus erythrophthalmus* has been confused by Boeck, as we learn from G. O. Sars, with a different species. Liljeborg's account of his species is as follows:—"Corpus forma sat robusta; epimera parva. Longit. circ. 7 millim. Oculi magni, reniformes, rubri. From inermis. Dorsum laxe. Annulli tres postici abdominis sine aculeis. Antennæ longitudine mediorum, hisutæ; superiores inferioribus parum longiores, pedunculi articulo primo ceteri cassisore, quam secundo vero breviore. Articulus secundus tertio non multo longior. Flagellum pedunculo paullo brevius, articulis circ. quindecim. Flagellum appendiculare longum, articulis sex. Antennæ inferiores pone superiores fixe. Pedunculus earum eodem avec nervarum superiorem circ. longitudine aequalis, articulo basali infra processus longo, articulo secundo non plano apicem articuli primi pedunculi antenna. Superiorem attingente, articulo tertio et quarto inter se circ. aequalibus. Flagellum articulis duodecim. Pedum thor. primi et secundi parvis manus valde inaequalibus, hæ illis multo majores. Illæ ferre ovate, carpo longitudine circ. aequalibus, praedita posticem setose. Marginis posticæ palmæ et carpi angulæ acutæ formantes; apud marem et feminam inter se similæ. Haæ apud marem valida, carpo multo majores, oblique triangulares, margine antico arcuato, postico infra oblique truncato, crenulato, setifero, processibusque tribus brevibus instructo. Apud feminam paullo minores sunt, ovate, et postico tantum processibus duobus praeditæ. Pedes tertii et quarti parvis sequentibus breviores, articulo tertio sat dilatato, ungue vero forma solita. Pedes sexti et septimi parvis ceteris longiores, inter se circiter aequalis, apicem pedum abdominalem ultimorum attingentes, articulo basali valde dilatato. Rami pedum abdominalem ultimorum cavi vel silliformes, supra et ad apicem acutæ, inter se et truncio longitudine circ. aequalis, antecedentes paulum superantes. Appendix caudalis brevis et crassa, postice truncata, supra postice eminentissi duabus parvis lateralis acutatis.—Color flavo-antiliadus fascis dorsoaliis lutescentibus. Rarus; in relictus piscatorum e 14-16 orygarum profundo acceptus." From all known species within the genus (*Gammarus*) it differs, he says, by its red eyes. It is not an uncommon species, I may remark, on the south coast of Devonshire.

"*Haploops tubicola, mihi,*" is described as the type species, with the same name as that for the genus. This is followed by the description of "*Haploops carinata, mihi,*" with a reference to "*Ampelisca Eschrichti?* nus, Liljeborg; l. c."

Additional characters are given for the genus *Ampelisca*, Kröyer. *Ampelisca macerophala*, Liljeborg, is redescribed, with a note that it stands very close to "*Ampelisca Eschrichti?*" Kröyer. *Gammarus maculatus*, Liljeborg, is recognised as a synonym of *Cancer Gammarus obtusatus*, Montagu, and *Gammarus longipes*, Liljeborg, is redescribed. The latter has been referred by Bruzelius to his genus *Antonius*, of which Boeck retains it as the type.

1855. Liljeborg, V.

Accepting the genus *Gammarus* as defined by Milne-Edwards, Liljeborg here refers to a subdivision of it or a subgenus, for which he proposes the name *Gammaropsis*, those species which have the third uropods not laminar but stiliiform, conical, and the telson single, tuberculiform. He notes that *Gammarus zebras*, Rathke, is a *Podocerus*; he describes his own species *Gammarus mutatus*, which Boeck identifies with *Gammarus locusta*; he
unites *Gammarus kröyeri*, Rathke, to *Gammarus pocillurus* of the same author, both of which are synonyms of *Gammarus marinus*, in Boeck's view. Under the *Gammaropsis* division he describes *Gammarus erythrophthalma*, n. s., which Boeck accepts as type of the genus *Gammaropsis*. Spence Bate and Bruzelius did not take account of the name *Gammaropsis*, as in Liljeborg it was only provisional, but to *Eurythoeus erythrophthalma*, Spence Bate, Boeck gives the name *Gammaropsis erythrophthalma*. G. O. Sars, however, maintains that the species which Boeck describes under this name is not Liljeborg's species, "which, among other things, has the secondary flagellum on the upper antenna considerably longer and consisting of numerous articulations, the lateral angles of the head rounded off, and the third pleon-segment's lower hinder angles not acute. Lastly, in Boeck's species, the pigment of the eyes is not red as in the typical form but black." A point which Sars does not mention is that in Boeck's species the fourth pleon-segment has, on the middle of the hinder rim, two small teeth, whereas Liljeborg expressly says "annuli abdominis supra sine aeculis." On the other hand, Boeck says nothing of the colour of the eyes, and Liljeborg says nothing as to the other points mentioned by Sars, except that the accessory flagellum is long, six-jointed. As Boeck does not appear to have himself taken the species which he describes, he probably had no means of ascertaining the colour of the eyes, but it still remains rather remarkable that both in his species and in Liljeborg's, the hands of the second gnathopods should be tridentate in the male and bidentate in the female. To Boeck's species Sars gives the name *Gammaropsis melamps*. For the opinion that *Gammarus* (*Gammaropsis*) *erythrophthalma*, Liljeborg, had been earlier described as *Gammarus maculatus*, see Note on Johnston, 1827–1828. The other species here described as new, *Gammarus* (*Gammaropsis*) *macronyx*, is assigned by Boeck to *Protomedeia fasciata*, Kroyer.

The subdivision or subgenus *Gammaropsis* is thus defined:—

"† Rami pedum spuriorum ultimorum depressi, lamelloso. *Gammarus*.”

1855. **Lindström, G., born 1829 (G. O. Sars).**

sexti paris forma singulari: pars basalis duplo longior quam later; ramus finalis interior rudimentarius et forma foli acuminati; ramus exterior magus, biarticulatus; articulo primo lamellosa, parte basali parvo, acuminato, setis instructo."

The type species is described under the name Bathyporeia pilosa, and figured Tab. ii. figs. 1-11. *Pontoporeia affinis*, n. sp., is thus described:—"Ocelli nigri, elongati. Antennae inferiores superiores longiores; antenna superiores flagello appendiculari triarticulato. Annulus abdominalis quintus setis illis, quas habet P. femorata, carens. Partes femorales pedum, ut etiam epimen, ornata textura singulari cellulosa, quae globulis adiposis formata est." It is figured Tab. ii. figs. 1-4. Lindström comments on the relationship of his species to the Arctic *Pontoporeia femorata*, to which, in the fuller description, he recognizes it as coming very close. It was the only Amphipod he found at 40 fathoms, the greatest depth his dredging reached. Subsequently, he seems to have given up its specific distinctness. See Note on Mibius, 1873. *Gammarus longicornis*, he says, may be found wherever sea-weed grows. He notes too, that there are certain forms of Crustacea which can stand great variations in the saltness of the water they inhabit. He mentions also *Amphitoë rathkii*, Zaddach, and *Corophium longicornis*, Latr.

1855. **Meissner, Georg.**

*Beobachtungen über das Eindringen der Samelemente in den Dotter (Gammarus pulce).* Zeitschrift für wissenschaftliche Zoologie. VI. pp. 272-294.
Taf. IX. 1855.

1855. **Schiodte, J. C.**

This paper is intended to show that the English well-shrimp, which Schiodte named *Niphargus aquilae*, is distinct from his *Niphargus stygicus*, out of the caverns of Adelsberg and Lueg in Carniola. Bate and Westwood, i. 317, say that Schiodte has been misled in describing *Niphargus aquilae* with "dorso carinato," by examining dried specimens, but on other grounds they incline to agree with his discrimination of the two species in question.

1855. **Stimpson, William.**

or 1856?

*Descriptions of some of the new Marine Invertebrata from the Chinese and Japanese Seas.* By Wm. Stimpson, Zoologist to the U.S. Surveying Expedition to North Pacific, Japan Seas, etc. Lt. John Rodgers, Commander. [From the Proceedings of the Academy of Natural Sciences, May and June, 1855.] Vol. VII. 1854, 1855. Philadelphia. 1856.

The Amphipoda of this paper include *Phoxus geniculatus* and *Phoxus obtusus*, both, in Bock's opinion, insufficiently described for identification. The three-jointed outer ramus of the last uropod in *Phoxus geniculatus* probably only indicates a two-jointed ramus with a terminal spine. *Dorothoe? productus* is another among the many riddles presented by
these numerous species briefly described and unfigured. The expression, "posterior caudal stylets with short rami, the outer ones uniform, the inner minute, spine-like," though not very intelligible, does not seem to suit either the genus *Ceratops* or the genus *Nereia* which are suggested by Spence Bate as alternatives for the reception of the species. *Amphipholis filifera, Gammarus flabelifer, Gammarus teniicornis, Leucothoe stylifera* have not so far as I know been subjected to criticism or re-examination. *Allochactes rubriornis, Allochactes penicillata,* and *Allochactes japonica,* in none of which is the telson described, will, I suppose, until further knowledge stand in the genus *Hyale.* *Orchestia pollicifera* is transferred by Spence Bate to *Talorchestia,* as the description shows that in this species the male is of the *Orchestia,* the female of the *Talithrus,* form. The next species described is *Corophium contractum,* and the two last are *Caprella hector* and *Caprella gracilis,* which from the brief descriptions Mayer finds absolutely impossible to determine. Future investigation in the same locality may perhaps settle what species Stimpson meant by *Caprella hector* with its second gnathopods "large, tridentate below, teeth unequal," and by *Caprella gracilis* "with a slender curved rostrum."

1855. **Stimpson, William.**

Under the heading *Choristognatha* are given four new species of *Anthura.* After these comes *Caprella solitaria,* which Mayer pronounces absolutely unrecognisable; *Iphimedia osea,* named apparently in ignorance of Rathke's species, and renamed "*Iphimedia Stimpson*" in the British Museum Catalogue, p. 374. Mr. Haswell in his Australian Catalogue gives *Iphimedia l ambigua,* but does not mention Stimpson's species, which was taken also at Port Jackson. Mr. Haswell does not specify reasons for doubting the genus of his species. There is more obvious reason for hesitating to keep Stimpson's species in Rathke's genus as he speaks of the gnathopods having "equal subcheliform hands of moderate size," whereas in species of *Iphimedia* (Rathke, not Dana) they are generally very small.

*Ealicerus flossus* is described at some length. It was taken at Botany Bay. Mr. Haswell considers that his own species *Ealicerus arenicola* from Shark Island, Port Jackson, may be identical with it. *Gammarus rubro-maculatus* from Port Jackson, referred to the genus *Mera* by Mr. Haswell, is now considered by that author to cover his own species *Mera spinosa* and *Mera ramsayi,* and Mr. Chilton's *Mera fowicka.* Differences in the form of the second gnathopods had been the chief ground of distinction, but he finds "on examining a series of specimens, a perfect series of gradations in this respect from the form figured by Stimpson to typical forms of *M. spinosa* and *M. ramsayi." There are no references to any figure of Stimpson's species either in Mr. Haswell's own works or in the British Museum Catalogue or in the copy of Mr. Stimpson's work kindly lent me by Mr. Spence Bate.

*Leucothoe affinis,* from False Bay, Cape of Good Hope, will be difficult to distinguish from its immediate relations. *Anonyx caricatus* from Simon's Bay, Cape of Good Hope, has been taken again in the same locality by the Challenger Expedition. It is re-described as *Lysianassa caricata* in the Brit. Mus. Catalogue.
1856. Bate, C. Spence.

This Report considers the second division of Crustacea as Edriophthalmæ, using Leach's term as synonymous with Tetracopoda of Grayville, and Chlorotetrapoda of Dana, though recognising that not all sessile-eyed Crustacea belong to this division, and that not all members of it have fourteen legs. Dana's view is accepted that the Isomöliopoda of Latreille cannot rank as an order parallel to the Amphipoda, but his order of Anisopoda is not approved, the true view being supposed to be that Isomöliopoda and Anisopoda should be separated from Amphipoda and Isopoda proper as subordinate groups.

In a discussion headed "The Homologies," the following opinion is advanced:—"The epistome appears with little doubt to be the inferior aspect of the mandibular ring, which is seen on the external lateral surface of the head, and which can be identified from the fact of its carrying the mandibles. This relation of the epistome to the mandibular segment is not admitted by Mr. Dana, who rather, from analogy with the higher types, than by direct evidence of the subject before him, identifies the epistome as belonging to the inferior (or external) antennal segments." Two modes of expression are applied to the Amphipod extremity or telson. In one it is spoken of as the twenty-first ring, only "to be contemplated in the character of an obsolete segment with its rudimentary appendages;" in the other, "it is a rudimentary appendage, modified upon the type of the preceding three" (pairs of appendages). I may here remark that Milne-Edwards, Hist. Nat. des Crust., pl. i. p. 23, regards the telson definitely as the twenty-first ring or segment. He considers that the cleft telson in certain species of Amphipods offers a striking example of the division of a ring into two symmetrical and lateral halves. He adds in a note that this is seen in Gammarus ohiensis, Gammarus locusta, &c.; but that in most Amphipods these rudiments of the seventh abdominal segment are completely wanting. This is a very strange observation for him to make, and quite the reverse of the fact. Huxley, The Crayfish, p. 161, regards the telson as a median outgrowth of the sixth abdominal segment, which has become moveably articulated therewith.

After a detailed account of the mouth-organs, gnathopods and peraeopods, Mr. Spence Bate produces many arguments to show that the epimeron or side-plate in the Amphipoda "belongs to the leg and homologically is the first joint (or coxa), and that it is not a lateral or separate portion of the annular segments of the body of the animal, and in fact that no side pieces or epimerals exist." He maintains the following propositions:—

1st. That seven joints are the normal number in the legs of all the Malacostracous Crustacea.
2nd. That the brachia is normally an appendage of the leg and attached to the coxa.
3d. That the moveable power of the leg is always between the coxa and the leg, and never between the coxa and the body.
4th. That the coxa (the so called epimeral) in Amphipoda overlaps the segment to which it is attached, and except by a small portion only, is not united by the whole of the margin in juxtaposition with the segment.
5th. That there are no epimerals where there are no legs.
6th. That epimerals are found in no other type, except the Edriophthalmæ among Crustacea."

It does not seem inconsistent with these arguments to suppose that the first joint of the leg is in fact coalescent with the side plate, and that the side plate is a protective outgrowth from the segment.

(Zool. Chll. Exp.—Part LXVII.—1887.)
THE VOYAGE OF H.M.S. CHALLENGER.

The microscopic structure of the Integumentary Skeleton is discussed; the process of moulting described; the fact noticed that the Amphipoda do not appear to be capable of throwing off a wounded limb; the "auditory cilia" of the upper antennæ are considered; the denticles at the base of the lower antennæ is regarded as an olfactory organ; this is now generally recognized as a duct for the excretion from the antennary gland. The internal structure of the Amphipod is very fully described. Some remarks are made upon the development of the young. The paper concludes with a list of all the then known British species, including many new ones in various genera to be subsequently described. The names which do not reappear, or reappear with important changes, in Mr. Spence Bate's list in 1857, are as follows:—

*Montagna dubius*, perhaps represented by "Montagna Alderii;" *Scopelocheirus brevatus*, for which appears *Scopelocheirius crenatus;* "Amanomyx Guerinianus," omitted; *Westwoodia cocula*, altered to *Westwoodia cocula;* *Westwoodia carinata*, altered to *Kroyera carinata;* *Gammarius elegans*, altered to *Urhothoe elegans;* *Thersites Guilliamsonia*, altered to *Thersites Guilliamsoniana;* *Podocerus pelagicus*, Edwards, omitted; *Sphemoceuthus dubius*, omitted; *Pectinipes Fabreii*, Edwards, omitted; *Aegina longispina*, Kroyer, referred to Dana's genus, *Protella;* *Caprella levis*, Gooder, omitted; *Caprella acanthifera*, Leach, placed as a synonym of "*Caprella acanturnifer, Edwards;"* *Caprella acutifrons*, Dean, omitted; *Caprella phasma*, Lutr., omitted, "*C. Phasma*? (Lutr.)," being given as a synonym to *Protella longispina.*

Plates xii. to xxii. give valuable illustrations of the structure, both external and internal of the Amphipoda. They do not, however, supply the want of descriptions, so as to give any scientific value to the names of new genera and species here first published. On plate xvi. the terms applied by Milne-Edwards to the seven joints of a leg or equivalent appendage are contrasted with their abbreviated equivalents as used by Mr. Spence Bate, (1) *Carpopodite* shortened to *cora,* (2) *Basipodite* to *basis,* (3) *Ichipodite* to *ischium,* (4) *Meropodite* to *meros,* (5) *Coxopodite* to *carpus,* (6) *Propodite* to *propodis,* (7) *Dactylopodite* to *dactylos.*

In view of their forthcoming work on the British Sessile-eyed Crustacea, the following Table was drawn up in concert by Messrs. Bate and Westwood on this occasion:—

**Classis Crustacea. Subclassis I. Malacostraca.**

*Note:* The table is a simplification of the classification system used in the original text, focusing on the key terms and genera mentioned. The full description is much more detailed and includes numerous scientific names and descriptions.
1856. Dana, James Dwight.

The Amphipoda are thus described:—

"Orchestia Californica, D. Oculi majusculi. Antennae 1mas breviores; 2das crassae, dimidio corporis multo longiores, marginibus subtillissine setulose; flagello parce longiore quam articulum precedens, depresso, formae 18 articulato, articulis non oblongis, partim transversis. Pes 1mas articulo 4to angusto, infra unâ spinâ armato; 5to angusto, breviore, processu parvo infra armato, apice oblique truncato; unguis brevi, vix digitiformis. Manus 2da grandis, subovata, infra palmâ subexcavata, spinam versus apicem acutam gerente, digito natu longo. Pedes sex postici spinulis brevibus multis ornati.—Long. 7".

"The 7th pair of legs is but little longer than the 6th, and much longer than the 5th.

"Owing to the broad epimera, the animal is narrow with high sides:"

The Latin diagnoses are given of Schidde's genus Nipharcus, and his species stygius and aygile. The full account of the former is given in English, as applying equally to the latter, except for the differences mentioned in the diagnoses. As these amounted to little more than assigning a smooth back to stygius and by mistake a keeled one to aygile, Spence Bate was misled by this paper, he says, to assume the identity of the two species.

The paper also gives the Latin diagnosis of Bathyporeia, Lindstrom, and in English the full description of Bathyporeia pilosa, the type species. A comparison is instituted between this genus and Aonicy, Kr., and the observation made that "the form of the first pair of feet has a remarkable resemblance to that in Aonicy." As no particular species of Aonicy is mentioned, it is difficult to estimate the merit of this comparison.

1857. Bate, C. Spence.

The classification adopted in the genus Orchestia is that given by Dana, including the three subgenera, Talitrus, Talorhrestia and Orchestia. The new species briefly described are Orchestia lavis, later removed to Orchestia mediterranea, Costa; "Allochrestes Danaii," in
the Brit. Mus. Catal., transferred to *Allorcheistes nilsensis*, Rathke; *Allorcheistes lubricatus* now *Hyale potamica*, Rathke; "Galathidia Lubbeckiana," which does not differ from *Allorcheistes lubricatus*; *Montagna marina*, now *Stenothoe marina*; "Montagna Alderii," now *Metopa alderii*, according to Boeck; *Montagna polymorpha*, now *Metopa polymorpha*, according to G. O. Sars, but see also Note on Liljeborg, 1850; *Danaia dubia*; "Lysianassa Audouinieta," by Boeck referred to *Arctia* (*Anonyx*) humidus, Kröyer; *Lysianassa marina*, afterwards referred to *Lysianassa atlantica*, Milne-Edwards; *Scopolocheirus crenatus*, later transferred to *Calliona crenata*; *Tetromatus typicus*, transferred by Spence Bate to *Ampelisca gainaziti*, Kröyer, by Axel Boeck re-established as an independent species, *Ampelisca typica*, Spence Bate, while the species described by Boeck is said by G. O. Sars to be undoubtedly the male of *Ampelisca tenuicornis*, Liljeborg, with which again Bate’s species does not agree. H. C. C. Kroyer, p. 145–6, decides for calling it *Ampelisca carinata*, which (with Nowman) he supposes to be the male of *Ampelisca squamosa*, Bruzelius; "Tetromatus Bellianus," transferred by Spence Bate to *Ampelisca belliana*, by A. Boeck to *Ampelisca leucogena*, Liljeborg; *Westwoodia coccata*, afterwards changed to *Westwoodia coccata*; *Krögera carinata*, changed to *Monoculides carinatus*; "Phoecus Krögeri," transferred to *Phoecus simplex*, Spence Bate; "Phoecus Holboelli," afterwards recognised as Kröger’s species of the same name; *Subularis marina*, later transferred to *Urothoe marina*; *Darwinius compressus*, identified by Boeck with *Laphytyus sturions*, Kröyer; "Acanthohotus Owenii," afterwards referred to *Acanthohotus* (*Oniscus*) testula, Montagu, then reinstated as *Acanthohotus oweni*, and finally, Brit. Seas. Crust., vol. ii. p. 528, referred to *Epiuera* (*Gammarus*) cornigera, Fabricius; *Decmanthe biqino/a*, placed by Boeck in his genus *Halirages*; "Decmanthe Gordoniana," afterwards recognised as a synonym of *Atylus* (*Ampithoe*) swammerdami, Milne-Edwards; "Calliope Leachi," later referred to *Calliope* (*Ampithoe*) brevicornis, Kröyer; "Lemboes Gammeroides," transferred to *Microdeutopvs* (*Gammarus*) anomalus, Rathke; *Lembose versicolorus*, transferred by Spence Bate to the genus *Microdeutopus*, by Boeck thought probably to belong to *Atonoë*; "Lemboes Darwinonis," later recognised as synonymous with *Microdeutopus* *erythrophthalmus*, Costa; *Lonchonurus gracilis*, later placed in Kröyer’s genus *Aora*, as *Aora gracilis*; *Eucydthnes tridentatus*, later seen to be a synonym of *Gammarrus erythrophthalmus*, Liljeborg, and by Boeck therefore named *Gammarrus erythrophthalmus*, though he seems, according to G. O. Sars, to have confused with it a different species; *Gammarrus ochestiformis*, later found to be synonymous with *Gammarrus* (*Gammarus*) brevicornis, Milne-Edwards; *Gammarus inopsimus*, subsequently found to be a synonym of *Melita* (*Cancer Gammarus*) polynota, Montagu; *Gammarus? politus*, afterwards placed in a new genus as *Liljeborgia polita*; *Urothoe elegans*, stated scarcely to differ from *Urothoe tristis* of Dana, but separated from it because forms from the Soloo Sea can scarcely be supposed to belong to the same species as British forms—an unsafe ground of distinction; "Throrhias Gillianowsonia," afterwards found to be a synonym of *Bathyproes pilosa*, Lindström; *Throrhias pelagonia*, the of the preceding species; *Leiothoe procura*, subsequently made a synonym of *Leiothoe* (*Lycocyt*) furina, Sars, Gylin; "Pleurodes Gammarridae," later named *Ampithoe garrillicata*, and probably belonging to the division that has been named *Gummiphilo*, the Aenetus of Templeton; *Amphithoe littoralis*, referred by Boeck to *Amphithoe* *polychroides*, Rathke, probably the same as *Amphithoe rubricata*, Montagu; *Gummiphilo hamulus*, *Gummiphilo confusatus*, probably the male of the preceding species; (in this and the preceding genus the spelling *thoe* was afterwards adopted for the termination of the names); "Cypothiphimus Darwinii," better named *Phalophitus darwinii*; *Erichthonius dilformis*, here entered without name of any author for the species, but afterwards in the Brit. Mus. Catal. distinguished from *Erichthonius dilformis*, Milne-Edwards, and made synonymous with *Carcops obtusus*, Templeton; "Siphonoecu
**REPORT ON THE AMPHIPODA.**

Krügeriana,” afterwards assigned to Siphonocetes (Cerapus) whitei, Gosse, with a suggestion in the Brit. Sess. Crust., vol. i, p. 67, that it may probably be the female of Siphonocetes typicus; by Boeck it is united to Cerapus abitius, Templeton; Siphonocetes crassicorneus, by G. O. Sars renamed Cerapus crassicorneus; Dyopedos porrectus, afterwards named Dalichia porrecta; Dyopedos facutatus, afterwards named Dalichia falacata; “Proto Goodsiiri,” no doubt the same as Proto ventricosa, O. F. Müller.

The new genera are explained as follows:—Family I. Orchestidae; thus defined:—“The upper antenna shorter than the lower. The coxae well-developed; the posterior pleopods short and robust, the last being single.” Genus 3, Galanthis, “Lower antenna scarcely longer than the upper. Mandible non-palpigerous. Posterior pleopoda Orchestiform. Telson divided.” This genus, in the Brit. Mus. Catal., is made a synonym to Nicca of Nicolet, in my view identical with Hyate, Rathke.

“Family II. Gammaridae. Body compressed. Legs long and slender. Posterior pleopoda well-developed, the last being generally the longest.

“Subfamily I. Sologeoboculidae. Antennae subequal. Coxae of the four anterior legs immensely developed.”

Genus 1, Montagna, “Upper antenna without secondary appendage. Mandibles non-palpigerous. Hands of both gnathopoda subcheliform. Posterior pleopoda single-branched. Telson entire.” The name Montagna was pre-occupied. The genus falls to the earlier Stenothoë of Dana. Spence Bate included in its some species which had the mandibles palpigerous; these have been referred by Boeck to his genus Metopa. Proholium, Costa, is likewise a synonym of Stenothoë. Costa did not describe the mandibles, but in the type-species, Proholium polygynus, Boeck found them to be non-palpigerous.

Genus 2, Danaia, “First pair of gnathopoda simple; last pair of pleopoda with a single stylet.” In the British Sess. Crust., vol. i, p. 67; a fuller definition is given as follows. “Antennae subequal. Superior antenna without secondary appendage. Mandibles destitute of a palpiform appendage. First pair of gnathopoda simple. Second subchelate. Telson single.” Boeck in 1870 established a new genus Cressa, with type-species, Cressa Schädel, distinguished from Bate’s Danaia by having a very long triarticulate mandibular palp. G. O. Sars, 1882, says that my figure of Danaia dubia, 1876, shows clearly that it is identical with Boeck’s Cressa Schädel. In that case the latter definition of Danaia requires amendment. My own specimens of Danaia dubia were destroyed by an accident, before my attention was called to the special interest attaching to the mandibles.

“Subfamily III. Tetromatidae. Eyes four; not compound. Upper antenna in advance of the lower.” Genus 6, Tetromatus:—“Head projecting forward as a snout. Upper antenna proceeding from the extremity; lower situated far posteriorly. Mandible palpigerous. Gnathopoda but imperfectly prehensile.” This genus was soon after recognised as equivalent to Ampelisca, Krüyer.

“Subfamily IV. Pontoporeidae. The shell of the head developed anteriorly beyond the head so as to look like a hood. Upper antenna situated in advance of the lower.” Genus 7, Westwoodia:—“Shell of the head produced to a point. Upper antenna not appendiculated. Telson entire.” The name Westwoodia being pre-occupied was soon after altered to Westwoodilla. Genus 8, Krügera:—“Head like Westwoodia. Hands of gnathopoda well-developed, and formed by the carpus being produced so as to meet the apex of the dactylos.”

In the Brit. Mus. Catal., p. 104, Krügera carinata, the only species assigned to the genus
THE VOYAGE OF H.M.S. CHALLENGER.

in this Synopsis, is referred to the genus *Monocelides*, Stimpson. But in the Catalogue the name *Kroyera* is retained for a genus thus defined:—"Cephalon produced and anteriorly depressed. Eyes not coalesced into one. Superior antenna not appendiculate. First pair of gnathopoda subchelate; carpus inferiorly produced along the anterior margin of the propodos. Second pair chelate; carpus produced along the anterior margin of the propodos. Fifth pair of pereiopoda considerably longer than the preceding. Posterior pair of pleopoda bimarnous. Telson squamiform, entire." Boeck spells the name as *Krøyeria*, and then rejects it, as pre-occupied in a different group of Crustacea, in favour of his own later name, *Pontocrates*. *Kroyera* having in fact lapsed as a synonym of *Monocelides* could not properly be revived, and must therefore yield to *Pontocrates*, Boeck, unless it should prove that *Kroyera carinata* has a right to be restored. See Note on J. Sparre Schneider, 1885.

"Family III. Corophiidae. With the segments of the pleon not fused together." Subfamily I. Podoerides:—"The peduncle of the upper antenna much shorter than that of the lower. Lower antenna very strong, and used in climbing. Last pair of pleopoda terminating in short strong hooks." Genus 1. *Pleonexes*:—"Upper antenna without secondary appendage. Peduncle of the lower antenna reaching nearly to the extremity of the upper antenna. The gnathopoda subcheliform. Posterior pereiopoda prehensile." Afterwards referred to *Amphithoe*, Leach. Genus 3. *Staunamphitoe*:—"Second gnathopod larger than the first. Posterior pleopoda with one branch squamiform, the other terminating in two hooks. Telson terminating in a single strong hook." This is doubtless the same as Templeton's *Anisopus*, but the name *Anisopus*, being pre-occupied, must yield to *Staunamphitoe*.

"Family VIII. Dyopedidae. The last segment of the pereion and the last of the pleon absent. Coxas of last two pereiopoda fused with the body of the animal." Genus 1. *Dyopelus*:—"The sixth and seventh pairs of legs attached to the sixth segment of the pereion. The last pair of pleopoda absent. Telson single." This was afterwards found to coincide with *Dulichius*, Krøyer, and Dana's name *Dulichidae* was therefore accepted for the family.
1857. Bate, C. Spence.

In a letter dated February 16, 1857, Mr. Spence Bate says "having had an opportunity, since the publication of the synopsis of the British Amphipoda, of comparing the necessary works at the British Museum, I am enabled to make the following corrections and additions:—

After O. littorea read (Loud.). After O. Dohayesi read (Savigny). Acanthodous Oceani (mihi) is A. testudo of (Montagu). Thersites (mihi) must yield to Bathyporeca (Lindström), and probably the species B. Guillianisonia is the ptosea of that naturalist. Leucotlioe procrea (mihi) is probably furina of Savigny; and also the genus Dyopedos (mihi) is Dolichia of Kröyer; consequently the family Dyopetalida will for the future be changed to Dolichidae."

1857. Bate, C. Spence.

He here divides Talitrus "into two genera, as has been done by Nicolet and Stimpson," adopts Orchestoleba, Nicolet, which is synonymous with Megalorchestia, Stimpson, thus producing the classification. Talitrus, Orchestoleba, Talorchestia, Orchestia. "Lysianassa Chausia in the synopsis (not Edwards') is evidently L. longicornis of Lucas (Exped. to Algiers)." "The genus Tetromatus, mihi, Pseudophthalus, Stimpson, is synonymous with Ampelisca of Kröyer." Hence, he says, the subfamily Tetromatidae should be re-named Ampeliscades. Pontoporeidae is given up as a name of a subfamily, because Pontoporeia of Kröyer must go to the "Lysiassidae." Phoxides is proposed as subfamily for Phoxus, etc. "Phoxus Kröyerii, mihi, will be changed into P. simples," the other name being pre-occupied. "After P. Holböllii, read Kröyer instead of mihi" in the synopsis. "The genus Lomchomera is evidently that of Latasia of Lucas (Exped. to Algiers)." "There is to be added to the genus Siphonocetus of Kröyer the species Ceranus Whitei of Gosse; this may probably be synonymous with S. Kröyeranus, mihi." "Ceranus gracilis (Gosse) should have been C. Thomsoni, Gosse." There are also two or three other notes about names of species.

1857. Bate, C. Spence.

This species is in my opinion but doubtfully distinct from Iphimedia osea, Rathke, the variations being perhaps only due to age or sex.

The introduction briefly reviews the progress of knowledge in regard to the Amphipoda since 1830, and gives an account of the results at which Costa had himself arrived.

Of his new genus Araneops, he gives the following description:—"Caput elongato-conicurn. Ocelli quattuor in capitis margine antico positae. Antenne superiores intesta; inferiores longiores, ponit illas inserte. Epimera quattuor anteriore infra valde producta, media angustiora. Pedes primi et secondi parii subrquales, prehensiles, angustius sorriti; tertii et quarti cylindracei, angustius longi, articulatam antepenultimum, ultimam duobus similibus valde majorum, apice attingente. Pedes quinti, seti [seta] et septimi parii articulo primo valde clato, laminari." He recognizes its close affinity with Ampeliscus, Knyer, of which it is in fact a synonym. The type species, Araneods diadema, Tav. i. fig. 1, is set down by Sp. Rate, Heller, and J. V. Carus, as a synonym of "Ampeliscus Gastrinardti," Knyer, by Boeck as a synonym of Ampeliscus tenuicornis, Lilljeborg, 1855. Costa's second species, Araneops brevicornis, Tav. i. fig. 2, is by Carus named Ampeliscus brevicornis (Marion), but by Boeck made a synonym of Ampeliscus macrocephala, Lilljeborg, 1852.

After mentioning Orchestia littorea, Costa describes his species Orchestia mediterranea, and Orchestia constricata, the latter of which Heller identifies with "Orchestia Montagui," Aud.

Of Lysiasass, Costa describes and figures his three species, 1. Lysiasass spinicornis, Tav. 1, fig. 4, a species not to be confused with Lysiasass (Ichnopus) episcoris, Lilljeborg, 1866; 2. Lysiasass loricata; 3. Lysiasass hennalis, which Heller thinks may be the same as "Lysiasass Costa," M.-Edw., which Costa mentions as being found with it.

Callisoma punctatum, Costa, and Callisoma hopei, A. Costa, are mentioned, but as nothing is said of Callisoma bartholomiei; Hope, it may be presumed that Costa had ceased to consider it a distinct species.

The genus Ichnopus, evidently by the derivation intended to be Ischnopus, is thus defined:—

"Antenne longa, graciles, superiores bivulga. Pedes quattuor anteriores longi, graciles, filiformes, haur prehensiles, primi anguiulato minuto infra pectinato tertiam; secundis submembranaceis, manu apice longo fimbriata, anguiulato vix conspicua." From Callisoma, which it resembles in the gnathopods, it differs, he says, in the antenna, while from Aliobrotus, which it resembles in the antenna, it differs in the gnathopods. He adds, "e in questo genere che abbiamo trovato quelle appendici simili alle branche de' decapodi, inserite all'origine de' piedi terciari in forma piramidale, con uno stelo mediano, ed una serie di lamini da cadam lato, accollate le une alle altre, e decresecenti dalla base all'estremiti, che rappresenta l'apice della piramide." For this form of the branche, see also Grube's account, 1866, of his Lysiasass longicornis 2, (which is probably Costa's Ichnopus taurus), and Boeck's remark, De Sk. og arkt. Amph. p. 323, that it is especially characteristic for many species of the genus Atylos, that, like Ichnopus, their branche have "en opisth Ribbe langs Midten, hvorfra der udgaa talrige Forder som Sideribbe i et Blad." I have called attention to a similar structure also in Eilidis hallarhros from Singapore. The type species of Costa's genus, Ichnopus taurus, is figured Tav. i. fig. 3.

The genus Epidia is thus defined:—

"Antenne superiores biseta; inferiores articulo primo incurvati. Pedes quattuor anteriores minuti, prehensiles, subrquales; tertii parii articulo ultimo spatuliformis; quarti compressi, valde
viati, articulo ultimo tantum tertii; reliqui simplices." This genus is not noticed in the Brit. Mus. Catal. Boeck points out that it is a synonym of Dana’s genus Urothoe, 1852, which, he says, “can better be seen from Costa’s drawing of Egidia paludella than from his description.” The type species, Egidia paludella, is figured Tav. iv. fig. 3.

Of Melita, Leach, a fresh definition is given, and Melita palmata, Montagu, is figured, Tav. ii. fig. 4.

The genus Nototropis is thus defined:—

"Antenna superioris uniseta. Pedes quatuor anteriores præhensiles, filiformes, subquadrato. Corpus rotundatum, dorso acute carinatum, segmentum segmentis abscisum, dorso acute carinatum et spinis spiculatis. Antenna superioris uniseta. Pedes quatuor anteriores præhensiles, filiformes, subquadrato." This genus, already briefly characterized in Hope’s Catalogue, 1851, is a synonym of Dexamine, Leach, and the species Amphithoe avanentophilantus, which, together with Amphithoe marionis, Edw., Costa here places in the synonymy of Amphithoe marionis, is by Boeck identified without doubt with Dexamine spinosa. The remaining species, Amphithoe quindecimtus, Tav. ii. fig. 1, is likewise by Grube and Boeck assigned to the genus Dexamine.

The genus Epineria, already instituted in 1851, is here more fully defined:—

"Antenna superioris uniseta. Pedes quatuor anteriores præhensiles, filiformes, subquadrato. Corpus dorso in parte ac in abdomine carinatum et spinosum. Epimeris quarta et quinti articuli thoracis maxima, simul clypeum semihumare formantia. Abdomen lamina horizontali terminatum." The type species, Epineria triristata, Tav. ii, fig. 2, is identified by Boeck and Westwood, ii, p. 528, and by Boeck, with Gammarus corniger, Fabricius, so that it becomes Epineria cornigera, Fabr.

The genus Probolius is thus defined:—

"Antenna superioris uniseta. Pedes quatuor anteriores præhensiles, prima minori, secundii cælato majores, minus maxima. Corpus dorso rotundatum incurvus, articulo horizontali loricæ ex epimeris tertii et quarti articuli thoracis procingue constitutum." The type species is Probolius polyplax, Tav. ii, fig. 3 (not 9), which Boeck found, upon examination, to be without mandibular-pulp. The genus he was accordingly able to identify with Stenothoe, Dana, 1852. The second gnathopods of Stenothoe polyplax have a remarkable likeness to those of Hieropontopus maculatus, Norman.

Under Amphithoe, Leach, Costa places several species: Section A, 1. "Amphithoe Precostii," M.-Edw., which is rather to be called Hyale precosti; 2. Amphithoe babirussa, A. Costa, Tav. ii, fig. 5, called Allorchestes Babirussa in the Brit. Mus. Catal. 3. Amphithoe gazella, Tav. ii, fig. 6; 4. Amphithoe aquilina, Tav. ii, fig. 7; 5. Amphithoe tenella, Tav. ii, fig. 8, which, with the two preceding species, may be called Hyale gazella, Costa himself noticing that aquilina is intermediate between the other two; in Section AA, 6. Amphithoe inquisipes, Tav. ii, fig. 10, already established in 1851; 7. "Amphithoe Pauohipa," a change in the spelling of "Amphithoe Pauohipa," M.-Edw., 1830; 8. Amphithoe commerson, Tav. iii, fig. 1; 9. Amphithoe penicillata, Tav. ii, fig. 9, which is probably a synonym of "Amphithoe Vailantii," Lucas, 1849 (see Note on Catta, 1876); 10. Amphithoe gracile, Tav. iii, fig. 4;
11. *Amphithoe elongata*, Tav. iii, fig. 5; 12. *Amphithoe micros*, Tav. iii, fig. 2, referred by Spence Bate to *Pherusa fictorius*, Leach; in agreement with Costa's own suggestion; 13. *Amphithoe seminarticulata*, Tav. iii, fig. 3, identified by Heller with *Gammarella brevicaudata*, M.-Edw., Costa himself suggesting that it may be the female of his own *Gammarius puncticarinus*, for which see below.

The genus *Elasmopus* is thus defined:—

"Antennae superiores biseta; inferiores articulo primo inermi. *Podes quattuor anteriores premucilis, secundi prinse majores; sex postici clavi, laminares, articulo ultimn tament toreti."

By Spence Bate and J. V. Carus this is made a synonym of *Podocerus*, Leach, but Boeck points out that the cleft telson, the laminar branches of the third uropods and the large side-plates exclude that identification. The type species is *Elasmopus raptus*, Tav. IV. fig. 5.

The genus *Cerolocerus* is thus defined:—

"Antennae superiores biseta; inferiores processus trapeziformis carinato, cum carunculis pedunculi articulo primo articulato autaque porcello praefixe. *Podes quattuor anteriores præhensiles, secundi multo majores; sex postici articolo primo tament dilatato."

The process of the
REPORT ON THE AMPHIPODA.

299

lower antennae, from which Costa derived the name, and, as he thought, the most striking peculiarity, of this genus, is rarely absent from the Gammarina. Spence Bate made the genus a synonym of Melita, Leach, Grube referred it to Megamorpha, Spence Bate, and Heller to Mexoa, Leach. The type species Ceradocus orchestipes, Tav. iv. fig. 4, becomes Mexoa orchestipes.

In the genus Leucothoe, Leach, Costa describes Leucothoe denticulata, A. Costa, with a reference to "Fn. Nap. Tav. ix., fig. 3. (senza testo)," and the remark that it is "diversa dalla L. furcata per le proporzioni degli articoli delle antennae, e pel margine unguiculare della mani del secondo pajo fornito di dentelli piu fini e tutti eguali." It has been identified with Leucothoe spinicarpa, Abildgaard, from which Leucothoe furcata, Savigny, is only separated by subtle distinctions. Costa points out that his Leucothoe partienopae, in Hope's Catalogue, needs confirmation.

A fresh definition is given of Eriothomius, Milne-Edwards, in which genus Costa describes:

1. Eriothomius difformis, Milne-Edwards, Mas, and 2. Eriothomius bidens, A. Costa, Tav. iv. fig. 9, which J. V. Carus names Cerapus bidens, while Boeck makes it a synonym of Cerapus obdeltus, Templeton. S. I. Smith having shown that Cerapus is distinguished from Eriothomius by having the second uropods uniramous, the species assigned to either of these genera without description of the pleon are left in confusion. The peculiar form of the second gnathopod in the male seems to be common to both genera.

After mentioning Podocerus calcaratus, Rathke, Costa defines the genus Microdeutopus as follows:

"Antennae superiores secta multi articulata terminata; seta acrocrania valde prominenti prolata; inferiores pediformes. Pedes quatuor anteriores pedunculati; primi paria majores, in setulodis diffusos, (nato) carpo maximo, manu parce, unguiculatum generale: (fem.) manu majori fore ut in g. Amphilioes: secundi minus, filiformes." The type species is Microdeutopus gyrtistalpa, A. Costa, Tav. iv. fig. 10.

Corophium acheronymum, A. Costa, is not figured, but thus described:—"Antennae superiores brevioribus et gracilioribus; inferiores corporis fere longitudines, validissimis, pedunculi articulo tertia infra ad apicem spinis duo fere vel tribus decrescentibus armato (nate); brevioribus, minus crassis, inerimibus (fem.); pedibus secundó paria ungue infra bidentato.—Long. lin. 2." Boeck and Carus doubtfully identify this with Corophium crassicornis, Bruz.

Hyperia papa, A. Costa, Tav. iv. fig. 11, is thus described:—"Pedibus quarti paria illis tertii paulo superanudibus, quinti paria ceteris distincro longioribus; sexti et septimi decrescentibus; pedibus sparsi abdominibus quinti quartis brevioribus, sextis pedunculo brevisimis, appendicidibus callo insignibus, interna majori laminam apicalem paulo superane, cetera angusta quarto breviores.—Long. lin. 3 ½." Unfortunately only a gnathopod and part of the pleon are figured, but there is enough to show that this species does not belong to Hyperia, but more likely to a genus of the Lycidae.

Costa further mentions Phironia semilunata, Risso, Phironia sedentaria, Forsk., and Typhlo ovoides, Risso.

1857. HUXLEY, THOMAS HENRY, born 1825 (Hagen).

Bate and Westwood, vol. i. p. xvi, say that Professor Huxley here gives the name of Endo-pharyngal arch to the long processes in the head of Taditus, by which the stomach is supported in its position.
1857. Kirkby, J. W.

For a fossil from the Magnesian limestone of Durham, which Kirkby considers to be the same as Trilobites problematicus, Schlotheim, and Palsocrangia problematica, Schlauroth, he gives the name Prospinicus problematicus, deriving the new generic name "from πρόσωπον a face or mask, and ὑπόσμος, quisicus," as better expressing the affinities of the fossil. "In all," he says, "six specimens have been obtained; two from Humbleton Quarry, three from Field House, Ryhope, and one from Tunstall Hill." He does not say on what he relies for the generic characters, but describes the fossil as follows:—referring first to a specimen "showing the cephalic segment or carapace, with two body-segments attached (Pl. VII. figs. 1, 2, 3)."

"The carapace is about as long as four of the succeeding body-rings, somewhat less in depth, and slightly compressed laterally; it is carinated along the back and wedge-shaped in front; the eyes are large, round, and prominent, and are placed far forward; from the lower part of each eye runs an indented line, at a short distance from the margin, up to the dorsal region, where it curves forward.

"The other five specimens consist of body-rings (2 to 6 in number) and the two great posterior or caudal segments; and are very similar to the figures given by Schlauroth. In one of the Durham specimens (fig. 7) there are six body-rings, and two posterior segments; the others (figs. 4, 5, 6) have likewise the two latter segments, but not so many of the former. The body-segments are narrow, almost uniform in size, but varying a little in depth, the central ones appearing to be the most produced; they overlap each other and the penultimate segment posteriorly; they are slightly compressed, and have traces of a median dorsal ridge; those in front have their extremities turned a little forward, while the posterior ones are bent in the contrary direction. The large penultimate segment is greatly developed laterally; it is strongly carinated dorsally; its ventral margins are slightly convex, as is also the posterior border, which has a deep notch not far from the dorsal ridge; the ridge or keel of this segment is very prominent except anteriorly, where at each side of the dorsal ridge is a transverse swelling; it is compressed also posteriorly. The next segment, which is the hindermost known, is more compressed than the preceding one, and considerably smaller.

"None of the English specimens show the true external surface, nor have any traces of feet or of antennae been found.

"The specimen with the carapace (figs. 1–3) is one-eighth of an inch long. The largest of those with the body-segments only (fig. 4) is nearly half an inch in length."

Since Prospinicus is no more appropriate to an Amphipod than Palsocrangia, it is obvious that Schlauroth's earlier name must take precedence.

Leydig in 1878 gives references to this work, pages 341, 342, 362, 441, with regard to the adipose body, the liver, and the circulation in Gammarus.
1857. Lindström, G.

This is a good résumé of the account given by Lindström in 1855, Öfö. K. Vet.-Ak. Förh., pp. 49–73, of life at various depths in the Baltic. A reference for a like account is given to the "Bibliothèque Univ. de Genève, January 1857, p. 71."

At page 13 he describes *Lysianassa magellanica*, with a reference to "Ann. des sc. nat., 3* série, t. ix, p. 398," and figures it "de grandeur naturelle," pl. i. fig. 3. "Longeur, 70 millim., largeur, 31 millim."

*Schiodte, J. C.*

THE VOYAGE OF H.M.S. CHALLENGER.

1857. SCHUR.

He only mentions one Amphipod:—"Gammarus Pulex (Canc. pulex L.). In Quellen und Bächen; nicht selten."

1857. STIMPSON, WILLIAM.

The species here described are "Caprella Californica," Coryphion spinicornis, "Orchestia Trajani," Alhorrhectes similis, Mura conoidea, for all of which see next paper.

112 "Det torde fortjene en nærmere Undersøgelse, om den af Fabricius og Prof. Krøyer beskrevne, paa Keperkaken (Balmenopeta loopo) levende Gymnus virkelig de samme Art som sagde Gymnus Ceti Lin. fra Grønlandshvalen."

Corophium californicum is accepted somewhat doubtfully by Boeck. Mayer, without definitely uniting Boeck’s species with Stimpson’s, refers each to Philinaris L. Corophium spinicorne, Stimpson, was apparently unknown to Spence Bay, as in the Brit. Mus. Catal. he makes a new Corophium spinicorne, which Boeck identifies with Corophium transicorne, Bruzelius. Corophium salmolus, which Stimpson took, “not in a very good state of preservation,” out of the stomach of a salmon, had almost better have been left there, instead of being drawn forth to create a very indistinct species. Eriechthonius rapae, n. s., here described, is redescribed by Boeck in his Californian Amphipod fauna, and transferred to the genus Coropium, but if S. I. Smith’s definition of the latter genus be accepted, Stimpson’s name Eriechthonius rapae must be restored, as the second uropods are biramous. Orchestia scalrites, Dana, is here referred to Megorchestia, Brandt, which is superseded by the earlier Orchestidae, Nicolet. Megorchestia californiana, Brandt, is here distinguished from Megorchestia scalrites, in common with which it is referred to the genus Orchestidae in the Brit. Mus. Catal. Orchestia californicn, Dana, 1854 [1856], is here mentioned, a species which does not appear in the Brit. Mus. Catal. Orchestia traslana is described, and distinguished from two closely allied species, Orchestia pugettensis, and Orchestia pickeringi, Dana. Allochrestes seminula is described and distinguished by minute characters from Allochrestes pugettensis, Dana. Allochrestes plumulosus, n. s., is distinguished from Allochrestes seminula by characters doubtfully of specific value. Both species are described as common at San Francisco. Dana’s species Allochrestes angustus, Gammarus pugettensis, and Iphimedia trimaculata are recorded. More confervicola, Stimpson, is renamed Gammarus confervicola. It “differs from G. Atchenis in the smoothness of the dorsal surface of the first three abdominal segments.” The last species described is Phocus grandis, n. s. Like several others from this paper, it is not recorded in the Brit. Mus. Catalogue. The description is as follows:—“This species is of a much larger size than is usual in the genus. Body broad and robust. Rostrum lamelliform, expanded over the bases of the superior antennae, with a broadly rounded extremity. Superior antennae bi-flagellate, the inner flagella very little smaller than the outer ones; both 12-articulate; penultimate article of peduncle entirely concealed beneath the rostrum. Inferior antennae a little longer than the superior ones; terminal article of peduncle broad at its extremity where its outer angle is produced and rounded; its inner angle bearing the 15-articulate flagellum. Eye transversely oblong. Feet covered with simple hairs. Those of the first and second pairs with small subcheliform hands; those of the third and fourth pairs with the third and fourth articles dilated, the fifth slender, the sixth very small. Feet of the posterior three pairs very much widened; those of the sixth pair largest. Caudal stylets of the first and second pairs with short styliform rami, the inner ones being a little shorter than the outer ones; those of the third pair with long, flattened, equal rami, the outer ones spinulose along their outer edges, both fringed with long setae on the inner sides. Terminal caudal spines of considerable length. The color is yellowish-white. Length, half an inch. It was dredged on a sandy bottom in ten fathoms, in the channel near the entrance of San Francisco Bay.”
1857. Valette St. George, Adolphe Jean Hubert, Baron de la, born November 14, 1831 (Valette).

The Gammarus puteanus, Koch, of this dissertation is referred by Bate and Westwood to Niphargus aquilex, Schistte. La Valette gives numerous measurements of the animal at different ages and in both sexes, as well as of various parts of it. The statement of Hosius that the third joint of the mandible-palp in all Gammaris ends in an incurved nail will not, he says, apply to Gammarus puteanus. He never found more than two articulations in the secondary flagellum of the antennae. In the very short, leaf-like branch of the third uropod, he could not find the plumose seta described by Caspary, though he found, as Caspary had done, several setae on the long two-jointed branch. He corrects some oversights committed by Milne-Edwards and Hosius in regard to the telson, and denies the statement of Caspary that the first pleon-segment carries branchiae, and of Hosius that all the feet but the first are furnished with them, there being in fact only five pairs.

He reckons 12 ganglia in the nerve-chain; refers doubtfully to the cone at the base of the 2d antenna as subservient to the sense of hearing; describes the organs on the antennae since known as "calceoli," questioning whether they may be olfactory organs, and remarking by the way that their size increases towards the end of the antenna, which, however, I may say, is certainly not the case in all Amphipods. He describes the oesophagus, stomach and intestinal canal, mentions the liver-tubes as having been already observed by Siebold and Leydig in Gammarus pulex, and further states that the intestinal canal about the beginning of the fourth pleon-segment sends forth two caecal tubes directed forwards. He thinks that these may have a renal function, but cannot decide the question, not having succeeded in obtaining evidence of the presence of uric acid. Together with other anatomical observations he notices that the heart has three pairs of lateral valves for the introduction of the venous blood, situated in the second, third, and fourth pleon-segments. For his priority in this observation, Deluge by an oversight has omitted to give him his due credit.

1857. White, Adam.

A popular history of British Crustacea; comprising a familiar account of their classification and habits. London, 1857.

In the preface White says, "the general arrangement is that of the classical 'Histoire Naturelle des Crustacés,' by Professor Milne-Edwards. Among the Amphipoda, I have been chiefly guided by Mr. Spence Bate's synopsis, published in the February number of the 'Annals and Magazine of Natural History.'" Of the "Division Edriophthalma, Leach," the two Orders, Amphipoda and Lernodipoda, occupy from page 158 to page 220.

Of Talitrus locusta he says, "it is to this species Archdeacon Paley alludes in the 26th chapter of his 'Natural Theology,' as an instance of the abundance of happiness in the lower creatures." The notion appears to be that as children skip when they are in good spirits, the skipping of Talitri must be due to mental emotion rather than the structure of their tails. Mr. Halliday's observation, Ent. Mag. iv. 252, is cited, that a small beetle, Cillenum laterale, feeds on this sandhopper.

On plate x, which is due to Mr. Spence Bate, there is figured Orchestia littorea, var., which Spence Bate subsequently identified both with his own Orchestia levii, and the earlier Orchestia mediterranea, Costa.
As first genus in the family Gammaridae, *Opis*, Kroyer, is here mentioned, on account of a species from Ireland, said to be *Opis typicus*, which does not appear in the Synopsis. "Montagu monoculoides, Montagu, sp.," is figured. In the genus *Anonyx*, is introduced, besides the species of the Synopsis, "*Anonyx albus*. A small species, of a white colour; has been found at Clevedon, in Somersetshire, by the Rev. A. Norman. It is perhaps to this genus that the *Gammarius notius*, Johnston, Zool. Journ. iii. p. 179, may be referred; it is about three or four lines long; the antennae have a whorl of short spines at each joint; the arms and legs are monadactyle. It is found at Berwick amongst caverns." *Anonyx elegans*, Thompson, another species not mentioned in the Synopsis, likewise appears here.

"*Anonyx Edvardii,"* is figured as Kroyer's, on the authority of Spence Bate, but wrongly according to Bocock, 1870, and Sars, 1882. *Tetronautus typicus*, Spence Bate, is figured.

White notes that the name Westwoodia is pre-occupied among Hymenopterous insects. *Iphimedia obsura*, Rathke, is figured, pl. x. fig. 6. "*Acanthonotus Oewini*" of the Synopsis is here given as *Acanthonotus testudo*; the name which White himself gave to the species afterwards known as *Epiniera cornigera*, Fabr. After describing *Cerapus spinosa*, figured pl. x. fig. 7, White says, "to the genus *Cerapus* belongs the Cancer carino-spinosus, Turton, which Mr. Spence Bate has more fully described under the name *Gammarius Mogrigrilii.*" In regard to Bate's *"Lebros Websterii,"* which has "first hand with a thumb on propodos," and his "*Lebros Damnoniensis,"* which has "first hand with a thumb on carpus," he merely says, "Mr. Bate has described two other species from the south of England—*L. Websterii* and *L. Damnoniensis—both furnished with a thumb on the first hand," as though it was indifferent whether the thumb was on carpus or propodos.

He omits, not without reason, the description in the Synopsis of *Gammurus palaei*, Fabr., borrowed from Milne-Edwards. He also omits the "*G. 1 subterraneus*, Leach," and accepts *Gammurus maculatus*, Johnston, without hesitation.

The "*Niphargus Stigianus,*" of Westwood, he changes into *Niphargus aquiler*, Schiodte, and asks whether this may not be the *Gammurus subterraneus* of Leach.

He notices under Bathyporeia, Lindst., that "Mr. Spence Bate now refers his genus *Theresite* to this, and the species *T. Gilliammiana* to Bathyporeia *pilosa.*" *Leucothoe prorsus*, Spence Bate, at its author's own instigation, is identified with *Leucothoe furcata*, Savigny.

Some account is given from Say of *Cerapus tubularis*, though not a British species, to introduce an account from Gosse of his *Cerapus chilei*. D'Orbigny's account of *Corophium longicorne*, figured pl. xi. fig. 1, is quoted from, and mention made that Gosse had taken *Unciola irrorata*, Say, in our seas.

*Jassa pelagica*, Leach, figured pl. x. fig. 8, and *Jassa fulvata*, Montagu, are given, with a notice that "Mr. Spence Bate believes that this genus [Jassa] is founded merely on females of the preceding [Podocerus], and the further remark that "it is perhaps to this genus [Jassa] that the Gammurus spinipes of Dr. Johnston is referable (Zool. Journ. iv. p. 417)."

Under Amphithoe, Leach, besides the species assigned in the Synopsis to Amphithoe, Leach, White gives "Amphithoe obtusata, Leach's Coast Screw," which is Montagu's species, both before and since known as *Melis obtusata*. He also gives Amphithoe *dubia*, evidently as the name of Johnston's *Gammurus dubius* from Berwick, and therefore not to be confounded with Amphithoe *dubius* of the Brit. Mus. Cat., which is the *Anisopus dubius* of Templeton.

The name *Sviampithoe* is altered to *Synampithoe*, obviously on philological grounds.

*Chelura terebrans*, Philippi, is figured pl. xi. fig. 2. Allman's remarks on its habits are quoted.

The "*Tribe Hyperita*" is then described as follows:—"Head very large. Mandibles large, generally ending in crests rather than teeth. First pair of jaws, of three joints, the two last lamellar, the thorax of six or seven joints; some of the legs prehensile and of curious..."
form; end of abdomen adapted for swimming but not for leaping. The species of this tribe are more or less parasitic, some of them being attached to Fishes, and others to Medusae."

The "Fam. Phronimidae," and "Fam. Dulichiidae, Spence Bate," are placed in this tribe. To the Phronimidae he assigns 1. Hyperia, with the species "Latrellii," Milne-Edwards, figured plate xi. fig. 3, and oblitinya, Milne-Edwards, remarking that Spence Bate regards "Hyperi Latrellii" as synonymous with "C. Gammarus Calba" of Montagu; 2. Metocus, Kroyer, with the species "Metocus Medusarum, O. F. L., sp.," as described by Gosse; 3. Phronima, with the species sedentaria, figured pl. xi. fig. 4, the account of which is followed by the remark, "We have apparently in the British Islands more than one species of the family Typhlus; they are not well made out. The antennae in this family are inserted on the lower part of the head, and are folded three or four times on each other."

This is no doubt added to explain the omission of Typhus notus, Johnston, which is included in the Synopsis.

The "Fam. Dyopedidae" of the Synopsis, with the genus Dyopodes, Spence Bate, and the two species Dyopodes porrectus and Dyopodes falcatus here become on Spence Bate's authority "Fam. Dulichiidae, Spence Bate," Gen. Dulichia, Kroyer, species, Dulichia porrecta, Spence Bate, and Dulichia porrecta, Spence Bate.

Of "Ordin II. Lemodopoda," White remarks that "Mr. Spence Bate mergers this Order in Amphipoda." Several of Gosse's observations on the shape and habits of Ceprella are quoted. The arrangement, not of the Synopsis, but of White's own Catalogue of British Crustacea, 1850, is here followed. Ceprella tuberculata, Goodir, is figured pl. xi. fig. 5, a representation which, but for the size of the species, would suggest rather Ceprella aculeifrons, Latreille, than Ceprella tuberculata, Bate and Westwood, or Ceprella linearis (Linn.), Bate; the figure appears to have been copied on a reduced scale from Goodir, with the lines indicating the natural reduced to match! Ceprella lobata, Müller, of the Catalogue, does not re-appear. Ceprella spinosa, Goodir, is added, and described as similar to Ceprella phasma, Montagu, but differing, "chiefly in the thoracic segment having five spines." Its segments also, he says, are considerably longer, and adds that "Mr. Bate refers this with doubt to the genus Protella of Dana, and to the species named Echinus longispina by Kroyer." To Proto he adds the species "Proto Goodiri," Spence Bate.

The "Fam. Cyamidae" are thus described:

"Body depressed, oval. Eyes compound; two very small ocelli on vertex; antennae very close together at the base. Five pairs of legs, more or less prehensile; second and third joints of the thorax without legs, but bearing very long cylindrical respiratory appendages, which are generally bent over the back. The species of this family are parasitic on the whale and dolphin. They gnaw the rough thick skin of these marine animals more or less deeply. There seem to be several species of Cyamus, attacking different parts of the bodies of these bulky beasts, some preferring the head and others the fins and other parts of the body."

"Gen. Cyamus, Llr. Head small, truncated, united to first thoracic segment. The characters of the genus are those of the family."

"Cyamus ceti, Whale Louse (Plate XI. fig. 6.)—Branchial appendages simple, and furnished at the base with two unequal and pointed upper edges. Under the fins, etc., of the whale."

"Cyamus ovalis.—Body much wider than in last, four pairs of branchial appendages in both sexes, those of third ring with a single short slender appendage at the base, those of the fourth ring with two of unequal length. Lives in clusters on the hard projections of head of whale."

"The Cyamus gracilis and Cyamus Thompsoni are also recorded as British; the latter was found on a dolphin and is described by Mr. Gosse."

Savigny's mistake about the eyes is retained in the description of the family. The figure of Cyamus ceti is criticized by Liitken as not good. Liitken also thinks it quite unreasonable
that English authors should include Roussel's South Sea species, *Cyamus ovalis* and *Cyamus gracilis*, in the English Fauna. Only on the supposition, he says, that the Cymid parasites on the Southern Whale are possibly also to be found on the Basque Whale, could these species be included in the Fauna of Great Britain.

1858. BATE, C. SPENCE.

*Description of Two Rare Crustaceans from the Coast of Durham, one of them a New Species.* Transactions of the Tyneside Naturalists' Field Club. Volume IV. Part I. Newcastle-upon-Tyne, 1858. pp. 15-16. Pl. II.

*Kroyera arenaria*, Spence Bate, the new species, is thus described:—

"Antennae inferiores quam superiores sunt longiores. Gnathopoda secunda sunt cheliformes; carpi prodromoter ultra ductilorum extremitates. Super regiones dorsales posteriorum, nullas deuter.*"

"This species differs from the one on which the genus was founded, chiefly in the absence of the carinated dorsal ridge, and in the peculiar form of the second gnathopoda. In *K. Carinata* they are subcheliform, but the *carpi* are produced so that they reach beyond the extremity of the fingers—a peculiarity I never saw in any other Crustacean." After further description, Mr. Spence Bate says, "this genus belongs to the subfamily Phoxides, the habits of which are not much known." If *Kroyera carinata*, the type species, be identified with *Minoclytes*, the name *Kroyera* would lapse as a synonym, and Boeck's *Pontocrates*, 1860, would take its place. On the other hand Spence Bate's specific name *arenaria* has precedence of Boeck's *norvegicus*, 1860, so that if Boeck is right in identifying his species with Bate's, the species becomes *Pontocrates arenarius*, Spence Bate, sp., with *Glyicerus norvegicus*, Boeck, 1860, and *Pontocrates norvegicus*, Boeck, 1870, for its synonyms. But for a different view see Note on J. S. Schneider, 1885.

The other species here mentioned is *Salantar arenarius*, Spence Bate, properly *Haustorius arenarius*, Slabber, a species by no means rare.

1858. BATE, C. SPENCE.

Interesting particulars are given in regard to the homes constructed in various ways by creatures belonging to the genera *Cerapus, Unciola, Siphonoecetes, Amphithoides, Podoceerus, Corophium, Chelura and Phronima.* The connection between the animal's structure and the character of its dwelling, in regard to the *Podocerus, Corophiotes* and *Chelura* respectively is pointed out. The nature of the habitation of *Phronima sedentaria* had not as yet been decisively made out.

1858. BATE, C. SPENCE.

From the Collection of the Royal College of Surgeons are described the following:—

"Macrocephalus, n. g.

*Cephalon* horizontaliter porrectum. *Antennae* inferiores nullae. Pedum *coxae* corpore fusco.

In *Ampneus* inferiores nonnullae. Pedum *coxae* corpore fusco.

"Amphithoe lacertos, n. s. Ut genus sed gnatopoda secundo permagna et chelato. Arctic regions.

In the Brit. Mus. Catal., Spence Bate identifies Macrocephalus longirostris with the earlier Orceophalus armatus, M.-Edw., which had been made the type of the genus Rhadibosoma by Adams and White. Pleustes tuberculata is identified by Bock with Amphithoe pungo, Krüyer, and as Pleustes panoptus, is accepted as type of the genus Pleustes. Lysianassa bidenticulata, in the Brit. Mus. Catal., becomes a synonym of Lysianassa nugae, but by Miers and G. O. Sars its right to specific distinction is vindicated. Sars names it Socarnes bidenticulatus, Bate.

1858. BEMMELN, A. A. VAN.

R. T. Maitland in 1875 includes this work in his list of authorities. In regard to Orchestia literata, Leach, he refers to it for the remark that "Deze soort en Talitrus saltator worden aan onze stranden zee-luizen, zee-vlooien en strand-vlooien genoemd."

1858. CHENU, and DESMAEST, E. (See under the date 1874.)

1858. GESTERFELDT, GEORG.

The first species mentioned among the Amphipoda is Gammarus pulex, de Geer, which he considers to be as much at home in the whole of Siberia as in Europe, while "the Gammarus from the hot springs of Natschik in Kamtschatka, of which Brandt makes mention, stands at least very near it, if it be not quite identical." This comes under section α of the genus, in which "das Innenglied des 6. falschen Fusspaars ist so lang oder mindestens halb so lang als das äussere (Brandt)."

Section β, in which "das Innenglied des 6. falschen Fusspaars ist noch nicht oder höchstens ein Viertel so lang als das äussere und oft nur rudimentir," contains the following:—
"Spec. 2. Gammarus verrucosus, mh. n. sp. Corpore lateraliter compresso; thorace et abdominе
incernibus, segmentis postabdominalibus presertim, secundo et tertiо, tuberculis numerosis
spinosis instructis; ramо stylorum caudalium posticum externо longissimo, margine longe
clito," found in the Angarа at Irkutsk, with Gammarus atchenes, Brandt, for its nearest
relation. This species is partially described and figured in the Brit. Mus. Catal., but there
by a misapprehension referred to "Brandt, Middendorff's Sibirische Reise." Spence Bate's
description of the pleon includes a feature not alluded to by Gerstfeldt in the "inferо-
posterior angle of the third segment produced into a long upturned tooth." Dybowski,
however, in his account and figure of the species, does not give this tooth or anything
more than an ordinary angle to the segment in question.

Spec. 3. "Gammarus Maackii, mh. n. sp. Corpore lateraliter compresso, thorace et antеabdominе
incernibus; segmentis postabdominalibus singulis dubs vel quatuor carinis spinosis arnatis;
ramо stylorum caudalium posticum externо longissimo, margine breviter acutato." It
comes near to Gammarus ochotensis, Brandt, and is almost as common in the Angarа at
Irkutsk as Gammarus verrucosus. In the Brit. Mus. Catal., where it is figured, it is
attributed to Brandt, instead of Gerstfeldt. It is redescribed by Dybowski in 1874, but
not figured.

As distinguished from the foregoing species, in which "Die Rückenseite des 4. und 5. Schwanz-
gärtns erscheint mit Stacheln besetzt," in the following species the fourth and fifth pleon-
segments are dorsally "stachellos."

"Spec. 4. Gammarus cancellus, Pallas," is described, with "tuberculorum (dorsalium) par
quintum maximum." In 1862 Spence Bate took this as type of his new genus Pallasea.
In 1874 Dybowski again describes it as Gammarus cancellus, Pallas, of which he describes
and figures a variety named Gerstfeldtii."

"Spec. 5. Gammarus cancelloides, mh. n. sp.," from the Angarа at Irkutsk, is thus described:—
"Gammarо Cancellо Pall. similis, tubерculis tamen dolabіbus minus elevati; a capite ad
caudam crescentibus, necque vero pari quinto, sed paribus octavo et nono maximis; in seg-
mentis thoracis et antеabdominis carinatus laterіalibus loco tuberculis valde prominentibus."
Spence Bate, in the Appendix to the Brit. Mus. Catal., inclines to regard this as a variety
of Pallasea cancellus, but Dybowski retains it as a distinct species, Gammarus cancelloides,
Gerstfeldt, of which he gives a description and figures.

"Spec. 6. Gammarus latissimus, mh. n. sp.," also from the Angarа at Irkutsk is thus described:—
"Corpore latissimo, fere unisiforme; fronte productо et quattuor paribus aculeatos, medius
dolabus verrucis impositis, armato; segmentis thoracis et anteabdominis carinatis et tuberculа
supra hаnnas laterales sitа versus declivibus; segmentis postabdominalibus tuberculis
laterіalibus destitutis, anterioribus tribus tuberculis dorsalibus, quorum duo posteriоrа acutea,
præditis." As already explained, this species was subsequently under a misapprehension
attributed to Brandt in the Brit. Mus. Catal., and is there made the type of a new genus
Brandtii. Dybowski, who had not met with it in Lake Bajkal, retains it under the name
Gammarus latissimus, in 1874.

Among those Gammarі in which "der Hinterrand des 3. Postabdominalsegmentе and meist
auch derjenige der beiden vorhergehenden verlängert sich in der Mittellinie in Art eines
sp. Corpore lateraliter compressо, margine posteriorе trium anteriorum segmentorum
postabdominalium et interdum etiam nonnullorum aut omnium anteabdominis et thoracis
in spinam acutam tendemque segmentо sequenti incipientem productо, ""aus einer Pfütze
an der Küste." This does not appear to be mentioned in the Brit. Mus. Catal. Nor does it
appear in Dybowski's long list of species from Lake Bajkal. The fuller description is as
follows:—"Der Körper ist ziemlich stark seitlich zusammengedrückt; die Stirn bildet nur
ein kurzes dreieckiges Spilschen; die Augen sind oval-nierenförmig. Die nur schwach
behaiten Fühler haben etwa die halbe Länge des Körpers und von ihnen überragen die unteren mit ihrem letzten Drittheile die unteren; das Ende des Stiels der oberen Antennen reicht nur bis zum Auftange des letzten Stiehles der unteren oder wenig weiter; ersteres besitzten an der Hauptgeißel 10–14, an der kleinen Nebengeißel, welche nur wenig länger ist als das erste Glied der Hauptgeißel, 2–3 Glieder; die Geißel der unteren Antennen übertrifft ihren Stiel kaum an Länge und besteht aus 4–5 Gliedern. Die vorderen Füße sind mit Haaren, Wimpern und Stacheln besetzt. Die vorderen Hände sind kleiner als die hinteren, aber verhältnismässig breiter, rhomboidal und am Vorderrande schräg abgestutzt, gegen die hinteren grösser und namentlich länger und fast eiförmig erscheinen; bei beiden Paaren ist der Innenrand an der oberen Hälfte mit kleinen Zähnchen, an der unteren mit stachelartigen Borsten besetzt.—Der Hinterrand der drei ersten Schwanzsegmente und gleichzeitig zuweilen derselbe Rand aller oder einiger Brustbauchringe verlängert sich in der Mittellinie des Rückens in einen nach hinten gerichteten, feinen, spitzen, dornartigen Fortsatz, welcher dem nächstfolgenden hinteren Segmente aufliegt und nur bei gekrümmter Lage des Rückens sichtbar wird.—Das 4. und 5. mit Stacheln besetzte Afterfusspaar geben etwas über das Ende der Körperhaut und das letzte falsche Fusspaar trägt auf ziemlich langen Basalgliede zwei am Rande mit Stacheln versehene, fast gleich lange Blättchen, die kürzer als die Basis erscheinen.—Die Seitenplatten der Körperringe vor der Basis der Füße sind verhältnismässig lang.—Die Farbung ist gelblich und die Länge des Körpers beträgt nur 2-2½”.

The principal divisions of the genus Gammarus here adopted by Gerstfeldt are taken from Milne-Edwards' Hist. nat. des Crustacés.

1858. Hancock, Albany, born 1806, died October 24, 1873 (R. Howse).

The fossil marks are explained by comparison with those which Crustaceans make at present. The tracks or runs of Sulcator arenarius are carefully described and figured. On sandy shores upon the north-east coast of England, "they are to be seen," Mr. Hancock says, "everywhere between tide-marks, but are most numerous about half-way down the beach, on inclined, oozy, glistening spots, where the sand is firm, and yet the moisture so profuse that it mirrors the light." The phenomenon is far from being confined to the north-east coast; it was moreover noticed by Say in his account of Lepidactylus, in 1818. Besides the tunnelling of Sulcator arenarius, the surface track of Krögera arenaria is likewise described and figured. It is curious that no mention should be made of the species which, so far as my experience goes, is much commoner than Krögera arenaria in the situations
described, namely, *Bathycephe* *pilosa*, which leaves its little labyrinthine tracks, and sometimes short straight ones, in vast numbers over such stretches of sand as Mr. Hancock describes. In regard to the species *Sculacor arenarius* and *Kroyera arenaria*, see Notes on Sp. Bate, 1851, 1857, and 1858.

1858. *Saussure, Henri F. de.*

The new species described is called *Amphitopus advenus.* "Habite: Le Mexique; pris en abundance dans une citerne de Vera Cruz." W. Faxon says, "After an examination of a large number of *Hyalella dentata* and *H. inermis* from Utah, I am satisfied that they are but varieties of one species. The form with dorsal teeth on the first and second abdominal segments is very probably synonymous with *Amphitopus advenus* Saussure and Allorchestes Knickerbockeri Bate, as pointed out by Professor Smith himself." *Hyalella advena* will therefore, in my opinion, be the best name for Saussure's species.

1859. *Bate, C. Spence.*

The fossil Crustacean is that supposed to be identical with the *Trilobites problematicus* of Schlotheim and by Schlauroth named *Palkocerangon problematicus*, which Kirkby changed into *Prosoponiscus problematicus*, thus far the only British fossil Amphipod. See Notes on H. Woodward, 1871 and 1877.

The new Amphipod is *Phaedra antiqua*, founded on a damaged specimen, which closely agreed with the fossil fragments. The new genus *Phaedra* is thus defined in the Brit. Sess. Crust., vol. i. p. 208:—

*Phaedra* :— "Cephalon produced anteriorly. Segments of the pereion short, of the pleon long. Superior antennæ shorter than the inferior, furnished with a secondary appendage. Posterior pair of pleopoda considerably elongated, biramous. Telson simple or notched."

1859. *Bate, C. Spence.*

After a discussion of earlier notices of well-shrimps, the new species *Niphargus fontanus* and *Niphargus kochiana* are figured and described, a new genus *Crangonyx* is instituted, with the species, *Crangonyx subterraneus*, to the description of which is appended the remark, "it is not improbable that this may be the *Gammarus subterraneus* of Leach; but we have no means of ascertaining."

The name *Crangonyx* is derived from *края* and καρπος.

The genus is thus defined:— "Like Gammarus, but not having fasciculi of spines upon the
posterior segments of the pleon, and having the posterior pair of pleopoda unbranched.

Telson single.”

De Rougemont is inclined to unite all these three species under *Gammarus puteanus*, Koch. The matter perhaps is not yet ripe for final determination.

1859? BRUZELIUS, RAGNAR MAGNUS, born 1832.

In a brief notice of earlier classifications, Bruzelius explains that he follows Dana, and divides the Scandinavian Amphipoda Gammaridea into four families, Dulichidae, Orchestidae, Corophidae, and Gammaridae, but defines the latter two differently from Dana. He mentions the writings on the Amphipoda with which he was acquainted. He then gives a definition and general description of the group.

In “Familia I. Dulichidæ, Dana,” he places *Latmatophilus*, n. g., thus defined:—

In “Familia II. Corophidæ, Dana,” Bruzelius arranges the genera *Corophium*, “Erichtontus,” *Jassa, Podocerus, Autonoe, Amphithoe*. To *Corophium*, Latreille, he assigns, 1. *Corophium longicornium*, Fabricius, which he describes; 2. *Corophium crassicorne*, n. s., pl. i. fig. 2; 3. *Corophium affine*, n. s. He next describes *Erichtontus*, as he spells it, with the type-species *diferminis*, Milne-Edwards, to which he makes “Podocerus Leachii,” Kröyer, a synonym.

He re-establishes *Jassa, Leach*, to receive *Podocerus capillatus*, Rathke; but *Jassa, Leach*, had lapsed as a synonym of *Podocerus, Leach*, and the genus *Janassa*, under which name Boeck revives *Jassa*, Bruzelius, is only separated from *Podocerus* by absurdly trivial distinctions. To *Podocerus*, Bruzelius assigns 1. *angulipes*, Kröyer, of which he remarks that *Gammarus zebra*, Rathke, is in all probability the female; 2. *calcaratus*, Rathke, which Boeck makes a synonym of *falcatus*, Montagu.

The new genus *Autonoe* is thus defined:—

To this genus Bruzelius assigns, 1. *Autonoe punctata*, n. s., pl. i. fig. 3, which is a synonym of *Aero gracilis*, Spence Bate; 2. “Autonoe anomala (Rathke)!”, pl. i. fig. 4, since called *Microdeutopus anomala*; 3. *Autonoe grandimana*, n. s., pl. i. fig. 5, which Boeck identifies with *Microdeutopus grnilotalpa*; Costa, with which Bruzelius himself compares
REPORT ON THE AMPHIPODA. 

313

it; 4. "Autonoe erythropthalma (Liljeborg)," for the Gammarus (Gammaropsis) erythropthalma of Liljeborg, since called Gammaropsis erythropthalma; 5. Autonoe longipes, Liljeborg, for Gammaropsis longipes, Liljeborg, 1852, which Boeck accepts as the type of the genus Autonoe; 6. Autonoe macronyx, Liljeborg, pl. i. fig. 6, for Gammarus macronyx, Liljeborg, 1853, identified by Boeck with Protomedeia fasciata, Kr0yer, 1842. To Amphithoe, Leach, Brzezinski assigns the species, 1. podoceroides, Rathke, with allomaculata, Kr0yer, for a synonym, and 2. pygmaea, Liljeborg, which Boeck identifies with "Photis Reinhardtii," Kr0yer, 1842.

In "Familia III. Orchestidea, Dana," Brzezinski places, 1. Orchestia, Leach, with the species littorae, Leach, including Euckore, F. Miiller; 2. Allorchestia, Dana, with the species "Allorchestes Nilsoni" (Rathke)," in the synonymy of which he gives "Amphithoe Prevosti?, H. Rathke; Amphithoe Nilsoni, H. Rathke; Orchestia Nitrospiensis, Kr0yer;" remarking also that he feels to have that Rathke's and Kr0yer's species are identical with the one he himself describes, but of Milne-Edwards' he is doubtful, as the figure seems to show two rami on the last nuptia. Brandt's subgenus Allorchestina he considers unnecessary.

In "Familia IV. Gammaridae, Dana," Brzezinski describes nineteen genera. The species which he calls Anonyx salinus, Kr0yer, was called Anonyx nanus by Liljeborg in 1855, while the Anonyx minutus, Kr0yer, which he thinks perhaps identical, is called Orchestea minutus by Boeck. "Anonyx Kr0yeri," n. s., pl. ii. fig. 7, was transferred to Callionea by Spence Bate. Pontoporeia furcigera, n. s., pl. ii. fig. 8, is said by Sars in 1882 to be the same as the earlier Pontoporeia femorata, Kr0yer. Brzezinski says that in his species the accessory flagellum of the upper antennae has three joints as against two in Kr0yer's species, and that Pontoporeia furcigera is much smaller than femorata, while he has always found that in individuals of the same species the number of joints in the flagella increases or diminishes with the size of the animal. Also the fork-like process on the fourth segment of the abdomen is considerably larger than in Pontoporeia femorata.

For Gammarus, Fabriciuss, Brzezinski draws up a scheme including thirteen species, which have since been distributed among various genera. "Gammarus Locius," n. s., pl. ii. fig. 9, was transferred to Mars by Spence Bate. Gammarus hevis, n. s., pl. ii. fig. 10, was identified by Spence Bate with Gammarus longimanus (Leach), Thompson, which Spence Bate places in the genus Megagammar. Gammarus breviceorfus, n. s., pl. iii. fig. 11, is identified in Bate and Westwood with Liljeborgia pallida, Spence Bate.

The new genus Eriopis, is thus defined:—
"Corpus elongatum, parum compressum, epiniceris parvis. Antennae superiores pedunculo gracili et flagello appendiculari perspinnulo instructae; inferiores subpediformes. Mandibulae duobus ramis, tuberculo molarie et palpo triarticulato instructae. Maxilla prima parvis palpibus biarticulatis ornata. Palpus pedum maxillarium e quatuor articulis compositus. Pedes primi secundique praesertim manus articulis quintis subcheliformi armati. Tris parvis posteriores pedum thoracis postice gradatim longiores. Rami pedum abdominalium ultimae parvis valde inequalibus; interior brevier, exterior abdominis longitudinaluere equales, duobus articulis complanatis instructae." This genus is identified by Boeck with Niphargus, Schindte, 1851, which had hitherto contained only fresh-water species. Eriopis elongatus, n. s., pl. iii. fig. 12, "habitat in locis profundis maris Bohnsiae." This is called by Boeck Niphargus elongatus.

The new genus Pararnphithoe is thus defined:—

(zool. chall. exp.—part lxvii.—1887.)

xxx 40
abdominis ultimi paris biramei, ramis elongatis." To this genus Bruzelius refers nine species; in section a, "dorsum magis minuere carinatum, posticum sepe dentibus armatum," 1. Paramphithoe panopla, Kröyer, by Bate, Boeck and Sars now called Pleustes panopla; 2. Paramphithoe pulchella, Kröyer, by Bate called Pherusa pulchella, by Boeck Pleustes pulchellus, by Sars, 1882, Paramphithoe pulchella; 3. Paramphithoe hystric, Owen, for which see Note on Lepechin, 1780; 4. Paramphithoe compressa, Liljeborg, identified by Boeck with "Atylus Swammerdami," Milne-Edwards; in section b, "dorsum rotundatum, segmentis dubius aut pluribus postice dentatis;" 5. Paramphithoe bicuspis, Kröyer, by Bate referred to Pherusa, by Boeck to Pleustes, by Sars, 1882, back to Paramphithoe; 6. Paramphithoe tridentata, n. s., pl. iii. fig. 13, by Boeck in 1870 named Halirages tridentatus; 7. Paramphithoe elegans, n. s., pl. iii. fig. 14, by Boeck identified with Decoxime bispinosa, Spence Bate, under the name Halirages bispinosa; in section c, "dorsum rotundatum, carina et dentibus destitutum;" 8. Paramphithoe leviscula, Kröyer, now known as Calliopus levisculus; 9. Paramphithoe norvegicus, Rathke, now known as Calliopus norvegicus, Rathke. Thus it appears that all the species assigned to Paramphithoe by the founder of the genus fall to older genera, with the exception of Owen's hystric and the new species tridentata; this latter he defines:—"Caput rostro perpusillo instructum. Dorsum rotundatum, laxe, segmenti septimni thoraces, primi seculadique abdominis margine medii posteriori dentem acutum formante. Antennis superiores inferioribus longissimis multo breviore. Pedes primi seculadique paris mamm fere oblongo-ovali, mediseris magnitudinis, instructi. Appendix caudalis indivisa, margine posteriori truncato et dentato." If Boeck's Acanthonotus is accepted as the generic name for Owen's hystric, Paramphithoe tridentata, Bruzelius, remains over to represent the new genus, and would, I imagine, take precedence of Boeck's Halirages, unless we may argue that the genus instituted by Bruzelius lapsed through the want of any suitable definition, coupled with the want of any species selected as the type.

After describing Acanthonotus serra, Kröyer, Decoxime tenuicornis, Rathke, and Iphainonia obesa, Rathke, Bruzelius proceeds to define the genus Ampelisca, Kröyer, identifying with it Costa's Araneops. He assigns to it six species (1) squamicornis, n. s., pl. iv. fig. 15; (2) tenuicornis, Liljeborg; (3) leviscula, Liljeborg; (4) macrocephala, Liljeborg; (5) "Gaimardi," Kröyer, by Boeck in 1870 named "Bathy Gaimardi;" (6) Ampelisca carinata, n. s., pl. iv. fig. 16, in which the front part of the back is rounded, and which therefore differs from the Ampelisca Gaimardi (Telamatus typicus), Spence Bate, which has "cephalon and pereion laterally compressed and dorsally cuneated." Bruzelius next describes Haploops tubulosa, Liljeborg; Haploops carinata, Liljeborg; Bathyporcia pilosa, Lindström. In the last he has noticed the variations in the antennae, which subsequently occasioned the institution of new species.

In the genus Elicerinos, he describes (1) Elicerinos obtusus, n. s., pl. iv. fig. 17, identified by Boeck with Leucoilhe phyllonyx, M. Sars, under the name Aceros phyllonyx; (2) Elicerinos affinis, n. s., pl. iv. fig. 18, by Boeck called Monoculodes affinis, as also earlier by Spence Bate, who gives it priority over his own Monoculodes stimpsoni, whereas J. S. Schneider inclines to identify Monoculodes affinis, Boeck, with Monoculodes stimpsoni, Bate, and definitely makes Elicerinos affinis, Bruzelius, a synonym of Monoculodes carinatus, Spence Bate; (3) Elicerinos saginatus, Kröyer.

He describes "Leucoilhe elyptica (Kröyer)," which Boeck calls "Metopa Bruzelii," Goës. Bruzelius notices that his specimens differed somewhat in the antennae and gnathopods from Kröyer's description, but was content to regard them as the young of Kröyer's species. Sars, in 1882, considers that the form described by Boeck is not the true Metopa Bruzelii, Goës, but a distinct species, which he names Metopa borealis, distinguished by its more considerable
size, shorter antennae, and differences in the gnathopods. He gives its length as 3 mm. The length given by Boeck is 2 mm. Bruzelius says the body's length is about 2 mm. _Leucothoe norvegica_, Liljeborg, is next described. Of this he says in a note that it is possibly the male, and _Leucothoe clypeata_ the female of one and the same species, an opinion in which Bate and Boeck agree with him.

After describing _Leucothoe articulata_, Montagu, and "_Laphystius Sturionis_," Krøyer, he defines the new genus _Nicippe_:

1859. _Bruzelius, Ragnar M._

The investigations were made upon "_Gammarus locusta_, Linné, and _Amphithoe postceroides_, Rathke." Sars, 1867, in regard to the inner structure of the Amphipoda, says, "Nous devons les études les plus consciencieuses et les plus exactes au savant suédois, M. Ragnar Bruzelius, qui a écrit sur ce sujet un mémoire accompagné d’une planche lithographique dans ‘Öfversigt af Vetenskaps-Akademiens Förhandlingar, 1859.’ "Ainsi que le lecteur le verra dans la suite, mes recherches sur cette espèce [Gammarus neglectus] s'accordent parfaitement, dans tous les points essentiels, avec les communications de ce naturaliste, fait qui mérite ici une attention particulière, attendu que les renseignements fournis par d'autres savants, entre autres par M. Spence Bate, semblent s'en écarter sous plusieurs rapports."

1859. _Danielssen, D. C., born 1815 (G. O. Sars)._  

_Beretning om en zoologisk Reise foretagen i Sommeren 1857._ Nyt Magazin for Naturvidenskaberne. 11te Binds 1ste Hefte. Christiania, 1859. (The Volume, "Ellevte Bind," is dated 1861.)

_Amphipoda are mentioned on pages 7–9, but without any descriptions. One new species is noted under _Oelicerus_, Krøyer, "O. arcticus n. spec. Af denne nye Art найдет jeg nogle faa Exemplarer ved Vadsø paa sandig Leerbund fra 40–60 Favne." This is regarded by Boeck as a synonym of _Oelicerus lyncus_, M. Sars, 1859.

1859. _Gegenbaur, Carl, born 1826 (Carus), 1827 (Hagen)._  

For an account of this work remodelled, see Note on Gegenbaur, Grundriss, &c., 1878.
1859. Gervais, Paul, and Beneden, P. J. van.

The Crustacés are the Classe Quatrième of the "Deuxième Embranchement. Animaux articulés." Of the "Sous-classe des Crustacés Édiopithalomes," the authors say, page 486, "les Édiopithalomes sont généralement partagés en trois ordres, nommés Isopodes, Amphipodes et Lémodipodes, auxquels on en ajoute maintenant un quatrième pour les Pycnogonides, qui semblent être, à plusieurs égards, un arrêt de développement des Lémodipodes Éphyridés." This view of the Pycnogonides is no longer generally held. On page 488, they define the Ordre des Amphipodes, dividing it into two families, "les Gammarides et les Hyperidés." To the former belongs the genus Crevette (Gammarus), of which they have at least three species in France, "deux d'entre elles vivent dans les cours d'eau et dans les étangs (Gammarus palier et Roseiil); ce sont ces Crevettes que l'on trouve souvent dans le cresson. La troisième n'a encore été observée que dans l'eau de puits. Elle est plus petite que les précédentes et étioke. Nous l'avons appelée Gammarus lactue." This can scarcely be called a scientific description of a new species; but see Notes on Gervais, pp. 156, 160.

In the family of the Hyperidés, les Théonimes (g. Phronima) are mentioned with the species volutaria. The Lémodipodes are divided into, "1" les Capelliidés, with the genus Caprella, and "2" les Cyamides," after briefly defining which they say,

"L'ancien genre Cyane (Cyamus), qui constitue à lui seul cette famille, comprend plusieurs espèces que l'on trouve sur le corps des grands Cétacés. On les nomme Poux de Baleines.

"Le Cyane du Dauphin (Cyamus delphini, Guérin) doit former un autre genre que nous noms Isocyamus." Nothing is said of the characters of this new genus. The Pycnogonides, among other habitats, live "sur le corps des poissons."

1859. Hogan, Arthur R.

This paper discusses the habits, food-supply and habitat of the species described in the immediately preceding paper by Spence Bate. As to their food, Mr. Hogan says, "some water drawn from the spring at Ringwood, has been proved, by microscopic examination, to contain numerous animalcules; and this will probably turn out to be the case with all other waters in which Niphargi are found." Some six or seven specimens of Niphargus aquilus, from a well near Tunbridge Wells in Kent, lived in my room from January 28, 1886, till March 3, 1886. As they all died at about the same time, it may have been the coldness of the night which killed them. Though they were very active in walking about the bottom of their jar, whenever I happened to look at them during their life-time, I never saw them attempt to swim. Another set of about a dozen were placed in a jar, 5½ inches high by 2¾ inches broad, on June 15th, 1886. Two of these were females with eggs. These two died within a couple of days, surrounded by some rapidly developed parasitic growth.
REPORT ON THE AMPHIPODA.

The rest lived on for a considerable time, the last not dying till November 24th, 1856. The water in which they were at first placed came from their native well, and contained a very little sediment. Every four days a small portion was poured away and replenished with water from the town waterworks.

1859. KINAHAN, JOHN ROBERT, born 1828, died February 2, 1863 (Busk).

In the list of Crustacea Amphipoda, Professor Kinahan avails himself of a list of William Thompson's collection furnished him by Spence Bate. Twenty-eight names of species are given, among them being Orchestia laevis and Orchestia deshayesii (Savigny). Gammarus fluviatilis is mentioned and distinguished from Gammarus pulex, but the proper use of the names is evidently inverted. "Hygeria Galba" was found "in thousands in Acalephae, floating through the Bay." The next entry is "Lesrigonius Fabricii (?).—This occurred with the last, but in fewer numbers. It is singular that in the supplement to Parry's 'Voyage,' this is figured as having occurred also along with the last. Can there be any intimate connexion, such as sexual, between them? I find some trifling differences between my specimen and L. Fabricii (Milne-Edwards), but await my friend Spence Bate's judgment on the point. I strongly suspect that Gosse has mistaken this animal for Metacerus melanosoma, the distinction between the genera being such as to easily cause a mistake. This is doubtless the species W. Thompson failed to identify, owing to the bad condition of his specimen." The name borrowed from Milne-Edwards should no doubt have been "Lesrigonius Fabricii," not "Lesrigonius Fabricii."

1859. LACHMANN, JOHANNES.

Gammarus is obviously in error (maintained throughout the paper), for Gammarus. The parasites found by Lachmann in the intestine (Darm) of the well-shrimp, are said to belong to the puzzling group of the Gregarines.

1859. SARS, MICHAEL, born 1805, died 1869 (G. O. Sars).

The Amphipoda recorded are; 29. Anonyx ampulla (Cancer) Phipps; 30. Anonyx gulosus Kroyer; 31. Anonyx Vahlili Kroyer; 32. Anonyx Holmelli Kroyer; 33. Stegocephalus spec,
a species found by Kroyer but left indeterminate; 34. Pontoporeia femorata Kroyer; 35. Pardalosea cespitosa Kroyer; 36. "Ampelisca Gaimardi" Kroyer; 37. "Ampelisca Sachrichitii" Kroyer; 38. Ampelisca lavigata Liljeb.; 39. Amphithoe serrata Kroyer, with the remark that the fourth side-plate is much too small in the figure in Kroyer's Grønl. Amphip., it being both in Norwegian and Greenland specimens, which Sars had examined, double as long as the third and somewhat deeper. 40. Amphithoe cristata (Acanthonotus) Owen, a species said to be very like Amphithoe serrata, but still more like a remarkable new species from the coast of Norway, Amphithoe parasitica, which is fully described, the Latin description being:—"A. serrata affinis, dignoscitur carina in medio dorsi segmenti thoracici quinta orinata et usque ad segmentum quartum abdominis porrecta, postice in quaque segmento in dentem triangularem cæstum desinente; ocelis magnis, paululum ovalis, convexis; epitome quarto et quinto insolitus magnitudine, anterioribus duplo longioribus, quarto infra et antice, quinto infra et postice in spinam fortis convus-a-cuminatam crente (in epitome quarto uncinitae, in quinto rectam); pedibus thoracicos primi et secundi partis magnitudine multiori et manu subeuforuni praedita; antennis aequationis aut inferioribus paulo longioribus, dividitum longitudinali corporis parum superantibus." This species was referred to Acanthonotus by Boeck in 1860, to Acanthonotus by S. Bate in 1862, and subsequently identified by Boeck with Ephemerina corniger, Fabričius.

A full description is given by Sars of Owen's Amphithoe cristata, which, "in the short form of the body, the sharp serrate-like back, and strong development of the fourth and fifth side-plates much resembles Amphithoe serrata and still more Amphithoe parasitica, but is distinguished from both inasmuch as the dorsal carina extends over all the person-segments and the four first of the pleon (while in both these species it is wanting on the four first person-segments) or, as Owen expresses it, 'segmentis 4 antibus in erista continua superne elevatis.' Where, however, the same author uses, 'religvis in spinis retrorsum inclinatis productis, he is so far incorrect as in fact these spines or processes are entirely wanting on the last three abdominal-segments." By Boeck this species is called Acanthonotous cristatus. The list continues with 41. Amphithoe hystrix (Acanthonous) Owen. Comparing his specimens with Kroyer's description, Grønl. Amph., p. 260, Sars was inclined to regard the Norwegian form as a distinct species from the Greenland, but by comparison of these with Owen's figure, which he says is more correct than his short description, he was convinced of the identity of the forms from the two localities. To Kroyer's description he offers corrections;—"Hovedet har i Midten af Panderenden et meget lidet, men tydeligt, horizontalt, tilgiket Horn, ikke, som Kroyer siger, kun en stump Vinkel. De øverste Følere ere meget mere end halvet eller næsten Totredielde saa lange som de nederste (efter Kroyer nae de ikke disse halve Længde); Skæftets første Led udsender fra Enden af sin øverste Rand en opad og udad rettet stærk og spids Torn, som næsten er ligneæ lang som selve Ledlet (efter Kroyer er denne Torn lang mindre) eller som andet Led, det tredie Led er kun halvt saa langt. Stiften, undersøgt kun hos et enkel Exemplar, bestod af 70 Led (efter Kroyer 'af 20 Led og dorover'), af hvilke de 7 (efter Kr. de 4) første Led have i deres underste Rand smaa Haarknupper, men af alle de fuldende Led viser, som Kroyer meget rigtigt anfører, kun hvert andet Led Haar og hvert andet er blottet for dem. Svinens første Led er af Længde som Skæftets tredie Led (efter Kr. er det betydeligt længere). I de nederste Følere Skæfte taltes hos det samme Exemplar 111 Led (efter Kr. bestan den 'af i det mindste 50 Led').

De øre Brydisegmenter ere, som Kroyer rigtig fremstiller det, beskrives med 5 eller, naar man regner Sidepladsernes Pig med, 7 Rekker af Pigge; Bagkroppens 2 første Segmenter viser derimod kert 9 Pigge (af hvilke de 2 nederste ere de mindste), det tredie 5, det fjerde 3, det femte og sjette 2 (det Pigge paa Midthirien af disse Segmenter mangler), og det syvende ingen. Heraf sees, at det rette Forhold ikke rigtigt fremstilles af Kroyer, naar man kun angiver 7 Pigge paa Bagkroppens andet Segment og slet ingen paa det femte og sjette.
Owen’s Afdelning stemmer derimod med Hansen til alle disse Pigges Form, Antal og Anordning ganske overens med Forholdet hos vor norske Form. Mindre nøjagtig er hans Beskrivelse, naar det hænder, at ’fjerde og femte Caudal-segment havo 3 og de andre kun 2 Pigge.’ Dette er urigtigt for det femte Segments Vedkommende, som i Virkeligheden kun har 2 Pigge, saaledes som Owen’s Fig. 7 ganske rigtigt udviser. Det første Brystsegment har, som baade Owen og Kroyer angiver, 10 Pigge, idet de 3 midterste ere dobbellete; den forreste Pig paa Midtlinien er den længste og ligger horizontalt fremad strakt og ligesom et Horn frembruget over Hovedet.—Hos Exemplarer af ¼’ Længde befandtes alle Kroppens Pigge allerede fuldkommen udviklede ligosom hos de voksne. Alle Sideplader ende nedenfor med en Pig, den fjerde og femte, hvilke ogsaa ere længere end de andre, hver med 2 Pigge. Da hverken Owen eller Kroyer har iagttaget Dyret i levende Tilstand, tilfoies sluttelig, at Kroppens Farve er gualbrun, Brystfødderne og Fødderne med rosemåede Ringe, oftest ere ogsaa Kroppens Pigge i Spidsen rosemåede. Øjnene ere bruntört, temmelig store (ikke ’smaa og hvide,’ som Owen siger), cirkelrunde, halvkugleformig frembruget, deres ydre Flade viser talrige polygonale Facetter.” For discussion of the species of *Acanthosaoma*, Boeck’s *Acanthosaoma*, see Note on Lepechin, 1778. Bacholz, in his description of “*Acanthosaoma hyaline* Owen,” in 1874, does not allude to Sars’s description. The long and strong spine of the upper antenna which Sars mentions is not shown in Bacholz’s figure, though to an unfigured small specimen he attributes ‘am ersten Basalglied der oberen Antenne ein ziemlich langer schlanker, am äussern oben Ende befindlicher Stachel.’

The next species is 42. Amphithoë panopla Kroyer, in regard to which Sars finds that "I Pigkkroppen hos vor norske Form er meget mere knæret," and after mentioning some other variations from Kroyer’s description, suggests the name *Amphithoë panoploides*, in case the Norwegian form should prove to be specifically distinct, which, however, Boeck does not consider it to be. 43. Amphithoë latipes Sars, nov. spec., is by Boeck called *Amphithoës latipes*. 44. Amphithoë serraticornis Sars, nov. spec., is identified by Boeck with *Calliopus exiliscutus*, Kroyer; 45. Amphithoë fulvocecata Sars, nov. spec., becomes in Boeck’s work *Halirages fulvocecatus*; 46. Amphithoë macrocephala Sars, nov. spec., is identified with *Dexamine bispinosa*, Spence Bate, as *Halirages bispinosus*; 47. Amphithoë albomaculata Kroyer (A. podoceroides H. Rathke), is probably *Amphithoë rubricata*, Montagu. Of the following many are discussed elsewhere; 48. Oäceros saginatus Kroyer; 49. Oäceros lyneus Sars, nov. spec.; 50. Gammarus locusta (Cancer) L.; 51. Gammarus mutatus Liljeb.; 52. “Gammarus Salini” Leach; 53. Gammarus dentatus Kroyer, redescribed; 54. Gammarus fissicornis Sars, nov. spec., by Boeck called *Liljeborgia fissicornis*; 55. Podocerus capillatus H. Rathke; 56. Ischyrocerus minutus Liljeb.; 57. Leucothoë norvegica Liljeb.; 58. Leucothoë phylloxyx Sars, nov. spec., by Boeck made the type of a new genus, as *Aceros phylloxyx*; 59. Glacumeone leucoips Kroyer, in regard to which Sars says that the eyes which Kroyer describes from examples in spirits as “smaa og lidet tydelige,” are in the living animal “stærkt iøjefaldende ved deres afstikkende opak melkehvide Farve,” and “paa de 3 fornste Abdominalsegmenter findes paa hver Side af Ryggen en læn, men temmelig bred, conisk-hjørnede Keule, som ikke omtales af Kroyer, og efter Figuren i Gaimard’s Voyage en Scandinavie, Crus. Tab. 19 Fig. 1, synes ogsaa disse Segmenter at være ganske glatte. De undre disse 3 Segmenter siddende snakkelte ’falske Fødder’ finder jeg temmelig store (ingenlunde ‘smaa og korte’ som Kroyer Siger)."

The ovaries are described as lying dorsally upon the gut and liver-tubes on either side of the heart, forming two cylindrical tubes closed at either end, reaching from the second to the sixth person-segment with an oviduct opening in the fourth segment. The inner surface is covered by an epithelium layer which is supported by a Tunica propria of finely granular appearance, and that in turn is surrounded by an outer skin which is homogeneous.

[Bruzelius traces the ovaries from the first to the seventh segment, with the opening of the oviduct at the base of the marsupial plate of the fifth segment. G. O. Sars traces the ovaries from the second to the seventh, with the opening of the oviduct as stated by Bruzelius in the fifth segment]. Neither la Valette nor Bruzelius could discover the lobes of which according to Spence Bate (1855) the ovary of Gymnarchus is composed.

The first origin of the Amphipod-egg is derived by la Valette from an epithelial cell of the ovary. In eggs not far developed he found a sharply defined membrane, a finely granular content, a germinal vesicle and many germinal spots. With further development of the egg-cell violet-coloured drops appear in the hitherto colourless contents, which soon as smaller or larger strongly refracting globules fill the whole egg and conceal the germinal vesicle. The coloured yolk develops itself within the cell-membrane.

La Valette could never succeed in observing zooosperms in immediate proximity to the egg or within it. Of the two skins of the egg one in later stages of the embryo's development sometimes disappears, but the one remaining is not, he says, as Meissner supposes, the chorion or outer, but always the inner, or yolk-skin. The inner skin has a finely shagreened appearance; the outer is completely homogeneous.

He thus sums up his view of the earlier stages of the development of the egg. An epithelial cell of the ovary increases in size, its nucleus becomes the germinal vesicle and fills itself with germinal spots, while within the cell-membrane the development of the fine-grained yolk begins. Along with this and perhaps partly at its expense along with the increasing size of the egg appears the violet yolk. The former he calls the formation-yolk, the latter the nourishment-yolk, which at successive stages changes from violet to brown-red and finally to yellow-brown. The formation-yolk divides and perhaps with it the germinal vesicle. In this way arise the yolk-balls including a nucleus, and these after continued division by hardening at the periphery obtain a membrane and become the cells of the embryo-skin. When this has completely sheathed the nourishment-yolk, the whole egg-content draws back on one side from the egg-skin, and by a constriction on that side is divided into two unequal portions still connected on the opposite convex side. On the side where the constriction has taken place the cells of the embryo-skin put out protuberances, marking the position of arteries, mouth-organs and limbs.

A full discussion follows of the micropylar apparatus of the Amphipod-egg, which Meissner first discovered in Gymnarchus pulex. It is confined to the inner or yolk-skin, the outer skin or chorion being completely closed. It lies, not as Meissner supposed, at the pole of the egg, but near the greatest diameter of its breadth. At its central point is a small tap with two small openings. The apparatus occurs at the part of the egg corresponding with the back of the embryo and the third person-segment of the developed animal. It is attached to a spherical sack which extends into the heart of the embryo, and which is still observable in
REPORT ON THE AMPHIPoda.

321

a young animal just escaped from the pouch, though it afterwards disappears. In regard to
the use of the apparatus, reference is made to the observations of Leuckart upon the
development of the Pupipares, showing that the microplex may have another function than
the reception of zoosperms, namely to act as a funnel for the introduction of nourishment.
In the case of Amphipods the Valette suggests that it may serve as a respiratory apparatus.
He recognises that the outer egg-skin is completely closed, as well as the sack in connection
with the microplex, but he thinks that both might be permeable to the medium surrounding
them.

1860. Boeck, Axel, born 1833, died 1873 (G. O. Sars).

Bemerkninger angaaende de ved de norske Kyster forekommende Amphipoder.
Forhandlinger ved de Skandinaviske Naturforskeres ottende Mode i Kjøbenhavn

Boeck thinks it likely that the division of the Amphipoda into the three principal groups,
Hyperidea, Gammaridea, Cephalidea, will always retain its value, while with growing knowledge
the minor subdivisions must be subject to variations. In his own classification he has paid
regard, he says, not only to the form of feet and tail, but even more particularly to parts
less open to view, the mouth-organs, the maxillipeds and the branchiae. Besides the
characters already in use, namely the presence or absence of palps in maxille and mandibules
and the number of joints to the maxillipeds, he considers the form of the inner plate in the
first pair of maxille and its garniture of hairs to be of high importance. He attaches weight
also to the arrangement of teeth and hairs at the upper end of the cesophagus, although from
the difficulty of the investigation he will not for the time delay over these points. He calls
attention to a double armature of teeth which the males of many species possess as opposed
to the females, and which he notices especially in the mandibules and first and second
maxillae. This, on which he no longer lays stress in his great work, is no doubt only a
misapprehension caused by the appearances which precede the moulting of the Crustacian
skin.

In his Classification of the Norwegian Amphipoda Boeck places first the tribe Hyperidea, Dana,
because he considers it to be united by a new and very remarkable form, Trischizostoma, to
the family Orchestide, as well as to the genera Anonyx and Opis among the Gammaridea.

In the subfamily Hyperidea he places "Hyperia galba, Mont. (Latreillii Edw.); Hyperia
spinipes, n. s.; Lestrigonus exulans, Kroyer; and "Lestrigonus Boeckii," n. s. (presumably
named after Professor Chr. Boeck), both of which he subsequently united with Hyperia
galba as synonyms of Hyperia medusarum, O. F. Müller.

In the second tribe, Posingomate, Boeck, he places the single new genus and species, "Trischizo-
stoma Raschii," Esmark and Boeck, in which, however, the genus at least is assuredly a
synonym of Guerinia, Hope and Costa.

In the third tribe, Gammaridae, for the first family Orchestidea, he refers to two genera occurring
on the Norwegian coasts, but only makes mention of "Allorchestia Nilsonii," Rathke’s species
which has since been named Hyale nilsonii. In the second family, Gammaridea, he gives
the following new species, Anonyx serratus, which he afterwards named Orchooneue serratus;
Anonyx pinguis, which becomes Orchooneue pinguis in his later work; Anonyx obtusifrons,
changed later on into Muniprates obtusifrons; "Anonyx Brezzi," dropped out of his later
works except for a reference in the Index of De Skand. og. Arkt. Amph., to p. 157, from
which it may be inferred that he identified his species with Anonyx galbus, Kroyer;
Ichnopyges spinicornis; Urothoe norvegica. He then mentions Bathyporeia pilosa, Lindstrom,

(zool. chall. exp.—part lxvii.—1887.)

XXX 41
from the description and figures of which his own specimens somewhat varied. His next new species is Pontoporia armata, which he afterwards named Priscilla armata. The genus Edicerus, Kroyer, he thinks should form two separate divisions, one containing sigutatus, Kr., affinis, Brux., lyceus, Sars, and norvegicus, n. s., the other norv-eulandiaz Dana, and obtusus, Brux. For the latter division he institutes a new genus, Acros, using a name pre-occupied among Aves (although there with a different meaning and pronuciation), and taking Acros obtusus, Bruzelius, as the type, which he afterwards named Acros phylloponus, Brux. This new species, Edicerus norvegicus, he renamed in 1870, Pontoporia norvegica, giving it as a synonym Krøyeria arenaria, Spence Bate, 1863. Spence Bate's genus is in fact not the pre-occupied Krøyeria but Kroyeria, which perhaps lapsed as a synonym of Monoculodes, and the species Krøyeria arenaria dates, not from 1863, but 1858, taking precedence, therefore, of Boeck's norvegicus. Boeck next gives Amplexica spinipes, n. s., stating that it is very like Amplexica squicornis, Bruzelius. For a specimen described by Liljeborg as Lencothoe articulosa, Montagu, he proposes a distinct name "Lencotho Liljeborgii," which in his later works he hesitates to uphold. He recognizes that Lencothoe articulosa should be called Lencothoe spinicornis, Abildgard. Making Probolium, Costa, a synonym of the earlier Stenotho, Dana, he adds a new species "Stenotho Dana," which he afterwards found to be synonymous with Stenotho (Montagu) marina, Spence Bate, 1855. After pointing out the resemblances between Eosirus and Lencotho, he adds a new species, Eosirus longipes. For Gammarus brevicornis, Bruzelius, and Gammarus fuscicornis, M. Sars, he establishes a new genus, Iluna, a name pre-occupied among Birds and Amphipods, and consequently in Boeck's later works giving place to the synonymous Liljeborgia, Sp. Bate, 1862. Iluna brevicornis he afterwards identified with Liljeborgia pallita, Sp. Bate. To Dexamine he adds a new species, "Dexamine Theo." For Amphithoe compressa, Liljeborg, he establishes the new genus, Epidesura, which was dropped when later on he found the species in question to be Atylus (Amphithoe) surmountianus, Milne-Edwards, 1836. He makes a new species, "Gammarus Batei," of which no notice is taken in his subsequent works, probably because he thought it too obviously a Gammarus lusula to be worth further mention. To the genus Paroamphithoe, Bruzelius, he leaves the species panopla and pulchella, but establishes a new genus Amphithopsis to receive the species, bicornis, elegans, brevisetosa, tridentata, and the two new species Amphithopsis glaber and Amphithopsis longicornis, the former of which he transferred first to Paroamphithoe, and afterwards to Planes, retaining the latter as type of the genus Amphithopsis. He discusses the genus Acanthonotus, Owen, which he afterwards called Acanthomoeóma, and the neighbouring genus, Iphimédia, Ratke. To Acanthomoea, Owen, he assigns the species, Acanthomoea hysterix, Owen, Amphithoë parasitica, Sars, and Eptemeria triceritata, Costa. He afterwards found reason to name the first Acanthomoea cuspidata, Lepechin, and the other two, Epimeria cornigera, Fabricius.

In his third family, Corophidae, Dana, Boeck places a new genus, Pontocerops, with a new species, "Pontocerops Sophia" (afterwards Sophias), for its type. After some discussion of species which he considers to belong to Leptocheirus, Zaddach, and to Gammaropsis, Liljeborg, respectively, he describes a new species, Amphithoe grandilatior, and a new genus, Hela, with a new species, Hela modesta, for its type. The name Hela, being pre-occupied, has been changed by S. I. Smith to Nechela.

The fourth tribe he calls Caprilidae. In it he places Proto pedata, afterwards recognized as Proto ventricosa; Eōina longicorina, Kroyer, he here assigns to Protella, though he afterwards called it Eōina phosma, Montagu, being properly Protella phosma; to Eōina, Kroyer, he adds the new species, Eōina (Cyprella) echinata, Eemark, which he afterwards claims as his own species, and Eōina laxis, which, according to Mayer, is the young of Eōina longicorina, Kroyer. He next establishes a new genus, Eōinella, with a new
species, *Eugenilla spinosa*, as type, also assigning to this genus *Eugena tronella*, Dana, and *Eugena acutata*, Dana, but in both cases according to Mayer without good reason for so doing. To *Caprella*, Lamarck, he adds three new species, "*Caprella Esmarkii*," *Caprella lacticornis*, *Caprella punctata*, the first two of which Mayer identifies with *Caprella equilibra*, Say, and the third a little doubtfully with *Caprella septentrionalis*, Kroeyer. Boeck himself in his last work inclines to identify *Caprella esmarkii* with *Caprella equilibra*.

In this work the descriptions of new genera are not very formally drawn out. That of *Tri Chiostoma* follows the statement that three specimens, all females, were captured by Professor Rasch off Séndino, by sinking a dead bird, if he remembered rightly, to a depth of about 100 fathoms, and is given thus:—"The deepest Individ. measured 45 m., and the one cited lies on of the sides inland the Amphipodera of the genus. Legen. is stappled by the first from the side to the anden; Ryggen rundt uden Kiel; Hovedet springer fortill frem i et langt og bredt Rostrum, der dækker Roldene af de øvrige Antenner. Øjnene er meget store og dække som hos *Hyperidernae* mesten hele Hovedets Sider samt støde mesten sammen oveni; de øvrige Antenner er de korteste; Skællet lidet og kort; Svøben dannes af et noget langt, paa den indre Side hårdekket forst, samt 12 til 14 andre kortere; Biøven bestaan ligeligt af et langt første og to meget mindre fuldendende Led. De nedre Antenner er en Trediedele lengere end de øvrige; Skældets tre første Led ere meget korte; de de fuldendende og inddyndes af samme Længde, hvorhos det første af disse er paa den indre Side angstet; Svøben bestaan af heved 20 Led. De stemme saaledes overens med Antennerne hos *Hyperidae* og Slegten Anonyx. Munddelede see ud som en trespalte fremstukt Tubus, som er dannet af de overordentlig forskellige Overlæge og de omdannede Maxillarfødders ydre Plader. Indenfor denne Tubus, efter hvilken Slegtsnavnet er givet, findes de spindes, stærkt forskellige, men spidse Mandibler og Maxiller, der ligne et Slags Bønde. Maxillarfødderne ere forsynede med firkantede og Mandiblere med treledede Palper. Første Par Fødder er omgivet til stærke Grifleresikker af en spændende Bygning; femte Led eller Haanden er meget stor, spidst, og fastet ved den indre Side til det foregæende Led. Kloden er ikke som sædvanligt fastet til den nedre Vinkel, slænede sig mod den bagre Rand med Spidsen opad, men er fastet til den bagre øvre Vinkel med Spidsen nedad; den stemmer saaledes i dette noget overens med Kroeyer's Slegt *Opis*. Det andet Par Fødder er dannet som hos Slegten *Anonyx*. Det tredie og fierte Par ere ulige; fierte Pars første og især tredie Led ere stærkt skibskformet udvidede, medens de hos tredie Par ere smalleere. De tre fuldende Par ere af den sædvanlige Bygning og tillige efterhaanden i Længde. Halen er meget bredt og stemmer i sin Form meget overens med *Hyperiderinae*, men de tre bagre Par Halo-beens Pedunkler ere kortere end hos disse. Andet Par Epimerer er særdeles stor, trekantedet med Basis nedad og den afstumpede Spids opad og skiber næsten det første Par.

"Pyret lignet saaledes *Hyperiderinae* i Hovedets, Øjenes, Antenneres og Halens Bygning, tildeels ogsaa ved Maxillarføddernes ydre Plade, der er operculiform; men her findes Palper, som *Hyperiderinae* nogle. I det Hele taget ere Munddelede hos dette Dyre i skifromelige, og synes at være bestemte til Sugning. Det nærer sig i flere Henseender *Orchididerinae*, men har ogsaa meget tilfælles med Slegterne *Opis* og *Anonyx* blandt Gammariderne ved Antennerne og Føddernes Danmæle."

I have given the above in the original language, as the translation by Dallas is accessible in the "Annals and Magazine for May, 1850," and the Latin description will be given further on.

The following remarks on the two species *Eucercus novi-zelandiae*, Dana, and *Eucercus obtusus*, Brunelsius, supply all that is here given by way of definition for Boeck's new genus, *Acetes*; as distinguished from the other species of *Eucercus*, in these two, he says, the upper antennæ are elongate, the rostrum is wanting, the eyes have their ordinary lateral position. The point of the mandible is not dentate, and the second joint of its pulp differs in form.
from that in _Edicerus saginatus_. The inner plate of the first maxilla is large and furnished with several strongly ciliated hairs. From regard to the marsupial plates and their relation to the branchiae, he would place _Edicerus_ and _Aceros_ rather with _Phoebus_ and the like than near to _Gammarnus_. In the form of the hands of the gnathopods he finds an approach to the subfamily of which _Leucothoe_ is the type. Whether _Aceros_ with a short penultimate syllable should be considered pre-occupied, because a genus of birds was called _Aceros_, with a long penult, is perhaps an open question.

For the new genus, _Iduna_, or at least for the two species which constitute it, he gives the following characters:—The accessory flagellum is especially long; while the principal flagellum of the upper antennae is short. The lower antennae are strong and almost subpediform. The molar tubercle of the mandibles is small; the inner plate of the first maxillae is, as in _Eusirus_, oval and furnished with a single plumose seta; the biting-plates (Tryggeploder) of the maxillipeds are small and their palps much elongated. The first two pairs of legs are provided with strong clasping hands, their fourth joint sending out from the lower hinder angle a strong process, as in _Leucothoe_; the following pairs of legs are very thin and long, the last pair is very long; the uropods (Halefodhern) are long and the telson deeply cleft. The first side-plate (Epimeron) is strong, larger than the next one. Thus they show great agreement with _Eusirus_, and differ much from the typical species of _Gammarnus_.

The marsupial plates, he says, in this genus are small, the branchiae long and broad; the palp in the first maxilla has the first joint short. Alas! he says, in _Eusirus_ and _Iduna_, the inner plate of the first maxilla is larger than [in] the other [members of the group], but in all furnished only with one bristle. In 1876, he says that this plate in _Liljeborgia fissicornis_ has one very long plumose seta and a smaller seta not plumose, and that in _Eusirus cuspidatus_ it has two plumose setae.

His genus _Epidesura_, he says, in many characters approaches _Dexamine_, Leach. The form of the antennae is as in _Dexamine_; the mandibles, however, have a very thin, weak, triarticulate palp; the palp of the first maxilla is bi-articulate, and the inner plate is furnished with six ciliated hairs; the biting-plates of the maxillipeds are large, the palps small, thin, with their fourth joint forming a small finger (Klo). The marsupial plates are especially large, furnished on the edges with close-set, long hairs; the branchiae of the last thoracic legs are of the same peculiar form which is found in _Ichnopus_; the two last segments of the pleon are coalesced and the telson is divided; the body is strongly compressed.

The new genus _Amphithoeopsis_ is instituted for those species (taken from _Paramphithoe_), Bruzelius, and united to two new ones), which have—an elongate, compressed body with moderate epimera and long antennae; the inner plate of the first maxillae furnished with four to five long, thick, plumose setae; the inner plate of the second maxillae with many simple setae at the extremity, but several on the inner side very strong and plumose; the maxillipeds large, with palps of moderate length; the two first pairs of feet with hands of nearly the same size, small; the third and fourth pairs of legs with the fifth joint very long, longer than the third joint; the telson simple; the last uropods with the branchiae long, often unequal; the marsupial plates much larger than the branchiae, closely margined with hairs.

In the new genus _Phoebocorpus_, the body is somewhat depressed, the epimera small, the antennae long and thin, the upper attached far in advance of the lower at the point of the projecting head. Their peduncle is very long, longer than the flagellum and without accessory flagellum. The mandibles are large, at the extremity divided and dentate, with long triarticulate palp. The palp of the first maxilla is biarticulate, the inner plate small and thick. The maxillipeds are long, narrow, with the fourth joint of the palp divided into two joints, of which the last forms a pointed tail (Klo). The two first ("sidste," last, by an obvious mistake for "förste," first) pairs of feet having the fifth joint forming a clasping hand, which in the second pair is much larger than in the first, and not
of the same size in both sexes. The three hinder abdominal-feet are biramous, the rami conical, without spines. Telson small and thin.

Of *Hela*, he says:—"This remarkable new genus is characterized by a long, narrow, depressed body; small, nearly rudimentary epimera; very long legs, of which the first two pairs are furnished with strong clasping hands, the first larger than the second; the last three pairs have the first joint not at all dilated, but narrow and cylindrical like the following joints; the fingers long and conical. The tail is of the usual form, without any of its segments coalesced. Its first three pairs of feet are especially long and thin, the two following pairs biramous, and the last particularly thin, uniramous [genet for engrenet], the rami longer than the peduncle. The mandibles have a divided, dentate point, a prominent molar tubercle, and a thin, triarticulate palp. In the first maxille the palp is long, thin, two-jointed, the inner plate small, furnished with a few bristles. The maxillipeds are very strong, with four-jointed palps. The branchial vesicles are found at the bases of the legs from the second to the sixth pair."

As to the new genus *Æginella* he gives his views in two passages; first he says, p. 670, under *Æginia*, Krøyer:—"Krøyer characterizes this genus by the triarticulate palp of the mandibles, and the biarticulate tail with two pairs of appendages, of which the first pair are biarticulate, the second uniarticulate. Dana refers to this genus some species, which differ from the type species *longicornis* by the structure of the tail, and he believes that this is of little systematic importance. But, as I have found two new species which completely agree with Krøyer's characters for *Æginia*, and besides, a species which is like these in that the mandibles have palps, but the tail of which is constructed as in the genus *Caprella*, I think that Dana's species must be transferred from *Æginia* to a new genus, of which this species of mine is the type. To this genus I have given the name *Æginella*." On p. 673, under *Æginella* mili, he says, "This genus, which forms a link between the preceding genus [Æginia] and that which follows [Caprella], I have already characterized by its not having palps on the mandibles, and by the tail being, as in the genus *Caprella*, biarticulate, with unjointed appendages" ("ved at den mangler Palpe paa Mandiblerne, og ved at Halen er, som hos Sletten *Caprella*, toledet mel uledede Appendices"). The discrepancy in the second statement is no doubt accidental, there remains, therefore, the single point in which *Æginella* differs from *Æginia*, namely, in having the abdominal feet unjointed. But Mayer points out, Caprelliden, p. 36, that Böcek is wrong in supposing the abdominal feet in *Caprella* to be unjointed. It is easy, therefore, to suppose that he may have made the same mistake in regard to the specimen which he names *Æginella*, in which case that genus will fall to *Æginia*, unless, since that is a preoccupied name, *Æginella* may be accepted as its substitute.

1860. LEYDIG, FRANZ.

See Note on Leydig, 1878.

1860. LÜTKEN, CHRISTIAN FREDERIK, born 4 October, 1827 (C. F. L.).

The preliminary object of these remarks was to show the error of the common supposition that there was only one species of *Cyamus* in the North Seas. Lütken here distinguishes six
species, leaving the name *Cyamus ceti*, Lin., to that parasitic on *Balaena mysticetus*, and giving the name *Cyamus nodous*, Ltk., to that living on the Narval, figured in the *Zoologia Danica*, tab. 119.

1860. **Philippi, Rudolph Amandus**, born 1808 (Hagen).

Among the Crustacea Philippi describes one Amphipod, at page 170, thusː—"Amphithoe andina Phil.

"Die *obern Fühler* sind so lang wie der vierte Theil des Körpers; die drei Glieder des Stieles sind gleich lang, nehmen aber von der Basis an allmählig an Dicke ab; die einfache, vielflächlige Geisel ist so lang wie der Stiel. Die *untern Fühler* sind etwas länger als die oberen, etwa so lang wie der dritte Theil des Körpers, im übrigen sind sie denselben ähnlich [ähnlich]; das Grundglied des Stieles ist etwas kürzer als das zweite, welches so lang ist wie das dritte; die Geisel ist etwas länger wie der Stiel. Die *Augen* sind klein und eiförmig. Das *erste Fusspaar* ist sehr kurz, kaum so lang wie das erste Brustsegment; seine Glieder sind ziemlich gleich lang; das drittletzte und das vorletzte sind dreieckig, das letzte kaumartig gegen das vorletzte umgeschlagen und so lang, wie der Vorderrand desselben. Das *zweite Fusspaar* ist wenigstens doppelt so lang, gleichfalls zum Greifen eingehender; das drittletzte Glied ist viel breiter als lang und nach hinten in einen Lappen vorgezogen; das vorletzte ist gross und dreieckig; das Klauenlid ist ebenso lang wie der Vorderrand des vorletzten Gliedes. Das *dritte und vierte Fusspaar* sind so lang wie das zweite und haben cyndrische Glieder. Das fünfte, sechste und siebente Fusspaar sind bedeutend länger als die vorgehenden, zeigen aber sonst die gewöhnliche Bildung, dasselbe gilt von den Anhängern des Schwanzes.—Die *Farbe* ist grau.

"Bemerkung. Diese Art weicht etwas von Amphithoe ab, indem die Hände dreieckig und nicht eiförmig, und die *obern Fühler* kürzer als die unten sind, doch scheint mir der Unterschied nicht erheblich genug, um eine generische Trennung zu rechtfertigen.

"Häufig in den Gewässern des hohen Theiles der Wüsteː z. B. Cachinal de la Sierra, Agua de Profetas, Rio frio etc.

The account of this species I have quoted in full, as I was neither able to find it mentioned in Mr. Spence Bate's Catalogue, nor to find Philippi's work in the British Museum. It may, I think, be presumed that the species belongs to the genus *Hyalella*, S. I. Smith, and may even be identified with the species *Hyalella inermis*, Smith; the name would be *Hyalella andina*. Philippi calculated the height of Cachinal de la Sierra by the quick-silver barometer at 7516 feet, by the Aneroid, in which he placed less trust, at 6290 feet, above the sea. Agua de Profetas, he says, lies 9180 feet above the sea, therefore, about at the height of Quito. At this place, he says, p. 56, "im Wasser waren Flohkrebse, Amphithoe andina, u. sp., Elmis, und kleine schwarze Blutegel, aber keine Schnecken, Mückeinarven etc. Auch sah ich sonst kein Insekt irgend einer Art." At page 89 he says, "Der Lagerräum von Rio frio liegt 10500 Fuss über dem Meere," and at page 91, after describing "die Vegetation des Theiles von Rio frio," he says, "im Wasser waren die gewöhnlichen Flohkrebse und Elmis."

*Hyalella inermis*, S. I. Smith, has been taken by Mr. Edward Whymper at heights still greater than those mentioned by Philippi for the habitat of his Amphipod.
1860. Vollenhoven, Samuel Constant Snellen, van.

Under "de Amphipoden of vloekraven," he mentions Rosell's species under the name "Gammarus Rossellii Gerv.," Pl. ii. fig. 1, distinguishing it from "Gammarus Pelae Le.," and Gammarus putucus Koch. He mentions also Talitrus saltator, Edw., Pl. i. fig. 5; Orchestia littoralis, Leach, Pl. i. fig. 6, of which he discusses the phosphorescence; "Corophium longicornes Dese," Pl. i. fig. 7; "Caprella lobata Latr.," of the female of which he gives a woodcut; and lastly, "Leptomera pelata Latr.," Pl. ii. fig. 2, with a reference to Slabber, "Natuurk. Verlust. Plaat X, fig. 1, 2." The figure shows that Proto ventricosa, O. F. M., is in question, though the explanation of the plate calls it Caprella linealis, probably by an accidental slip.

1861. Bate, C. Spence.

A new species, "Vihilia Edwardsii," is described, and the differences between the mother and the young taken from the incubatory pouch are given in detail. A new genus, Platyscelus, is thus defined:—"This genus agrees in every respect with Dana's genus Dithyrus, except that, after the base in the third and fourth pairs of pereiopods, the remaining joints are developed, whereas in Dithyrus they are wanting." In the Brit. Mus. Catal., p. 329, Spence Bate adds a note to his description of this genus, "it appears to me to be not improbable that Platyscelus may prove to be the female of Typhis, from which it differs only in the form of the superior and length of the inferior antennae." With Typhis oscula, Risso, Claus decisively identifies the species Platyscelus serratus here described as new. Typhis being preoccupied, Claus renames the genus Eutyphis, though on his own showing, Dithyrus, Dana, Thyropus, Dana, and Platyscelus, Spence Bate, have each, in the order named, a prior claim.

The new genus Brachysetes is thus defined:—"Cephalon anteriorly rounded. Eyes occupying the lateral walls, which encroach upon the inferior margin. Pleon not distended, nearly as deep as the cephalon, and not wider. Pleon nearly as broad as the pereion; fourth and fifth segments fused together. Antennae obsolete or very rudimentary. Oral appendages membranous and rudimentary. Gnathopods completely subebehalete. Pereiopoda having the base of the three posterior pairs largely developed; fifth pair having the remaining joints not obsolete. Pleopoda biramous. Telson single." The type species is Brachysetes crus-culun, of which the female and young are described and figured.

Mr. Spence Bate remarks in regard to the young of the genera he has been discussing, that the adult form which approximates nearest to them is that of the genus Oxycephaeus, "which bears so close a resemblance to the young of Platyscelus, that they might readily be accepted as belonging to one genus." Again, he says, M. Guérin-Méneville's "figure of the young of Rhabdosoma appeared to me to be a fair representation of an adult Oxycephaeus." He thinks that the unimproved type in many genera of the Hyperina is to be found nearer to the young than to the adult form. Alluding to the dwelling of many Hyperina in the gill-cavities of Meduse, he thinks we may assume that eyes, small in the type, have been monstrously increased in these creatures to make up for the depreciation of light that reaches them through the transparent animals they lodge in. To find out their nearest allies among the normal Amphipods, we must compare their young with the more aberrant forms, and
the link Mr. Bate considers is certainly to be found in *Phoxus* and other genera of the subfamily *Phoxides*.

Claus, in 1879, identifies *Brachyscelus*, Spence Bate, 1861, with *Thamyris*, Spence Bate, 1862, and adopts the later *Thamyris* as the name of the genus, perhaps regarding *Brachyscelus* as pre-occupied, but the only earlier name it like in Scudder's nomenclator is *Brachyscelis*.

1861. Bate, C. Spence, and Westwood, J. O.

A History of the British Sessile-eyed Crustacea. Part I., October 1, 1861. Part II., November 1. 1861. Part III., December 2. 1861. Pages 1–144. London. (The dates at which the Parts were published have been kindly supplied by Mr. John Van Voorst, the publisher.)

As this work, now complete in two volumes dated respectively 1863 and 1868, is now in the hands of every one who studies the Amphipoda in earnest, only such notes upon it will be given as are absolutely necessary to the plan of this Bibliography. In the first three parts no new species are included. A "tabular arrangement of the Amphipoda" is given, at page 10, in the following manner:

1861. Beneden, P. J. van.

The same, as a separate extract, Bruxelles, 1861.

The part of this work relating especially to the Amphipoda extends from page 95 to page 99 and is devoted to "les Caprellidés." The five genera allotted to this family are called
Leptomera, Nauprealia, Cercops, *Lexina*, and Caprella. Cyamus is spoken of as non-parasitic, and the Cyamus from *Balena australis* is supposed to be identical with that from *Balena mysticetus*. The genus *Nauprealia*, Latreille, is upheld against those carcinologists who have supposed it to represent a mutilated *Leptomera*. A new species, *Nauprealia tristis*, is figured and described, but it is very obvious that a young and mutilated specimen of *Proto ventricosa* is in question. Considering the habit of the Caprellidæ of clinging to supports by their kind pericasts, to have one of the family naturally destitute of these limbs would be most surprising. *Caprella obesa*, also described as new, is thought by Mayer to be possibly the young of *Caprella aequifrons*, Latreille. The specimen was only two millimetres in length.

The following species are described as new, pp. 135–138, 1. *Lysianassa ciliata*, said by Grube to be " *L. humidi* Costi, simillima," by J. V. Carus, 1885, who quotes the description, thought to be possibly the same as *Lysianassa amboutniana*, Sp. Bate, but separated both from that species, and from the genus *Lysianassa* by the telson, see Note on Grube, 1866. 2. *Amphithoe brevijaurae*, which Grube in 1864, re-named *Dexamine brevijaurae*; 3. *Amphithoe* (*Hyale*) *istrica*, which he called *Nasa istrica* in 1864, and which may stand as *Hyale istrica*, or as *Hyale precosti*, M.-Edw. (see Sp. Bate, 1865); 4. *Amphithoe* (*Amphitonotus*) *aureus*, which in 1864 he called *Dexamine aureus*, a species obviously founded on a malformed specimen of *Dexamine spiniventris*, Costa; 5. *Amphithoe* (*Amphitonotus*) *leptonyx*, in 1864 re-named *Dexamine leptonyx*, and separated by some not very striking marks of distinction from *Dexamine tenunicoris*, Rathke; 6. *Gammarus recurvus*, which in 1864 he named *Crangonyx recurvus*; 7. *Colomastix pusilla*, the type of a new genus thus defined:—

"Genus ad Podocerum aequedens, corpore depresso-rotundatum epimeribus humilibus. *Antennae* breves, articulis paucis, flagellis distinctis nullis, nec tamen pediformes. *Pedis parvis* 1nmi styliformes, 2idi subcheleiformes, proximorum 5 ambulatorii."

In the list headed, "Ausbeute von Triest, Fiume, Portoré und Cherso," besides the species already mentioned, Grube records, p. 125, the capture of *Lysianassa longicornis*, Lucas; *Lysianassa spinicornis*, Costa; *Amphithoe picta*, Rathke; *Gammarus olicii*, M.-Edw.; *Gammarus bousto*, Linn.; *Lencithoë denticulata*, Costa. At page 24 he mentions *Podoceros pulchellus* in a sponge, and at page 73 "eine Gammarine," taken among stones on the banks of the Wanasee, therefore no doubt the *Crangonyx recurvus*, already named.

1861. Heller, Camil.

*Ordasitie botte*, M.-Edw., is the only Amphipod mentioned.

(*Zool. Chall. Exp.—Part lxvii.—1887.*)
1861. **Heller, Camil.**

The only Amphipod described in this work is *Orcheadia inaequalis*, which is said to be strikingly distinguished from all other known species by the unequal development of the gnathopods of the second pair. The expression may be intended to refer only to other species of *Orcheadia*, otherwise the *Melita polimata* which Spence Bate at one time established as a distinct species under the name *Gammarus inaequimanus*, and *Melita (Gammarus) fresnelli* of Savi's Egypt would constitute other well-known species exhibiting the same unequal development. The fact that in Heller's specimen not only was the right gnathopod much larger than the left, but all the five pereiopods on the right side showed a somewhat stronger development than those on the left, makes it highly probable that he had before him a monstrosity rather than a true species. Grube's *Decamere anisopus* seems to be a parallel case.

1861. **Heller, Camil.**

Reports Amphipoda collected from Madeira, 2 species; St. Paul 3; the Cape 1; Chili 2; a total of eight species.

1861. **Herklots, Janus Adrian.**

Symboke carcinologice. Études sur la classe des Crustacés. Leyden, 1861.

1861. **Hogan, A. R.**

See Note on Hogan, 1859.
1861. Kinahan, J. R.

At "the Cnook, a bank about seven miles from land in an easterly direction," he met with several species of Crustacea rare elsewhere, among which he mentions "Tetromatun Bellianus." In the "List of Species obtained in Kingstown and Killiney Bays, and a few from Boldogue," the Amphipoda are "Lysianassa longicornis, Anonyx denticulatus, Ampelisca typicus, Urothoe marinus, Urothoe elegans, Iphimedia obesa, Iphimedia Eblanae, Acanthozetes testudo, Dexamine spinosa, Gammarus locusta, Gammarus flaviatilis, Gammarus palmaat, Gammarus Othonis, Gammarus longimanus, Amphithoe rubricata, Amphithoe littorina, Podocerus falcatus, Podocerus variegatus, Corophium longicorne, Chelura terebrans, Hyperia Galba, Caprella tuberculata," without further information, except a notice that "detailed notes on the species will accompany the final Report."

1861. Lovén, Sven, born 1809 (G. O. Sars).

An account is given of a remarkable marine fauna found in the large fresh-water lakes of Southern Sweden, called on our English maps Wetter and Wener. The Amphipods mentioned are Pontoporeia affinis, Lindström, Gammarus (Gammaracanthus) boricalus, Sabine, and Gammarus cancellatus, Gerstfeldt. The inference from the whole fauna, of which these are a small portion, is that the lakes just mentioned were at one time part of the sea, but cut off from it, along with their inhabitants, by the rise of the land described in works on geology.

1861.

1861. Pagenstecher, Heinrich Alexander, born March 18, 1825 (G. Pfeffer).

*Phronima sedentaria.* Archiv für Naturgeschichte. 27 Jahrg. 1 B. p. 15. 1861.

Some account of this important paper is given in Bate and Westwood, ii. pp. 25, 26. Claus, 1862, makes some observations upon it. See also Delage, 1881, p. 96.

1861. Steenstrup, Japetus, og Lutken, Chr.

Catalogue of the specimens of Amphipodous Crustacea in the Collection of the British Museum. London. 1862. iv and 399 pages. Plates I.—LVIII. with Plate Ia. Plate XXI. has its lower half devoted to Plate XIV.

This ambitious work, beyond the promise of its title, aims at bringing together, in systematic arrangement, all the Amphipoda then known to science. The preface explains that the arrangement of the species follows the classification proposed in the British Association Report for 1855, and adopted in the "British Sessile-eyed Crustacea" then in course of publication, but that observation during the progress of the Catalogue had "suggested a more natural arrangement by the absorption of the Orchestia as a subfamily into the Gammaride, establishing the Phoxides as a distinct family, and placing them between Corophiidae and Hyperiidae."

The new species described and figured are, in Fam. I. ORCHESTIDAE:—Talorchestia ? Africana, with the remark that "it may be the female of the Orchestia that Krauss supposed to be O. Botte;" "Orchestia Aucklandiae," Hab. Auckland, as to which Mr. G. M. Thomson writes to me from New Zealand, expressing the opinion that Auckland Islands must be intended. Orchestia Fuegensis; "Orchestia Nova-Zealandiae," which along with Orchestia tenellus, Dana, G. M. Thomson unites under the common name Orchestia euglycosa, Dana; "Orchestia Telluris," of which G. M. Thomson remarks that it "is by no means a terrestrial species. It lives in burrows in the sand just above tide-marks;" Orchestia megapalophthalma (Orchestia megapalophthalmus, Leach MS., and White's Cat. Crust. B. M.); Orchestia tripodochirus (Leach MS. B. M.); "Allorchestes Pielmuontensis"; "Allorchestes Knückerbockeri," a species which W. Foxon thinks may be synonymous with Ampelisca elegans, Saussure, 1858, and the later Hyalella dentata, S. I. Smith, as Professor Smith had himself suggested, in which case the name would be Hyalella azteca; Allorchestes carinatus; "Allorchestes Sayi"; Allorchestes microphthalmus (Gammarus microphthalmus, MS. Brit. Mus.); "Allorchestes Inca," said to be perhaps a sex-form of Allorchestes hirtipalma, Dana; (for reference of species of Allorchestes to the genera Hyalella and Hyalella, see Note on Rathke, 1857).

In Fam. 2. GAMMARIDE. Subfam. 1. STEGOCHELIDAE:—Montagyna longimaana, perhaps only a variety of Stenochela monocolidae; "Montagyna Guerinii," which Spence Bate says bears a strong resemblance to Stenochela walbus, Dana.

In Subfam. 2. LISIANASSIDAE:—Anonyx longicornis, subsequently transferred by its author to the genus Leptophyreuma; Anonyx obsesus, subsequently made the type of the genus Acubi-stoma, Lilljeborg; Anonyx ampliapodites, Stimpson, MS.; Anonyx punctatius, Stimpson, MS.; Anonyx annulatus, Stimpson, MS.; Anonyx longipes, which with Bate's "Anonyx amphiia, Kröyer," Boeck names Trophoidea longipes, as respectively female and male of one species; Philias rissanus.

In Subfam. 3. AMPELISCIDAE:—Ampelisca ingenus (Pseudopalaethus ingenus, Stimpson, MS.); "Ampelisca Japonica," (Ampelisca Japonica, Stimpson, MS.).

In Subfam 4. PROXIDES:—

Grayia, new genus, is thus defined:—"Cephalon produced, hood-shaped. Eyes two. Superior antennæ not appendiculate. Gnathopod subchelate. Pereiopoda subequal, and terminating in a sharp-pointed curved dactylos. Posterior pleopoda biramous. Telson squamiform, entire." This genus differs from Ceolicerus of Kröyer in having two eyes, and in the fifth pair of pereiopoda not being longer than the preceding."

To this genus two species are assigned, Grayia imbricata, n. s., which, in the opinion of A. M. Norman and myself, is the young of Amathilla saleni, and Grayia pygnetensis, Dana, as to
which Spence Bate in a note, page 104, remarks that Gravgia pauletensis may belong to the genus Caelurus, certainly not to Iphimedia, in which Dana had placed it.

Westwoodilla hyalina, n. s., seems to me not distinguishable from Westwoodilla caerulea, Spence Bate; "Monoculodes stimpsoni," I should have been inclined to unite with Monoculodes carinatus, Spence Bate, but that J. S. Schneider keeps them distinct. Spence Bate in his appendix sinks the name Monoculodes stimpsoni in favour of Monoculodes affinis, Brazilius, Boeck makes Monoculodes carinatus, Spence Bate, = Monoculodes affinis, which G. O. Sars thinks very doubtful. Schneider accepts Spence Bate's second thoughts.

Amphiloche, new genus, is thus defined:—"Cephalon produced, anteriorly depressed. Eyes two; posterior to the superior antennae. Superior antennae not appendiculated. Gnathopoda subchelate; in both, the carpus is inferiorly produced. Pereiopoda subequal; coxae of the third pair not so deep as the preceding. Posterior pair of pleopoda double-branched (I). Telson single."

"This genus is distinguished from Monoculodes by having two eyes situated laterally, from Krögera by having the second pair of gnathopoda not chelate, and from both by the shortness of the posterior pair of pereiopoda."

Boeck accepts the name of this genus, but suggests that it ought to be changed as being preoccupied among the Coleoptera, but the name to which he refers is, according to Scudder, differently spelt, Amphiloche. The third uropods are in fact double-branched. The type species of the genus is Amphiloche manadica, n. s.

"Urothoe Bairdii, n. s." is a synonym of the earlier Urothoe norvegica, Boeck, 1860; Urothoe breviscornis, n. s., as suggested in the Brit. Sees. Crust. i. 198, is not distinct from Urothoe norvegica, Spence Bate.

Liljeborgia, new genus, is thus defined:—"Cephalon not much produced. Pereion long, slender, and compressed. Inferior antennae longer than the superior. Coxae not deeper than their respective segments. Gnathopoda resembling each other in form; second pair larger than the first, subchelate; carpus continuous with the propodite, and produced anteriorly along its inferior margin. Pereiopoda having the dactyl styiform. Posterior pair of pleopoda biramous. Telson single, entire."

"This genus is distinguished from Urothoe by the large gnathopoda, small coxae, and the form of the telson."

The type of this genus is Gammarus pallidus, Spence Bate, 1855. Boeck established a genus Iduna in 1860, which is synonymous with Liljeborgia, but through prior yields to it, the name Iduna being preoccupied. It should be noted that the telson, described as entire, is in reality deeply cleft.

"Phedra Kivakani, n. s." Boeck thinks may belong to the genus Liljeborgia. Lysianassa spinifera (Stimpson, Mar. Invert. Grand Manan, p. 49) is not mentioned in the index, but the description is quoted under the genus Phedra, with the remark that it "seems to be closely related to this genus, only differing from it, apparently, in the telson consisting of two long spines."

Otus, new genus, the name of which being triply preoccupied, was changed by Liljeborg into Ostus, is thus defined:—"Cephalon produced anteriorly. Pereion distended. Pleon compressed. Antennae simple, subequal. Mandibles having an appendage. Maxillipeds unguiculate. Ischia having a broad plate nearly as long as the four succeeding joints; bases furnished with a long narrow process. First pair of gnathopoda chelate; second subchelate. Pereiopoda short, robust, strong. Posterior pair of pleopoda biramous. Telson single, squamous."

"This genus differs from Iphimedia in the form of the maxillipeds, in the distinctly chelate character of the first pair of gnathopods, and in the larger relative proportions of the second." The type species is Otus carinatus, n. s.
**THE VOYAGE OF H.M.S. CHALLENGER.**

In Subfam. 3. **GAMMARIDES**:

Brachylites, new genus, is thus defined:—"Cephalon not produced into a rostrum, but elevated into a crest. Antennae subequal; the superior without a secondary appendage. Gnathopoda subequal, subchelate. Four anterior coxae as deep as their respective segments of the peduncle, not narrow or pointed. Three posterior pairs of pereiopoda short, subequal, having the base dilated at the upper posterior extremity, and narrowing with a concave sweep to the lower. Posterior pair of pleopoda biramous. Telson squamiform, divided." The type species, *Brachylites latissimus*, is referred to "Gammarsus latissimus, Brandt, *Voyage de Middendorff*," the figures and descriptions having been "taken from specimens sent by Professor Brandt to the Museum at Paris," but, as already explained, that species was in reality instituted by Gersfeldt, and is retained by Dybowskii in the genus Gammarsus.

"Dexamine Blossemilliana n. s.;" "Dexamine Longibrini, n. s.," in the appendix held to be a variety of *Atylus swammerdami*; "Atylus Huxleyanus n. s.," probably belonging to Boeck's genus *Halitrigon*; *Atylus villosus*, n. s.; *Atylus gibbosa*, n. s., called *Tritaxa gibbosa*, in Boeck's arrangement; *Atylus austrias*, n. s.; *Theresa cirrus*, n. s., identified by Boeck with *Amphithoe bicapitis*, Kroyer, which G. O. Sars places in the genus *Paraamphithoe*, Brandtus; "Theresa Barretti, n. s.; Calloipe Ossiani, n. s.," united by Boeck to *Amphithopis latipes*, M. Sars, 1858; *Calloipe grandisculus*, n. s., a variety of *Calloipe longicruris*, Kr.; "Eusirus Helvetior, n. s.," which Boeck assigns to his own *Eusirus longipes*, 1860.

The genus *Seba* is thus defined:—"Slender, smooth. Antennae long, subequal. Coxa small, four anterior deeper than the three posterior. Gnathopoda uniform, subequal, chelate." The type species is *Seba immersus*. For both genus and species the authority is hesitatingly given as "A. Costa, *Pochi Costi di Messina*." Professor A. M'Nee-Edward has kindly searched for the paper referred to, but without success. The genus is not mentioned in de Nate's letter to Costa, 1850 (see Appendix). See also Note on *Seba*, 1758-1760, p. 18.

**Gossea**, new genus, is thus defined:—"Slender, compressed. Superior antenna without a secondary appendage, and having the joints of the peduncle short and subequal. Gnathopoda subchelate; first pair larger than the second. Posterior pair of pleopoda biramous; rami longer than the peduncle and extending considerably beyond the telson. Telson single, squamiform."

"The animals of this genus are very likely, upon a superficial examination, to be confounded with those of *Microdentopus*; but the differences in the superior antenna, posterior pair of pleopoda, and telson, are considerable and important." The type species is *Gossea microdentopus*, of which the spelling was afterwards corrected to *microdentopus*; both here and in the "British Sessile-eyed Crustacea" it is figured from a defective specimen, only $\frac{3}{4}$ of an inch long, and bears a suspicious resemblance to a young *Calliopus laxicruris*. M. Chevreux mentions a specimen in his list, 1883, but this he afterwards identified as *Calliopus norvegicus*, Rathke, as he himself informed me.

**Stimpsonia**, new genus, is thus defined:—"Slender; the inferior pair of antennae considerably longer than the superior. First pair of gnathopoda larger than the second; carpus broader and longer than the propodos; second pair imperfectly chelate, having the carpus much longer than the propodos. Posterior pereiopoda long. Posterior pleopoda biramous. Telson tubular." The type species is *Stimpsonia chelifera*, n. s. Since the generic name is prooecanic among Verens, this species may well be placed under Costa's genus *Microdentopus*.

*Proctodecta hirsutinovus*, n. s., description subsequently completed by A. M. Norman, 1868; "Proctodecta Whitei n. s.," = *Cheirocraftis subdenticulata*, $\S$, Rathke, according to Norman and Boeck. "Bathyporeia Robertoni, n. s.;" both this and Spence Bate's other species, *Bathyporeia pelagica*, are in my opinion synonyms of *Bathyporeia pilosa*, Lindström. G. O. Sars in his *Oversigt*, 1882, speaks of having convinced himself that *Bathyporeia*
robertsoni is a distinct species, though very near to Bathyporeia pilosa. He does not give his reasons. Henri Blanc, 1884, accepts my view. Melita proxima, n. s., according to Norman, Melita obtusa, & Melita ophiusa, n. s. The genus Merca, Leach, is given as Merca; the new species assigned to it are Merca truncatipes (Amphitretus truncatipes, Spinola, MS. H. M. White, Cat. of Crust. in B. M. 1847); "Merca Blanchardi": Merca pseudima, Merca postei, Eucysthea hepinianus, n. s., an obscure species founded on a single imperfect specimen, is perhaps the female of the preceding species in the same genus, named erythrophalinaeus. Amathia dentata is given as the name of a species from Lundicherry, with the synonym "Gammaraus dentatus, Catalogue of the Crustacea in the Museum of the Jardin des Plantes." It is neither described nor figured, but said to resemble closely Amathia subinini and Amathia carinata: the genus Eucysthea falls to the earlier Gammaropsis, Liljeborg, 1854.

Pallava, new genus, is thus defined:—"Superior antennae longer than the inferior, and furnished with a secondary appendage. Inferior antennae subpediform, having the peduncle considerably longer than the flagellum; the flagellum short and stout. Mandibles having an appendage. Maxillipeds subpediform, having a small squamiform plate to the ischium only. Gnathopoda uniform, moderately large. Pereiopoda subequal. Posterior pleopoda biramous. Telson single, cleft."

This genus is very nearly allied to Amathia, from which it differs more in the general aspect of the animal than in structural details. The form of the inferior antennae, together with the altered condition of the maxillipeds, are appreciable characters that distinguish the genera from each other." The type species is Oxynus cancellus, Pallas, from which Pallava cancelloides, Gerstfeldt, differs apparently in a very slight degree, according to the Appendix, p. 350. The name Pallava, according to Boeck, is preoccupied for a Dipterous insect, but the insect's name in Scudder is given as Pallasia.

gammaraeus, new genus, is thus defined:—"Dorsal margin carinated, and having the posterior central margin with one or more segments produced posteriorly. Pleon without fasciuli of spines. Superior antennae having a secondary appendage. Inferior antennae longer than the superior. Mandibles with an appendage. Maxillipeds subpediform, unguiculate, having the squamiform internal processes but slightly developed. Gnathopoda subchelate and subequal, having the carpus inferiorly produced. Coxa of the third pair of pereiopoda not so deep as the fourth. Posterior pair of pleopoda biramous; rami foliaceous. Telson double."

This genus is selected from that of Gammaraus of authors generally, comprising the Division A.A of M. Edwards and +16 of Liljeborg." Boeck remarks that it is not the inner, but the outer, plates of the maxillipeds that are little developed. The type species is Gammaraus loricatus, Sabine.

Upon Gammaraus semi-carinatus, n. s., the remarks are added that "this may be the Gammaraus macronatus of Say," and that "the species is of considerable interest, as associating the genera Amathia and Gammaraeus with Gammaraus." Sp. Date knew of no other distinctly carinated species carrying the dorso-caudal fasciuli of spines. Previously, on p. 208, he gives Say's species as Gammaraeus macronatus. Gammara sub-carinatus (Gammaraus subcarinatus, Stimpson, MS) comes from Behring's Straits. Gammaraus multifasciatus (Gammaraus multifasciatus, Stimpson, MS) is from Grand Manan. Gammaraus Redmanni (Gammaraus Redmanni, Leach, MS. H. M., Gammaraus ornatus, White, Cat. Crust. B. M. 1847 (not Edwards)) is from Jamaica. Gammaraus tenuimanus, n. s., is probably an accidental variety of Gammaraus locusta, as indeed is hinted in the Brit. Hess. Crust. vol. i. p. 384.

Megamon, new genus (answering to Gammaraus, Div. A.aa. M. Edwards and Gammaraus, Div. +2. Liljeborg), is thus defined:—"Dorsal segments of the pleon without fasciuli of spines.
Eyes round. Superior antennae long; inferior about half the length of the superior. Gnathopoda subchelate, the second pair being the larger. Posterior pair of pleopods biramous. Telson double.

"This genus is distinguished from *Merea* by the relative size of the second pair of gnathopods, by the greater size of the coxae, and by the more compact form of the animal generally; and from *Gammworax* by the absence of the fasciculi of spines upon the dorsal surface of the caudal segments and the shortness of the inferior antennae. It is included by most authors in the genus *Gammworax*, but distinguished as a group by itself." In the Brit. Sess. Crust. p. 400, it is said to be distinguished from *Merea*, as well by the coxae and second gnathopods, as "generally by the greater length of the posterior pair of caudal appendages." Heller and Boeck make it a synonym of *Merea*. The new species assigned to it are *Megamvora serrata*, n. s., which is no doubt a synonym of *Merea subramonculata*, Stimpson; *Megamvora semiserrata*, n. s.; "Megamvora Alderi*, n. s.,” which in the Brit. Sess. Crust, vol. i. p. 407, occurs as *Megamvora† alderi*, with the rather singular observation that "the character of this animal appears to justify its admission as a species in the present genus, but we desire to express our conviction that it will ultimately be ascertained to be the female of a species of *Melita*, probably *Melita proxima*." This conviction is confirmed by A. M. Norman, who considers *Megamvora alderi* the ♂ and *Melita proxima* the ♀ of *Melita obtusa*.

Fam. 3. Corophidæ. Subfamily I. Podocerides. receives "Amphithoë Falklandi, n. s."; "Amphithoë Australiensis, n. s."; "Amphithoë Desmarestii, n. s.,” identified by Catta, 1876, with *Amphithoe penicillata*, Costa, but which is more probably a synonym of *Amphithoë vaillantii*, Lucas, 1849; *Podocerus oceus*, n. s. "Ceranus Hunteri, n. s.,” entered by S. I. Smith as a synonym of *Erichthonius difformis*, M. Edwards.

*Nania*, new genus, is thus defined.—Antenne subequal; superior without a secondary appendage; inferior arising posteriorly to the superior. Gnathopoda subchelate; second pair very large. Pereiopoda strong, subequal. Posterior pair of pleopoda biramous, ramis styliiformes. Telson tubular, tipped with one or two rudimentary denticles.

"This genus differs from *Eurytheus* chiefly in the absence of the secondary appendage to the superior antennae and in the larger size of the second pair of gnathopoda." The type species is *Nania tuberculosa*, n. s., which Boeck considers a synonym of his *Podoceropsis sophia*; *Nania rimapalmata*, n. s., is changed to *Nania rimapalmata*, in the Brit. Sess. Crust., p. 474. *Nania excavata*, n. s., is doubtfully distinct from the preceding; *Nania nudata*, n. s., may perhaps belong to some other genus.

*Cratippus*, new genus, is thus defined:—"Boly long. Antenne short; flagella rudimentary; superior pair without any secondary appendage. Coxa not so deep as the pereion. Gnathopoda subchelate; second pair having the propods much larger than that of the first. Pereiopoda subequal. Three posterior pairs of pleopoda having short rami. Telson squamiform (†).” "The rudimentary character of the flagella of the antennae, the absence of the secondary appendage, and the shortness of the coxae are characters that separate this genus from *Podocerus*; the size and form of the second pair of gnathopoda distinguish it from *Corophium*; and the shortness of the antennae and relative proportions of the gnathopods separate it from *Dryope* and *Unciola*.” The type species is *Cratippus temuipes*, n. s., but both genus and species have been anticipated by *Odomastix pusilla*, Grube, 1861. Grube (and subsequently Norman in his also synonymous *Exunqua stilipes*, shows that the first gnathopods, instead of being subchelate or "scarcely subchelate," are exunquian, without a finger.

*Dryope*, new genus (answering to *Unciola*, Gosse, Marine Zool. i. p. 141, not Say) is thus defined:—"Animal long and slender. Superior antennae without a secondary appendage; inferior antennæ not longer than the superior. Coxa not so deep as the pereion. First pair of gnathopods larger than the second, subchelate; second pair small, imperfectly chelate.
Posterior pair of pereiopoda longer than the others. Posterior pair of pleopoda short, almost rudimentary, double-branched. Telson single, squamiform.

"This genus differs from Unciola of Say in the absence of a secondary appendage to the superior antenna, in the form of the second pair of gnathopoda, in the shortness of the posterior pair of pleopoda, and in the character of the telson." The type species is Unciola irrata, Goeze (not Say). Dryope convalpum, n. s., re-named convalpumata in the Brit. Sess. Crust., seems to me to be only a variety of Dryope irrata. The secondary appendage, though very small, is not wholly wanting to the upper antenna.

Corophium spinicorne, n. s., is considered by Böck a synonym of Corophium crassicorne, Brander, 1859. The name too was pre-occupied by Stimpson in 1856.

"Phronima Borucensis, n. s." (Phronima Atlantica, White, Cat. Crust. B. M. 1850) is no doubt, as Spence Bate himself suggests, to be identified with Phronima solentaria, Forskål. Subfam. 2. Phronimides. Phronima longijaw, n. s., is doubtfully distinct from Phronima seminuta, Risso, with which Sp. Bate is inclined to unite Phronima nicetensis, M. Edwards. Anchylomera antipodes, n. s., was taken "near the Antipodes."

Fam. 3. Platyscelidae. Platyscelus, here given as a new genus, though already described in the Ann. and Mag. of Nat. Hist., July 1861, is a synonym of Dithyrum, Dana. Of the species "Platyscelus Rissoi, n. s.," and Platyscelus serratus, n. s., the latter is united by Claus to Typhis oviformis, Risso, and he inclines to treat the former in the same manner.

Brachyscelus is here given as a new genus, but the description of it and of the type species, Brachyscelus crusculum, appeared in the Ann. and Mag. of Nat. Hist. for July 1861.

Thamyris, new genus, is thus defined:—"Superior antenna short, three-jointed. Inferior antenna obsolete. Posterior pair of pereiopoda represented by bases in the form of a membranous scale only."

"In all other respects this genus so nearly corresponds with Brachyscelus, that future research will probably demonstrate their closer connection." The type species is Thamyris antipodes, n. s. Claus decides that Thamyris is the male of Brachyscelus. His own genus Schneb. went he recognizes as an additional synonym, and names the genus Thamyrus, but Brachyscelus has the priority. Brachyscelus in turn must yield to Daivilia, Dana, if the suggestion of Bovallius be accepted, that Daivilia is identical with Thamyrus.

Amphipromus, new genus, is thus defined:—"Cephalon round, anteriorly oblique. Percion not broader than the cephalon. Pleon having the fourth and fifth segments fused into one. Superior antenna having the peduncle three-jointed; third joint large, inferiorly convex and anteriorly produced, having the superior margin subtilly excavated to receive the short flagellum. Inferior antenna five-jointed. First pair of gnathopoda complexly subchelate; second pair not subchelate. Third and fourth pairs of pereiopoda largely dilated, having the remaining joints as long as the base; fifth pair rudimentary. Posterior
pair of pleopods biramous, foliaceous. Telson nearly as broad at the base as the preceding segment of the pleon."

"This genus is very closely allied to Pronoe, but differs in the form of the superior antennae and of the gnathopods, and in the fusion of the fourth and fifth segments of the pleon into one." The type species is Amphipronoe cespitata, n. s. Claus gives up this genus as not defined with sufficient accuracy. On the supposition that the first and second gnathopods have been interchanged in the description, he thinks it might be the same as his own genus Parapronoe. In any case the distinction drawn between Amphipronoe and Pronoe grounded on the fusion of the fourth and fifth segments into one, seems untenable, the rule in the Hyperini being that the fifth and sixth segments, not the fourth and fifth, of the pleon, codose.

In Fam. 5. Oxycephalidae. "Subfam. 1. Synopiades" is certainly out of place. In Subfam. 2. Oxycephalidae, Oxycephalus tubercolatus, n. s., is, according to Claus, a synonym of Oxycephalus piscator, M.-Edwards; "Rhabdosoma Whitei, n. s.," according to Claus, is the male of Rhabdosoma arnatrix, M.-Edwards.

1862. Bate, C. Spence.

The supposed jaw in Mr. Spence Bate's opinion may be the dactylos or last joint of a leg of a small Hyperini Crustacean. He figures a leg of Phronima longispina for comparison, and supposes that Dr. Wallich may have been misled by seeing a second row of marginal armature within the external one, such as appears in Crustacea near the period of moulting.

1862. Claus, C.

In the heart of Phronima sedentaria, "the three pairs of lateral openings, which serve as venous Ostia for the reception of the blood flowing back from the body to the heart, are found in the second, third, and fourth thoracal segments." From the point of the heart an arterial vessel, constituting the abdominal Aorta, stretches from the middle of the sixth peron-segment almost to the middle of the third pleon-segment. The Aorta cephalica is also mentioned. Claus also here speaks of two fine strings in the third and fourth peron-segments running "von der ventralen Fläche des Herzens aus schräg nach oben und vorn zum Magen," which he supposes may serve for fastening, although at first inclined to regard them as arteries. In his later work on the Phronimidae 1875, he finds that these are really lateral arteries, constant in the genera of the Phronimidae, and in Paraphronima and several other Hyperini supplemented by a third pair. He says that Pagenstecher has attributed
to the thorax a ganglion-pair too many, and in the last pereon-segment figured a ganglion in a place, where none such exists. The habituation which the female Phronima sedentaria occupies is discussed.

Phronima elongata, n. s., Taf. xix. Figs. 2, 3, 7, is described. This subsequently became the type for a new genus as Phronimella elongata.

Phronima sedentaria, Taf. xix. Figs. 1, 4, 5, 6, is described, and the suggestion made that Phronima atlantica of Guérin and M.-Edwards (Phronima custos, Risso) is the not completely adult form of Phronima sedentaria. With reference to the sort of metamorphosis which Pagenstecher had shown that this species undergoes as it advances in age, Claus states that he has noticed similar facts in regard to Phronima elongata, in which, he says, the most interesting peculiarity is "die Anwesenheit zweier einfachster stummelförmiger Fühlhörner unterhalb der grösseren 2gliedrigen Antennen (Fig. 7.). Die junge Ph. elongata hat also wie die übrigen Hyperinen zwei Antennenpaare und es ist das obere Paar, welches in der späteren Zuständen persistirt."

1862. Claus, C.

Ueber Phronima elongata Cls. Hierzu Tafel VI. (Fig. 6–11). Würzburger naturwissenschaftliche Zeitschrift. III. Band. 1862.

Claus gives a further description, believing that he has found the male form. This in 1872 he decided to be "das noch junge Männchen vor Eintritt der Geschlechtsreife und vor der Entfaltung sämtlicher Antennenglieder." He corrects an oversight in the previous account, where the fourth pair of feet, instead of the third, was stated to be the longest. Of the second uropods, he says, "das mittlere Paar der 3 Springfüße sehen wir an dem ausgebildeten Weibchen vollständig hinwegfallen, bei dem Männchen dagegen entwickelt sich dasselbe jederseits zu einem engen und kurzen Schlauche, der an seiner Spitze einfach bleibt und kann über das letzte Leibsegment hinaus ragt. Die hakenförmige Anlage dieser Extremität, wie wir sie in den 4–5 Mm. langen Jugend-stadien antreffen, würde demnach in beiden Geschlechtern eine verschiedene Veränderung im Laufe des weiteren Wachthums erleiden." He figures and describes the mouth-organs.

1862. Costa, Achille.

In a species discovered by Costa the lower antennæ are furnished with a slender flagellum as long as the body. This seemed to him a difference of almost generic value, but the rest of the organization was so perfectly identical with that of Lysianassa that he was content to let it rank as a specific distinction. It is now known to be only a sexual character of the adult male. He names the species Lysianassa filicornis. The Latin description of it is:—

"L. antennis superioribus corporis quarto brevioribus, pedunculi articulo primo valde incrassato, infra spinæ acuta terminato; inferioribus seta gracillima corporis longitudinem sequente; pellicis primiti paris unum elongato-conico, uncincio calibrisculo praedito, sexuali parvis longioribus, gracilioribus, max. ovato-rotundato, setis terminato; pellicis spuris abdominalibus acuto terminalis. Longit. corp. millim. 10." Tav. II, fig. 18–23.
1862. COSTA, Achille.

While watching some specimens of Diphyia (Callolaria) quadrivalvis, Costa noticed some movements in the urticating apparatus which surprised him. He found them due to a little Crustacean encased in the "bottone," which stand at the extremity of the secondary filaments. "Entro que' bottoni, come entro di un sacco cisterico, era un piccolo Crostaceo, nello stato quasi embrionale, co' piedi toracici ripiegati contro il petto ed immobili, e con i falsi piedi addominali in continuo movimento. L'abito generale dell'animale ci potrebbe a vedervi qualche affinità con le Phrosine; però la struttura de' piedi non presenta nulla de' caratteri propri di' Crostacci di tal genere; siccome non ci è permesso vedervi con esattezza alcuno de' generi già noti nello stato adulto. Laonde, sa'vo sempre a ben fissarne le note caratteristiche, noi le chiameremo Diphyicola rubens." He proceeds to ask, whence come the eggs of the Crustaceana, in what way do they penetrate into the appendages of the Diphyia, when do they leave this receptacle, etc.? The observation is most interesting, but it seems rash to have constituted a new genus, with practically no characters. Figures 5, 6, are given on pl. iii., of the animal in a very embryonic condition in its involucro, and "figura 7. Il Crostaceo osservato in altro bottone più sviluppato, ed avente già tutte le parti ben determinate. Eso rimaneva avvolto da una semplice membrana, la quale come per un funicello era attaccata al filamento accessorio indicata."

1862. BATE and WESTWOOD.

At page 161 Geniceros parteimana, n. s., is figured and described, on which the authors remark that "Kroyer in his generic description states that both pairs of hands are very large," whereas in their species "neither of the hands can be described as being large, and the second is decidedly smaller than the first." In vol. ii. p. 528, 1868, the authors mention specimens which they think must be the male form. "They differ from that described in having the upper antennae but little longer than the peduncle of the lower, the lower antennae as long as the entire animal, and the gnathopoda with hands somewhat larger, but scarcely equal to the 'very large' hands as described by Kroyer in his description of the genus."

At page 177 Kroyera altamarina, n. s., is figured and described. By J. Sparre Schneider, 1885, this is made a synonym of Pontocrates norvegicus, Boeck. See note on Schneider, 1885. At page 206 Lioloboria sheltoniana, n. s., is figured and described. This appears to be a synonym of Cheiroratus similecula, Rathke, 1843.

At page 226 is given the new genus Periclimenes, thus defined:—

Antepenultimate pair of pleopods having the peduncle very short, rami long, subfoliaceous. Penultimate pair having the peduncle long, rami styliform. Ultimate pair short, unbranched. Telson single.” The authors remark further, “this genus bears a near relationship to that of *Phlias* of Guérin. The only distinction of importance which we are enabled to discover exists in the form of the posterior pair of caudal appendages; these are biramous in the description and figure of *Phlias*, as given by the author in the ‘Magasin de Zoologie’ for 1836.” Of *Phlias rimosus* the authors had a specimen at command, but they say “the specimen being small, we were not able to make out the form of the last pair of caudal appendages without dissection, and we felt unwilling to destroy our only specimen,” by this means saving their specimen and destroying its use. Such economy was particularly undesirable in the present instance. The genus *Pereionotus* was instituted to receive the *Oniscus testudo* of Montagu, which was preserved in the British Museum, and had been supposed by Adam White to belong to the genus *Acanthomantes*, Owen. See Note on Montagu, 1808. It is only by a minute comparison of the figures as well as the descriptions given by the various authors, respectively, of *Phlius serratus* by Guérin, 1836, of *Pereionotus testudo* by Bate and Westwood, and of *Liriomus muscum* by Grube (1853) 1861, that the close connection between these three forms can be appreciated. When also the minuteness of the specimens is borne in mind, the possibility of error in one or more of the descriptions will be taken into account.

At page 212 *Dexamine velohemensis*, n. s., is figured and described. This is named *Atylus velohemensis* by Bosc.

*Calligo phingali*, n. s., figured and described at page 263, may possibly, the authors say, “be only an exaggerated variety of *C. Osiusii*.” By Bosc both of these species are considered to be synonyms of *Amphithoe latipes*, M. Sars, 1858.

At page 333 *Gammarella noromonu*, n. s., is figured and described, with the remark that “this animal bears so close a resemblance to the preceding that we are inclined to think that it may only be the female of that species,” i.e., *Gammarella brevicauda*, M.-Edw. The specimen described has the flagella of the upper antenna longer than those observed in *Gammarella brevicauda*, though in other respects agreeing with the female of that species. It is possibly a young male.

The genus *Amathia*, Rathke, is here (p. 359) renamed *Amathilla*, *Amathia* being pre-occupied among Polyps, Decapod Crustacea, and Moths.

At page 411 is introduced the new genus *Eischadus*, thus defined.—

“Slightly compressed. Eyes on a prominentily-advanced lobe between the superior and inferior antennae. Superior antenna without a secondary appendage. Gnathopods subchelate. Coxa of the third pair of pleopods having the anterior lobe as deep as the coxa of the second. Posterior pair of pleopods biramous, rami unequal. Telson squamiform, single.”

This genus has since been recognised as a synonym of *Photis*, Kroyer, 1842. The type species, *Eischadus longicombatus*, figured and described as new at page 412, is by Bosc considered a synonym of “Photis Reishardii,” Kroyer, with which it agrees in the exuviate and dentate palm of the second gnathopods.

---

1862. GERSTAECKER, CARL EDUARD ADOLPH, born 1823 (Hagen).

1862. Gerstaecker, C. E. A.

The Articulata by Gerstaecker (Hagen).

1862. Hoeven, J. van der.

I take the notice of this work from R. T. Maitland, 1876. See Note on Maitland, under that date, for the information affecting the Amphipoda.

1862. Lovén, Sv.

This paper gives further particulars of the distribution of the three species of Amphipods mentioned in the author's previous paper (see Note on Lovén, 1861), and compares the shape and size of various specimens of the fresh-water Gammarus loricatus, with a specimen from Spitzbergen.

Of Amphipoda they mention Gammarus locusta, Montagu, "Gammarus Sabinei," Leach, two species of "Amphitoë," "Leptomera pedata, Müll.," and "Caprella linearis, Hbst."

It may save trouble to future enquirers to quote the negative observation in this work; "il est aussi à noter que, dans les collections que nous avons pu consulter, il ne se trouve aucun Amphipode." Milne-Edwards suggests that new researches might well be undertaken to fill up this and other lacunae.

1863. Gerstaecker, A.

1863. Bate and Westwood.

At page 490, the species Dryope crenatum palma, Spence Bate, is renamed Dryope crenatum palmae. At page 497, a species is given as Corophium benelli, Milne-Edwards, which Norman regards as unquestionably the female of Corophium crassicornis, Bruzelius. To the Corophium benelli here figured and described, Corophium spini cornus, Sp. Bate, is made a synonym. Chelura terebrans is misprinted as Chelura terebrans, and the figures of the gastrapods are wrongly lettered.

At page 51 (Vol. II.) the genera Podalirius and Acyntos of Kröyer are rejected, but on insufficient grounds, so that for Caprella typica (page 75), Podalirius typicus, Kröyer, must be reinstated.

Cymans erraticus, Roussel de Vauzême, is, at page 86, regarded as a synonym of Cymans eti, Linn., but erroneously in the opinion of Litken, who also considers it rash to include Cymans ovalis and Cymans gracilis, as is here done, in the British Fauna. (N.B.—Part XIII. containing pages 65–112 was published July 2, 1866. The Amphipoda end at page 98. For the Appendix see under 1868. The intervening parts containing the Isopoda were published—Part XIV., October 1, 1866. Part XV., December 2, 1866. Part XVI., May 1, 1867. Part XVII., June 1, 1867. Part XVIII., August 1, 1867. Part XIX., October 1, 1867. Part XX., April 1, 1868. Part XXI., August 1868.)

1863. Carus and Gerstaecker.

Handbuch der Zoologie. 1863.

Mayor notes the erroneous statement, vol. ii. p. 363, that the mandibular palp is wanting in all the Caprellidae.

1863. Claparède, Jean Louis René Antoine Edouard, born 1832 (Hagen).

Pages 101–102 contain the section "Über die Blutbahnen bei den Caprelliden," illustrated by Taf. xvi. Fig. 17–18. He says that in all the Caprellides he examined the arterial current of the blood took its course along the side of the foot occupied by the flexor muscles, and the venous current along the extensor side; he points out that Frey and Leuckart were in error in saying that the whole arterial stream ran to the end of the leg, there to bend round into the venous stream. "Am peripherischen Ende jedes Fussgliedes (vgl. Fig. 17) spaltet sich nämlich die arterielle Blutströmung in zwei Zweige, wovon einer als arterieller Strom in das folgende Glied dringt, während der andere sofort umbiegt und auf der Streckseite in den venösen Strom übergeht." The arterial and venous currents are kept separate, he says, in the long legs by a very transparent membrane, in which he detected an elongate sharply defined opening, just where one part of the blood-corpuscles passed over from the arterial into the venous stream. On this subject Delage, p. 130, says in 1881, "dans les pattes, les vaisseaux afférents sont placés du côté de l'extension. Ils suivent donc le bord supérieur dans les deux premiers paires de pattes, et l'inférieur dans les trois dernières paires." Chaeum
THE VOYAGE OF H.M.S. CHALLENGER.

se continue au sommet de l’appendice avec le vaisseau efférent correspondant qui suit le bord opposé, et communiqué avec lui en plusieurs points de son trajet par de petites éclippées qui s’ouvrent dans les lacunes du membre.” Mayer observes that in the hind legs of 

1863. KINAHAN, JOHN ROBERT.

“The only Amphipod I could meet in this [the littoral] zone,” the writer says, “after much research, was Orchestia littorea, although O. Meliterraenca occurs abundantly in Dublin and Plymouth. In the other zones we met, along with a multitude of others, Caprella tuberculosa, Naora bicuspilata, Amphithoe rubricona and Ugitorina, Lestrigonus falcatus; but I met with no specimen of Gammarus palmatus, although this latter occurs at Dublin.”

1863. LORENZ, JOHNS RON.

Twelve species of Amphipods are named as distributed in the Quarnero, from the surface down to 45 fathoms. See pp. 288, 293-295, 303-326, 349.

1863. PACKARD, ALPHEUS SPRING, JR., born February 10, 1839 (S. I. Smith).

In regard to the typographical errors, see Note on Packard, 1867. The lists, he says (of course with no special reference to the Amphipods), “seem to afford very satisfactory evidences that there are three distinct assemblages of marine invertebrates intermingled on the coast of Southern Labrador.” See also Note on S. I. Smith, 1883.
1863. SARS, M.

At page 290 he records "Epigera spinosa A. Boeck. Ikke sjelden mellem Sertulinerer pa 30-40 F. D. ved Bejan. Det levende Dyres Farve er hvidtagig og stærkt marmorert eller plettet med rustbruunt, øinene miniersde."

1863. SARS, GEORG OSSIAN, born 1837 (G. O. Sars).

Pages 205–212 relate especially to the fresh-water Amphipoda observed on this journey. First Sars discusses Pontoporeia femorata, Knöyer, Var., to which he strongly inclines to make Pontoporeia affinis, Lindström, a synonym. Secondly, he gives a full description of a species under the following heading, "Gammarus pulex De Geer, an a specie vulgo hoc nomine descripta diversus." As to its habitat he says, "har jeg altid kun truffet vor Gammarus in større stillestående Vande, aldrig i Elve." If it should prove a distinct species, he proposes to name it in correspondence with its habitat Gammarus lacustris, a name which he afterwards changed to Gammarus neglectus. Thirdly, he describes "Gammarus cancelloloides Gerstfeldt, Var. (o)." This form, he says, had been already described by A. Boeck as a new species, under the name Gammarus quadrispinosus. It is rather in deference to Lovèn's opinion, than upon his own judgment, that he hesitates to accept Boeck's view.

1863. STIMPSON, WILLIAM.

Synopsis of the Marine Invertebrata collected by the late Arctic Expedition under Dr. J. J. Hayes. From Proceedings of the Academy of Natural Sciences of Philadelphia, May, 1863.

The Amphipods recorded are Amonyx ampulla, Knöyer, which is a synonym to Amonyx rugae, Phipps; Phronia tricusps, n. s., which is identified by Boeck with Amphithoe fulvocincta, M. Sars, 1858, under the name Halirages fulvocinctus; Gammarus locusta, J. C. Fabr. and Themisto arctica, Knöyer. Gammarus pulex, Stimpson, from Grand Manan, is here placed as a synonym to Gammarus locusta, Fabr.

1864. BATE, C. SPENCE.

A new species "Merca fissula" is thus described:—"The body is long and slender; the superior antennae are about half the length of the animal, the peduncle being scarcely longer than (ZOOL. CHAL. EXP.—PAST LXXX.—1887.)
the flagellum; the secondary appendage being half the length of the primary, the second joint of the peduncle being about the same length as the first. Second pair of gnathopods having the propodos large; palm without teeth, and defined by a small pointed process. Posterior pair of pereopods having the posterior margin of the base smooth.

"In its general appearance this species bears a near affinity to

**Mura grossimana**, as well as to

*M. tenella*, from the Fejee Islands, the only appreciable distinctions being in the shorter length of the second joint of the antenne, the absence of teeth from the palm of the hand in the second pair of gnathopods, and in the even margin of the last (the only remaining) pair of pereopods, and perhaps also in the shortness of the peduncle of the ultimate pair of pleopods." Habitat, a sponge in Esquimalt Harbour.

Tanais loricatus, n. s., is also described in this paper.

1864. COSTA, ACHILLE.

He first describes "**Ampelisca rubella**, nob. Tav. II, fig. 7. A. saturate rosea; antennis capitie thoracique parum longioribus, subequalibus; scape in superioribus ele quartum, in inferioribus tertio totius antenne formante; pedibus primi et secundi parvis subequalis, longe pilosis (secondi gracilioribus paulloque longioribus), ungue acuminato, infra dentato; terti et quarti articulo secundo et quarto brevissimis, ungue recto acutissimo; quinti et sexti articulo primo callo dilutato, orbiculari-cordato, ungue minutissimo retrum verso; septimi coxeris brevioribus, articulo primo minus dilato, inferius lobato-producto, articulis 2–5 brevioribus subequalibus, ungue apice, obtuso; lamina carodi ovato-elliptica, postice profunde seissa.—Long. mill. 7." He says that from **Araneops diadema** and **Araneops longicornis**, the two species of *Ampelisca* which he had previously described from the Gulf of Naples, the present species differs sensibly, in colour, smaller size and other more important organic characters. He gives a fuller description in Italian.

He next describes "**Protomedea fasciata**, nob. Tav. II, fig. 8. P. albida, fascias fascis nigro punctatis, antennis subequalibus, scape superiorum tilio inferiorum breve; pedibus thoracici quinti, secuti et septimi parvis articulo primo margine integro.—Long. mill. 7–8." It has, he says, great affinity with *Protomedea hirsutima*, Bate and Westwood, but differs in having the first joint of the fifth pair of feet not serrate, in the distribution of the hairs (peluria) of the feet of the second pair and in the antennæ. It keeps its colour in alcohol.

1864. COSTA, ACHILLE.

Costa here notices that in 1850 Natale had placed Cocco's *Orio ornithoramus* in a new genus, as "**Ornithoramus Cocco**." With this Costa himself proposes to arrange three new species in two new genera, forming a little natural group, the Ornithoramphini. The genus **Natalius** is thus defined:

The genus *Natalius* may perhaps be identical with *Oxycephalus*, M.-Edw., with which Carus doubtfully unites it, citing the palpi maxillares duo as "[? antennae II]." but that they are the lower antennae is beyond question. The genus might be distinguished from *Oxycephalus* on the ground of its subphrenales gnathopods, did not the description of the type species indicate that they are in fact complexly chelate. The species *Natalius candidissimus*, Carus gives doubtfully as a synonym of *Oxycephalus similis*, Claus, 1879; but except that the specimens were taken in the same waters, the authors do not happen to take any common characters, on which a comparison can be founded, unless the slenderness of the first and second pereopods be considered such. It is strange that Costa makes no reference to *Oxycephalus*, and stranger still that he does not refer to *Erythoramus* *coste*, described by de Natale, 1850, in a letter to Costa, beginning "Carissimo Achille."

The genus *Carcinornis*, A. Costa, is thus defined:

The type species, *Carcinornis acutirostris*, A. Costa, is described as follows:—"C. albus, utrinque vitta lata purpurea per totam fere corpus coeruleo notatus; capite cum rostro tertium fere totius corporis partem formante, rostro acuminato; antennis setosis; pedibus tertii et quarti paris subquadratis—quinti, sexti et septimi longitudine decisecundatis, margine antico minutissime serrulatis, articulo primo nocie dilatato; pedibus spuriis quarti, quinti et sexti segmenti abdominalis fere seque terminatis. Longit. millim. 5—6." The second species, *Carcinornis inflaticeps*, A. Costa, is very briefly described in this way:—"C. capite inflato, cum rostro minus acuminato quarto totius corporis partem formante; ceterum precedentibus similis. Longit. millim. 5—6." The genus *Carcinornis*, if really distinct, may eventually be identified by the coloration assigned to the type species. *Carcinornis inflaticeps* is suggestive of *Oxycephalus typhoideus*, Claus, from the harbour of Messina, which has been already mentioned (p. 241) for comparison with *Ornithoramphus cocco*, de Natale.

**1861. Grube, A. E.**

He here renames several of the species described by him in 1861; see Note on Grube, 1861. He says that the Amphipod, which Spence Bate treats as Rathke's *Decamine tenuicornis,*
differs from it in several respects. He figures as a new species *Iphimedia multipinna*, and describes it in great detail. It seems closely to resemble *Iphimedia obesa*, Spence Bate, which is itself probably a form of *Iphimedia obesa*, Rathke.

The genus *Colonosticta*, Grube, 1861, is here more fully defined:—

The new genus *Iceridium* is thus defined:—

"*Corpus* depressum *ex* ovali oblongum, postice elongatum. *Antenae* breves, articulis paucis, *inferiores* superioribus breviores, *tenaciore*. *Caput* *(deorsum* visum) quadrangulum, angulis *anterioribus* prominentibus, *oculis* *ferentibus*. *Pedes* omnes *ambulatorii*, *longitudine sensim* crescentes. *Podobranta* ex segmentis *compositum*, *appendices* *anteriores* 4 binume, setigere, *segmenti* *tertii* brevissime, *simplices* ceetes. *Telson* *nullum.*" The type species, *Iceridium fuscum*, Grube ((Sitzungsberichte der Schles. Gesellsch. vom 18ten Februar 1863)," is described and figured. The specimen, 3-5 mm. in length, a female with young in the brood-pouch, was taken at Neresine on the Island of Lussin. Compare the Notes on Montagu, 1803, Guerin, 1836, Spence Bate, 1865, for the affinity of this genus with *Oniscus testudo*, Montagu, and *Philias*, Guerin.

A list of the Amphipoda observed is given on pages 72 to 75.

A new species is described as follows:—" *Kroyeria* Sp. B. ? *Kr. haplocheles* Gr. n. sp. ? Hat den Habitus einer Kroyeria, würde sich aber von den anderen Arten dieser Gattung dadurch unterscheiden, dass der Corpus des zweiten Fusspaares in keinen unteren Fortsatz ausläuft, die schmale Scheere also einfach ist, auch durch die beiden stachelarten Zacken des Telson; allein das 7. Fusspaar ist abgebrochen, und es bleibt daher unsicher, ob dies Thier überhaupt zur Gattung Haplocheles [Kroyeria] gehört ; Lussin." In this passage Haplocheles is evidently a slip of the pen, *Kroyeria* is a mis-spelling of *Kroyera*; for the position of *Kroyera* itself see Note on Spence Bate, 1858. Under " *Meganoea* Sp. Bate," he places *Ceradocus orchesiris*, A. Costa, of which "die Antennen sind rot, der Hinterrand der 6 letzten mit Extremitäten versehenen Segmente läuft in einen Rückendorn, am zehnten auch seitlich in Zähnen aus." The observation is added that, "Die Gattung Ceradocus von A. Costa lässt sich nach den von ihm aufgestellten Charakteren nicht halten und es liegt keine Nothwendigkeit vor, sie neu zu begründen; wenn man bei ähnlicher Beschaffenheit der Antennen und der Hand des zweiten Fusspaares wie billig, das Hauptgewicht auf die Beschaffenheit des dritten Paares des Springfüses legt, so lässt sich dieser Amphipode der Gattung Meganoea unterordnen, deren bei Spence Bate abgebildete Arten allerdings sämmtlich keinen Rückendorn auf den hinteren Segmenten besitzen, sich aber durch den gezähnten Hinterrand an dem Seiten- oder Hüfttheil des zehnten Segmentes auszeichnen. Die Gattung Melita, deren hintere Segmente bei mehreren Species Rückendornen tragen, zeichnet sich durch die ungleiche Grösse der Aeste des letzten Springfusspaares aus, und die Einordnung des in Rede stehenden Amphipoden in diese Gattung würde die Umlagerung eines sonst durchgreifenden Gattungscharakters erfordern; ich muss hierin Herrn Professor Heller bestimmen."

1864. Leydig, Franz.

On plumose hairs, p. 35, n. 2; on olfactory tubes and calceoli, pp. 98, 99, n. 4; on the brain of the Arthropoda, p. 185.

1864. Müller, Fritz.

Für Darwin. Leipzig, 1864. 8 maj. m. 67 Holtzschn.

Facts and arguments for Darwin, by Fritz Müller. With additions by the Author. Translated from the German by W. S. Dallas, F.L.S., &c., with illustrations. London; Murray, 1869.

In this translation of the celebrated work, Für Darwin, are figured Melita exilii, n. sp., "Orchestia Darwinii," n. sp., two forms of the chaeta of the male of this species, portions of the penultimate pereopods of "Melita Messelina" and "Melita insatiabilis," an embryo of a Corophium, portions of the legs of "Hyperia Martiensii," n. sp., and the second gnathopod of the male and of the female of "Orchestia Tucuratinga," while mention is made of Corophium dentatum, n. sp., without either figures or description, and of "Orchestia Tucurawana," n. sp., which is apparently the same as "Orchestia Tucuratinga."

A protest may be entered against the inconvenient course of publishing new species at various points of a highly argumentative essay, especially when the descriptions are almost of necessity confined to those isolated characters with which the argument happens to be concerned.

Fritz Müller has found the secondary flagellum on the upper antenna "in species of the genera Leucothoe, Cyrtophium, and Amphilochoo, in which genera it was missed by Savigny, Dana, and Spence Bate." "A species proved by the form of the epistern (oostv. Sp. Bate) of the caudal feet (uropoda Westw.), etc., to be a true Amphilocho possesses it." "In many species of Cerapus it is reduced to a scarcely perceptible rudiment." "It is sometimes present in youth and disappears (although perhaps not without leaving some trace) at maturity, as was found by Spence Bate to be the case in Acanthomastus Owenii and Atopus carinatus, and I
can affirm with regard to an Atylus of these [Brazilian] seas, remarkable for its plumose branchiae."

He regards the telson as a segment, notwithstanding its want of appendages. In favour of this view he says, "we have the relation of the intestine, which usually opens in this piece, and sometimes even traverses its whole length, as in Microdeutopus and some other Amphipoda. In Microdeutopus, as Spence Bate has already pointed out, one is even led to regard small processes of this tubular caudal piece as rudimentary members." He speaks of the appendages of the first three pleon-segments as being "reproduced in wearisome uniformity throughout the entire order" of Amphipoda. This remark is not very applicable to Cerapus (see S. L. Smith, 1889), and has a disadvantageous tendency to discourage the examination of these organs in other genera.

In "Orchestia Darwini, n. s.," he figures two forms of the powerful chela of the second pair of feet in the male, "two forms united by no intermediate terms." Faxon, in Dimorphism in the Genus Cambars, 1884, thinks that possibly "these are to be explained in the same way as the two forms of the male Cambars, which appear to be "alternating periods in the life of the individual," the one form assumed during the pairing seasons, the other in the intervals.

In Melita Mosaicina, n. s., and Melita insatiabilis, n. s., in the case of the females "the coxal lamelle of the penultimate pair of feet are produced into hook-like processes, of which the male lays hold with the hands of the first pair of feet."

He remarks that generally throughout the Amphipoda the heart "extends in the form of a long tube through the six segments following the head, and has three pairs of fissures, furnished with valves, for the entrance of the blood, situated in the second, third, and fourth of these segments," as found by La Valette in Niphargus and by Claus in Phronima. Only in Brachycerus he found the first pair of fissures wanting to the shortened heart.

"The Amphipoda," he says, "are distinguishable from the Isopoda at an early period in the egg by the different position of the embryo, the hinder extremity of which is bent downwards. In all the animals of this order which have been examined for it, a peculiar structure makes its appearance very early on the anterior part of the back, by which the embryo is attached to the 'inner egg-membrane,' and which has been called the 'micropylar apparatus,' but improperly as it seems to me." To this statement he appends a note. "Little as a name may actually affect the facts, we ought certainly to confine the name 'micropyle' to canals of the egg-membrane, which serve for the entrance of the semen. But the outer egg-membrane passes over the 'micropylar apparatus' of the Amphipoda without any perforation, according to Meissner's and La Valette's own statements; it appears never to be present before fecundation, attains its greatest development at a subsequent period of the ovular life, and the delicate canals which penetrate it do not even seem to be always present, indeed it seems to belong to the embryo rather than to the egg-membrane. I have never been able to convince myself that the so-called 'inner egg-membrane' is really of this nature, and not perhaps the earliest larva skin, not formed till after impregnation, as might be supposed with reference to Lápita, Cassidina, and Philoscia."

"The young animal, whilst still in the egg, acquires the full number of the segments and limbs." In the Hypermus, indeed, "the young and adults often have a remarkably different appearance; but even in these there is no new formation of body segments, and limbs, but only a gradual transformation of these parts." The sexual differences in the Amphipoda are also discussed.

No new Amphipoda are included in the list of Crustacea. Olist carinatus, Bate, is recorded among those taken.

1864. Sars, G. O.

At page 231 he mentions, Gammarus cancelloides, Lov., as occurring in various localities, and his own Gammarus lacustris as a characteristic form for their Alpine regions, in still waters. He is confirmed in the view that it is distinct from Gammarus pulex.

1864. Stimpson, William.

A note is prefixed saying—“The following descriptions are extracted, by permission, from the Zoological Report of the Boundary Commission. They were written in the year 1860, and accompanied by illustrative drawings of all the species, which, it may be hoped, will soon be published.” Whether the hope has been gratified I am unable to say.

The first Amphipod described is “Caprella Kennertyi,” which Mayer considers indeterminate. Amphithoe hameralis, more than an inch long, a little resembles Amphithoe falklandi, Spence Bate, from the Falkland Islands, in the dilated first joints of the first and second pereopods. Of Anonyx filiger I give the description for convenience of comparison with the Challenger species:—“Head with a strong triangular process on each side beneath the base of the superior antennae; extremity of this process not acute. Superior antennae very short, about as long as the head, with a long thick pencil of hair on the inner side of each; basal joint large, with a strong protuberance above, forming a prominent angle at its anterior extremity; flagellum seven-jointed, the first joint constituting one-third of its length; accessory flagellum tri-articulate. Inferior antennae longer than the body; the pelaece, however, constitutes but a small part of their length, being but little larger than the superior antennae; the very slender filiform flagellum appears as if serrated above, but is not provided with calcareae. The first pair of feet in our single specimen appear to be pointed and simple, the dactylus not being retracted against the manus, which has no palm. Second pair with a minute truncate hand, supporting a small tuft of hair at the base of the dactylus. The dorsum in this species is sharp, or carinated, but not dentated, being entire and smooth in outline for the greater part of its length, and similar in the thoracic and first three abdominal segments. There
is, however, a deep, triangular sinus between the third and fourth abdominal segments, the latter being strongly protuberant, projecting over the very small fifth segment. The second abdominal segment is subtruncate below, and has a deep semicircular sinus on the anterior lateral margin, near its lower extremity. Rami of the last pair of caudal styles are shorter than those of the second pair, and telson rather elongated and slit in two down the middle. Length about one-third of an inch. It resembles an English species of which a figure has been privately circulated by C. Spence Bate, Esq., under the name of *Lysianassa Chausica*, M.-Edw. Dredged in deep water by Lieut. White."

The *Lysianassa chausica* here referred to was afterwards identified by Spence Bate with *Lysianassa longicornis*, Lucas, as to which see Note on G. O. Sars, 1882.

*Gammarus sclateri* has the "first, second and third joints of the abdomen armed above with a sharp central spine on the posterior margin, and with four or five minute spines, or sharp comb-like teeth on each side of the middle spine, the margin bearing these latter spines being a little concave. At the corresponding part of the fourth and fifth abdominal segments, there are also two or three spines similar to the central spine of the other segments though not quite so large." Stimpson thinks it no doubt closely allied to *Gammarus longicornis*, Brandt, a species which Spence Bate renames *Megamara longicornis*, and inclines to identify with *Gammarus dentatus*, Kroyer. *Amphithionotus septemdentatus* is "strongly compressed and carinated, like *A. carinata*." *Amphithionotus occidentalis* is "closely allied to the Arctic *A. panopla*, Kr., and the east coast species, *A. cataphractus*, Stun., but differing from both in being more elongated, having less height and breadth."

The generic name *Amphithionotus*, as already observed, is inadmissible, having lapsed as a synonym of *Dexamine* before it was adopted by Stimpson. Of the species which Stimpson here mentions for the sake of comparison, *Amphithoe carinata*, Kroyer, is now called *Atylus carinatus*, Fabr.; *Amphithoe panopla*, Kroyer, is called *Pleustes panopius*, and *Amphithionotus cataphractus*, Stimpson, is called *Rhachitropis cataphracta*. In *Amphoeica pugetica* "the last three joints of the abdomen are separated from the preceding ones by a deep notch, and project into two sharp teeth."

---

**1864. ZADDAH, ERNST GUSTAV, born 1817, died 1881.**

To the existing fauna of the neighbourhood in which this fossil was found Zaddach ascribes seven species of Amphipods, viz., the fresh-water "*Gammarus fluvialitis*, Riep.,” four species which he dredged in the Bay of Dantzig, at some distance from the coast, and only two, he says, which live near the coast, *Gammarus locusta*, Mont., and *Talitrus saltator*, Klein. Of these he says that they frequently let themselves be thrown by the waves on to the strand, where, by help of their styliform uropods, they make powerful leaps, or with great dexterity bury themselves in the wet sand in order to be washed back into the water by the next wave, or gather round the remains of a dead fish for a meal, but never go beyond the narrow shore of which is regularly washed to a greater or smaller extent by the waves. In these remarks Zaddach can scarcely be accurate. The sand-hopper, *Talitrus (saltator) locusta*, lives at the edge of high water-mark, and may follow down the ebb and retreat before the flow of the tide, but does not surely play with the waves in the manner described. The dexterous delving in the sand seems also more appropriate to species of *Urothoe*, *Lepidactylis* and *Enydcide* than to the shuddering *Gammarus locusta.*
Zaddach supposes his species to be the first fossil Amphipod discovered, since, he says, the genus *Gammarella* Jordl, from the carboniferous period, which Bronn mentions in his *Lethaea geognostica*, 1856, is remote from the present Amphipods, and represents a special order of Crustaceans intermediate between Amphipods, Stomatopods and Decapods, or rather ancestral to them all and belonging to a time when their several characters were not yet separated. He is apparently unaware of the Permian fossil, called *Palaocrangon problematicus* by Schauroth in 1854, and *Protoponticus problematicus* by Kirkby in 1857.

After a careful and detailed description of the fossil, Zaddach establishes for its reception a new genus, *Palaogammarus*, which he thus defines:—"Caput altius quam longius. Antennæ et superiores et inferiores validæ, scapus triarticulatus, longitudine subequalibus, illo flagello appendiculari ornata. Pyzma longa, duo anteriores angustissimæ, primo cingulo dorsali subjecta, quartum maximum, apice duplo latius quam basi. Postabdominis segmenta anteriores propriis laminis lateralis instructa. Pedes quarti parvis infrim, ad ambulandum apti, quinti et sexti parvis costis permagnis in laminas ovalibus mutatis, ceteris articulis gracilibus, unguibus minimis rectis." For this genus he would find a place among the genera *Gammara*, *Pontoportica* and *Talitrus*. In 1878, however, he recognizes that the characters on which he had relied for separating it from *Gammara* were probably only due to the accidental condition of the specimen. He speaks of the peduncles of the lower antennæ as triarticulate, but they are from his figures clearly of the ordinary structure, though the composite basal joint is not visible. The amber being found on the coast of Samland, he names the species *Palaogammarus sambicensis*, with this definition:—"Antennis superioribus inferiores longitudine superantibus, inferiorum flagello ex octo articulis composito, segmenti undecim et duodecimi margine dorsali spinis obsoleti, pedibus spinis longitudine aequalibus, appendicibus in abdominis apice nullis." The absence of the terminal appendages, as he afterwards noticed, should not have been included in the specific character, that being almost certainly due only to the defectiveness of the specimen.

To the question how this broken Amphipod got into the amber, the answer is suggested that the amber-producing woods probably came down in former ages close to the sea-shore, and that the creature with the sand attached to it may have there been introduced into a mass of resin. In 1878, he says with regard to it, "die Uebereinstimmung zwischen der tertiaren Art und einer jetzt lebenden läßt sich nicht nachweisen, aber wahrscheinlich ist jene den Arten *Gammarus marinus*, locusta, Edwarsii sehr ähnlich gewesen. Der Stammbaum unseres gemeinen Flohkrebces reicht also bis in jene länge vergangene Zeit hinauf, in der sich die oligocänen Schichten ablagerten." The fresh-water *Gammara pulex* might well have been added to the list of species compared.

1865. Bate, C. Spence.

Grube's *Nicoa istrica* is considered identical with *Nicoa prevostii*, M. Edw. *Anonyx filiger*, Stimpson, is said to be closely allied to *Lysimachus longicornis*, Lucas, "or *L. chaussa* (Spence Bate), not *Allothia chaussia* (Milnc-Edwards)." "The female of the genus *Gammarella* approximates so nearly in form to *Crangonyx*, only having the eye coloured with black pigment, that we have little doubt," Spence Bate says, "of the near relationship of Professor Grube's *Gammarus recurvus* to *Gammarella normani*, which is probably the female of *G. brevicornis*." *Iphimela multispinis*, Grube, which Grube himself likened to *Iphimela nodosa*, Dana, shows, in Spence Bate's opinion, "a closer approximation to *L. elona*, the dorsal teeth being less strong (probably a sexual distinction)." The difference
of *Colomastix paulli* 2, Grube, "from *Cratippus tenuipes* consists in the form of the first pair of gnathopods, which in *Colomastix* terminate in several curved spines, whereas in *Cratippus* it is scarcely subchelate." Even this distinction as suggested by Prof. Grube, may be only of sexual importance; and we think it insufficient to warrant the formation of a new genus." It may be observed that *Colomastix* was not instituted in 1864, but in 1861, and therefore takes precedence of Spence Bate's *Cratippus*.

On *Icriidium faveum*, Grube, Spence Bate observes:—"There is a slight discrepancy between Prof. Grube's excellent figures and the description. First, the telson is undoubtedly present; and since the ante- and penultimate pairs of pleopoda are attached to one somite, we must rather consider that the two somites are fused into one than that one is wanting. We therefore perceive that one, instead of two somites, only is wanting; but it is contrary to previous observation that this deterioration takes place in the anterior portion of the pleon instead of the posterior; for undoubtedly one of the anterior pairs of pleopoda is the missing pair."

1865. Costa, Achille.

He mentions "*Lestrigonos Fabricii*" (Milne-Edwards) (no doubt meaning *Lestrigonos Fabricii*), from the Indian Ocean, *Lestrigonos rubescens* (Dana), from the Pacific, *Lestrigonos evulans*, from Chili, as the earliest known members of the genus, followed by "*Lestrigonos Kinahanus*," Spence Bate, from the British waters. To this he considers a form recently taken in the Gulf of Naples upon a *Melissa* to be closely allied. The distinguishing characters he takes from the proportions of the upper compared with the lower antennas, and from the form of the uropods. He thus describes the species:—"*Lestrigonos mediterraneus*, nob.:—L. antennae superis inferioribus paulum brevioribus; pedibus sparsis quarti et quinti segmenti abdominis stylis lanceolatis, externo parum longiori, in marginem interno lato ducto dentato-serrato; in margine externo integro; stylo interno margine utroque integerrimo; fusco-rufus, antennae, pedibus (articulo primo excepto) cana et albo-dis. Longit. millim. 5."

1865. Goës, Axel Theodor, born 1835 (Hj. Théol).

From this brief but learned work notes will be quoted under the numbers which Goës attaches to most of the species he mentions.

He begins with the Gammarideae:

Lysianassa Gryllus, Mandt. fig. 1, "Eurytane Magelanica, Lilljeborg." Why he rejects Lilljeborg's genus is not explained.

2. "Lysianassa Vahlri," Kröyer, "in itinerarii arcticis cum sequente omnino confusa, sub nomine Talitro nuggae (Ross, Parry's attempt to reach the North Pole, 205), sive Gammaro nuggae (Sars, Append. to Parry's First Voy., 229) edita.—Var. segmenti abdominale terti angulo postico rotundato, neque truncato nec emarginato, statura minore.

3. Lysianassa lagena, Kröyer, "=Cancer nuggae, Philfs." Of these, between three fathoms and sixty, there is "copia stupenda, co ut, si perite ac prudenter in captura versaris, hos pelagi voraciissimos vespillosus habebus multariis cadavere avium vel phocarum brevi e fundo elio ere potes." Lysianassa tumida (Anonyx), Kröyer, "=An. tumida, Bruzel."

4. Lysianassa albigata, n. s., which Boeck transfers to Anonyx.

5. "Lysianassa Martensi," n. s., fig. 2, which Boeck transfers to Anonyx.

6. Lysianassa cripyata, n. s., fig. 3, considered by Boeck to be a synonym of his Orchomene servatus.

7. Lysianassa producta, n. s., fig. 4, identified by Boeck with the earlier Anonyx punctus Lilljeborg, 1865, to which Goës himself says it is "proxima et vix distincta." Lysianassa albigata, n. s., fig. 5, called by Boeck Hippomedon abdominal.

11. Lysianassa unbo, n. s., fig. 6, by Boeck referred to his own genus Orchomene, by Sars, 1882, to Lepidopecreum, Bate and Westwood. A comparison of the description and figures of Lepidopecreum carinatum, Bate and Westwood, with those of Lysianassa unbo, Goës, excites the strong suspicion that they are the same species, and that the English authors have not noticed the boss (umbo) on the fifth side-plates, while the little two to three-jointed accessory flagellum has been accidentally wanting in their specimens. The definition of Lepidopecreum will in that case need some alteration. The type species would still be Lepidopecreum longicorne, Sp. Bate, 1862, with carinatum and unbo for synonyms.

15. Lysianassa l'embula, n. s., fig. 7. "Medium tenet inter Lysianassae et Steganophalos." On this Boeck observes, "Whether this form belongs to Lysianassa or is an intermediate form between that and Stegoccephalus I cannot decide as I have not seen the animal. Among the Lysianassae we have a form in which the back is carinate, Orchomene unbo, while I do not know of any with carinate back belonging to the Stegoccephali. The hand of the second gnathopods also refers this form to the Lysianassae, but the very elongate hand of the first gnathopods shows that it cannot belong to the genus Orchomene, which it otherwise resembles by its deep side-plates. Before it can be placed in a new genus of the Lysianassae fresh investigation is required."

"=Stegoccephalus ampulla, Bell." "Formae duas occurunt:—Altera epimeri quarto septum, albo ac lato, articulo pedum sexti et septimi paris primo dilatato, angulo infero postico subrecto ut acento.—Fig. 8. Altera epim. quarto latiore quam altior, articulo pedis sexti primo angustio, angulo infero postico lobulo rotundato determinato, pedes septimi articulo eodem dilatato margine infero postico rotundato nec angulato. —Fig. 9. An differentia sexualis?"

*Montagua clypeata* (Lepechin), Kröyer, called *Metopia clypeata* by Boeck.

"Montagua Buzelli," n. s., fig. 10, "= Leucothoe clypeata, Buz."

See Note on Bruzelius, 1859.

*Montagna glacialis* (Lepechin), Kröyer, called *Metopia glacialis* by Boeck.

*Ous carinatus*, Sp. Bate.

*Vertumnus cristatus*, Owen, "Acanthonotus, nomen gerensis plicatum anno 1801 editum."

*Vertumnus serratus* (Oudinet), Fabr., "= Amph. serru Kröy., "= *Acanthonotus serru Buz."

*Vertumnus inflatus* (Acanthonotus), Kröyer, fig. 11.

"Paramphithoe*, Buz. A. Epimera quarta dilatata (Pleustes, Sp. Bate)."

*Paramphithoe exigua*, n. s., fig. 12, identified by Boeck with his *Amphithopsis glaber*, 1860, which he afterwards called *Pleustes glaber*.

*Paramphithoe media*, n. s., fig. 13, by Boeck called *Pleustes media*.

*Paramphithoe panopla* (*Amphithoe*), Kröyer, "= Paramph. panopla Buz.; "= *Pleustes tuberculatus* S. Bate," called *Pleustes panopla* by Boeck, 1876.

"B. Epimera quarta non dilatata.

*a. Caude appendix fissu aut incisa (Atylus, Leach—S. Bate)."

*Paramphithoe carinata* (Gammarnae), Fabr., "= Atylus carinatus, Leach; "= *Amphithoe carinata*, Kröy.," now accepted as *Atylus carinatus*.

*Paramphithoe Smittii*, n. s., fig. 14, by Boeck called "Atylus Smittii.

*Paramphithoe inermis* (*Amphithoe*), Kröyer, is mentioned.

*Paramphithoe fragilis*, n. s., fig. 16, "Forma Amphithonotis propinqua.

In accordance with this suggestion Boeck calls it *Tritropis fragilis*, which will now become *Rhachotropis fragilis*.

"b. Caude appendix indivisa vel obsolete incisa [Calliope, Pherusa, Leach, et *Paramphithoe*, S. Bate]."

*Paramphithoe lasiuscula* (*Amphithoe*),Kröyer, "= Amphithoe serratocornis, Sars, 1858; = Paramph. lasiuscula, Bruzel., "= Calliope lasiuscula, S. Bate.*

*Paramphithoe bifida* (*Amphithoe*), Kröyer. See Note on Bruzelius, 1859.

*Paramphithoe triuncis* (*Acanthonotus*), Kröyer.

*Paramphithoe fulicincta* (*Amphithoe*), Sars, 1858, fig. 15; "= Pherusa triuncis, Stimpf.," 1863. 34. *Paramphithoe pubella* (*Amphithoe*), Kröyer. 35. *Paramphithoe lystrix* (*Acanthonotus*), Owen.

"Amphithonotus Malmoense," n. s., fig. 17. This in 1870 was made the type of a new genus, *Acanthropus* by Boeck in the subfamily Odecerinae.

*Oeicerus saginatus*, Kröyer, fig. 18. 32. *Oeicerus propinquus*, n. s., fig. 19, by Boeck made a synonym of *Oeicerus lanuginosus*, M. Sars, 1858.

*Oeicerus longirostris*, n. s., fig. 20, called *Monoculodes longirostris* by Boeck.

*Oeicerus affinis*, Bruzelius, Amphip. Gammar., "93, f. 18 (non rite delineata) secundus articulus pedunculi autem, sup. apice interdum dilatato; rostrum variat, nunc leviter curvatum, nunc fere gonioculatum; segmenta abdominis quatuor antica dorso interdum carinato.—Fig. 21 et 21." Boeck refers *Oeicerus affinis*, Göös (non Bruzelius), partly to *Monoculodes norvegicus*, Boeck, 1860, and partly to *Monoculodes borealis*, Boeck, 1870, with which J. Sp. Schneider, 1883, agrees, but "non sinc dubio," the generic rostrum represented in Göös' fig. 21 being the attribute of *Monoculodes borealis*.

*Oeicerus brovicolarum*, n. s., Fig. 22, by Boeck named *Halticola brovicolarum*.

*Oeicerus latimanus*, n. s., Fig. 23, by Boeck called *Monoculodes latimanus*.

REPORT ON THE AMPHIPODA.

antenn. supern. pedunculi articulo valde abbreviato, pedes ordinis tertii et quarti articulo quarto valde dilatato, unguis pedum 3, 4 et 5 obtusus, foliaceus, angustus elongatus.—

Fig. 24 et 24." See Note on Bruzelius.

The new genus *Syrtchoë* is thus described:—

"Frons pro ducta, ocelli oedicerorum, antennæ supernæ flagello appendiculari instructæ, mandibula palpo triarticulata."

45. *Syrtchoë crenulata*, n. s., Fig. 25.

*Syrtchoë bicuspid*, n. s., Fig. 26. This is identified by Boeck with the earlier *Tiron acanthurus*, Lilljeborg, 1865; Boeck calls attention to the fact that Lilljeborg's work is referred to by Goës, and must therefore have priority, though both authors published in 1865.

46. *Phoxus plumosus*, Kröyer. He also mentions *Phoxus Holbøll*, Kröyer, and *Bathyporeia pilosa*, Lindström, 1855, for this giving also a reference to "Lovén, Öfvers. af K. Vet. Akad. Forhandl. 1861!"

47. *Haploops tubicola*, Lilljeborg. "Ex abysso ad Aukpudartok Groenlandie copiam magnam retulit TO'RELL specimenum valde robustorum et ocellis quatuor, dubus in vertice, dubus in angulo infero laterali antico capitis insignium,—ceterum cum nostra plane congruentium." Boeck refers to this statement by Goës as to the eyes, without being able to confirm it from his own experience, so that in his generic account of *Haploops* he writes "Ocelli duo (quatuor?)"; but he considers that the genus is distinguished from *Ampeliscæ* by other characters, especially the peculiar form of the last peracarida.

48. "*Ampelisca Euchelidae*," Kröyer, "= A. macrocephala Lilljeborg." These two species are however, kept apart both by Boeck and J. Sp. Schneider.

52. *Gammarus pallidus* (Lilljeborgia) Sp. Bate, "= G. fssicornis Sans," 1858; "= G. breviceornis Bruzel.;"—Fig. 27. "ad Spetsbergiam in sinu Storfjord paucos fundo argill. org. 5 prof. prehendit MALEOES 1864, valhiores quam nostros quadruplo statum, fere pollares, apinis segmentorum abdominis 4:1 et 3:1 sat longis succincta, pedibus septimi ordinis valde incassatis, ocellis indistinctis." Boeck separates *Lilljeborgia pallida*, Sp. Bate, 1855, and *Lilljeborgia fssicornis*, M. Sans, 1859, but the distinctions are tolerably subtle. He assigns *Gammarus pallidus*, Goës, fig. 27, to the latter species.

53. "*Gammarus Loreni*," Bruzelius, by Bate called *Mero loreni.* "*Gammarus Torelli*," n. s., Fig. 28, by Boeck called *Mero torelli.*

"Formae due occurrunt paullum diversae; vide Fig. 29 et 29." By Boeck called *Melita dentata.*

55. *Gammarus spinosus*, n. s., Fig. 30, by Boeck called *Melithilippa spinosa.*

56. *Gammarus brevicauda* (Cancer) Linn., in the synonymy of which he mentions *Gammarus boreus*, Sabine; *Gammarus arcticus*, Scoresby; *Oisicus puteus*, Fabr., Fl. Gr. 1780; and says that it scarcely differs from *Gammarus silchenes*, Brandt. He gives notes on its distribution, and remarks "Oculorum forma variat, nunc oblongo-reniformis, nunc angustissimae linearis, nunc evanescentes."

57. *Gammarus brevicornu*, Sabine, "= Gaumnaracanthus loric. S. Bate."

58. "*Gammarus Sabini*," Leach, "= Anathia Sabini S. Bate;" "= Cancer macrocerus articulatus, dorso carinato serrato, spinis caudis bifidas STRÖM."

60. *Amphioe macronyx* (Gaumnarur), Lilljeborg, "Forma artica, clathor, manus 3 secund pedum ordinis subquadrata, margine postico crenata 3-6 obsoletis (nee tuberculis) spinæ angularis interdum evanescente, ungue crassior atque brevior; antenne pedesque omnino longiores. —Fig. 31." This is identified by Boeck with *Protamphideis fasciata*, Kröyer.
61. Autonoe depressa, n. s., Fig. 32, transferred by Boeck in 1870 to a new genus Gosia, near to Leptocheirus.

At this point Gosse pass the from the Gammaridae to the Corophidae.

*Amphithoe reinhardtii* (Pholis), Krüyer, "= Amph. pygmaea Lilljeb". Boeck restores the name *Photis reinhardtii*, Krüyer.

*Siphonocutes typicus*, Krüyer.

64. *Closunomus lencopis*, Krüyer, "= Unciola lencopis S. Bate."

In the Hyperide he gives

65. *Themisto littillida* (Gammarus), Mandt, "= Th. arctica Kröy.;" "= Th. crassicornis Kröy.;" "Antennas interdum elongatas, multiarticulatos flagellos.—Fig. 33, 33." Among the places of capture he names "Finnmarkian (Malmgren), ubi alia etiam forma occurrunt a typica paullum discrepans: pedes terti et quarti articulo 4:1 angustiores, art. quinto longiores; pedes quinti septimos paulllo breviores aut inter se longitudine aequales."

*Themisto compressa*, n. s., Fig. 34, 34, referred by Boeck to his new genus Parathemisto.

"Ad nostras oras alia etiam forma occurrat paullum diversa, pedes primi ordinis articulo quinto fore cylindrico unique setoso, ungue minuto." This variety Boeck identifies with his own *Hyperia spinipes*, 1860; the *Hyperia exulans* with *Hyperia medusarum*, O. F. Müller.

67. *Hyperia medusarum* (Metoces), Krüyer, "= ? Cancer medusarum Müll.," 1776; "= Oniscus medusarum Fab., F. Groosl. 1780 p. 257; Ice prototypica ab his relata Strömi (Om Sønsmør etc. I, t. 1, f. 12) non sit distincta." "= Antennas longissimus multiarticulatis."

Gosse notes of this and the preceding species, that they are found free as well as on Medusae.

In the Dulichidae, he mentions 68. *Dulichia spinosisima*, Krüyer.

In the Caprellidae, he mentions 69. *Caprella septentrionalis*, Krüyer, "= Squilla lobata FAB., Fann. Greuel. 1760, p. 248 (non Müller); = Capr. cercopoides White, Append. to Southernland's John. 203 f. 1 et p. 207; nunc tuberculatus nunc fore lavis."

70. *Caprella spiniceps*, Bell, Append. to Belcher's list of Aret. Voy., p. 407. t. 35. f. 2.

1865. Gosse, P. H.

A Year at the Shore. London, 1865.

Pages 151-154 discuss some Amphipods. The habits of *Gammarus locusta*, "the common Locust Screw," and *Gammarus pulex* are mentioned, and some of Lovén's remarks are reproduced, in regard to the discovery of *Gammaracanthus loricatus*, Sabine, *Pontogoniella affinis*, Lindström, and *Gammarus candeloides*, Gerstfeldt, in Lakes Wetter and Wener in Sweden.
1865. Heller, Camil.

Kleine Beiträge zur Kenntniss der Süßwasser-Amphipoden. Mit 1 Tafel: (Taf. 17.) (Aus den Verhandlungen d. k. k. zoologisch-botanischer Gesellschaft in Wien [Jahrgang 1865] besonders abgedruckt.)

The new species Orchestia cavimana is here described and figured. It was taken on Mount Olympus in Cyprus, at a height of 4000 feet by Dr. Kotschy. The new species, "Gammarus Veneris" was also taken by Dr. Kotschy in Cyprus, 50 feet above the sea. This species is said by Heller to be intermediate between Gammarus marinus and Gammarus pulex. In "a review of the hitherto known South European fresh-water amphipods," he says that "they all belong to the genus Gammarus Fabric." He arranges them as follows:

A. First gnathopod somewhat larger than the second, telson simple, undivided; third uropod with a single ramus. (Subg. Crangonyx, Sp. Bate.)

1. G. recurvus.

AA. First gnathopod not larger than the second, telson deeply split, or double; third uropod with two rami:—

a. First gnathopod almost as large as the second, eyes rudimentary, the three last segments of the pleon without bundles of spines, the outer ramus of the third uropod bi-articulate. (Subg. Niphargus, Sch.)

2. G. pulex.

b. First gnathopod smaller than the second, eyes well developed. The three last pleon-segments with bundles of spines, the outer ramus of the third uropod uni-articulate. (Subg. Gammarus, Sp. Bate).

a. The three first pleon-segments prolonged backwards to a pointed spine-tooth.

β. The three first pleon-segments straight behind, without spine-tooth.

† The outer ramus of the last uropod only a little longer than the inner.

4. G. pulex.

†† The outer ramus of the last uropod much longer than the inner.

5. G. pungens.

These divisions are founded on 1. Crangonyx recurvus, Grube; 2. Niphargus (Gammarus) pulex, Caspary, with which Heller unites Niphargus stygius, Schiodte, and Niphargus agiler, Sp. Bate; 3. Gammarus roeselii, Gorvais, identified with Spilla fluviatilis, Riesel, and Gammaridus pulex, Herbst; 4. Gammarus pulex, Desmarest, identified with Gammarus fluviatilis, M.-Edwards, and 5. Gammarus pungens, M.-Edwards. Of this last he says that it closely agrees with his own new species Gammarus veneris, only that, according to M.-Edwards' short description, Gammarus pungens appears to have the inner ramus of the last uropod quite rudimentary. Of Gammarus veneris itself, Heller thus describes the last uropod, "ramus inferior pedum sexti parvis postabdominis exteriore multo brevior, ramis hirsutissimis." Gammarus roeselii, he says, "lebt in tiefen stehenden oder schwach fließenden Gewässern. Ich kenne ihn aus der Umgebung von Salzburg, Wien und Ofen, in Tirol habe ich ihn noch nicht angetroffen."
Bidrag till kännedomen om underfamiljen Lysianassina inom underordningen Amphipoda bland kraftdjuren.

The two papers, written in different languages by the same author, are essentially the same. In the suborder Amphipoda Lilljeborg mentions as common to both the arctic and antarctic zones the genera Orchestia, Leach, Anone, Kroyer, Iphimedia, Rathke, Atylus, Leach, Ampelisca, Leach, Hyperia, Latreille, Themisto, Guérin-Méneville, Cyamus, Lumarck (properly Latreille). He speaks of Themisto and Anone as peculiar to the zones in question, but immediately after qualifies this statement. Lysianassa magellanica, he makes the type of a new genus Eurytenes, which he thus defines:

"Corporis forma crassa et robusta, epimeris magnis et pedibus brevibus. Antennae superiores flagello appendiculari preditae, pedunculo crasso et cibus sequentia 2:do et 3:to brevibus, et flagelli segmento 1:mo longo. Antennae inferiores segmento pedunculi 1:mo magno et inflato et extus visibili. Mandibulae palpigerae acie laci et tuberculo rotari magno instructae. Maxilla 1:mi paria palpis biarticulato angusto, apice duobus vel tres setis vel aculeis minores mobiles gerente, et cæcum ramus interior latus et brevis et setis multis ciliatis instructus. Maxillipedia lamina trunci segmenti 2:di, sicc laminae exteriores magnis interiore tenuissime nodulos, et corum palpis quadriarticulato et ungiferus. Pedes trunci sive thoracici 1:mi et 2:di paria subcheliformes, illi calidi et breves, uniquely evothi, hi longiores et graciliores, magno minusisimo. Reliqui pedes trunci forma solita, robusti. Laminae branchiales simplices minimegue pectinatim plicata. Pedes caudales ultimi paria ramis lamellosis. Segmentum 7:um sive ultimum caudae profunde bifidum, laciniis acuminate ad apicem vero non spiniferum. Tantummodo una species: Eurytenes magellanica (H. Milne Edwards)." The definition inserted in the Swedish paper adds to the account of the mandible, "processus accessorio vero minimo et simplici," which is in the English paper appears in the description of the species. The species is now known as Eurytenes magellanica, having been identified by Böeck with Gammarus magellanicus, Mandt, (rather Lichtenstein in Mandt), 1822. A full and interesting account of the species is here given, with good figures, Plates I., II., III., figs. 19–22. Lilljeborg agrees with Spence Bate in numbering the limb-joints, not from the first free joint, but from the true first joint, "to which the gill-sack and lamina for covering the eggs are attached.

A tabular view of the families of the Amphipoda gives them in two groups; those in which "Pedum caudatum omnia parsia adsum—Normalia, S. Bate," are 1. Gammaridae, Dana. 2. Orchestidae, Dana. 3. Corophiidea, Dana. 4. Cheluridae, Allman. 5. Hyperidae, Dana. Those in which "Pedicr caudatum unum vel plura parsia adsum—Aberrantia, S. Bate," are 6. Dulichiidae, Dana. 7. Caprellidae, Dana. 8. Cyamidae, Dana. The Hyperidae are distinguished from the four preceding families by having the "maxillipedes imperfecti et palpo carentis." The Cheluridae are separated from the three preceding by having the "Segmenta caudalum posteriora coalesita;" but since the establishment of the genus Gophila, Wrzesińskiowski, this character has lost some of its definiteness.

In a tabular view of the genera of the Gammaridae, Lilljeborg introduces Microplax as a new name for Iduna, Böeck, Iduna being preoccupied, but Lilljeborgia, Spence Bate, 1862, has the priority. Otius is substituted for Otus preoccupied, and Calliopeus for Calliope.
REPORT ON THE AMPHIPODA.

preoccupied. The genus *Tiron* is “typified” in a new species called *Tiron acanthornis*, and thus defined:—

The new genus *Oediceropoides* is also typified by a new species, which, because the upper antennae are particularly short, is called *Oediceropoides brevicornis*, with this definition:—

In the subfamily *Lysianassina* Lilljeborg gives five genera, which correspond to thirteen out of the seventeen which Boeck has assigned to it.

*Lysianassa*, Milne-Edwards, he defines as follows:—

“*Pedes trunci thoracici 1:mi pari minus subcheliformi carentes, unque non flexibili, segmento 6:to sive manu apicem versus attenuato idemque basi unguis cito erantere. Mandibulae tuberculo notari minima. Laminae extreiores maxillipediae margine intdore nodulosa vel leviscula.”* Within this he distinguishes three species thus:—

<table>
<thead>
<tr>
<th>Segmentum</th>
<th>fissum.</th>
<th>pectinatum plicata</th>
<th>1. <em>spinoarius</em> (A. Boeck).</th>
</tr>
</thead>
<tbody>
<tr>
<td>7:miu caude</td>
<td>Laminæ</td>
<td>branchiales</td>
<td>non plicata</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>non fissum, margine posteriori convexo</td>
</tr>
</tbody>
</table>

Of these the first is *Ichnopus spinoarius*, Boeck, 1860, the second was called “Scarcus *Valli*” by Boeck in 1870, the third is the original type species of *Lysianassa*.

The second genus, *Burgesia*, has been already described. The third genus, *Anonyx*, Kröyer, is thus defined:—

“*Pedes trunci (thoracici) 1:mi pari minus subcheliformi armati, unque flexibili, margine inferiore manu plus vel minus definito. Mandibulae tuberculo notari mediioceri vel magno. Laminae extreiores pedum maxillarium margine intdore planusque nodulosae, raro dentato vel nudo.” To this he assigns the following fifteen species, 1. *Anonyx ampulla* (Philips); 2. *Anonyx nummularia* (Philips); 3. *Anonyx longipes*, Sp. Bate, Pl. iii. fig. 22, which is rather to be called *Anonyx nummularia*, Philip; 4. *Anonyx longipes*, Sp. Bate, Pl. iii. figs. 23-31, called *Tryptella longipes* by Boeck, 1870; 5. *Anonyx globosa*, Kröyer, including his own *Anonyx norvegicus*, 1851, and the *Anonyx bulbosa* of Baé and Westwood; 6. *Anonyx nanus*, n. s., Pl. iii. fig. 32-34, called

(KOOL. CHALL. EXP.—PART LXVII.—1887.)

Xxx 46
THE VOYAGE OF H.M.S. CHALLENGER.

Tryphosa nanoides by Boeck, 1870; 5. Anonyx punidus, n. s., Pl. iv. fig. 35–41; 6. Anonyx brachy cercus, n. s., Pl. iv. fig. 42–49, called Menigrates brachy cercus by Boeck in 1870; 7. "Anonyx Brueulli," Boeck, which is recognised as standing near Anonyx gulosus, and was subsequently regarded by Boeck himself as a variety only of that species, see the table of errata and addenda to De Skand. og Arkt. Amph. 8. Anonyx nanus, Kröyer, by Boeck in 1870 called Tryphosa nanus; 9. Anonyx punguis, Boeck, later called Ouchon ome punguis by Boeck; 10. Anonyx serratus, Boeck, Pl. iv. fig. 50, afterwards called Ouchon ome serratus by Boeck; it is here identified with Anonyx Eduardsi (Spence Bate), but wrongly according to Sars; 11. "Anonyx Eduardsi," Kröyer, afterwards called Oonesimus edwardsi by Boeck; 12. Anonyx litoralis, Kröyer, called Oonesimus litoralis by Boeck; 13. "Anonyx Holbøllii," Kröyer, called Hippomedon holbølli by Boeck; Anonyx denticalatus, Spence Bate, is here said to be the male of this species; 14. Anonyx obtusifrons, Boeck, which was afterwards called Menigrates obtusifrons by Boeck; 15. Anonyx tunidus, Kröyer, Pl. iv. fig. 51, which Boeck calls Aristus tunidus.

Boeck, it will be observed, requires seven genera for these fifteen, or perhaps thirteen, species. Anonyx bruelii falls to Anonyx gulosus (circula), and Anonyx brachycercus is considered by Boeck, in 1876, to be a synonym of Anonyx (Menigrates) obtusifrons. In Lilljeborg's synoptic table Anonyx brachycercus is separated from Anonyx obtusifrons by the maxillipeds. In brachycercus these have the outer plates large, "ultra medium articuli 3dii palpi extensus, ad marginem intericem tantummodo epicem proprius nodulosus, nodulos discretis 4, et ad marginem exteriorem setam unam et pilos minimos gerentes," while in obtusifrons he finds from Boeck's description that these plates "have some few scattered coarse teeth on the inner margin." These delicate characters seem little suited for important subdivisions. I am inclined to think that the teeth on the inner margins of the outer maxilliped-plates are very liable to accident, so that their absence cannot always be depended on as characteristic.

The fourth genus, Callisoma, Costa, has the species Callisoma kröyeri, Brueulli.

The fifth genus, Acidostoma, which is new, is thus defined:—

"Forma corporis et antennarum cum gener Anonycis congruit, oris partes appendiculares tamen plane diversa. Labii rami laterales anglacti. Mandibulæ processus accessorio, maxillo 1sti paris palpe, et palpe maxillipodeum unque carentes, et basi oris con-Menigrates productus prævent. Pedes trunci 1sti paris robusti, maximo præcident. Pedes 2sti paris graciles, unque carentes." To this genus, as the type species, is referred Anonyx obsessus, Sp. Bate, which is described and figured, Pl. v.

1865. MÜLLER, FRITZ.

The new genus, Batea, is thus defined:—"Antenne simple. Coxa of the first pair of gnathopoda rudimentary, those of the second pair of gnathopods and the first two pairs of peraeopods largely developed. Coxa of the second pair of pereiopods deeply excavated upon the upper part of the posterior margin. First pair of gnathopoda rudimentary, consisting of coxa and basis only; second pair of gnathopods subchelate. Mandibles having an articulated appendage. Maxillipeds having a squamiform plate on both the basis and ischiuim joints. Fourth and fifth pairs of pleopoda with styliform rami, sixth pair with subfoliaceous rami. Telson single, deeply cleft."

"Species Batea Catharinensis, F. M."

Fritz Müller dates from Desterro, Brazil. He gives figures of the male, and notes in his
REPORT ON THE AMPHIPODA.

363

description several differences presented by the female. Among other points he mentions that "the first pair of gnathopoda are shorter in the male, with but few hairs near the top; they are as long as the basis of the second pair of gnathopoda in the female, slender, flexible, with long hairs on the anterior margin, and shorter curved hairs at the distal extremity."

1866. BATE, C. SPENCE.

In reviewing Lilljeborg's work on the Lysianassina, Spence Bate remarks, "the closest inspection of specimens of <i>Coprella aquilifera</i> from the United States of America has not enabled us to distinguish it from specimens found at Hong Kong and England by so much as a variation that could be tortured into being of specific value. This, moreover, appears to be true of forms that we find described as specifically distinct; but as yet no forms have been determined by competent zoologists as specifically identical in both extreme zones, there being no intermediate locality in which they are known to exist." He thinks "the carcinologist may have confidence that the figure in the British Museum Catalogue fairly and faithfully represents the general form of the type specimen of <i>Lysianassa magellanica</i>.

Part of the inferior antennae "may have been hypothetically inserted." He draws the conclusion that Lilljeborg's identification cannot be maintained between his <i>Eurytenea magellanica</i> and the <i>Lysianassa magellanica</i> of Milne-Edwards. He compares the <i>Anonyx amputa</i> of the British Sessile-eyed Crustacea with Kroyer's figure in Voy. Scand., pl. xiii. fig. 2, with which he thinks it identical.

Spence Bate objects to the placing of his <i>Anonyx obscus</i> in the new genus <i>Acidostoma</i> "as all the distinguishing conditions are changes in degree only."

1866. COSTA, ACHILLE.

He notices that Guerin, in the Icon. Regn. Anim., figures a species of <i>Cyanmus</i> parasitic on a species of <i>Delphinus</i>, which he calls <i>Cyanmus delphini</i>, and which differs from the parasites on species of <i>Balaena</i> in important characters, and that Gervais and Van Beneden have proposed for it a separate genus <i>Iocyamus</i>, without however formulating the generic characters. As he has himself found a <i>Cyanmus</i> differing apparently from Guérin's, he concludes that there must be more than one species parasitic on the <i>Delphinus</i>. He describes and figures (pl. iv, fig. 2) the new species as <i>Cyanmus chelipes</i>, remarking, "Ne possediamo un solo individuo femmina rinvenuto sopra un Delfino comune pescatosi nel golfo di Napoli. Osservazioni. Se la figura data dal Guérin del <i>Cyanmus Delphini</i> è esatta, la nostra specie ne differisce per le antenne interne men lunghe, pe' piedi del primo paio a mano pronsile, per quelli del secondo proporzionatamente meno grossi e per una diversa forma delle mani de' medesimi, pel primo articolo de' piedi del quinto seo et settimo paio non fortemente intaccato nel margine posteriore." Lütken gives no opinion upon this species, probably not having met with the account of it.
1866. Dohrn, Anton, born December 29, 1840 (Paul Mayer).

Dohrn remarks, as Gosse had done before him, that Caprellës can upon occasion swim with activity. In his account of the nervous system, he says that "the brain mass consists of two large, differently-formed swellings, of which the upper is considerably larger than the lower. The former shows three distinct sections, a larger upper, a central giving off the optic nerves, and a small anterior one. The upper mass is pierced by the two branches of the aorta, the lower by the oesophagus; behind this the broad oesophagean commissures pass obliquely backwards, entering the first mass of the ventral chain, which likewise consists of two coalescent ganglia. The hinder smaller ganglion belongs to the coalescent first pleon-segment and is considerably smaller than the anterior, properly suboesophagean ganglion." Mayer observes that the coalescence here spoken of is true of the genus Proto, but in most genera and species of the Caprellidae, the ganglia in question come together without actually coalescing. Dohrn cannot agree with Frey and Leuckart in the view that the ganglion of the second pleon-segment is more powerfully developed than any other, although he thinks that no doubt the importance of the ganglia depends on the extent of the regions they have to supply. He studied the nerves in the young animal, but as a matter of fact in some adult Caprellës the second pair of limbs are so greatly developed that the statement by Frey and Leuckart is just in accord with the general principle which Dohrn accepts. Dohrn found that the last pleon-segment and the rudimentary pleon, at any rate in the young animal, were without nerve-masses, but on the other hand he discovered that the last ganglion, in the sixth pleon-segment, corresponded not merely to two coalescent nerve-masses, but rather to five, some of which he naturally supposed were derived from the pleon. Mayer, investigating young animals of Caprella and Protella, has since seen "behind and between the two strong nerves that run from the seventh pleon-ganglion to the corresponding pair of legs, no less than seven ganglia, three pairs and an odd one. The second and third pairs rapidly unite into a single mass, and do not appear to give off any nerves. The last odd one shows traces of coalescence out of an original pair. It is the largest of the pleon-ganglia, and no doubt, as Mayer says, corresponds to the single ganglion which provides in the normal Amphipoda for the three segments preceding the telson.

Dohrn finds only two liver tubes in the Caprellidae, and therefore concludes that when Spence Bate speaks of the liver in the Amphipoda as consisting of four tubes, it is an error of observation. The number, however, varies in different genera.

In treating of the circulation, Dohrn attributes to the heart five pairs of fissures instead of three. The first, he says, is in the cephalic segment, where the aorta parts from the dorsal vessel; the second, third and fourth lie in the middle of the corresponding segments. The fifth lies in the middle of the fifth segment at the end of the dorsal vessel. The fourth is by far the largest.

In regard to the sexual organs, Dohrn supposes, but erroneously, that there are two pairs of testes in Caprella, though in the other Amphipoda he is aware from concurrent testimony that there is but one pair.
1866. Grube, A. E.

Grube explains, to begin with, that he names the seven joints of the leg numerically according to their position, except the seventh, which for brevity he calls the finger (die Klau). On the first joint his remark is that he reckons "das Basalstück, an welchem die Klene und das zum Tragen der Eier bestimmte hornenartige Blatt befestigt ist, und das von der Epimeraplatte aussen überwachsen aber doch von dieser unterscheidbar, ist als Ies Glied oder Hüftglied." He defines the Amphipoda genuina, the Gammarella, and the two families, Orchestide and Gammaride.

After discussing "Orchestia littorea," and "Orchestia Montagna, Aud.," Taf. ix. fig. 1, with some of their synonyms, Grube gives a definition of Allorchestes, Dana, including "Telson simplex vel bipartitum." To this genus he assigns 1. "Orchestia Pericii, Lucas," Taf. ix. fig. 2; 2. a new species, "Allorchestes Helleri," Taf. ix. fig. 3, which he had previously classed as "Allorchestes tribulatus, Spenze Batte? jurv.," but which is probably Hyale nilsonni, Rathke; and 3. a new species, Allorchestes stylifer, Taf. ix. fig. 4, "carpo... satis late, postice in processum styliformem curvatum excentum," a peculiarity which, with some other slighter distinctions, separates it, he says, from Amphithoe (Allorchestes) prevosti, Milne-Edwards. He then gives a definition of Nicea, Nicolet, including "Telson profunde divisum," and, depending apparently only on comparative lengths of the antenna for the generic distinction, he assigns his Amphithoe (Hyale) iotrica to this genus as Nicea iotrica δ, Taf. ix. fig. 5. He describes a new species, Nicea longicornis, from a single female specimen, 4 ram, in length, having "antennae superiores inferioribus paulo longiores et fortiores, usque ad segmentum quintum pertinentes, articulis 14, 2° longitudine 1°, dupla 3°." It reminds him of Calliope, but for the last uropods, while Gammarilla and Crangane are excluded on other accounts. The character of the antenna at any rate seems little to accord with Nicea (Hyale), and, as no figure is given, it might be rash to suggest Pherusa fasciata.

Leach, for this species, on the presumption of some error in Grube's description.

In defining the genus Lysianassa, Grube gives "Telson squamiforme integrum vel fissum," and in it describes, 1. Lysianassa spinicornis, A. Costa, Taf. ix. fig. 6; 2. Lysianassa loricata, A. Costa; 3. his own Lysianassa ciliata, Taf. ix. fig. 7, which has the "telson oblongum longitudine appendicem pedes bistyli 3°, usque ultra medium fissum," and is thereby excluded from the genus Lysianassa as generally defined, and from identity with Lysianassa audominiinae, Sp. Bate, as proposed by Heller; 4. Lysianassa humilis, A. Costa, which in Heller's opinion is probably the same as Lysianassa costa, M.-Edw.; 5. Lysianassa longicornis, Lucas, Taf. ix. fig. 8, with remarks on the differences between the two sexes, extending not only to the size and shape and armature of the antenna, but also to the form of the first gnathopods and of the telson. "Das Telson, dessen Form als charakteristisch für die Species gilt, war hier bei Männchen und Weibchen verschieden gestaltet, bei beiden zwar länglich, oben etwas verschmälerl mit geraden Seitenrändern, aber bei jenen ganzrund und abgerundet bei diesen hingegen länger und scharf und tief eingeschnitten, daher zweispitzig, jede Spitze mit einem Stachelchen besetzt." Though he had specimens with eggs well advanced in development, Grube states that he had sought in vain for the marsupial plates. On the whole I incline to infer that, while assuming to describe the female of Lysianassa longicornis, Lucas, he has had before him not only a distinct species, but the species of a distinct genus, probably Ichnopus taurus, A. Costa. He figures and describes (seemingly
from the female only), what he calls "gefielerte Kiemen," the branchiae not simple, but carrying symmetrically arranged supplementary vesicles, an arrangement now known to exist in several species, and already described by Costa in _Ichnopus_. He also draws discriminating characters from the mouth-organs of the three species _longicorns_, (probably the ? so-called), _spinicornis_ and _cilata._

Grube makes _Leptocheirus_, Zaddach, and _Ptilocheirus_, Stimpson, synonyms of _Protoseleia_, Krøyer, in agreement with Spence Bate and other writers, but Boeck places _Leptocheirus_, with _Ptilocheirus_ for a synonym, in his subfamily _Leptocheirinae_, and _Protoseleia_ in the subfamily _Microcheirinae_, the differences being in the maxillipeds, the side-plates, the second gnathopods, and the last uropods. In the _Leptocheirinae_, moreover, it is noted that the first joint of the mandibular palp is elongate. Grube describes _Protoseleia birentiana_, Sp. Bate! Taf. x. fig. 2," but in the description of "Taf. x. fig. 2," he calls it _"Protoseleia pilosa_ (Zadd.)," having apparently convinced himself of the identity of his own specimen with Zaddach's species. His new species, _Protoseleia guttata_, Taf. x. fig. 3, as well as the old one, must evidently be placed in the genus _Leptocheirus_.

He figures his species _Crangonyx recurvus_, Taf. x. fig. 1, and describes it anew.

Being unacquainted with _Gammarus marcianus_, Leach, Grube refers a species, which he had previously called _Gammarus oberti_, M.-Elw., to _Gammarus pectinatus_, Rathke. He describes _Gammarus gracilis_, Rathke, recognising that it may be only a variety of _Gammarus pectinatus_. All these _Gammarus_ are by Boeck accepted under the name _Gammarus marcianus_, Leach. Grube concludes this paper with a description of _Gammarus locusta_, Lima.

1866. Heller, Camil.

_Orchestia montagni_, Audouin, is given as a distinct species from _Orchestia littorea_, Leach, but _Orchestia constricta_, Costa, is made synonymous with _Orchestia montagni_. The new species described and figured are _Nica phontocornis_; _Nica fuscocornata_; _Nica Bucichi;_ _Nica multicornis_; _Nica macronyx_, which will be _Hypse prevosti_, if Catta is right in identifying it with _Amphithoe prevosti_, M.-Elw.; _Nica camptonyx_; _"Nica Schmittii;"_ _Nica rufta_; _Nica crasipes_; _Probolium megacephos_, which being without mandibular palp must be transferred to Dana's genus _Stenothoe_; and, for the species, is identified by Catta, 1876, with Costa's _Probolium polygonum_; _Lysianassa pilicornis_; _Ichnopus affinis_; _Ichnopus calciferus_, identified by Boeck with his own _Ichnopus spinicornis_, 1860; _"Anonyx Schommars;"_ in Boeck's opinion, perhaps, together with the next species, belonging to his genus _Ambasia_; _Anonyx fliticos_; _"Anonyx Narbonis;"_ (at p. 59 by a misprint assigned to Krøyer), said to differ little from _Anonyx maris_; and by Boeck referred to his genus _Tryphoea_; _Iphimelisa variata_, not figured, and not in my opinion specifically distinct from _Iphimelisa obesa_, Rathke, which includes two other synonyms or varieties, _Iphimelisa ebanus_, Sp. Bate, and _Iphimelisa multiformis_, Grube; _Eusiris bicus_; already described by Boeck as _Eusiris longipes_; _"Melita Coronati;"_ _Melita integrifrons_; _"Melita Donatoi;"_ which, like _Melita grossimana_, Montagu, and _Melita Loveni_, Bruguies, has the finger of the second gnathopods fringed with hairs on the outer margin; _Amphithoe bicupis_, a name preoccupied by Krøyer, and the species identical with _Sunamphithoe conformata_, Sp. Bate; from _Sunamphilotha hannahi_ Heller himself observes that it is distinguished only by the greater
length of the upper antennae and by the presence of two terminal hooks on the telson; 

"Amphithoe Brunnii;" Podocerus minutus, identified by Boeck with Podocerus falcatus, Montagu; Heller himself distinguishes it from Podocerus variegatus, "especially by the presence of a simple hook on the outer branch of the third uropods," (compare Amphithoeides, Kossmann, 1880); Podocerus longicornis, with forty joints to the flagellum of the upper antennae, yet given by Boeck as a synonym of Podocerus angulipes, Kröyer, which has that flagellum of six to eight joints; Podocerus longicornis, said by Heller to approach Amphithoe crassicornis, Costa, and by J. V. Carus, 1885 (probably on Nebeski's authority) entered together with the preceding species in the genus Amphithoe, without special notice of the secondary flagellum in each of these species; "Microdeifopus Titi;" Cyrtophium bore, probably the same as Cyrtophium dorensis, Sp. Baté, Dr. Heller having apparently taken the account of the transverse ridge to mean a longitudinal carina; Cratippus crassicornis, without much doubt to be united with Cratippus tentipes, Sp. Baté, and Eumagnus stiltipes, Norman, under the common name Colomartus pusilla, Grube; Caprella obtusa, which Boeck identifies with Caprella septentrionalis, Kröyer, and Mayer with Caprella acutifrons, Latreille, & juv.; Caprella monocantha, which again according to Boeck is Caprella ovata, Boeck, but according to Mayer, Caprella equiloba, Say, & juv.; Caprella opes = Caprella acutifera, Leach; Caprella leptonyx = Caprella acutifera juv.; and Caprella armata, according to Mayer another synonym of Caprella acutifera, Leach.

Costa's Lysianassa filicornis is said to be a synonym of Lysianassa longicornis, Lucas; Lysianassa humilis, Costa, possibly of Lysianassa costae, Milne-Edwards, and Lysianassa ciliata, Grube, of Lysianassa audouini, Sp. Baté. Boeck regards Grube's ciliata and possibly Costa's humilis as belonging to his genus Aristia, of which he makes Amonyp humidus, Kröyer, the type, with Lysianassa audouini, Sp. Baté, (wrongly given) as a synonym. Amphithoenotes spinicentris, Costa, is renamed Dezamine spinicentris, Amphithoenotes, Costa, being synonymous with Leach's genus Dezamine. Under the name of "Atylus Costa" are united Costa's two species Nototropis spiniculcauda and Nototropis guttatus, though surely guttatus, in right of priority, should have been retained. The close agreement between Lencophtha articulosa, Leach, and Lencophtha denticulata, Costa, is pointed out. Both these species are united by Boeck under the older name Lencophtha spinicarpa, Abildgaard. Three species described by Costa under the names Gammarus penicillatus, Gammarus obtusipenis, Amphithoe spinicarnata, are all referred, the two former as males, the last as female, to Gammarola brevicaudata, Sp. Baté. Cerviculus ochetricies, Costa, which Sp. Baté transferred to Melita, here becomes Merca ochetricies. It is in all probability the Gammarus fasciatus of O. G. Costa. Attention is called to points of agreement between Merca grossima, Leach, Merca seissina, Costa, and Merca inter- 

A table is added of all the Amphipods found in the Adriatic up to the date of this work. Valuable descriptions and figures are given of several of the previously known species, as well as of the species discovered by Heller himself.
1866. SCHIÖDT, J. C.

This paper deals principally with the mouth-organs of the Isopoda. Of the biting Isopoda the mouth is said to present three principal types, and the first type is said to comprise Onisile, Aselli, Idothea and Spheronuba, and to be essentially the same as the type met with in the majority of the Amphipoda.

1867. BATE, C. SPENCE.

Spence Bate demurs to Grube's view that "Allorchestes imbricatus (Sp. B.), is but the young of A. helleri." He "suggests to continental carcinologists to determine whether or not there be two freshwater species [of Gammarus], viz., G. pulex and G. fluviatilis, as from the great confusion of the two names by various authors, he is inclined to think that they, and also the figures, are but the result of imperfect drawings and descriptions of one and the same species." Gammarus borellii, sp. n., Goës, he says, "evidently belongs to the genus Meganomor of the Brit. Sessile-eyed Crustacea." In the "Naturalist in Vancouver Island and British Columbia, by J. Keast Lord. London, 1866," vol. ii., ch. xiii., pp. 262-281, with a plate, a description is given by Spence Bate of the "Vancouver Island Crabs." In this chapter, he mentions from Esquimalt Harbour, Allorchestes verticillatus, Dana; Allorchestes brevicornis, Dana; Marsuparia, Sp. Bate; Amphithoe peregrina, Dana; Amphithoe orientalis, Dana; Amphithoe illicornis, Dana.

1867. COSTA, Achille.

It mentions 72 species of Crustacea, the principal object being to show the specialities of the Italian waters, as discovered by Cocco, De Natale, O. G. Costa, Hope, and A. Costa himself. The numbers 32-59 refer to the Amphipoda. 35 is Orchestia crassicornis, n. s., near to Orchestia littorea, "but differing in the proportions and robustness of the lower antenna, especially of the male. They are shorter and more robust than in the three allied species, littorea, mediterranea, and condriete." On 37, Orchestia deshayesi, Audouin, it is remarked that the hand of the second gnathopod varies greatly. 40, Lysianassa filicornis, A. Costa, "by the length and tenuity of the lower antenna approaches L. longicornis, Lucas, from which it is distinguished chiefly by the proportions of the upper antennae, those of the abdominal false feet and other characters. Nevertheless, the two species in question, on account of the extreme length of the lower antenna, may very well constitute a distinct group or subgenus, for which we have proposed the
name of *Lysianassina*." On 45, *Epimeria trierristata*, A. Costa, the observation is made that it is very close to *Acanthomurus ocellii*, Bate and Westwood, so that at first sight they might be thought the same, but that specifically they differ much in the length of the antennae and the hands of the second gnathopods. Nor does Costa admit the propriety of placing the species in the genus *Acanthomurus*. Bock, who has not apparently seen this paper, makes both names synonyms to *Epimeria cornigera*, Fabricius. As to 47, *Gammarus longicawatus*, A. Costa, and 48, *Gammarus montanus*, A. Costa, it is recognised that these two fresh-water species, of which the first is identified by Bate and Westwood with *Niphargus aquiler*, Schiodt, may be only varieties of one and the same species. 49, *Guerinia nitens*, A. Costa, is figured. In regard to 51, *Microdentopus gryllotalpa*, A. Costa, the form of the carpus of the first gnathopod is said not to be accurately given in the figure of the species by Bate and Westwood. As a matter of fact, their figure probably represents a different species. Costa further observes that the carpus of this species is found to vary in regard to the number and proportions of teeth on its lower margin. 59 is *Caprella gigas*, A. Costa, from the Bay of Naples, undescribed. 54 is *Orio zanclea*, Prest. 55, *Cheiropristis messanensis*, Cocco. 56, *Omnithorhamphus cocoi*, De Nat. 57, *Carcinococcus costa*, De Nat. (not an Amphipod).

1867. Gerstäcker, A.

The works on Amphipoda are described in pages 487–495.]

1867. Marcusen, Joh.

the Mediterranean, as Bathyporeia pontica; there are several nest-builders, as species of Podocerus, Cerapus and Siphonaxestes. The resemblance of its Crustacean fauna to that of the northern seas is illustrated by the presence, among others, of species of Bathyporeia, Podocerus and Siphonaxestes.

1867. Norman, Alfred Merle.

The new genus Cheiroceratus, assigned to Fam. Gammarideæ, Norman. (Subfam. Gammarides B. & W.) is thus defined:—“Superior antenna shorter than inferior, having a secondary appendage. First gnathopods not subchelate. Second gnathopods subchelate, very large. Telson double. Last pair of pereiopods very long.” The type species, Cheiroceratus mantis, here fully described as new, is identified by Boeck with Gammarus assimilis, Lilljeborg, 1851.

In the family Corophiidae, Bate and Westwood, the genus Unciola, Say, is described as having the “last uropods double-branched,” which is not in accordance with Say’s own account. In the description of the new species, Unciola planipes, we also read, “uropods of last pair two-branched, small, scarcely reaching beyond telson, or the basal joint of preceding pair; outer branch tipped with long simple hairs; inner branch terminating in a single spine.” The figure (G. S. Brady del.) gives only a single branch, and a prolongation of the peduncle tipped with a spine. Boeck gives the species as a synonym of his Glauconome krøyeri, 1870. The Museum Normaniæ, 1886, gives “Unciola planipes, Norman, = Unciola leucopia, B. & W. (non Krøyer).”

1867. Norman, A. M.

Eight Amphipods are added to the British Fauna. Among these are the new species Anomyx melamphthalimus, the new genus, Enomyx, “differing from Anomyx in having the first gnathopods chelate, and the second stronger than the first, subchelate, nail large and strong. Posterior uropods two-branched. Telson cleft,” with its new species Enomyx chelatus, “dredged parasitic on Echius esculentus, L.”; and the new genus Micropodoops, “allied to Microleberopus,” but with differences shown in the italicized part of the following definition:—“Antennæ with secondary appendage. First gnathopods subchelate. Second gnathopods larger than first, subchelate, greatly developed in ♂, much smaller in ♀. Uropods terminating in simple spines, those of last pair with a singleramus. Telson tubular.” The new species for which this genus was formed is named Micropodoops maculatus.
REPORT ON THE AMPHIPODA.

1867. Packard, A. S., Jr.

Packard’s article on the marine invertebrates found at Caribou Island, Straits of Belle Isle, which was published in the Canadian Naturalist and Geologist for December 1863, is, he says, embodied in the present article, with typographical corrections. “Valuable information regarding the identification of several species of Amphipoda has been kindly communicated through Dr. Lütken by Mr. A. Boeck.” The Amphipoda occupy pages 297–301.

“Monocelides uncarinus” (Packard, 1865, Pl. VIII, fig. 4) is thus described:—“Female. Cephalic ring produced into an obtuse, tumid rostrum, smaller than in M. carinatus Haeck, of the British shores; the segments of the thorax and abdomen are not carinated above as in that species, being nearly smooth, while the abdominal segments are slightly sinuated just behind each suture. Eyes small, round, situated just above and opposite the insertion of the superior antennae; not colored in the adult, but black in the young. Superior antennae a little longer than the peduncle of the inferior pair; inferior antennae reaching to the hinder edge of the fourth thoracic, including the cephalic, ring; the penultimate and last joint of the peduncle equal in length; flagellum about half the length of the whole antenna. Both pairs of gnathopoda very equal in size, the propodos being long, ovate; anterior pair slenderer than in M. carinatus, palm very oblique, with minute hairs; dactylos two thirds the length of the propodos; carpos minute, not prominently produced as in M. carinatus, but rather continuous with the propodos. The second pair are much stouter and more ovate than in M. carinatus, according in this respect more with that of M. demissus, Stimp. In form it closely repeats that of the anterior pair; carpus with a long, slender, spine-like prolongation from the palm, forming a thumb closely appressed to the propodos, but not extending to the middle. Palm of the propodos on the anterior half fringed with hairs. Dactylos one-half as long as the propodos. Anterior pair of thoracic legs subequal; posterior pair of thoracic legs twice as long and much larger than the anterior, coxae regularly short, pyriform. Abdominal legs large, equal in size, reaching nearly to the tip of the caudal styles, which are lanceolate, very slender, acute; the first pair being a very little longer than the third. Color pale, mottled with slate. Length, .50 inch.

“IT differs from M. demissus of Grand Menan, in its color, and the very unequal antennae. From M. carinatus of the British Isles it may be readily distinguished by the very equal gnathopoda and non-carinated segments, the slenderer antennae, and the smaller, round eyes.

“Caribou Island, eight fathoms, sand.” See also Note on S. I. Smith, 1883.

1867. Sars, Georg Ossian.

In this masterpiece Professor Sars has taken the opportunity to describe, with great fulness of detail and a clearness that leaves nothing to be desired, the whole structure of an Amphipod, illustrating the description by figures which are not only elaborate and artistic but possess the further virtues of being in the most satisfactory manner explanatory and intelligible. In the period of active investigation since this work was published, one or two of its statements
have been called in question. In a note to p. 41 Professor Sars says that in some males of the genus Tanais the eyes are not only pedunculate (pédicillé) but even mobile. This statement, to say the least, requires confirmation. In regard to the apparatus for the circulation of the blood, Delage observes that, while Sars is the first who clearly pointed out the existence of a posterior aorta with definite walls, he reproduces the old mistake of attributing to the heart six, instead of three, pairs of lateral slits (valvules); nor does he recognise the delicate walls which more or less confine the currents of the blood. In regard to the species Gammarus neglectus, which Sars describes with so much valuable detail, Fr. Meinert inclines to believe that it should not be separated from Gammarus pulex, auctorum, the differences being at best minute, and these capable of being bridged over by intermediate examples. If the species stands, Meinert thinks it should retain the name Gammarus lacustris, which Sars gave it in 1863. For altering this Sars gives the insufficient reason that he had met with a casual reference in Nilsson's "Skandinavisk Fauna," tome 4, page 420, to a species named in parenthesis "(Gammarus neglectus Lilijeborg)," on which the trout, var. Salmo punctatus, fattens in the Scandinavian mountain-tarns. It is certainly an error to suppose, as Sars appears to do on the authority of Hoernes, that Gammarus pulex is only found in very rapid rivers.

On page 59, under the heading Organes exécuteurs, Sars observes "Comme organes exécuteurs et avant tout urinaires, correspondant aux vaisseaux de Malpighi des insectes, on doit indubitablement considérer les 2 minces appendices cylindriques (pl. 6, fig. 25 p.), qui débouchent en haut dans l'intestin à la naissance du rectum. Puisque l'un tout contre l'autre et contre la face dorsale de l'intestin, ces appendices pénètrent profondément, chez les individus adultes, avec leurs bouts obtusément arrondis dans le dernier segment thoracique. . . . On doit sans doute encore faire entrer dans cette catégorie un canal flexueux en forme de fronde, de structure glanduleuse, qui se trouve dans le premier article fortement tuméfié des antennes inférieures et débouche sur la pointe du procès épine que le 2e article envoie en bas, la soi-disant épine olfactoire." The reader therefore must not be led astray by the references to the "olfactory spines" on page 48, and in the descriptions of pl. iv. fig. 21 and pl. vi. fig. 27. A further safeguard is supplied on page 62, where Professor Sars says, "Le sens olfactif ou le sens qui chez les crustacés semble s'en rapprocher le plus, est, comme chez le genre Mysis, restreint à la tige extérieure des antennes supérieures; chacune de ses articulations porte généralement au bout, dans le bord supérieur, un appendice cylindrique très petit, correspondant exactement dans sa structure aux papilles appelées olfactoires des décaptodes." As to the analogy of the urinary organs first mentioned with the Malpighian tubes of insects, see Note on Spencer, 1885.

Of the pleopods Sars figures and describes the peculiar spines and special setae (à bout bifurqué), which have either escaped the notice of authors in general or not been thought worthy of attention.

The other Amphipods described in this work are Pseudosa cancillidens, Garsfeldt, var. quadrispina, Emark; Gammarocanthus loricatus, Sahune, var. lacustris; Pontoporia afinity, Lindström, said to come very close to Pontoporia femorata, Krøyer.

1868. Bate and Westwood.

The gnathopods of Orchestia brevidigitata, n. s., from Banff are figured and described. The length is given as about eight-twentieths of an inch, the colour a light olive-green. It is
REPORT ON THE AMPHIPODA.

373

said to bear a close resemblance to *Orchestia euchore*, Müller. As Boeck identifies the latter with *Orchestia gannarellus*, this species also may be a variety of the same.

A short account is given, and the second gnathopod figured, of Krøyer's *Leucothoe clypeata*, under the name *Montagna clypeata*, with the suggestion that *Montagna pollexiana*, Spence Bate, may be the male of Krøyer's species; in that case it would become a synonym of *Metopa clypeata*, Krøyer. The second gnathopod of *Montagna norvegica* is figured and described, with a reference to *Leucothoe norvegica*, Liljeborg, 1850, and to the Brit. Mus. Catal., p. 370, where Spence Bate expresses the opinion that this species is most probably a synonym of *Montagna clypeata*. Boeck agrees with this view, naming it therefore *Metopa clypeata*, Krøyer (but see Note on Liljeborg, 1850).

At page 501, *Opis leptochela*, n. s., is figured and described. Of this Norman, Last Report, etc., p. 335, 1868, says, "this I find to be the species described by me under the name *Euonyx chelatus* (Brit. Assoc. Report 1866 (1867), p. 202)." My specimen differs from that described by B. and W. in having the second gnathopods larger and stronger than the first, and the hand furnished with a strong nail. This difference is perhaps one of sex. The species cannot, I think, be placed in the genus *Opis.* Boeck, apparently unaware of Norman's genus, says of *Opis leptochela*, that it cannot belong to *Opis,* as the first gnathopod has a very elongate wrist and an elongate chelate hand, thereby resembling the genus *Krøgeria*, which belongs to the subfamily *Edicerinae.* It ought therefore to become the type of a new genus, which might be called *Leptochele*.

At page 503, *Opis quadrimana*, n. s., is described, and the first gnathopod figured. On the ground that this does not agree with *Opis* either in the mouth-organs or the structure of the first gnathopods, Boeck, in 1870, makes it the type of a new genus, under the name *Normania quadrimana*, Bate and Westwood.

A species is partly figured and described as probably belonging to *Amphicola bicornis*, Liljeborg, but by Norman and Boeck the form in question is said to be *Amphicola teucriornis*, Liljeborg. *Haploops tubicola*, Liljeborg, is figured and described, and said to have been taken by Mr. Norman "in the Shetlands," where "Hebrides" should be read instead of "Shetlands."

At page 507, *Monoculodes longicornus*, n. s., from Banff, "length about one-fifth of an inch," is briefly described, and the first and second gnathopods are figured. "Specific character. Dorsal surface slightly carinated. First pair of gnathopoda long and narrow, resembling the second pair."

At page 508, *Krøyeria brevicarpa*, n. s., is described. The gnathopods are figured. This is identified by Boeck with *Krøgeria haplocheles*, Grube, 1864, and therefore named *Ponto-crates haplocheles*.

At page 509 the new genus *Lepidoleperurus* is defined as follows:—"Cephalon having the orbital or intra-antennal process considerably developed and produced. Percon well-developed. Pleon having the last four segments very short. Eyes not made out; supposed to occupy the intra-antennal process;—superior antennae having the upper surface of the first two joints of the peduncle considerably produced anteriorly, having no secondary appendage. Inferior antennae posterior to the superior. Mandibles furnished with a biarticulate appendage. First pair of gnathopoda moderately robust, subchelate. Second pair feebly and chelate or subchelate. Posterior pair of pleopoda short, biramous. Telson—?" The type is figured and described as *Lepidoleperurus carinatus*, n. s. It was "taken at Banff by Mr. Edward, associated with *Anomyx longicornis*, with which it is very closely allied, being perhaps a young female." There seems little, I think, to justify the establishment of a new species, and the name for the two forms should therefore stand as *Lepidoleperurus longicornus*. In the description of *Anomyx longicornis*, the telson was given as "very long and deeply cleft," so that "telson cleft" may be presumed to be properly part of the generic
character. G. O. Sars, 1882, mentions the capture at Lodshavn of a single specimen (?) of "Lysiosoma carinatum, Sp. Bate," but does not describe the telson. In a specimen which I owe to the kindness of Mr. David Robertson of Glasgow, I find the telson very narrow, cleft almost to the base, each tip having two small spines. Sars thinks that Lysiosoma unda of Gois should be included in this genus, and not in Boeck’s Orthonome. See Note on Gois, 1865.

Niculpa tenuima, Balzelius, is figured and described.

Cheirocratus manulis, Norman, is figured and described, but with some variations in the generic character, which need correction. The upper antennae are much shorter than the lower, not subequal, and the third uropods are not unbranched, but biramous. The species is identified by Boeck with the earlier Cheirocratus arenulatis, Liljeborg.

At page 515, Megamara multidentata (Norman, MSS.), from Guernsey, is figured and described. This is "Mora Batei," Norman, published in the Annals and Magazine of Natural History for December 1868, and therefore taking precedence by a few days of the name Megamara multidentata. This is indicated at page 530 by the citation, "Mora Batei Norm. (See our Vol. ii. p. 515)," but no notice is there taken of some slight discrepancies between the two accounts, which were no doubt drawn up from different specimens.

On pages 517–518, Norman’s Unciola planipes is figured and described as Unciola leucopis, Kröyer, Kröyer’s genus Glaucosoma being identified with Unciola, Say. Norman, Last Report, etc. 1868, says, "Unciola leucopis, Kröyer. B. and W. consider my U. planipes as 'probably identical' with this species. It may be so, but there are points of difference which make me think it wiser to keep them apart until the examination of Greenland specimens shall settle the question definitely." Kröyer’s species, it should be observed, was named leucopis from "λευκός, albus, et όψις, oculus." Boeck gives "? Unciola planipes, Norman," as a synonym to his own Glaucosoma kröyeri, 1870. Sars in 1882 accepts Glaucosoma leucopis, Kröyer, as identical with Unciola irrorata, Say.

Hyperia tauriformis, n. s., from Banff, briefly described and partly figured on page 519, is identified by Norman with Metoecus medusarum, Kröyer, which Boeck names Tauria medusarum, O. Fabr., 1780, but Bovallius, 1865, points out that Bate and Westwood, and Boeck likewise, have misunderstood Dana’s account of his genus Tauria, so that neither the name Hyperia tauriformis nor Tauria medusarum is admissible. The name will perhaps become Hyperia abyssorum, Boeck.

On page 520, Hyperia prehensitis, n. s., from Banff, is figured and described. "Specific character. Superior antennae about the length of the head. Both pairs of gnathopods with the carpus and propodos simple. Three hind pairs of pereiopoda subprehensile at the tips." Length, three-twentieths of an inch.

On page 521, Hyperia cymosum, Sabine, is described. "It looks like a young H. Gailba, with rudimentary antennae, but one of the specimens sent to us had the incubatory pouch of the adult female fully developed, so that we cannot mistake it for a young animal." By Boeck Sabine’s species is identified with Hyperia medusarum, O. F. Müller.

Themisto crassicornis, Kröyer, is next figured and described, a species which Boeck identifies as Themisto libellula, Mandt.

On pages 531–535, Vibilia borealis, n. s., from Banff, is figured and described, a letter from Thomas Edward, on its habits and colouring, being quoted.

In the Supplemental Notes, among other matters of interest, the names are mentioned of the genera and species of which A. M. Norman had published descriptions in December 1868.

The Introduction, signed C. S. B., is a general account of the structure, functions and distribution of the Amphipoda.
1868. BRADY, GEORGE STEWARDSON, born April 18, 1832 (G. S. B.).

"Gammarus and Asellus are scarcely to be found in" the British lakes, according to this observer; "marine forms of Amphipoda, analogous to those of the large lakes of Sweden, have not been found." (Zool. Record, 1869.)

1868. Czerniavski (of Tschenkajski), Woldemar.

Materialia ad Zoographiam Ponticam comparatam. Studiosi universitatis charcoensis Voldemari Czerniavski.

At page 78 is given "Ordo VI. Arthrotraca Cls. s. Edriocephalata. Subordo. a. Isopoda."

At page 90, "Subordo. b. Lamellipoda," contains Fam. 24. Caprellides. Gen. 41. Protella, Dana. 51. Protella (typica, n. s., (juv.), Tab. vi. fig. 7–10; 52. Protella intermedia, n. s., Tab. vi. fig. 11–13. Gen. 42. Caprella, Lamarck. 53. Caprella podolesterol, n. s., Tab. vi. fig. 14; 54. Caprella ferox, Tab. vi. fig. 15–20; 55. "Caprella Danilevskii," n. s., Tab. vi. fig. 21–34. Of these, the two species of Protella, both less than 4 mm. in length, are considered by Mayer to be certainly young, possibly female, forms, with nothing to show whether they belong to Protella or Caprella. Caprella podolesterol is in much the same indefinite situation. Caprella danilevskii he considers to be either identical with or extremely like Caprella inermis, Haswell, but he leaves the names undisturbed, while he makes Caprella ferox definitely a synonym of Caprella aequalifera, Leach. From a comparison of specimens brought by the Challenger from the Dardanelles with a specimen of Caprella inermis sent me by Mr. Haswell from Australia, and a further comparison of these specimens with Czerniavski's figures, it becomes, I think, quite clear that we have in Caprella danilevskii to deal with a species of very wide range, and that the name danilevskii must take precedence of inermis, which is moreover preoccupied.

At page 93, "Subordo. C. Amphipoda. Divisio. Gammarina, Kröyer. Subdivisio. I. Domi-
cola," contains Fam. 25. Cheluridae Allman. "Gen. 43. Chelura (Philippi), unemend." To this is assigned Chelura pontica, n. s., Tab. vii. fig. 1–18. But the figures and long description do not seem to distinguish it from Chelura borealis, Philippi.

2-iii-7-iii paris latas. Long. corp. usque ad 5 mm. Colore griseo cum maculis parvis nigris. Femina femina C. diformi similis.

60. Cerapus purpureus (Dana), is followed by a quotation of the description, and "Var. Pontica m. Antennae superiores flagello longitudine variabili, plus minusve breviori quam pedunculo. Pedes 2-di paris digito minus longoato, articulo ejus 1-mo crasso, 2-do margine posteriori increasato, apice obtuso setis nonnullis obtuso. Osci rubri. Long. corp. usque ad 3-8 mm. Color ut in precedente." The quotations which I have omitted in regard to this and the preceding species are given in V. Carus, prodr. Faun. Medit., p. 353, but Czerniavski's own descriptions of his varieties are omitted by Carus.

61. Cerapus bidens, nov. sp. Varetati pontica Cerapi macrodactylus similimus, nisi pedes paris 2-di digito immobile paulo curvato et in apice bidentato, articulo 5-to intus maxime eroso, tuberculo subbasali valde forti. Long. corp. usque ad 5-2 mm." These differences, from a species confessedly variable, are but of doubtful specific value. The species is not noticed by Victor Carus, Faun. Medit., except in so far as he intimates that the name is preoccupied, by giving "C. bidens, V. Crs. (nee Czern.)," to take the place of Costa's Erithonicida bidens.

Gen. 47. Podocerus, Leach, is given with the synonyms, Ichygrocerus, Kröyer, Cerapus (pars), Milne-Edwards, Jassa Leach, Milne-Edwards, Gammarus (pars), Rathke, Cratophium, Dana. "62. Podocerus Ocius, Sp. Bate;" 63. Podocerus dentex, n. s., Tab. vii. fig. 35, is thus described:— "Mas. Froms obtusa. Antennae superiores inferiores paulo breviores et multo debilioris, flagello 3-articulato, articulo precipue non multo longiore, articulis valde decrescentibus, filis olfactoriis tenuioribus in margini inferiore instructo, flagello secundario rudimentario; a. inferiores increasata, flagello 3-articulato, articulis valde decrescentibus, sub apice spinis unguiformibus duabus armato. Amba paria antennarum margine inferiore sat setosa. Pedes paris 1-mi manu pyiformi, trilium majore quam carpo, palma setulosa et spinulis nonnullis (3) subbasali armata, ungue forti, curvato, margine posteriorius paulo dentato; p. 2-di manu magna, elongata, palma excavata, dentibus duobus posterioribus magnis et duobus vel tribus subapicalibus multo minoribus terminata setis plumosis dense obsita, ungue curvato, margine posteriori increasato; p. 3-ii et 4-ii breviore ungue minore, vix curvato. Long. corp. usque ad 4-3 mm. Color flavescens-brunescens, maculis nigris. Osci nigri." Gen. 48. Sunamphithoe (Sp. Bate), emend.," is thus defined:—

"Ut Amphithoe. Telson crassum et vel uno hamulo vel duobus terminatum. Pedes paris 5-ti, 6-ti, 7-mi tarso (articulis 5-mis Sp. Bate) ad apicem dilatato." In the synonymy Czerniavski refers to Amphithoe podoceroides, Rathke, and Amphithoe biocupus, Heller. He also assigns to this genus, "64. Sunamphithoe valida nov. sp., Tab. vi. fig. 36," thus described:— "Mas. Osci ovales. Antennae superiores segmentum 6-tum thornis attingentes, inferiorioris paulo longiores, pedunculo apice articulum 3-tum inferiorium aequante, flagello filiformi duplo longiore quam pedunculis, 12-15 articulato (articulis in apice filo olfactorio instructis); a. inferiores validiores, pedunculo longissimo (flagello superiorum equali), flagello brevissimo, fere tripulum breviore quam pedunculis (3/4 articulis 4-ti aequante), articulis 7-9 valde decrescentibus. Amba paria antennarum setulis quadrigem perbrevibus instruit. Pedes paris 1-mi et 2-di maxime inaequalis, p. 1-mi carpo sat magno, triangulari, manu subpyriformi, palma obliqua, denticulo spiniformi postice terminata, ungue in margine posteriori leviter dentato; p. 2-di manu valida sensi-ovali, palma transversa, concava, postice dentem (fere indicem) validum, rotundatum exhibente, ungue maxime curvo, postice dentato. Pedes ceteri ut in S. hamulo Sp. Bate conformati, p. 7-mi tarso ad apicem maxime dilatato. Telson crassum, retrorsum paulo augustatum, marginibus lateralis rectis, hamulis duobus fortibus terminatis. Flavescentes, cum maculis nonnullis parvis fusces. Femina. Pedes paris 2-di 1-mo non majoros,
manu simili, nisi abbreviata et dilatata, carpo multo minore postice in processum elongatum, obtusum egresso. *Lamina foliosa* elliptica, margine longo-cirrato. *Ova* ovalis, flavescens, long. 9.36 mm. Long. corp. 5 usque 6.3 mm, 2 usque 6.2 mm." The fig. 36, referring to the 2 of this species, only represents "corpuscula setigera sensitiva," not therefore greatly contributing to the understanding of the species itself.

*Gen. 50. Grubia, nov. gen., is thus defined:—*

(Zool. Chall. Exp.—Part LXVII.—1887.) XXX 18
minores, margue parvo, minus curvato, p. 6-ti et 7-mi multo longiores, longitudiue 2-di paris, articulo 2-do dilatato, 6-to (tames) teuni et multo longiore quam in antecessente, ungue tenti curvo. Pedes spurii paris 1-mi et 2-di fortes, spinus multis armati, pedunculo maxime dilatato, rami longis, paris 1-mi multo longiores, spina magna inter ramos postita, paris postremi pedunculo maxime incrassato, margine apicis externo-inferiore piloso, ramis brevissimis—ramo interno vix longior—in apice spinus et pilis parvis armatis. Telesm basi lata, fer recta, lateribus maxime convexis in apicem obtusum convenientibus, dorsifertis postice carina lavi in denticulum parvum antronsum producta, subitus fasciculum minitum spinarum gerens. Color lucide-brunneus vel subgriseo-lavus. Mas. Pedes paris 2-di 1-mo majores, fortissimi, carpo brevi triangulari, manu valida oblonga, pene alterum tantum longiore quam lata, margine anteriore convexa, ungue fortissimo curvo, 2-articuli proximi equante. Femina. Pedes paris 2-di 1-mo simillimi. Lamini fotorix longe, ad apicem paulo latiores, cirris longis mollibus dense marginate. Ora ovalia, flavescentia, long. 0,54 mm. Long. 2-usque ad 12 mm., 3-7 mm.

Gen. 52. Melita, Leach. 68. Melita palmata (Montagu) Leach, with "Gammarus Dugesi (= ?)." M. Edwards," among the synonymus, followed by a long description.

Gen. 53. Niphargus, Schilbde. 69. Niphargus ponticus, n. s., Tab. viii. fig. 12-14. "Capit segmentis tribus inaequantibus junctis pauro brevisius. Segmentorum abdominalium quodque in dorso postice setulam spiniformem gerens. Antennae superiores abbreviata, reversae segmentum 4-tum attinentes, paulo setose, pedunculo paulo breviori quam caup, articulo 1-mo oblongo, erasso, 2-do dimidium 1-mi vix excedente, paulo longiore quam 3-ti, flagello 4-articulato, longitudine peduncului aquante, articulis longis, decessentibus, flagello secundario bi-articulato, roque longo ac art. 3-ius, pedunculi. Antenne inferiores pedunculo haud incassato, articulo 1-mo (brevisimo) et 2-do (paulo longiore) junctis 3-ti breviorebus, 3-ti elongato, longiore quam art. 2-dus superiorum, 4-ti . . . . . . Oceli subovales, sat magni. Pedes paris 1-mi et 2-di carpo elongato, subitus dilatato, latiore et longiore quam manus, manu quadrangulare-longato angulis rotundatis, palma transversa, convexa, postice setulis spiniformibus armatis, ungue curvato acuto, in basi dilatato et in margini posteriori setulam 3-cuitente, p. 3-ti et 4-ti articulo 2-do lato, 4-to anteroribus dilatato subitus latiore, 5-ti paulo dilatato, ungue brevi basi increassato, vix curvato; p. posteriores 3 validiore, spinis nonnullis armati, articulo 2-do latissimo subitus angustato, ungue majore. Pedes spurii paris postremi pedunculo erasso, rano interiore minutissime-tuberculiformi, vix distincto, externo magnio, erasso, longe-conico, segmentum tribis posticos junctis longiore, articulo 1-mo fere duplo longiore quam pedunculo et in apice spinis 3-4 armato, 2-do dimidium fere primi accessor, in apice bisetoso; p. paris anteceentium fere quone (naque ad basin ramorum ultimi) prominentes. Telesmus lateraliiter oblongum attenuatum pedunculo pedis postremi longius, apice bi-spinuloso. Color brunnescentia. 1 exempl. long. corp. 2,1 mm.; ant. sup. 0,75 mm.; pes caudalis 0,31 mm."

Gen. 54. Pherusa, Leach, with Amphithoe (pars), M. Edwards (sec Dana); Pherusa, Sp. Bate
and Westwood, Grube, Heller; and Pararhpubilidium (pars), Brazilus, in the synonymy, receives
70. Phorura pustulosa, n. s. Tab. viii. fig. 15, thus described:—

"Atythe bipinose" Sp. B. permuto similis.

"Caput rostro acutissimo, levis curvato, 3 articuli 1-mi antennae sup. aquae.
Segmenta abdominis 1-urn et 2-dum dorso (cajusque) in deum postum acustissimum excurientem,
segmenta tria anterioria angulis infero-posterioribus retrorsum acute productis, 3-urn margine
posteriori in lateribus excavato, infra 3-dentato supra unidentato. Antennae superiores
inferiores longissimis nullo breviore, reverse segmentum 5-tum attingentes, pedunculo
breviore quam caput, articulo 1-mo inavezato ambobus ceteris junctis longitudinalis, flagello
filiformi, articulis 17 elongatis, paribus vel imparibus, quoque in apice paulo latiore et
filo olfactorio setulisque minutissimis instruto, ceteris levibus. A. inferiores reverse
abdomen attingentes, superioribus duplo longiores, pedunculo incassato, duplo longiore quam
pedunculus superiorum, articulis 1-mo et 2-do brevibus, juncis 3-do atquantibus, 3-do et 4-to
reque oblongis, flagello articulis 37-40, primo elongato, ceteris initio brevibus ad apicem
crescentibus. Oculi magni, ovales. Poles paris 1-mi et 2-di mediores, similis, carpo
elongato-triangulari, sed mullo breviore quam manus, p. 1-mi vix fortiores quam 2-di. Poles
ceteri fortes, crescentes, ungue magni forti curvo, p. utilisorum 3 spinosi, articulo 2-do
ovali, postice serrato et infra rotundato-producto. Poles parisii similis, ramis styliformibus
spinulosis, in apice ungue vix curvato instructis, p. 1-mi et 2-di pedunculo gracili, mano
exteriore brevior, 1-mi 2-dum prominentes, usque ad basin ramorum ultimi pertinentes,
p. posterioris (2-di) pedunculum segmentorum 12-mi et 13-mi junctorium longitudinalis, incassato
ramis ferre aequo longis, pedunculo longioribus, praeter spinulis setisque plantaris ornatis.
Telson et lateris visum acutum acuminitum, supero visum ovato-haquulatum, acuminitum.

"Mas. Poles paris 1-mi et 2-di manu carpoque sat fortius, nullo latoriis quam artifici ceteri,
manu secundum elongate-pyiforni ad apicem angustiore, palma obliqua, convexa, spinulis
debillibus dense obsita, ungue longiore quam palma, palmo curvato, debili; rarissime manus
(adulti) forma ut in femina.

"Femina. Poles paris 1-mi et 2-di manu carpoque minoribus, uce latoriis quam artifici ceteri,
manu subquadraangulari longiore quam lata, in medio marginis anteriores fascicula
setulorum ornata, palma obliqua-convexa, tenuitie spinulosa, ungue in margine posteriorie
setulis nonnullis tenuioribus ornato. Sacculus oriferus [oviger] maximus; laminae fotorix
permaximae, elongate-ovales, epinerae permuto excedentes, margine longo-circutae.

"Junior. Oblitius centroderadibus segmentorum 1-mi et 2-di abdominis vix excutientes,
oubustissimis.

"Long. corp. ε et θ usque ad 5 mm.

"Color variebiliis; griseo-flavescens, supe rubro tenuiter maculatum; rariter in parte anteriore vel
omne rubro fassissinse pigmentatum, aspectu nigrum.

"Ova late ovalia, flavescentia, long. 0.4 mm."

"71. Phorura sp.1 an nova! (inermis m.)." Only the habitaculum is mentioned.

Gen. 55. Decasimine, Lench. receives, under 72. Decasimine spiniventris (Costa) Grube, "Varietas
pontica iiului. Tab. viii. fig. 16. Caput marginibus ante-culturalibus dentiforme acute
productis. Segmenta abdominis tria anterioria in margine posteriorie dorsi denticleus
lateribus carentia, 3-urn et 4-tum denticleus anterioribus nullis, 6-urn dentibus tribus
posticis fortibus. Antennae superiores artificiis 23-24, a. pedunculo 1-mo 1/4 longitudinis 2-di
longiores, infra in taberuclum obturna fortore excenti, articularis flagelli anterioribus filum
offactorium gerentis; a. inferiores illis duplo breviore et teniores, articularis 16-17, 1-mo
et 2-do brevibus, 2-do (articularis 1-mus Hell.) super in denticulum excenti. Poles paris
7-mi tarso paulo breviore quam tibia. Laminae fotorix feminae elongatiissimae, in dimidio
basali angustae, dimidio apicali oblongo, cirris parius marginatis. Cetera ut a Hellerio
observata. Long. corp. ε usque ad 6 mm., θ usque ad 7 mm. Ova ovalis, flavescentia,
long. 0,53 mm. Variatio. A. Antenna inferioris superiormas paulo breviores, articularis 18-23. Variatio. B. Antenna inferioris superiormas longiores et fortiores, articularis 28 valde crescentibus, 1-mo infra in tubulum acutum (org. audit.), 2-do supra producto, margines superiores ut 3-ii dense pilosis; transitionem ad D. spinosum faciens.“

"Caput rostro brevissimo, obtuso. Oculi rotundi. Antenna superiors usque ad dimidium segmenti 4-ti pertinente, 10-articulato, pedunculo incrassato dimidio flagello paulo longiore, articulis decrecentibus, flagello ad apecem sensim attenuato, articulis in apice filum olfact.

"B. Varietas brevicornis m. Mas. Precedenti similius; sed antennae abbreviatae, paulo crassiores, superiors segmentum 3-tum paue attingentes, articulis 11-12, inferiores usque ad segmentum 4-tum pertinentes, 14-articulato. Oculi ovalis. Pedes parsis 2-di articulo 2-do et 3-do ut in varietate Adriatica haud dilatatis. Long. corp. usque 6,6 mm. Color sordide-flavescens."

"Genus 58. Orchestia (+ Talitrus) Leach," receives "76. Orchestia Botte, Elw.," Tab. viii. fig. 28-32, with "O. cucurritu, Cott.," "O. littoreus, Grube," "O. Montagu (pars)," Rathke, in the synonymy. A description of the species is followed by the description of a variety, "Varietas feminaformis mihi. Tab. viii. fig. 33. O. Botte similimaria, nisi pedes 2-di pars articulo 2-do oblonge-ovato, carpo paulo abbreviato, longiore quam lato, in margine anteriore
convexo, manu subquadrangula, marginibus anteriore et posteriore parallelibus, palma vix obliqua, fove transversa, brevi, leviter convexa, spinosa, ingle leviter curvato, obtuso. 1 exempl. long. corp. 8,1 mm.; long. manus 2-dae 0,66 mm."

"77. Orchestia Montagu, Aud. Tab. viii. fig. 34-39." has in the synonymy "O. littorea, Rathke;" Talitrus saltator, M.-Edwards, Zool. Neg., "Talitrus locusta, L., Sp. Bate and Westwood, British Sesayle-eged Crustacea, p. 16-23 (♀ et ♂ secund., ), fig." Cerniaevski remarks, "Species maxime variabilis, transitionibus gradatis cum O. Botte omnino juncta. Long. corp. ♂ usque ad 19,1 mm., long. manus 2-dae usque ad 2,8 mm.; long. ♀ usque ad 18 mm., long. manus 2-dae usque ad 0,8 mm." Whether the attendant remarks in Russian would throw any light upon the novel identification of Talitrus with Orchestia in this synonymy, I am unable to say.

A remark in Russian is here made upon Nicae pontica and "Nica Perieri." "93. Orchestia Deshayesii Aud.," has a "Variatio localis. Tab. viii. fig. 52-53. Antennae superiores capite paulo longiores, dimidium articuli 3-ii inferiorum superantae, usque ad articulum 4-tum pertinentes, 8-articulatae, inferiores dimidio corporis magis minusve breviores, articulis 18, 1-mo et 2-do brevissimis, 3-ii iis junctis duplo longiore, dimidia longitudine 4-ti, flagello usque longo ac art. 4-tus vel illo breviore. Oculi subbicolors. Pedes pars I-ii spinulosi, carpo postice tuberculiforme pecto, manu subutus dilatata, ungue curvato, acuto. Pedes ceteri spinulosi, posteriores 3 articulo 2-do subquadrate rotundato, art. 4-ti subus dilatato, p. 5-ti paulo longiores quam p. 4-ti, prolatis breviores quam p. 5-ti; p. 7-ti proximis paulo longiores. Telson triangulare rotundatum, line rectulatorum. Color sorridus flavescens. Mas. Pedes pars 2-di manu permagna subpyriformi, ad apicem maxime angustata, palmis usque dimidium marginis posteriores occupante, dente subbasali valde acutoque, subtruncatum pecto, apicem manus attingente, ungue valido curvato, cum dente quasi chelum formante, praelata. Femina. Pedes pars 2-di manu breviori quam dimidium manus maris, latissime subboumba, palmis transversa (per elongationem subtruncatum lamini dubius formae approximatis, a margine posteriore medio exhibitis, anteriores subquadrate, posteriores ultro longiori augusto, plicata), profundissime bilobata, lobis ambobus inter se formae approximatis (posteriores magis prolongato), apice rotundatis et molle spinulosis, ungue abbreviato, crasso, curvato, obtuso. Long. corp. ♂ 2 millim., ♀ 8 millim." The length of the male accidentally omitted.

As already hinted, in order to derive the full advantage offered by this work, the carcinologist who knows not Russian, must either find leisure to learn it, or venture on the perhaps more difficult task of finding an interpreter.

1868. Edward, Thomas, born Dec. 25, 1814 (Smiles), died Apr. 27, 1886 (Pall Mall Gazette).

This acute and ardent naturalist is able, from personal observation, to deny that the Hyperiidae "exist only in the gill cavities of the medusa." He maintains that they exist far more
commonly swimming freely. In regard to the species which had been established, he says, "I consider the genus Lestrigonus of Milne-Edwards and subsequent writers to be nothing more nor less than the male of Hyperia. I am led to this conclusion from the remarkable similitude which exists among them, and from the fact that in all the species (five in number) which I have met with, the sexes have always been associated, except in the case of Lestrigonus Kinahani." Lestrigonus elongatus he positively identifies as the male of Hyperia galba. He has found the males, not yet described, of Hyperia oblicia and Hyperia melwarum, and of a new species, which he provisionally names Hyperia minuta.

Although Lestrigonus kinahani "may be, and is occasionally, found in company with H. galba, the one is easily distinguishable from the other. They are nothing alike, either in form or colour; not to speak of the long and slender antennae of the one in comparison with those of the other. H. Kinahani is longer, more shrimp-like, especially behind, and not so round and dumpy as H. galba, and the colour is always much darker. The eyes too are dark instead of being of a light green." [Compare Note on Montagu, 1813]. He further says of Lestrigonus kinahani, "there appears to be little or no difference between the young and the old. They are both slender, and of a dark lead colour, and both have the remarkable long and hair-like antennae."

In his second note Edward says that of Hyperia oblicia he has seen "thousands, nay, millions, or countless hordes." He has never found them parasite on fish, but in examining the stomachs of herrings on two successive days, he found them all full of this Amphipod. "From one," he says, "I took 59, from another 47, and from a third 33; and all the others were more or less well crammed." As contrasted with "the vast legions which occasionally appear" of Hyperia oblicia, he says, "I have only taken H. melwarum on three or four occasions, and but a few each time. This species is decidedly the gem of the whole. It is partially pellucid, being beautifully banded, alternately, with rings of a crystal hue and others of a deep red. As regards H. minuta, I have only taken it twice, and even in fewer numbers than the last." Of the species just mentioned, he adds, "in their general manners all three resemble each other, their restlessness and activity being one of their most remarkable traits, and beyond the power of description. But if I were to particularise any of them as being more lively and more restless than the rest, I certainly should give H. minuta the character, as being the most active species which, so far as I remember, I have as yet seen. All three seem to me far more active in their whole movements than either of their congeners, L. Kinahani or H. galba, and they do much better in confinement."

"Lestrigonus Kinahani and Hyperia galba generally appear here [at Banff] about the beginning of July, and disappear again towards the end of September; H. oblicia usually about August, and continues till spring; H. melwarum in December, and remains till March (on one occasion I took two of this species as late as the month of May); and the time I found H. minuta was from October to December. During these periods, too, I have never failed to find the females of all, save the first, to contain, in some cases eggs, in others well-developed young. With reference to H. oblicia, I not unfrequently find females of this species with young from September to January, thus extending over a period of five months."

Recognising Lestrigonus as applying only to male forms of Hyperia, Edward retains the name only provisionally for "Lestrigonus Kinahani," to which he had not definitely been able to assign a female. He does not give authorities for the specific names he adopt, but there is good reason to believe that he uses the nomenclature of "The British Sessile-eyed Crustacea."
1868. HELLER, CAMIL.

The new species of Amphipoda described and figured are, 1. "Alloorchestes Paulensis," which is stated to be rather like Alloorchestes verticillata, Dana, apparently belonging to the genus Hyale; 2. "Anonyx Chilensis," said to approach the genus Callisoma in the almost cheliform structure of the second gnathopod, but appearing to correspond more nearly, so far as described, with Boeck's genus Orchestomene.

As only two or three pages referring to the Amphipoda are embalmed in this handsome and expensive work, for the benefit of students who may not be able to consult it, I here append the Latin descriptions of the new species:

groupées circulairement autour d’un centre vers lequel elles convergent et s’inclinent ou se redressent, suivant l’occurrence de manière à augmenter ou à diminuer les saillies et conséquemment à éviter les dangers du contact.” This seems to want confirmation.

1868. Jarshinski, F. (? Larzynsky, Th.)

[On the Leydigian organs at the antennæ of the Crustacea Amphipoda. Transactions of the first meeting of Russian naturalists at St Petersburg, 1868, 4to, pp. 176-179 (written in Russian).]

“...The so-called Leydigian organs on the first pair of antennæ, first observed by La Valette in Gammarus puteanus, and afterwards accurately described and stated to be sensitive organs by Leydig, are the subject of a paper by F. Jarshinski (l. c.), who has observed them in various genera of Amphipoda.” (Dr. von Martens, Zool. Record for 1870.)

Fries refers to a paper in the above Transactions, and another in “Amtl. Bericht der Münchener Naturforscher-Versammlung, 1877 (p. 172),” in which G. Joseph records the occurrence of a blind Gammarid (Niphargus orcinus, u. s.) in the brooks of the hill-grottoes of Carniola, which probably from these reaches the lake of Zirlenitz, where it can be freely gathered. It comes to the surface after sunset in calm weather.

Packard’s new species, Monoculodes sulcatus, mentioned on p. 613, is called Monoculodes subocularis on p. 617. It is stated that “the genus Pontoporia is reunited with Lysianassa” by G. O. Sars in his Hist. Nat. des. Crust. d’eau douce de Norvège, p. 82, note. But Sars only says, “il vaudrait peut-être mieux les réduire, en attendant, à un seul genre.” In the text he retains the name Pontoporia.

At page 56, under the heading “Tetraecapoden,” Martens notices the continental and terrestrial habits of some members of the genera Gammarus, Talitrus and Orchestia. In Madeira he had met with a Gammarus, which was more frequently to be found on the banks of the brooks than under water; in Japan an Orchestia presented itself “am Waldrande, zwischen abgefallenem feuchtem Laibe, aber doch nicht im Wasser.” After referring to Dana’s Orchestia sylvicola from New Zealand and Orchestia tahitensis from Tahiti, and Heller’s Orchestia caumana from Cyprus, he describes the Japanese species as Orchestia humicola,
with the description: "Die vier vontern Epimeralstcke verhältnissmässig gross, gerundet, das fünfte etwas kürzer und viel schmäler als das vierte. Die obern Fühler nicht länger als das erste Basalglied der untern. Diese halb so lang als der Körper, die Geissel ungefähr eben so lang als der Stiel. Glieder der Geissel kurz. Zweites Fusspaar fast doppelt so lang wie das erste mit einer kleinen, flachen, länglich-elliptischen Hand, deren Daumen kaum zu erkennen ist. Drittes und viertes Fusspaar um wenigstes länger, aber dünner, mit einfacher spitzen Endgliede, wie die folgenden; das fünfte wiederum etwas länger, sonst gleich. Das sechste und siebente unter sich gleich, sehr lang und kräftig. Auffallend mit mehreren kurzen Endhörnchen, aber an den Seiten ohne Borsteu." The genus Amphitoe, without the accessory flagellum that distinguishes Gammarus, is not, he remarks, found in the fresh waters of Europe, although in Eastern Siberia "Amphitoe muricatus Pall. sp." is found in the Angara (Lenisei), and in North America Amphitoe dentata, Say, in the fresh-water marshes of South Carolina. Corophium, the Hyperina, and the Lernidipoda, have, so far as he knows, no fresh-water representatives. It is not, I should think, by any means certain that Say's "Amphitoea dentata" really belongs to the genus Amphitoe as now accepted, while the Oniscus muricatus of Pallas is clearly excluded from it by having an accessory flagellum.

Caprella megaccephala, n. s., from Cape Sainte-Marie, where it was dredged up from a rocky bottom at a considerable depth, is described on pages 89–91, and figured pl. 20, figs. 12, 13. The chief character relied on seems to be the head, of which Milne-Edwards says, "chez le mâle, la tête, légèrement arrondie, est inclinée en avant, et ne porte ni pointe ni tubercule; elle se rétrécit un peu postérieurement, mais on n'aperçoit cependant pas le sillon qui la sépare du premier anneau thoracique, avec lequel elle est complètement confondue. La pièce, ainsi constituée, est remarquablement allongée." After further description, the remark is made, "la Caprella scavens (Temp.) provient de la même localité; elle se rapproche davantage de notre espèce, à raison de la longueur du premier segment, mais la tête est surmontée d'une pointe conique et les pattes de la deuxième paire sont pourvues d'une main tridentée en dessous." The corresponding hand in this species is described as "trop-longue, cintrée en dessous ou en avant, pourvue sur son bord postérieur de deux deuutantes tré-schoquées l'une de l'autre. Le doigt terminal est robuste, très-arrondi, et ouvra, près de sa base sur son bord supérieur, une petite échancrure ou encoche." In Caprella jamarii, Dana, from Rio Janeiro, the hand is more elongate "et pourvue de trois denticulations en dessous." Mayer thinks that Milne-Edwards' species may just possibly be Caprella squillibrata, Say.

1868. Norman, A. M.

This paper gives the definition of the genus Haploops, Lilljeborg, which includes the character "eyes two, simple," but the British specimens of Haploops tubicola, Lilljeborg, are described (Zool. Chall. Exp.—Part LXXV.—1867.) XXX 49
as agreeing with those found by Torell off the coast of Greenland, in having four simple eyes. "The number of eyes, therefore, would not seem to be constant." Compare Note on Göös, 1865.

A new genus, *Tessarops*, is thus defined:—"Eyes four—two (large, compound) situated above the origin of the superior antennae, and two (nearly simple) below the others, at the base of the superior antennae. Superior antennae furnished with a very slender secondary appendage. Both pairs of gnathopods simple, not subchelate. Last pereiopods short, stout. Pleon having dorsal margins of segments toothed. Telson squamiform. Last uropods two-branched." To the description of the species *Tessarops hastata* are prefixed as possible synonyms, *T. acanthurus*, Lilljeborg, 1865, and *T. syranoi bicupris*, Göös, 1865. Boeck has decided that the three species named are in fact but one, and that *T. acanthurus* has priority.

A new species, "*Mera Batei*," is described and figured. Attention is called to the difference in size and structure of the second gnathopod in the two sexes of this genus. *Megamorea othonis* is assigned as female to *Megamorea longimanata*, *Megamorea alderi* as female to *Melita obtusa*, to which *Melita procina* is united "as another and the more usual form of the male."

The genus *Megamorea*, Bate, is thought to be in effect not distinct from *Mera*.

The new genus *Helleria* is thus defined:—"Eyes compound. Superior antennae slender, much shorter than inferior, with [out] secondary appendage. Both gnathopods subchelate. Last pereiopods rather short, furnished with long plumose setae. Fifth and sixth segments of pleon coalesced into one. Last uropods two-branched. Telson squamiform, cleft almost to the base." The new species is named *Helleria coalita*. But the name *Helleria* must be changed, being preoccupied among Isopoda.

1868. Norman, A. M.

"As a rule," Mr. Norman observes, "those Amphipods which occur also on the British coast attain a much greater development within the Arctic circle." He notices, without naming, new species of *Atylus, Cryptophium, Corophium, Pleustes*, and one "allied apparently to *Calliopeus*," with "a new genus allied in general characters of eyes, of gnathopods, and pereiopods, especially in the broadly flattened meros and carpus of the last pair, to *Haplopus*, but having the antennae furnished with an appendage."

1868. Plateau, Félix.

"*Gammarus pulex* (Koch) is not blind, but sensible to light." (Zool Record, 1870.)
1868. Sars, Michael.

On p. 260 twenty species of Amphipods are mentioned as occurring at depths between 250 and 300 fathoms. For one of them, "Lyssanausa magellanica, Lilljeborg, vix M. Edwards," the depth is given, 300 to 400 fathoms.

1868. Wagner, Nicol.

Of this paper, which I have not seen, Messrs Friedländer assure me that the exact title in German is:—"Hyalosoma dux, eine neue Form aus der Gruppe der Daphniden," so that the attribution of Hyalosoma to the Amphipoda is no doubt accidental.

1869. Bessels, Emil.

"E. Bessels has given a résumé of his researches into the development of these Crustaceans [Amphipoda], the detailed description having been unfortunately lost during his journey." (Zool. Record, 1870).

1869. Cajander, Alfred Henrik, born 1843, died 1868 (Note to his Contribution).

He remarks that the Crustaceae of Finland were all but uninvestigated up to that time. In the list which he here gives only one Amphipod is included, thus mentioned:—"Cerophinium longicorne Latr. Alands och Åbo skärgård h. o. d." The notes say, "h. o. d. = här och der," and "När en art uppgivs för skärgården menas dermed, att den förekommer i havet." The author's early death precluded him from advancing the subject.

1869. Forel, F. A.

"One species of Gammarus, two of Cyclops, two of Daphnia, two or three of Cypris, have been found at a depth of 75 meters, about 250 feet, in the Lake of Geneva; at 300 meters one species of the order Amphipods, one Cypris, one Cyclops." (Zool. Record, 1870.)

1869. Grube, A. E.

In this paper Grube describes and figures "Urothoe marinus Sp. Bate. ; var. pectinatus Gr.," in which the third peraeon appears not only very much broader and flatter than either of the following pairs, but has the hand and two preceding joints in their whole breadth on the lower rim, the hand and wrist also in the centre, armed with a comb of spines. The telson is split only to the centre, and is much longer than broad. Other differences concern the last uropods and the eyes. At page 35 a list is given of the Amphipods, eight species, which Grube obtained at St. Vaast.

1869. Heller, Camil.

Of "Gammarus Veneris, Heller," he says, we have in this species obviously a Gammarus marinus, cut off from the sea and forced to live in fresh water, becoming changed accordingly to suit its new conditions of life. His Orchestia cavimana he considers in like manner derived from "Orchestia Montagui."

1869. Hilgendorf, Franz.

In the "Uebersicht der ostafrikanischen Crustacea," pp. 103-115, he names the following Amphipods, "Talitrus Copefetii, Aud.," "Orchestia Bolze, M. E.," "Orchestia inquasitis, Hell.," "Orchestra Deshayesii, Aud.," "Amphithoe flosa, Sav.," "Amphithoe costata, M. E.," "Amphithoe Copeletii, Aud.," "Lencothoe furina, Sav.," and under the head of Læmodipoda he gives "Caprella secunda, Templet.," and "Caprella nodosa, Templet."

Martens notes Tesserops kastata, n. g. et. s. "to be compared with Tiron acaudatus (Lilljeb.) and Syrrocho bicuspid (Göes)." Boeck places the three together under the name Tiron.
REPORT ON THE AMPHIPODA.

389

1869. Münther, Julius, died February 2, 1885 (Friedländer, Nature novitates), and Buchholz, Rudolph, died April 17, 1876 (Taschenberg).

In the Crustaceen Fauna of their district, the authors say, "aus der Ordnung der Amphipoden sind bis jetzt nachgewiesen:—Gammarus Locusta Fabric., G. fluviatilis Edw. (paler L.) und G. ambulans Fr. Müller; ferner Corophium longicorne Latr., Talusus saltator Müller Edw., Orchestia Echore Fr. Müller, O. Gryphus Fr. Müller und Leptocheirus pilosus Zachhich." 

1869. Nardo, Giovanni Domenico.

The Bibliography extends from the year 1524 to the year 1868, occupying the first part of the work. The second part, pages 283 to the end, is concerned with the fifty-four species mentioned in the title. The "Edriotalmi amphipodi" are described on pages 330-332. First Nardo gives "Sp. 46.) Orchestia littorea L. Leach. Cancer locusta, L., Chier., sp. 58, fig. 74.—Volg. Soletto de fossa," with a note to the effect that, since his work in 1847, he had noticed characters which seemed to distinguish this species from Orchestia littorea. Fig. 9, on pl. xv., purporting to be copied from Chierèghin, negatives all idea of an Orchestia, the upper antenna, though shorter than the lower, being far too long for that genus. The proportions of the antenna, coupled with the large rami of the third uropods, would point rather to some genus like Cheirocerus, Norman.

Nardo next gives "Sp. 47.) Lysianassa Poster. Cancer selectus, Chier., sp. 59, fig. 75.—Volg. Soletto de mar." He repeats the Latin description quoted in 1847, and adds an Italian quotation, "L'esterna superficie di tutto il corpo, aggiunge, rilevansi liscia e tutta seminata di piccole macchie di color rosso sopra un fondo biancastro, ed ha sul margine superiore tanto del quinto che del sesto pezzo delle articolazioni del tronco caudale, un poco per cadun pezzo di lunghetti, sottili ed avvienuti punzigli, rivolti verso la parte posteriore. Abita il nostro golfo ne' siti fangosi. Non serve ad alcun uso per essere minutissimo, ed è difficile raccoglierne in qualche numero." The extreme minuteness of the specimen leads Nardo to suspect that it had not attained its full development. Chierèghin's figure is reproduced, pl. xv. fig. 8, with a line a tenth of an inch long to show the natural size. The upper antennæ are much shorter than the lower, but filiform,
quite unlike those of *Lysiana*. Five short filiform legs are represented, followed by two very long ones, with the first joint in each dilated, the rest slender. The pleon is elongate.

"Genere Lusyta, Nardo," follows, containing

"Sp. 48. *Lusyta algensis*, Nardo; Simon, mod. cist. *Cancer algensis*, Chier., sp. 60, fig. 76–79. *Podoceros . . . . . Leach; Annot. aut. all'opera ms. del Chiereghin." Nardo says that Leach wrote with his own hand at the foot of the page containing the figure given by Chiereghin, the generic name *Podoceros*, without indicating the species. Nardo himself considers it to differ from *Podoceros* and also from *Cerapus* and *Cerapodina*, though like the two last, especially from its habit of living in a case. As the genus is not separately defined, its characters must be derived from those which are said to be the essential ones of the species;—"Estremita della testa un poco prolungantesi in rostro; occhi posti lateralmente alla base di tal rostro, alquanto peduncolati; due lunghi antenne sorzano dal discotto del rostro terminante in punta; hanno ciascuno nove articolazioni; e lungo il loro lato inferiore dei lunghi sottilissimi peli; al discotto ne sorzano altre due più corte, di sole sei articolazioni, pelose anch'esse come le prime.

"I primi due piedi sono grossetti, eguali, di cinque articolazioni, avventi il quarto pezzo più grosso degli altri, e su di questo nasce un dito incurvato verso l'ingiù, terminante in punta ed atto a piegarsi sul lato inferiore del detto quarto pezzo.

"Seguono cinque altri piedi per ogni lato. I tre primi pa' sono sottili, composti di sei pezzi, l'ultimo de'quali termina in una punta rivolta un poco verso l'ingiu. Gli altri due pa' sono un poco più grossi e più lunghi coll'ultimo pezzo che è più ingrossato e parimenti terminante in punta alquanto più aguzza. Altri due pa' di piedi analoghi, sono posti sotto l'ottavo pezzo. Nel quinto, sesto e settimo nascono invece che piedi delle appendici membranose e filamentose.

"La superficie del corpo è fissa e di color bianco candido."

Its dwelling is said, on Chiereghin's authority, to be on the leaves of the *Zostera marina* in tubes shaped like a *Cornucoquia*, formed of very fine threads agglutinated together, out of which it thrusts its upper half, when seeking food, and by rapidly waving its arms and antennae puts the water into motion to draw small animals towards its mouth. The original Latin definition is quoted, without the improvements upon the Latinity given in 1847, thus;—

"Cancer algensis, macrurus, thorace vostrato, manubis adacrylitis, pelibus decem, termine candi triphylo." The figures 7, 7b, on plate xv., show the shape of the tube, slightly curved, narrow at one end, widening gently to the mouth at the other extremity; figures 7a, 7c, portray the animal very indistinctly, but with the upper antenna decidedly longer than the lower, which is unsuitable to *Podoceros*. The description of "i primi piedi," i.e., evidently the second gnathopods, suits the genus *Cerapus*, but in the well-ascertained species of that genus the tubes are straight, and open at both ends. J. V. Carus 1885, gives *Lusyta, Nardo*, as a synonym of *Podoceros, Leach*, but without explanation and without mention of the species *algensis*.

The "Edriotalmi lancedipodi" are described on pages 323–324. In this division Nardo gives

"Sp. 49.) *Cápeella linearis*, Milne Edw. *Cancer linearis*, L., Chier. sp. 61, fig. 80. — — Olivi; Zool. Adr. *Opeina Linearis*, Latr., Martens; Reise nach Venedig, p. 497." He says that in 1847 he erroneously marked it as "*Cápeella noea species*?" He finds that it differs from *Cápeella monacantha* [monacantha], Heller, by not having the spine at the base of the second pair of feet, and some other trivial characters. Heller's species is identified by Heller and Mayer with *Cápeella equilibra*, Say; Mayer gives up Nardo's species as undecipherable. The fig. 4, on plate xv., however, will fairly suit *Cápeella equilibra*, in which the spine above-mentioned has escaped the notice even of good observers.
He next mentions "Sp. 50, C. FABRIUS, Nardo. Cancer linearis, L., varietas, Chier, sp. 61, fig. 81-82. Caprella nova species! Nardo; Sinom. mod. citata." The specific name, he says, was omitted in the "sinonimia" by a typographical error. He finds it very near to, if not the same as, Caprella armata, Heller. Both are by Mayer made synonyms of Caprella acanthifera, Leach. It is figured on pl. xv. figs. 5, 5a, the magnified figure leaving no doubt of its identity.

The last species is "Sp. 51, C. FABRIUS, Nardo," not derived from Chiereghini's work. Nardo recognizes its likeness to Caprella acanthifera, Heller [Latreille], with which the description and figure, pl. xv. fig. 6, justify Mayer in identifying it beyond doubt.

1869. NORMAN, A. M.

Numerous species of Amphipoda are recorded, with occasional notes on the nomenclature. The genus Ecangula is thus defined:—"Antennae short and strong; flagellum rudimentary, upper pair without a secondary appendage. Body wide; coxa shallow. First gnathopods long, slender, filiform; dactylos obsolete. Second gnathopods subechinate, slender, but yet much stouter than the very delicate first pair. Periopods rather short, subequal; propodus longer than carpus. Uropods all two-branched; branches short, simple. Telson squamiform.

"This genus seems to be most nearly allied to Cratippus, from which it is distinguished by the remarkable character of the first gnathopods." The type species, Ecangula stilipes, is also fully described, and partly figured, pl. xxxii. figs. 7-12.

The genus is, like Cratippus, Sp. Bate, a synonym of Colomastix, Grube, 1861. The species is no doubt the same as Cratippus tenipes, and probably also the same as Colomastix psellida, Grube.

1869. SANGER, N.

"The journal and paper are written in the Russian language." "At Reval . . . occur . . . species of Crangon, Mysis, Gammarus, and Carephium longicorne (Fabr.) at about 40 feet." (Zool. Record, 1870.)

1870. BENEDEN, ÉDOUARD VAN.

1870. Beneden, ÉDOUARD van, et Bessels, Émile.

"The development of the ovum of various orders of Crustacea is the subject of several papers by Ed. van Beneden. . . . It is very remarkable that there is a difference between the fresh-water and marine species of Gammarus; in the latter the separation of deutoplasm and protoplasm occurs immediately after the complete cleaving of the yolk, as in Chondracanthus and the Copépodes; in the fresh-water species, on the contrary, the deutoplasm is not included in the multiplication of the egg-cells. An abstract of these papers will also be found in the Quart. Journ. Microsc. Scienc., January 1870, pp. 81-84." (Zool Record, 1870.) Compare Note on Clans, 1884. For Dermaptilus tophi, see Note on Huxley, 1877.

Van Beneden says at the outset, "Nous ferons suivre le nom des cétacés de l'énumération des communs et des parasites qu'ils hébergent." He then gives "Balena mysticetus, Cyamus ceti Linn.—Cyamus ovalis. Ce crustacé, commercial comme les Cirripèdes, vit sur la peau et a été signalé par la plupart des baleiniers qui ont fait la pêche au Nord." Lütken objects to the synonymy here given, and also to classing the parasitic Cyamus with animals that are merely communs. The next entry referring to the Amphipoda is "Balena biscayensis, Eschr. Cyamus biscayensis. Le docteur Monedero a publié la figure qui représente la jeune baleine qui a été capturée en 1854 sur la plage de Saint-Sébastien, dans le golfe de Gascogne, et à côté de la baleine il a donné le dessin d'un Cyame qui a été probablement trouvé sur elle. Malheureusement on n'en a pas conservé pour les comparer." Under these circumstances it is a rather strong measure, as Lütken thinks, to establish a new species.

Under Balena australis, is mentioned Cyamus erraticus, Roussel de Vauzème, and two figures are given, with the remarks that Roussel de Vauzème "admet trois espèces sous les noms de Cyamus ovalis, Erraticus, et Gracilis. Nous avons tout lieu de croire, comme le pensaient Audoubon et Milne-Edwards, que ce naturaliste n'a pas tenu assez compte des modifications que l'âge apporte dans la forme. Nous avons trouvé de jeunes animaux au milieu d'adultes auxquels les caractères du Gracilis conviennent fort bien. Nous reproduisons la forme d'un de ces jeunes individus." Lütken upholds all the three species as distinct. Van Beneden refers also under this heading to Latreille's three species of Cyamus, two brought by De Lalande from the Cape of Good Hope, the other coming from some eastern Cetacean.

Under Hyperoodon (rostratum) butchkof, he mentions "Cyamus (Platyctamus) Thompsoni (Gosse). Ce Lomodiode vité également sur la peau mais sans s'y fixer."

Under Globiceps melas he mentions, "Cyamus globicipitis, Latk. Comme les autres Cyames, on l'a trouvé à la surface de la peau."

Under Monodon monostomou he mentions "Cyamus monodontis et C. nodosus Latk. Ces Cyames sont signalés sur ce cétacé par M. Latkken."
In the concluding observations he says, "Parmi les commensaux libres se trouvent les Cymes qui se cramponnent à la peau des Mystiètes et sur plusieurs Cétéodoutes. C'est le seul commensal de la baleine du Groenland."

1870. Boeck, Axel.

(Appendix by Lütken).

In this predromus to his greater work, Boeck accepts only two divisions of the Amphipoda, which he calls "Hyperidae, Dana 1852," and "Gammaridae Dana 1849," although in point of fact, the names which Dana employed for his subtribes of the Amphipoda in 1849 were Gammaracea and Hyperiacea, and in 1852 were Caprellidea, Gammaridea and Hyperidea.

In the division Hyperidae Boeck includes two families, Hyperidae and Tryphaniidae. Among the former he describes Melocosa abyssorum, n. s., which he afterwards called Tauria abyssorum, by G. O. Sars identified with Tauria (Oniscus) Methwaraen, O. Fabr., 1790, for which see Note on Borallus, 1885. In a new genus, Parathomida, he includes Themisto compressa, Gosse, and Parathomida abyssorum, n. s., synonymous, according to G. O. Sars, with Hyperia obliqua, Sp. Bate (non Kröyer), so that the name will be Parathomida obliqua. To Themisto, Guérin, he assigns Gammarus libellula, Mandt, and Themisto biminova, n. s. In his family Tryphaniidae, he places the new genus and species, "Tryphana Malvai," but according to G. O. Sars, the genus Tryphana is a synonym of Lycza, Dana, in the family Typhidae, as limited by Claus.

In the division Gammaridae he places:—

Family I. Protonotae, containing only Trischizostoma serrati, Esmark and Bueck.

Family II. Orchistidae, with three genera, Orchistia, Talitrus, and Hyale.

Family III. Gammaridae, with twenty-two subfamilies, as follows:—Subfam. I. Lysinassina (v), Dana, 1849, comprising, together with species not new, Lysianassa phalosa, n. s., which, according to G. O. Sars, is the male of Lysianassa costa, Milne-Edwards; "Ambasia Daniellisi," n. g. et s.; Ichnopus minutus, n. s.; Socarnus, a new genus doubtfully identified with Ephydryphora, White, 1848; Calliasma, Costa, 1851; Hippomenes, a new genus to include Anonyx holboell, Kröyer, and Lysianassa abyssa, Gosse; Cypocaris anonyx, n. g. et s., named by Lütken, but described by Bueck; Eurytyus, Liljeborg; Aristus, a new genus to receive Anonyx tunidus, Kröyer; Anonyx, Kröyer, with a new species, "Anonyx Liljeborgii," Oudemans, afterwards corrected to Oudemans, n. g., doubtfully identified with Alderota, Milne-Edwards, 1840, but not including any new species; Menigos, a new genus to receive Bueck's own species, Anonyx obtusifrons; Orchomene, a new genus embracing Anonyx pinguis, Bueck, Anonyx serratus, Bueck, Anonyx minutus, Kröyer, Lysianassa umbra, Gosse, which Sars refers to Lepidoporeena, Sp. Bate, and Orchomene Goenii, n. s.; Tryphosa, n. g., with four species, of which only "Tryphosa Heringi" is new; Normania, a new genus to receive Opis quadririma, Spencer Bate et Westwood, 1868; Opis, Kröyer, afterwards altered to Opis; Acidostoma, Liljeborg. Of the new names, Tryphosa is inconveniently near to Tryphosa among Lepidoptera.

Subfam. II. (by mistake printed III.), "Ponoptopora. Dana 1852," contains Pontoporia, Kröyer, with the species Pontoporia femorata, Kr., Pontoporia faroejera, Bruzelius, according to Sars not distinct from femorata, and Pontoporia affinis, Lindström; Priscula armata, described here as a new genus and species, but in the later work accompanied by the synonym Pontoporia armata, Bueck, 1860; Arpissa typica, n. g. et s.; Bathyoporeia.

(ZOOL. CHALL. EXP.—PART LVII.—1887.) XXX 50
Lindström, including *Thersites guilliamontiana*, Sp. Bate, and *Thersites pelagicus*, Sp. Bate, as synonyms, female and male respectively, of *Bathygryca pilosa*, Lindström.

Subfam. III. "Stegecephalina, Dana 1852," contains *Stegecephalus*, Krøyer, with the species *Stegecephalus ampulla*, Phipps, and "*Stegecephalus Christianensis*," n. s.; *Andania*, n. g., with the new species, *Andania abyssi*, and *Andania modestis*.

Subfam. IV. Amphioxinae, contains *Amphiocha*, Sp. Bate, including, besides the type species, *Amphiocha manudens* (more correctly manudenu), *Amphiocha odontonyx*, n. s., *Amphiocha biginosa*, n. s., *Amphiocha tenimanus*, n. s.; *Gitana*, n. g., with "*Gitana Sarsii*" n. s., and *Gitana rostrata*, n. s.; *Astya abyssi*, n. g. et s.

Subfam. V. "Phoxina, Spence Bate 1857," embraces *Phoxus*, Krøyer, with the species *Phoxus holothii*, Kr., and *Phoxus simplex*, Spence Bate, 1857, the latter in Sars' opinion being a wrong identification, so that he names Boeck's species *Phoxus fulcatus* on account of the peculiar rostrum; *Harpinia* (a preoccupied name afterwards changed to *Harpinia*), a new genus to receive *Phoxus plumosus*, Krøyer, and *Harpina crenulata*, n. s.; *Sulcator arenarius*, rather to be called *Hastorius arenarius*, Slabber; *Urothoe*, Dana.

Subfam. VI. Sternothinae, new, includes *Sternothoe*, Dana, Boeck's own *Sternothoe danai*, being here recognised as a synonym of *Montagna marina*, Sp. Bate, with the name *Sternothoe marina*; *Metopa*, a new genus to receive *Leucothoe elongata* and *Leucothoe glacialis* of Krøyer, *Montagna obtorti*, Sp. Bate, *Montagna bruneri*, Gös (as to which, Sars, in 1882, points out that Boeck's species is distinct from that of Gös, and he therefore names it *Metopa borealis*), *Metopa affinis*, n. s., *Metopa longicornis*, n. s., *Metopa megachiron*, n. s., *Metopa longicornis*, n. s., and *Metopa nasuta*, n. s.; *Cressa*, a new genus with the new species, "*Cressa Schröeder" and *Cressa minuta*. If the species *Schröeder* be, as G. O. Sars considers it, a synonym of *Danaia dubia*, Spence Bate, the genus *Cressa* will become a synonym of *Danaia*, in which Boeck's species *minuta* is very doubtfully distinct from its congener. The difficulty with regard to the mandibular palp has been already mentioned.

Subfam. VII. Syrrhoine, new, receives *Syrhoes*, Gös, with the species *Syrhoes crenulata*, Gös, and *Syrhoes levis*, n. s.; *Tiron acanthurus*, Lilljeborg; *Brusilia typica*, new genus and species.

Subfam. VIII. Pardalisinae, new, has *Pardalisca*, Krøyer, with the species *Pardalisca cuspidata*, Krøyer, *Pardalisca boecki*, Malm, and *Paralysca abyssi*, n. s.; the new genus *Halice*, with the new species *Halice abyssis* and *Halice grandicornis*, the latter, according to G. O. Sars, Ov. Norg. Crust. p. 106, being undoubtedly the male of the former; *Nieqye tumida*, Brünnl. 

Subfam. IX. "Leucothoinae, Dana 1852," includes *Lelijehorgia phylida*, Sp. Bate, and *Lelijehorgia piseicornis*, M. Sars, the latter doubtfully distinct from the former; *Enisurus cuspidatus*, Krøyer, and *Enisurus longipes*, Boeck; *Leucothoe spinicarpa*, Abildgaard; the new genus *Tripopis* (a preoccupied name), for the species *acutus*, Lepech., "*Helleri*" n. s., and *fragilis*, Gös, of which the first two should perhaps be called *Rhachotropis acutatus*, and the third *Rhachotropis fragilis*.

REPORT ON THE AMPHIPODA.

n. s., and Halimeda brevicornis, altered from Oediurus brevicornis, Goës; Pontocrates a new genus, with Oediurus norvegicus, Bocce, 1860, for the type, a species which was named Kröyer (or Kröger) crassaria, by Sp. Bate, and Hancock, in 1858 (see Notes under that date); Pontocrates haplochelis, Grube, 1864; Aceros, Bocce, with the species Aceros phyllopus, M. Sars; Halicrenon longicaudatus, new genus and species; Oediurus brevicornis, Liljeblorg; Paramphithoe, Brinzelius, 1859, to receive the species Amphithoe globus, Bocce, Paramphithoe media, Goës, Amphithoe panopla, Kröyer, Paramphithoe parva, n. s., Amphithoe palchella, Kröyer, Amphithoe biocipis, Kröyer, all of which in the later work are transferred to Phaestus, Sp. Bate, 1858.

Subfam. XI. Iphimedia, new, contains Vertumnus, White, 1847, altered in the later work to Acanthophalacoma, here receiving the species Acanthophalacoma crassus, Owen, Oniscus servatus, O. Fabricius, and Acanthophalacoma typhus, Kröyer; Iphimedia obscura, Rathke; Oicles, Liljeblorg, 1865, to receive Otus carinatus, Sp. Bate; Laphystius sturionis, Kröyer, the original spelling Laphysius being subsequently recognised.

Subfam. XII. Epimerina, new, has "Acanthocome n. g. (Acanthocoma, Owen)," for Oniscus capitosus, Lepechin; and Epimeria, Costa, for Gammarus corniger, Fabricius.

Subfam. XIII. Dexammine, new, receives Dexamine spinous, Montagu, Dexamine thea, Bocce, "Dexamine Heberghi," n. s.; and Lampra, new genus, afterwards named Tribula, for the single species Atylus gibbus, Sp. Bate.

Subfam. XV. "Gammarinae. Dana 1849," contains Gammarus, Fabricius, 1776, with the species locusta, Linne, 1867, marinus, Leach, 1815, pulex, Pennant, 1777, and neglectus (Liljeblorg), G. O. Sars, 1867; in all of which the synonymy given demands attention; Pallasia, Spence Bate, 1862, in the later work spelt correctly Pallasia, with the single species Pallasia quadriramosa (Esmark), G. O. Sars, 1867; Meana, Leach, for the species Gammarus homali, Brunzelius, Gammarus tolloni, Goës, and Gammarus longimanus, Thompson; Molita, Leach, for the species obtusa and palmata of Montagu, and for Gammarus dentatus, Kröyer; Elasmocharis, Sp. Bate, 1856, for Elasmocharis latipes, n. s.; Chericerus, Norman, 1865, for "Gammarus Sundevalli," Rathke, and Gammarus assimilis, Liljeblorg; Gammarocarabus boreaticus, Sabine; Nyphargus, Schist. 1851, for Ericus elongatus, Brunzelius; Anactilla, Bate and Westwood, for Gammarus sabini, Leach, Gammarus angulatus, Rathke, and Gammarus pinguus, Kröyer; Melichippus, a new genus to receive Gammarus spinosus, Goës, and the new species longipes and borealis.

THE VOYAGE OF H.M.S. CHALLENGER.

Subfam. XVI. Leptocheirinae, now, contains Leptocheirus pilosus, Zaddach, and the new genus
Goksin, for Antonoë depressa, Goëc.

Subfam. XVII. Photinae, now, said by a slip, which is repeated in the larger work, to have
"Podes 7m in Paris breviores quam 66 Paris," receives Photis reinbachi, Kroyer, "Photis
Lütkeni," n. s., which Norman identifies with the earlier Eioschius longirameatus, Bate and
Westwood, while Boeck makes longirameatus a synonym of Reinhardi; Microgrotopus
muculatus, Norman; "Xenolea Batei," a new genus and species, which is so like the
earlier Nassa vinapina of Spence Bate, that I do not think they should be kept distinct,
although Boeck says that the apex of the telson in his species is cleft or sinuate. On
the other hand the genus Nassa, 1862, must yield to Podocereopsis, 1860.

Subfam. XVIII. Microdeutopinae, new, contains Microdeutopus, Costa, 1853, for the species
Microdeutopus griffithi, Costa, and Gammarus anomalous, Rathke; Aora gracilis, Sp.
Bate; Antonoë, Brueli, 1859, for Gammarus longipes, Lilljeborg, and Antonoë phumosa,
"falcatus," Montagu; Janassa, a new genus for Podocerus variegatus, Leach, which is
probably only a form of Podocerus falcatus, while the name Janassa is preoccupied among
fossil fish; Cerapus, Say, 1817, to receive Cerapus abditus, Templeton, Cerapus diversiformis,
Milne-Edwards, Cerapus longirostrus, n. a., and Cerapus hunteri, Sp. Bate, the last three of
which S. I. Smith places in the genus Erichthoönus, Milne-Edwards, making the species
hunteri synonymous with diversiformis.

Subfam. XIX. Amphithoidinae, now, contains Amphithoë podoceroides, Rathke, Amphithoë
grandimana, Boeck; Sunamphitoides barnus, Sp. Bate; Sunamphitoides longicornus, n. a.

Subfam. XX. Podocerinae, new, includes Podocerus, Leach, to receive Ischyrocerus latipes,
Kroyer, Podocerus megacephus, n. s., Ischyrocerus anguipes, Kroyer, Cancer (Gammarus)
falcatus, Montagu; Janassa, a new genus for Podocerus variegatus, Leach, which is
probably only a form of Podocerus falcatus, while the name Janassa is preoccupied among
fossil fish; Cerapus, Say, 1817, to receive Cerapus abditus, Templeton, Cerapus diversiformis,
Milne-Edwards, Cerapus longirostrus, n. a., and Cerapus hunteri, Sp. Bate, the last three of
which S. I. Smith places in the genus Erichthoönus, Milne-Edwards, making the species
hunteri synonymous with diversiformis.

Subfam. XXI. "Chelurinae. Allman 1837," has only Chelura terebrans, Philippi.

Subfam. XXII. "Corophina. Dana 1849," contains Corophium, Latreille, 1807, to receive Cancer
groswi, Linne, Corophium crossei, Brueli, 1859, with "Corophium acherusicum,
Costa," 1856, and "Corophium crassicorne (Brueli), Spence Bate and Westwood,"
1863, given in the synonymy, Corophium affine, Brueli, with "Corophium Bonelli,
Milne-Edwards." q., 1830, in the synonymy, this last being, according to G. O. Sars,
"Corophium Linnei, p. 112, distinct from Corophium crossei, Brueli, to which Boeck in
his later work doubtfully makes it a synonym, withdrawing it from Corophium affine;
Siphonacetes, afterwards corrected to Siphonacetes, Kroyer, 1845, to receive Siphonacetes
vulcanus, Kroyer, "Siphonacetes Colletti," n. s.; Glacuonome, Kroyer, 1845, a preoccupied
name, which must yield, as pointed out by S. I. Smith, to Uncita, Say, but here used
for the three species, leucopis, Kroyer, which Smith identifies with Uncita irrudata, Say,

Fam. IV. "Dulichidæ. Dana 1849," comprises Dulichium, Kroyer, 1845, with six species,
spinosisimus, Kroyer, falcatus, Sp. Bate, "Nordlandia," n. s., tuberculata, n. s., curvicauda,
"n. s., porrecta, Sp. Bate; Paradulichia typica, new genus and species; Leptothyridus,
Brueli, 1859, with the species tuberculata, Brueli, and spinosisimus, n. s.;
"Xenolea Frouenfeldi," new genus and species.

Fam. V. "Caprellidae. Leach 1815," has two subfamilies:

Subfam I. Caprellinae, new, contains Proto goodalei, Sp. Bate, which is now made a synonym
of the following species, Proto ventricosa, Müller; Ceripola dolphi, Kroyer; Aegina, Kroyer,

The new genera are described as follows:—

Gen. IV. Searo ras. "Labium superius prolongatum, prominentia, cume hypoostomi apico acuto conjunctum. Mandibulae mediocriter elongatae; palpo multo profundius quam tuberculo molar promineni affixo. Maxillae 1mi paris dentibus perlatis; lamina interiore prolongata, angusta et in apice duobus setis plumosis instructa. Maxillae 2di paris laminis angustis, elongatis. Pedes maxillares laminis exterioribus ovatis, in margine interno nodulos parvulos gerentibus; lamina interiore prolongata; articulo palpi 2do elongato; articulo 4to ungiformi. Antenne breves. Pedes 1mi paris breves; mant apicem versus attenuata et laud subcheliformi. Appendix caudalis longitudine medioceri, usqvo ad medium fissu."

Gen. VI. Hippomnemon. Mandibulae breves; mala interiore angusta; in sinistra dente parvulo accessorio instructae; palpo in eadem altitudine ac tuberculo molaris permagni affixo. Maxillae 1mi paris palpo in apice multis, brevibus, latvis, parum serratis dentibus instructo; lamina interiorem sat brevi, in apice duobus setis plumosis instructa. Maxillae 2di paris
THE VOYAGE OF H.M.S. CHALLENGER.

laminis brevisibus. Pedes maxillares breves, lati; lamina externa ultra articulum palpi 2dum porrecta, in margine interno dentibus crebris, validis armata; lamina interna brevi. Antennae elongatae; antennae inferiores articulo 3to multo longiore quam 4to. Pedes 1mi paris sat elongati; imprimis articulos 4tus; manu invalida, subcheliformi. Appendix caudalis elongata, profunde fissa, ultra pedunculum pedium saltatoriorum paris ultimi porrecta."

Gen. VII. Cyphocaris, Lütken, n. g. "Mandibulae brevissimae; palpo longo et latissimo, in eadem altitude ac tuberculo molaris robusto affixo. Maxille 1mi paris palpo apicem versus dentibus paucis sed validis et una seta proelongata plumosa armata; lamina interna elongata, et in margine interno setis multis plumosis instructa. Pedes maxillares lamina externa brevissima, in margine interno dentibus paucis sed validis armata; palpo proelongato; articulo 1mo et 2do eadem longitudine; articulo 4to cylindrico, non ungviiformi, seta robusta plumosa instructo. Antennae inferiores articulo 1mo ab integumentis capitis non tecto, sed extus visibili, in incisura corundem sito. Pedes 1mi paris parvi; manu apicem versus acuta, vix subcheliformi. Pedes 2di paris elongati, ungve destituti. Appendix caudalis profunde fissa, longe ultra articulum basalem pedum saltatoriorum paris ultimi porrecta. Segmentum truncat 1num valde gibbosum; caput sub anulo situm, ex parte tectum; epimerum 1num nullum, 2num parvulum; 3tium et 4tium coagula, magna."

Gen. IX. Aridius. "Mandibulae elongatae, angustae, in apicem vero latae, sine dente accessorio; tuberculo molaris prominenti, acuto, palpo in eadem altitude inixo. Maxille 1mi paris perlatae; in margine crebras setas plumosas gerentes; lamina interna etiam brevi, ovata, in apice brevis setis plumosis instructa; at palpo angusto, in apice paucis spinis instructo. Maxille 2di paris item laminis latissimis, in margine setis multis instructis; lamina externa angustiore quam interna. Pedes maxillares laminae exteriore permagna, in margine setis paucis modo armata et ferme ad finem articuli palpi 3tii porrecta; articulo palpi 3to brevi et gracili; 4to ungviiformi; lamina interna brevissima, triangulare, ad basis lata, et in apice uno dente et setis pluribus plumosis armata. Antenne superiores pedunculo elongato, angusto. Pedes 1mi paris manu apicem versus angustiore. Pedes 2di paris elongati; manu sat angusta. Pedes saltatorii paris ultimi ramo interiore paulo breviore quam exteriere; ramo interiore in margine externo et interno serrulato, exteriere in margine interna modo. Appendix caudalis brevissima, non ad finem pedunculi pedem saltatoriorum ultimi paris porrecta, usque ad basin fissa."

Gen. XII. Menigrates. "Mandibulae brevissimae; palpo brevi, profundius quam tuberculo molaribus robusto affixo. Maxille 1mi paris lamina interna ovata, in apice setis duplex plumosis instructa; palpo in apice paucis spinas gerentis. Maxille 2di paris laminis mediocris, crebris elongatis. Pedes maxillares latissimis, breves; lamina externa ultra finem articuli palpi 2dii porrecta, paucis spinis gracilibus et nodis et in apice spina una valida armata; articulis palpi brevissimis et latis; articulo 4to processum brevem, obtusum, tuberculiformem
REPORT ON THE AMPHIPODA.

399

Subfam. III. Syrrochiena. Gen. III. Bruleia. "Mandibulae crassissimae, late, pyramidales, in apice insuavate, non dentatae. Maxille 1mi paris palpo angusto. Corpus subdepressum; epimeris serratissimae, prominentibus, magnitudinis mediocris; epimero 4thi maximo. Pedes 1mi et 2di pariis manu parva, subcheliformi. Pedes 3ti et 4ti pariis perangusti, elongati; articulo 3dio perbrevi. Pedes trium parium ultimorum elongati; articulo 1mo parum dilatato. Pedes saltatorii 1mi pariis rano exteriores breviore qvam interiores; 2di pariis rano interiores latisimis, exteriores parvo. Appendix caudalis longa, non fissa."

Gen. IV. Hailmeston. "Mandibulae in apice parum modo deputate et crasse; palpo prolongato et angusto. Pedes 1mi pariis carpo tam longo aut multo longiore qvam manu ovata et in angulo inferiore postico parum dilatato. Pedes 2di pariis carpo prolongato, calce parvula predito aut destituto; manu tam longa aut breviore qvam carpo."

Subfam. XIII. Dexamininae. Gen. II. Lampae. "Pedes maxillares laminar inexteriores angustioribus, valde curvatis et mo do in summo dimidio spinis paucis sed validis armatis; laminis interioribus latioribus et longioribus qvam apud genus Dexamine, spinis multarum curvatis et gracilibus armatis. Epiphragma minima; epiphragma qvatuor anteriore 5to non altiora, in marginie inferiore armata. Pedes qvinqve parium ultimorum articulo 4to et 5to perbrevibus; ungve parvo."

Subfam. XIV. Atylinae. Gen. II. Postogenea. "Mandibulæ palp a palpo valide et articulo 3tiio paulo breviori quam 2do. Maxillæ 1mi pariis lamina interna parvae (3–6) setis plausosis instructa. Pedes maxillares lamina externa et interna spinis (non dentibus) elongatis instructis; palpo brevi; articulo ejusdem 3tiio in fine marginis exterioris product. Antennae superiores inferioribus paulo longiores. Pedes saltatori 1mi et 2di pariis ramis exterioribus brevioribus qvam inferioribus. Pedes saltatori tiiii pariis pedunculo perbrevi, breviore qvam appendice caudali. Appendix caudalis duplex. Corpus lovi, non carinatum; epiphragma perbrevi; epiphragma 4to et 5to non altiora quam 5to."

Gen. III. Halicrepis. Mandibulæ palpo elongato; articulo 3tiio breviore quam 2do. Maxillæ 1mi pariis lamina interna ovata, in marginie internere setis paucis plausosis (3–5) instructa. Pedes maxillares laminae exteriore magnitudinis mediocris, non ad finem articuli palpi 2di porrecta et in marginie internere spinis tenuibus armata. Corpus non valde compressum; dorso rotundato, non carinato; segmentis trunci utilium et postabdominis anterioribus pluraque in medio marginie posteriorie in dentes retroversos desinentibus; epiphragma magnitudinis mediocris vel parvii. Antennae pedunculi brevissimae sed flagellis praelongatis, multiauarticulatis; superiores inferioribus multo breviore. Pedes 1mi et 2di pariis elongati, angusti; manibus parvis. Pedes saltatori 1mi et 2di qve pariis ramis exterioribus brevioribus qvam inferioribus; pedes saltatori ultimi pariis pedunculo longiori qvam appendice caudali. Appendix caudalis parva et integra."

Gen. VII. Laethocis. Mandibulæ articulo palpi 3tiio perlate, dimidium longitudinem articuli 2di ferme asquanti. Maxillæ 1mi pariis lamina interna parva, ovali, in marginie setis plausosis paucis instructa; palpo multisarticulato, parvo. Maxillæ 2di pariis laminae angusti. Pedes maxillares laminae interna longitudinis mediocris, in apice dentibus tribus armata; lamina interna per magna, in marginie internere dentibus multis, parvis sed firmis, apicem versus paulo majoribus, armata; palpo parvo, parum modo longiori qvam lamina externa; articulo palpi ultimo ungualiformi. Corpus elongatum, angustum, non carinatum; capite inflato; epiphragma parvissimae; epiphragma 4to et 5to. Antennae pedunculis brevissimae.
flagellis prelongatis, multiarticulatis; superiores inferioribus longiores. Pedes 1mi 2dique
paris graciles, longitudinal et forma fere aequales. Appendix caudalis integra.”

articulo palpi 3tio breviore quam 2do. Maxille 1mi paris lamina interiore sita lata, non
vero longo, in margine interiore setis compluribus plumosis instructa. Pedes maxillares
palpis angustis, elongatis; laminae exteriores brevi, lata, in margine interiore dentibus paucis,
parvis armata. Corpus elongatum, maxime postabdominis in
margine posteroire dentibus majoribus aut minoribus armata. Epimeraea parvula.
Antenne elongatae, graciles; superiores et inferiores longitudine fere aequales. Pedes
angusti, elongati; pedes 1mi et 2di pars manu subcheliformi, parva; pedes trium parium
ultimorum articulo 1mo parum modo dilatato. Pedes saltatorii ultimi paris ultra finem
corundem 1mi et 2di paris longe producti. Appendix caudalis elongata, plus minusve
fissa.”

3tio multo breviore quam articulo 2do angusto. Pedes maxillares articulo palpi 3tio vix
dilatato. Epimera minora quam apud genera precedentia [Ampelisca and Haploops].
Antenne inferiores articulo pedunculo 1mo et 2do extra visibilibus, in inquise capsitis sitis.
Pedes 7mi pari articulo 1mo deorsum et postice perdilatato; articulo 3tio brevi; articulo
4to et 5to elongato. Pedes saltatorii ultimi paris pervbreves. Appendix caudalis brevis,
lata, parum fissa.”

Subfam. XVII. Leptocherinsea. Gen. II. Goësia. “Corpus subdepressum; epimeris non altis;
epimero 2do minore quam apud genus Leptocheras. Antenne superiores flagello accessorio
fere obsoletae. Pedes 2di pari isdem 1mi pariis validiores, sed non multo longiores, in
margine anteriore setis longis plumosis instructi; manu magna, subcheliformi; corpo non
prolango. Ceteroqvin forme ut apud genus Leptocheras.”

elongato; flagello accessorio absenti. Pedes 1mi paris carpo elongato. Pedes 3tii et 4tii
paris articulo 1mo latissimo. Pedes saltatorii ultimi paris biramae; ramis invicem longi-
tudine fere aequivales. Appendix caudalis in apice insinuata.”

Subfam. XXI. Podocerine. Gen. II. Janasea. “Mandibulae palpo perlato, non vero longo;
articulo palpi 3tio obovato. Antenne robuste, setis densis instructae; superiores flagello
perbrevi, ex articulis paucis (3) constanti; articulo ejusdem 1mo perlongo; flagello
accessorio fere obsoletae. Antenne inferiores superioribus multo longiores et eressiores;
flagello ex articulis paucis constanti; articulo ejusdem 1mo permagno, prolongato.
Corpus subdepressum; epimeris parvis. Reliqua cum genere Podocerus ferme con-
veniunt.”

Fam. IV. Dullechidae. Gen. II. Paradullechia. “Antenne multo breviore quam apud genus
Dullechia. Pedes saltatorii ultimi paris liramosi; ramo minimo. Reliqua cum genere pre-
cedenti conveniunt.”

Gen. IV. Xenodice. “Pedes maxillares 2dii pariis lamina interiore magnitudinis mediocris, in
margine interiore setis pluribus (7) instructa. Antenne superiorum et inferiores longitudine
fere aequales; flagellis multiarticulatis sed multo breviobrius quam pedunculo. Antenne
superiores flagello accessorio instructae. Pedes 1mi 2dique paris magnitudine et forma fere
aequales; manu parva, subcheliformi. Pedes 3tii et 4tii paris ejusdem magnitudinis,
elongati. Pedes trium parium posteriorum longitudine gradualiter crescentes, filiformes.
Pedes saltatorii 1mi 2dique paris elongati, biramei.”

Fam. V. Caprellidae. Subfam. II. Cymamine. Gen. I. Platypylamus (Lütken), “distinguitur a
Cymaae propriis annulo primo corporis a capite sequente, pedibusque primum paris pedes secundi
paris fere aequantibus hissequae antepositis.”

It may be proper to observe that the generic characters above quoted are more or less dependent
on the characters of the families and subfamilies, which Böeck describes at great length. Occasionally there are discrepancies between the one set of characters and the other, which is excusable in so comprehensive a work. For instance, the character of Platycymus does not suit the words "segmento truncato uno cum capite coalito" included in the definition of the family Caprellides. Several of the subfamilies have been by some accident wrongly numbered in the original.

1870. Brady, George Stewardson.

Mr. Brady says, "The higher orders of Crustacea are almost always represented in salt-marsh pools by Carcinus marinus, Palaeon varians, Crangon vulgaris, Mysis vulgaris, Gammarus locusta, Corophium longicorne, and Spharomana vugicauda; in Hylton Dene I met also with Orchestia littorea, and at Seaton Sluice with Onices asellus." In the "debateable ground" between fresh and brackish water at Hylton Dene he found Corophium longicorne along with Palaeon varians and Mysis vulgaris.

1870. Dohrn, Anton.

"He regards the dorsal spine as a very essential character of Zoea, and thinks that the dorsal accumulations of cells in the embryos of some Isopods and Amphipods, the so-called micropyle-apparatus in the Amphipods, the dorsal sucker of the larva of Liunadia and the Cladocera, the frontal fixing apparatus of Caligus and Cladocera, and the peduncle of the Cirripods are to be regarded as transformations of the dorsal spine of Zoea" (Dr. von Martens in Zoological Record for 1870).

1870. Iarzynsky, Th.

In all, fifty-two species are named in this catalogue, but, as usual in such lists, some deduction must be made from the total, on the score of synonyms entered as separate species. Notice is given, without any description, of Montagia variegata, n. sp., "Lysianassa Giesi," n. sp., "Amphelisc Koresi," n. sp., "Oedicerus Brandii," n. sp., Urnios, n. gen., Urnios viridis, n. sp., with the remarks "similia Gammaro longicandus Brandt (mari Ochotico). Hab. mari glaciale ad litus murmanicum (ad insulas Gavrilienae)," and "Dulichia Malnogrenii," n. sp.

It is not easy to say what object is served by publishing names of undescribed species and genera, which neither convey any information of importance, nor can reasonably establish any claim to priority of discovery.
1870. Malm, August Wilhelm, born 1821, died March 4, 1882 (Hj. Théel).

This short paper describes a new genus, Boeckia, which is said to come close to Pontoporia, Krüyer; *Boeckia typica*, n. sp., in which the second gnathopod has a very long wrist and a very short hand, with the side-plate covering that of the first gnathopod and exceeding in size each of those that follow it. There is further a description of "*Paralichia Boecki*" n. sp., and figures of both species.

The new genus *Boeckia* is thus described:—"Epimera primi paris ab iis secundii paris occulta, hec omnium maxima. Carpus pedum secundii paris vable elongatus; manus brevissimis, vix prohealulibus. Pedes quinti, sexti, septimi paris longitudine sensim accrescentes; articulus primus paris septimi parum dilatatus. Pedes saltatorii brevissimi, aculeus validus armati. Appendix caudalis brevissimis, postique leviter emarginata, non vero fissa. Lamina interior maxillae primi paris elongata, perparum lata, extremitate setis nonnullis predita. Pedes maxillares elongati; lamina exterior angusta, margine interiore dentibus elongatis instructo; articuli palpí graciles." The genus is named in honour of Axel Boeck, who mentions *Paralichia Boecki* both in 1870 and in his later work, but in neither takes any notice of the genus *Boeckia*. Yet the description which Boeck himself gives of *Leptocheirus pilosus*, Zuddach, tallies so completely with Malm's figures of *Boeckia typica*, as to leave no doubt that they refer to the same species. Since, however, Malm's name is not included in Boeck's list of authors, and his name only, without the title of his work, is cited as authority for *Paralichia Boecki*, it is possible or even probable that the work itself for some reason never came into Boeck's hands.

1871. Cunningham, Robert Oliver, born March 27, 1841 (R. O. C.).

Under Amphipoda, page 497, he mentions the following species:—"61. *Orchestoides tuberculata*, Nic. Common on the sandy beach of San Carlos de Ancud, Chiloe." "62. *Allocorches salamun*, n. sp. (Pl. LIX. fig. 14). A single specimen of an Allocorches, apparently undescribed, was taken by me in a freshwater stream in the neighborhood of the Chilian settlement of Punta Arenas (Sandy Point) in the Strait of Magellan. Unfortunately it is considerably injured; so I abstain from describing it, and content myself with bestowing upon it the above provisional name." It may be presumed that this is some species of *Hyalella*. The figure appears to give nine pereon-segments with ten side-plates attached to them. "63. *Atyus Batei*, n. sp. (Pl. LIX. fig. 9). Cephalon not produced into a rostrum. Eyes oblique. A mesial dorsal carina. Last segment of pereion, and first four of pleon, produced into dentiform processes." "A single specimen from Possession Bay, Strait of
In the figure the last segment of the peraeon, the first two and the fourth of the pleon, are produced into dentiform processes. It is likely enough that it is identical with, or at most a variety of the species next mentioned. "64. Alpheus Hadleyanus, Rate. Taken in the Strait of Magellan. "65. Themisto antarcticus, Dana. Taken in numbers in the towing-net between the river Plate and the Strait of Magellan, during a calm which succeeded a violent gale, in November 1867." 66. Ichinodida Normani, n. sp. (Pl. LIX, fig. 7). Cophalou produced into a sharp-pointed rostrum. First three segments of pleon having a sharp-pointed tooth on each lateral margin. Eyes subimiform. Superior and inferior antennae of nearly equal length. Colour purplish. Length 4 lines. One specimen of this species, named in honour of the Rev. A. M. Norman, was dredged off Elizabeth Island in February 1867." The figure shows a peraeon of six segments with only five side-plates! Neither figure nor description is adequate for the determination of a species. "67. Caprella dilatata, Dana. Taken in numbers on the screw of H.M.S. 'Nassau' in August 1867." Dana's species is considered by Mayer to be the same as Caprella acutifrons, Latreille.

1871. BRANDT, ALEXANDER.

Dr. Brandt supposes a piece of whale-skin bent with Cyami which he found in the St. Peters- burg Museum to be the skin of the extinct Rhytina borealis bearing the parasite for which J. F. Brandt proposed the genus Sirenocyanus. He notices the great similarity between the specimens thus found and Cyamus ovalis, Roussel de Vauzine, and Liitken subsequently came to the conclusion that the supposed "Cyamus Rhytina" was actually Cyamus ovalis, attached to the skin, not of Rhytina borealis, but of Balanus japonica.

1871. BÜTCHLI, OTTO.

The spermatozoids of Gammarus pulex described on pp. 415, 533, pl. 40, fig. 7.

1871. CLAUS, C.

This paper describes the discovery of an organ of hearing in the Oxycephalidae, and many other details of great interest; alludes to Phronima elongata under the new name Phronimella...
elongata; brings Oxyechalus oceanicus, Guérin, as a male not fully developed, under Oxyechalus piscator, Edw.; assigns Rhabdosaoma whitei, Sp. Bate, as the male form, to Rhabdosaoma armatum, Edw.; describes Oxyechalus tenutostris, n. sp.; Simorhynchus, n. g.; Simorhynchus antennarius, n. sp.; Schuchagenia, n. g., afterwards recognised as =Thamyris, Sp. Bate; Schuchagenia rapax, n. sp.; and in conclusion remarks that the genus Synopia, Dana, belongs not to the Oxyechalidae, but to the Gammaridae.

For the descriptions of the genera, etc., see Notes on Claus, 1879.

This account, borrowed from "Indianapolis Journal, Sept. 5, 1871," refers to a Gammaroid Crustacean, not found in the Wyandotte Cave, but in the waters of the Mammoth Cave. Cope afterwards called it Stygobromus vitreus. See Note on Cope, 1872.

Remarks bearing on the Amphipoda are made in "Chapter VIII. Principles of Sexual Selection," and "Chapter IX. Secondary Sexual Characters in the Lower Classes of the Animal Kingdom." See pages 200, 233, 237, and especially 265–271, in which Fritz Müller's "Facts and Arguments for Darwin" are utilized, together with information received from Mr. Spence Bate.

On page 485, note 39, these observations are made, "Fritz Müller has shewn ('Facts and Arguments for Darwin,' Eng. Trans. 1869, p. 79) that the males of several Amphipod Crustaceans become sexually mature whilst young; and I infer that this is a case of premature breeding, because they have not as yet acquired their fully developed claspers. All such facts are highly interesting, as bearing on one means by which species may undergo great modifications of character."

On page 568 Darwin says, "an ear to be capable of discriminating noises—and the high importance of this power to all animals is admitted by every one—must be sensitive to musical notes. We have evidence of this capacity even low down in the animal scale; thus Crustaceans are provided with auditory hairs of different lengths, which have been seen to vibrate when the proper musical notes are struck. (Helmholtz, Théorie Phys. de la Musique, 1868, p. 187)."

1871. Dohrn, Anton.

An account of this paper is given in the Zoological Record for 1870, by Dr. von Martens.
1871. Grube, A. Ed.

According to Dr. von Martens, in the Zool. Record for 1871, he enumerates sixty-two species of Crustacea, observed in the neighbourhood mentioned, and describes "Urothoe martiana," Sp. Bate, p. 55, pl. ii. fig. 4.

1871. Metzger, Ad.

According to Dr. von Martens, in the Zool. Record for 1870, he gives a list of Crustacea observed hitherto on the coast of East Friesland (between the mouths of the rivers Ems and Jade), containing nineteen Amphipoda, including two Esemipodida. He describes "Orchestia, sp., from the strand of East Friesland, allied to A. [O.] mediterranea, and supposed to be perhaps a second male form of O. littorea, Lesch." "Bathyporeia, sp., dredged and found in the stomach of haddock," is shortly indicated; so also, "Pedocerus, sp., frequent between Sertulariae in the Estuaries." The number was not obtainable at the British Museum Library.

1871. Metzger, Ad.

The Amphipoda are referred to on pages 28–32. Atylus falcatus, n. s., is thus described:—

"Pedes 2di parvis longiores et param angustiores quam 1mai parvis, manu ferme cadem longitudine ac carpo.

"Pedes 3tii parvis articulo quarto brevissimi, multo breviore quam quinto; articulo utroque conjunctis longitudinem tertii vix sequantibus; articulo quinto subcurvato, in margine intorma basin versus spinis validis et obtusis armato; ungue pervalido, incurvato (falcato).

"Pedes 4tii parvis articulo quarto brevissimi, articulis quarto et quinto conjunctis multo brevioribus quam tertio; articulo quinto subrecto, ungue parvo.

"Pedes 5, 6 et 7mi parvis articulo quarto cadem ferme longitudine ac tertio, longitudinem quinti multo superanti.
"Appendix caudalis duplo longior quam ad basin lata; fere usque ad radicem fossa; incisura utraque in apice spinis singulis armatu.

"Longitudo animalis 10 mm."

It can be recognised at the first glance, Metzger says, by the great sickle-shaped finger of the first pereopod. The upper antennae are somewhat shorter than the lower. The hinder edges of the three first pleon-segments are slightly cramulate, their lower angles are almost rectangular, and only a little drawn out posteriorly. (The species described under the name *Atylus uncinatus* by G. O. Sars, in 1882, seems to be identical with Metzger's *Atylus fulcatus*. It must, I should think, belong to the genus *Tridacta*, Böeck, but, as unfortunately neither description takes note of the mandibles, the generic position is left a little uncertain.)

The male of *Bathyporeia pilosa*, Lindström (*Bathyporeia pelagica*, Bate) is not rare, he says, "im flachen Wasser am Strande der Inseln und selbst im Wattenmeer (Ostereems, Memmertseagelge)," but with the female he has never happened to meet. (On British coasts, *in the sand, uncovered by the tide*, I may notice that the female is far more frequent than the male.)

He confirms the supposition that "Megaiona Alderi," Bate, is the female of *Melita proxima*, Bate. *Nannia excava*, Bate, is found along with *Nannia eirupalma*, Bate, the latter the more rare.

*Siphonoecetes cuspudatus*, n. s., is thus described.—"Rostrum frontale gracile, aculeiforme, paulo longius quam anguli laterales capitis, oculos gerentes. Antennae inferiores longitudinale animalis parum modo breviore.

"Pedes 1sti parvis manu vix longiore quam carpo oblongo.

"Pedes 2di parvis manu multo longiore quam carpo triangulari.

"Pedes 3 et qti parvis articulo tertiio paulo longiore quam lato; angue longitudinom articuli quarti et quinti junctorum equanti.

"Ramus exterior pedum saltatorinis. 1sti parvis in margine exteriore spinis brevibus circiter 8 instructus, in margine interiore minus; ramus interior in margine exteriore spinis 3 armatus, in margine interiore minus at denticulatus.

"Pedes saltatorii ultimi parvis ramo parvo rotundato, eadem fere latitudine ac longitudine.

"Appendix caudalis spatiiis binis sebridatis instructa. Longitudo animalis 6 mm.

In further description he says, among other things, "das erste Fusspaar zeigt einen ovalen, am Ende astgestuften Carpus, dessen innere Vorderzähne mit einem langen Dorn versehen ist; die Hand ist kaum so lang wie der Carpus, und der schräge Palmnarr mit zwei grösseren Dornen bewaffnet, zwischen welchen der an der Innenseite sägezähnige Finger einschlägt. Das zweite Fusspaar ist etwas kräftiger als das erste, der dreieckige Carpus kürzer als die Hand und an dem nach innen gerichteten Winkel mit einem kurzer aber kräftigen Dorn endend." At the first glance Metzger took it for a species of *Corophium*.

1871. Sars, G. O.

"G. O. Sars states in several genera of *Crustacea* there are two sorts of males, one nearly resembling, the other very different from the females; the former is much more common and may be found all the year round, the other only in one season; the latter may be the fully developed and the former the incomplete stage of the male. This has been observed in *Diastylis*, *Pontogoria*, *Aspeculae*, and *Philomeles*, and exists therefore in very different orders." (Dr. von Martens in Zool. Record for 1872.)

Compare Note on Faxon, 1884, and Note on Chilton, 1883.
1871. Smith, Sidney Irving, born February 18, 1843 (S. I. S.).

Dredging in Lake Superior under the direction of the U. S. Lake Survey. pp. 373–374. Number XI.

Along with Mysis relicta, Lovén, Postoporella affinis, Lindström, "was found at every haul from the shallowest to the deepest." Cragonomyx groewelis, Smith, n.s., was also taken, and is here described, with the remark that "the incubatory lamellae of the female are very large, projecting much beyond the corse of the anterior legs, as in C. recurvatus, Grube, which our species much resembles in the form of the antennule, antenne, gnathopoda, etc., while it differs much in the ultimate pleopoda and in the form of the telson." Gammarus lacustris, Smith, n.s., length 15 to 20 mm., is also here described. It was afterwards named Gammarus limnax.

1871. Troschel, Franz Hermann, born October 10, 1810, died November 6, 1882 (P. Bertkan).

Handbuch der Zoologie. 7th Ed. 1871.

Mayer notices the inaccurate supposition, page 515, that the pleon is entirely wanting in the Caprellidae.

It is explained that the Crustacean fragment, on which this new genus and species were founded "was noticed and figured in Messrs. Huxley and Salt's important work on the Eurypteridae (Memoirs of the Geological Survey, Monograph I., 1859, p. 25, pl. XIII, Fig. 7). Professor Huxley observes, 'The fossil figured is evidently Crustacean, but it exhibits no character by which it can be identified as a part of a Pterygotus.' (See Fossil Sketches, No. 11, Fig. 2)."

"It presents us with the side-view or profile, of what appear to be three laterally-compressed and thin-crusted somites or body-rings. The foot "are articulated along the border" of the somites. From the dorsal line to the border these somites are said to measure between 1\(\frac{1}{2}\) and 2\(\frac{1}{2}\) inches, while from front to back they measure 10 or 11 lines."

"The third segment (c) is 10 lines broad and measures 2 inches from the dorsal line to the sharply-pointed epimeral border; from the posterior side of this the limb (c 3) is given off of which six joints are visible, the first or basal joint not being seen. Joint (2) is broadly rounded, joint (3) is narrower and more elongated; joint (4) is hollowed out to receive joint (5) which is larger but similar in form to (4) and also to joint (6) which is, however, the smallest of the three \(\frac{1}{3}\) joints 4, 5, and 6 have each their distal borders sharply pointed. The 7th and terminal joint is a simple claw, not chelate. The total length of this entire appendage is 2 inches."

(Zool. Chall. Exp.—Part LXVII.—1887.) XXX 52
THE VOYAGE OF H.M.S. CHALLENGER.

It is referred "to the order Amphipoda—Normalia and to the division Gammaridea among some of the naturalia forms of which occur limbs not unlike the fossil before us." It is therefore named "Neogammarus Saltysi, after its discoverer." What forms among the Gammaridea are here intended it is not easy to guess. The appendage as figured is more suggestive of an antenna or limb of an Isopod than of any form with which I am acquainted among the limbs of the Gammaridea or any other division of the Amphipoda Gammarina. The combination of a transverse first "(2)" joint with a second "(3)," of great relative size, articulated to the middle of it, is, I should say, quite unknown in the group, and almost impossible as an ancestral character.

1872. Boeck, Axel.

The species described are Caprella californica, Stimpson = 11 Caprella linearis, see Mayer, Caprelliden, p. 79; Caprella verrucosa, A. Boeck = 1 Caprella acanthifera, Leach, juv., see Mayer, Capr., p. 82; Eriochthonius rapax, Stimpson, which Boeck transfers (erroneously) to the genus Cerapus; Podocerus californicus, A. Boeck; "Amphilohi Stimpsoni," A. Boeck; "Paramphihoi Bairdi," A. Boeck, and "Metopa Esmarki," A. Boeck. An explicatio tabule concludes the paper, but unfortunately the plate to which the explanation refers never appeared. The report of the Society's meetings during 1871 states, under March 10th, p. 532, that "A. Boeck indlevende Tegninger af 6 nye Arter Amphipoder, som Esmark havde sendt ham fra Californien, og fremsatte nogle Besættelser om Amphipodernes Udbrudelse og Udseende i de forskellige Egne af Jovlen." If the drawings are still in existence, it is very desirable that they should be published.

1872. Boeck, Axel.

This, and the succeeding volume published in 1876, constitute a work of vast labour and research, of foremost importance to the student of the Amphipoda. The introductory part contains, first, a general account of the bodily structure in this group, dealing chiefly with the mouth-organs, on which Axel Boeck laid special systematic weight; secondly, an alphabetical list of nearly three hundred authors with the titles of their works relating to the Amphipoda, down to the year 1870; and thirdly, a chronological review of the development of this branch of natural history from Aristotle down to the year 1855. It winds up with an article on the geographical distribution of the Amphipoda, and an account of various systems, including the author's own, which have been proposed for the classification of this group.

It is to be regretted that this ingenious author should have in some cases thought it necessary to ground generic distinctions on very minute differences; and it sometimes detracts from the pleasure and facility of consulting his accurate plates, that many of the figures are exceedingly small, and that not unfrequently the parts of animals in different genera are represented in embarrassing confusion on the same plate. Most of all it is to be regretted that by his early death this author was prevented, not only from putting the last touches and corrections to his almost completed work, but from further pursuing a study in which there is so much still to be done, and in which he was so eminent a master.
To the following Table, drawn from Boeck's work, I have only added, for facility of reference, the numbers of the pages on which the several groups are described:—

There are no new species described in this volume, but the descriptions of those already known and the attendant observations are of the highest value.

Of the family Prostomatidæ he gives the following definition:—"Instrumenta cibaria valde prominentia et conjuncta processum 3 fissum, tubiformem formantia. Labium superius praerogatum, angustum. Mandibulæ styliformes, acutes, palpis longis triarticulatis instructæ. Maxillæ angustæ, elongatis, in apice acuminae. Pedes maxillares angustos, exterioribus brevibus et latoribus; articulo palpi 4to longo, non ungervormi. Corpus compressum, latum; epimeris lati. Antenna superiores breves, flagellis accessorii instructæ. Pedes 1mi paris manu parvulid subcheliformi. Pedes 2di paris elongati, angusti; manu subcheliformi, parva. Pedes saltatorii biramei; rami lati. Appendic caudalis parvula."
The genus Trischizostoma is thus defined:—"Caput antice in rostrum frontale crassum, latum, in apice rotundatum, productum. Antennen inferiores articulit 4th longitudinem 5th superiori. Pedes 1sti pars manus permagna, inflata, ovata; usque non in angulo inferiore anteriori, ut solito, sed in angulo inferiore posteriore inarticulato, antice versi. Pedes 4thi pars articulit 3thi valde dilatato et latiore quam pelum 3thi parum. Epimerum 1stum parvum. Epimerum 2ndum deorsum valde dilatatum, 1stum partim tegens. Oculi permagni. Appendix caudalis lata." In regard to this genus see Note on Costa, 1853.

1872. Brandt, Alexander.

A new species, "Cyamus Kenterli," is figured and described, with the following diagnosis, "Corpus maris pyriforme, feminae obverso-pyriforme vel rhomboidale. Maris primi parvis manibus dexter armate, feminae fere edentulae. In utroque sexus manibus sequendi parvis dentibus dentibus minutis, quorum basalis multo major. Branchia simplicia, elongata, longitudine corpus fere aequans. In mare appendicu branchialium sex parvae equales. Habitat in sinu Metschigmensi Marii Beringii, in Balaenii." Liitken considers that the accessory branchiae on the third and fourth segments are double, not triple, and that Brandt has confused with these appendages the postero-lateral angles of the segment which form a process bent downwards and forwards.

Cyamus ovalis, Roussel de Vanzéme, is recognised as including "Cyamus Rhytinx (f)" which in 1871 Brandt supposed that he had re-discovered, though with notice of its great resemblance to Cyamus ovalis.

The name Cyamus ceti, anotornum, is upheld for Oniscus ceti, Lin., against the proposal of Liitken to institute the designation Cyamus mystici. For Cyamus ceti, Sp. Bate (Catal. Amph. Crust. p. 366, pl. lviii. fig. 2), a very narrow elongate form from Tahalma, which has nothing in common with Oniscus ceti, Lin., he gives a name proposed by Liitken, Cyamus pacificus. Without absolutely deciding, Brandt seems inclined to regard Cyamus monodontis, Liitken, as a variety of Cyamus ceti (to which Liitken himself regards it as "valde affinis"), and to agree with Bate and Westwood (Brit. Seas. Crust. vol. ii. p. 86) in making Cyamus erraticus, Roussel de Vanzéme, a synonym of the same Cyamus ceti, which Liitken regards as a very decided error. Brandt notes that Cyamus bgooris, Liitken, is recognised by its author as in close relationship to Cyamus erraticus, and this latter he is willing to regard as a link between Cyamus ceti and Cyamus bgooris, leaving it perhaps an open question whether they may not all be one species. Cyamus globisipités, Liitken, he thinks probably identical with "Cyamus Delphinit," Guérin (Icon. du Règne Anim. T. III. p. 25, pl. xxvii. fig. 5). Remarks are made on Cyamus nodorum, Liitken, and Cyamus gralliis, Rouss. de Vanzéme. Cyamus thompsoni, Gosse, which Liitken transferred to a new genus, under the name of Platyzam/is thompsoni, Brandt would have been content to leave united to the other Cyamus.
1872. Claus, C.

Claus here states his conviction that the cell inhabited by Phronima is derived exclusively from smaller or larger specimens of Pyrosoma eaten out for the purpose. He describes the differences presented by the male form of Phronima sedentaria. Guérin's Phronima atlantica he regards as nothing but "das noch jugendliche, kleine, aber doch schon fort- pflanzungsfähige Weibchen" of the same species, and thinks that Spence Bate did wrong in giving a separate specific name, "Phronima Bornensis," to White's variety of Phronima atlantica from Borneo. Compare Note on Streets, 1877.

Referring to his own earlier observation of rudiments of a second pair of antennae on the head of the young Phronimella elongata, he says that he wrongly concluded that the Phronimidæ in general might have both pairs of antennae in rudiment to start with, the females eventually developing only the front pair. He found, however, that in the little, sexually indifferent, young ones of Phronima sedentaria there was no trace of the hinder pair; in individuals 4 mm. long sexual difference was shown in the front antennæ, and in larger forms the position of the coming second pair of antennæ was indicated. The sexual organs of the male are described and figured.

1872. Cope, E. D.

The new genus which Cope established for the Gammarid, which he found in the Mammoth Cave, is thus described:——

"Stygbromus, Cope, Gen. nov. Gammaridarum. Near Gammarus. The first antennæ with flagellum, and much shorter than the second. Two pairs of limbs cheleate by the inflexion of the last claw-like segment; other limbs clawed. Terminal abdominal segment very short, spiniferous; the penultimate segment with a stout limb with two equal styles, the antepenultimate short, two-jointed and undivided. Eyes none.

"This genus is nearer to the true Gammarus than the allied genus described from the Austrian Caves, the *Niphargus* of Schödte (Proc. Entom. Soc. London, 1851, p. 150). In the latter the first antennæ are larger, and the body terminates in a very long style; the last abdominal limb is undivided like that which precedes it. In *Stygbromus* the penultimate limb is like that represented by Schödte for *Niphargus*, though I am not certain whether it is homologically identical. The last limb is about equally divided, but the simple basis is long and stout.

"It is just possible that the antepenultimate limb represents the basis and one style only, for in that of one side a slight process appears at the extremity of the basal segment, though it is not visible on that of the other. The terminal limbs are recurved and appressed to the last abdominal segment, forming a fulcrum or prop. The animals of this genus are aquatic, and swim much as the common *Gammarus*. The absence of eyes is another example of the adaptation to darkness."

The type species he describes thus:—"Stygbromus vitreus, Cope. 'Gammaroid Crustacean.'" Cope, Annu. Mag. Nat. Hist., Nov., 1871. Two last pairs of limbs appressed to last
abdominal bristles and of nearly equal length, forming a brush. Last segment of abdomen with two terminal bristles. Last segment of the limbs from the third to the seventh, with a long, straight claw directed forwards. Fringed limbs behind this point very small. Outer or second antennae half as long as the first, which embrace eleven segments, and are about as long as the last five abdominal segments. Total length of head and body 2:1 lines or '0045 m. There are few conspicuous hairs, the most so are those which stand at the extremity of the last joint of the limbs, rising from the base of the claw. Color transparent."

S. I. Smith, 1875, considers Cope's description very inadequate, but identifies the genus *Stygobromus* with the earlier *Crangonyx*.

He describes the three species as follows:—

"*Crangonyx Scammonii*, n. sp.—Male. Body moderately depressed, of an egg-ovate form; segments slightly separated; third and fourth segments furnished with a branchia at each side; this, near its base, divides into two cylindrical filaments spirally coiled from right to left; at the base of each branchia are two slender accessory filaments not coiled, quite short, and situated one before and the other behind the base of the main branchia; second pair of hands kidney-shaped, with the carpal articulation halfway between the distal and proximal ends, and having two pointed tubercles on the inferior edge, before the carpal joint; third and fourth segments somewhat punctate above, all the others smooth, the sixth and seventh slightly serrate on the upper anterior edge, and without ventral spines. Colour yellowish-white. Long. '70, lat. '39 in., of largest specimen.

"Female similar to the male in all respects, except in being a little more slender, and in wanting the accessory appendages to the branchia; the ovigerous sacs are four in number, overlapping each other.

"Hab. On the California grey whale (*Rhachianectes glaucescens* of Cope) on the coast of California, very numerous."

"*Crangonyx suffusus*, n. sp.—Body flattened, elongate; segments subequal, outer edges widely separated; branchia single, cylindrical, slender, with a very short papilliform appendage before and behind each branchia; superior antennae unusually long and stout; first pair of hands quadrant-shaped; second pair slightly punctate, arcuate, emarginate on the inferior edge, with a pointed tubercle on each side of the emargination; third joint of the posterior legs keeled above, with a prong below; pleon extremely minute; segments all smooth; no ventral lines on the posterior segments. Colour yellowish-white, suffused with rose-purple, strongest on the antennae and branchiae. Length '41, breadth (of body) '25 in. All the specimens which have passed under my observation, some eight or ten in number, were males.

"Hab. On the 'humpback' whale (*Megaptera versabilis*, Cope), Monterey, California."

"*Crangonyx mysticeti*, n. sp.—Body flattened, subovate, segments adjacent; branchia single, short, stout, pedunculated, a single papilliform appendage behind each; head short and wide; first pair of legs very small; hands all simple and smooth, fingers greatly recurved; carpal articulation in the second pair of hands halfway between the proximal..."
REPORT ON THE AMPHIPODA. 415

and distal ends of the hand; pleon very minute. Colour dark brownish-yellow. Length 33 in., breadth (of body) 16 in. Two female specimens.

"Hab. On the northern bowhead" whale (probably Balaena mysticetus, Linnaeus, near Behring Strait.

"This is the most compact of the three species, as well as the smallest. I find, in comparing large series of C. Scammoni, that a considerable variation in form obtains, so far as regards comparative length and breadth, even in adult specimens, and these differences are greater than those observed, in the same characters, between the sexes." Lütken is of opinion that the Cyamus mysticeti here mentioned is the same as his own Cyamus mysticeti, 1870. A. Brandt, 1872, as already noticed, does not admit the propriety of giving up the old name, Cyamus ceti, for this species. Indeed, no names would be safe, if subsequent confusion of heterogeneous animals, under a name rightly established to begin with, were allowed to make such a name void. For "no ventral lines," in the description of Cyamus suffusus, Lütken thinks "no ventral spines" should be read. The species may, he supposes, be the same as his own Cyamus pacificus, which also lives on Megaptera versabilis, C.

1872. DALL, W. H.

He here adds, in regard to Cyamus suffusus, "the females, which were unknown at the date of my description, now prove to resemble the male in every respect, except in regard to the sexual organs, and in being a trifle more slender in form." All the specimens came from the humpback (Megaptera versabilis, Cope). Dall favours "the hypothesis that each species of whale has its own peculiar parasites, and that there is rarely more than one species of Cyamus found upon one animal."

1872. FRIC (FRITSCH), ANTON.

Among the Crustacea which have been observed in Bohemia, and are here described, Dr. von Martens, Zool. Record for 1872, says that two Gammaridae are included.

1872. HOY, P. R.

He records from the stomachs of white-fish, and from dredgings at depths of 50 to 70 fathoms, three species of Amphipods determined by Dr. William Stimpson. Nothing, however, but
the names is given. They are styled "Gammarus Hoyi—Stimpson; Gammarus bruvistilus—Stimpson; Gammarus filicornis—Stimpson." Gammarus is of course an accidental error for Gammarus. S. I. Smith, 1874, calls the first two of these species "Pontoporeia Hoyi," the third "Pontoporeia filicornis." See p. 433.

1872. Murie, James.

Dr. Murie does not agree with some of Dr. Brandt's deductions in regard to the skin of the Rhytina. He quotes or refers to his remarks upon "Cyamus Rhytina," and reproduces Brandt's figures of it. But the paper was written before Lütken had criticised Brandt's supposed discovery.

Under Crustacea he enumerates two species of Gammarus, one of Crangonyx ? and Pontoporeia affinis, Lindström. The specimens to which he applies the last name are, he says, "small Amphipods varying in length from \( \frac{1}{10} \) up to \( \frac{1}{2} \) inch, of nearly uniform flesh-colour. They are referable to the genus Pontoporeia; and though they have not yet been satisfactorily examined, I have little doubt as to their being identical with the Pontoporeia affinis of the Swedish lakes and of Lake Superior. They occur in great plenty in from 30 to 45 fathoms."

Annual Report of the Trustees of the Peabody Academy of Arts and Sciences. V. p. 95.

In regard to his Crangonyx vitreus, see Note on S. I. Smith, 1875.

1872. Uljanin, B.

Thirty-eight species of Amphipoda are enumerated as inhabitants of the Black Sea. (Dr. von Martens, Zool. Record for 1872.)
1872. Whiteaves, J. F.

Under Crustacea he says, "Several curious Amphipods were taken, among the more conspicuous of which were fine specimens of an Epimeria, which Mr. Smith refers doubtfully to E. coulter of Boeck." Epimeria cornigera is obviously intended.

1873. Hartmann, R.

Sitzungsberichte der Gesellschaft naturforschender Freunde zu Berlin, 1873. p. 94.

"The strange shovel-shaped appendages in the male of Gammarus pulex are mentioned." (Dr von Martens, Zool. Record for 1873.)

1873. Hesse, E.

The new genus Ichthyomyzocus is thus defined:—

"Corpus ovalaire, légèrement déprimé, bombé en dessus, plat et même un peu creux en dessous.

"Tête petite, aplatie, triangulaire; front lamellueux s'avancant horizontalement en pointe arrondie et recouvrant la base des antennes; celles-ci grosses, courtes, à peu près d'égale longueur et composées de cinq à sept articles.

"Yeux grands, réuniformes, très-carrés, placés obliquement, en dessus de la tête et formés de cornicules bien distinctes.

"Abdomen moins large que le thorax, formé seulement de cinq ou de deux anneaux, également sans bordure épimérique, les derniers portant de chaque côté des tiges arrondies terminées par de petites lames ovales et pointues.

"Bouche profondément, formée d'un lobe supérieur, de pattes-mâchoires latérales armées de griffes, et d'autres plates, sous lesquelles on aperçoit de petites mandibules qui environnent l'orifice buccal.

"Pattes thoraciques au nombre de sept paires, dont les trois premières sont ancreuses et dirigées du côté de la bouche; les quatre autres paires plus grèles et plus longues, terminées par un ongle légèrement recourbé, quelquefois l'article femoral étant large et plat. Les jambes pates branchiales composées d'une double tige cylindrique, fusiforme, divisées en nombreux anneaux garnis de longs poils rigides et pennés. L'abdomen, dans l'état de repos, se repliant sous le thorax, et celui-ci garni, chez la femelle, de larges plaques membranueuses qui, en s'immergant les uns dans les autres, forment une poche incubatoire.

"Ces Crustacés vivent en parasites sur les Poissons."
The species are described and figured under the following headings:—

A.—Abdomen formé de cinq articles et terminé par trois tiges." Ichthyomyzoque orné.—Ichthyomyzozus ornatus n. sp., figs. 1, 2, on *Morrha vulgaris.* "C'est probablement un mâle."

B.—Abdomen formé de cinq articles et terminé par trois paires de tiges." Ichthyomyzoque du Gade mornus.—Ichthyomyzozus Morrhus, n. sp., figs. 3–7, on *Morrha vulgaris.* "C'est un individu femelle." Ichthyomyzoque de la Bauadroïste commune—Ichthyomyzozus Lophii, n. sp., figs. 8–18, on Lophius piscatorius. "Notre dessin représente une femelle adulte, mais sans œufs."

C.—Abdomen formé de deux articles et terminé par deux paires de tiges." Ichthyomyzoque de la Squatine ange.—Ichthyomyzozus Squatina, n. sp., figs. 19–27, on Squatina anguillar. In *Ichthyomyzozus lophii,* a singular appendage is described on the thoracic feet of the first three pairs, "placé à deux extrémités et à la base des griffes qui les terminent. Cet appendage ressemble, pour la formé, à un pêlit dont aurait conservé seulement l'œil une et le style. Nous ignorons si les autres espèces ont aussi des appendices de ce genre, ou s'ils sont propres à celle-ci seulement." He compares it to the *gaflah* which sailors use.

By the front of the body, M. Hesse considers that these animals come very near to the Isopods, but by the lower extremity of the body they resemble the Amphipods. The upper part of the head is broader than the lower, at the extremity of which the buccal opening is placed. "Du haut du front et de la base du prolongement frontal part une ligne verticale en relief, nasiforme, qui descend perpendiculièrement en diminuant de longueur jusqu'à l'orifice de la bouche, dont elle forme le labre supérieur. De chaque côté et au dessus de cet orifice, on aperçoit une paire de pattes-mâchoires composées de deux articles, dont le second est terminé par une longue griffe crochue et acuminée, dont la pointe est dirigée vers le bas. Au-dessous de celle-ci sont également placées deux paires de pattes-mâchoires plates et ovales, dont la première, qui est la plus grande, est large, plate et accompagnée de son fouet ; l'autre, plus petite, se trouve des deux côtés de la bouche. Enfin, entre celui-ci on aperçoit les mandibules, qui sont petites et cachées, en ne laissant voir que les denticules dont elles sont bordées. La région thoracique est, comme cela a lieu pour les femelles de *Cymothoaulaeus* raviens, entièrement recouverte de larges lames ovalaires membranes et très-minces, qui partent de l'insertion de chaque patte et se portent horizontalement en dedans, de manière, en s'imbriquant les unes dans les autres, à former une poche incisuraire. Les fausses pattes abdominales ou les organes de la respiration ne se composent pas, comme dans les *Cymothoaulaeus,* de grandes lames plates, ovalaires, membranes, recouvrant en se superposant ; elles se rapprochent, par leur conformation, de celles des *Amphipodes.* Elles ont un pédoncule aplati, presque aussi large que long, sur lequel sont fixées, de chaque côté, deux tiges assez longues, presque cylindriques, multiaiteuées, larges au milieu et étroites à leur extrémité, chaque aumoë étant bordé d'une série de poils longs et rigides, et pennées. Les pattes thoraciques sont au nombre de sept paires. Les trois premières, et la première surtout, sont ancrées." "Les quatre autres paires de pattes sont ambulatoires." "Elles sont formées de cinq ou six articles, dont le premier et le dernier sont les plus longs. On remarque aussi, dans les pattes ambulatoires, l'article fémoral est très-large et très-plat, et que, sous ce rapport, ils ressembleraient aux *Amphipodes.*" In the abdomen, which is much narrower than the thorax, the last segment "se termine par un prolongement gros et arrondi, vers le bas duquel on aperçoit facilement l'orifice anal qui est relativement très-grand. Les trois derniers anneaux donnent attache, de chaque côté, à deux ou trois paires de tiges arrondies, dont les extrémités se dépassent bien que cependant elles soient, à raison de leur point de départ, d'une longueur inégale. Elles sont terminées chacune par deux petites lames ovales et pointues à leurs deux extrémités ; et sous ce rapport, ils ressemblent aux *Amphipodes* de la division des *Crevettes marines,* tel que les *Corophies* ou les *Hybridines,* ainsi que les *Videlles* et les *Pholadines."
The expressions "les fausses pattes branchiales" and "les fausses pattes abdominales on les organes de la respiration" would appear to be incorrect; if accurate, they would be inconsistent with the arrangement of this genus in the order Amphipoda. That one species of the genus should have a pleon of only two segments, while its congeners have the five segments which are the normal number for the pleon among the Hyperins, is a very strange peculiarity. But as to this and other points, see additional Note on Hesse, in Appendix.

1873. Lütken, Chr. Fr.

After repeating the observations on Cyamus which he had made in 1860, Lütken gives an exceedingly valuable report upon the historical development of our acquaintance with the group of Crustacea, which are called whale-lies. From Frederik Martens in 1675 to the date of his own work, Lütken's vigorous research can scarcely have let any statement of importance on the subject escape him, or any serious error pass the ordeal of his criticism without correction.

The definition he gives of Cyamus, Latr., is as follows:—
"Corpus erossus, lamel laminare. Pedes primi parisi minuti, sub pedibus secundi parisi fere vel minus ad absconditi; annulus corporis primi a capite indistincte sejunctus vel cum hoc plane confluens. Pedes maxillares quinqu-articulati. (Marcus femininis velus majores.)"

The species described are, 1. Cyamus mysticeti, Lk., from Balena mysticetus, the common, or Greenland Whale; 2. Cyamus monodonitis, Lk., from Monodon monoceros, the Narwhal; 3. "Cyamus Kessleri," Brandt, "coming from the northern part of the great eastern ocean, probably from a true whale of the group of Balena australis and Balena bicornis"; 4. Cyamus erraticus, Roussel de Vauzême, from Balena australis, the Cape Whale; 5. Cyamus boops, Lk., the Oniscus ceti of O. Fabricius, 1780, from the Northern Hump-back, the Krepokak of the Esquimaux, Myraptera boops, and possibly parasitic on other species of Megaptera; 6. Cyamus pacificus, Lk., from a whale (of unknown genus and species) in the Pacific in the neighbourhood of Panama, a species nearest in form to Cyamus boops, but also near to Cyamus erraticus; 7. Cyamus orellis, Rouss. de Vanz., from protubercans on the head of Balena australis and from the North Pacific "Slætbag" (Balena japonica?); 8. "Cyamus Rhytius," J. F. Brandt, Steller's species, for which Brandt proposed a new genus Sirenocyamus, and which Lütken agrees with Brandt in thinking possibly akin rather to Proto than to Cyamus; 9. Cyamus nobonns, Lk., the Otiscus ceti of the Zoologia Danica, III. p. 69, pl. 119, f. 13-17, 1789, from the Narwhal, Monodon monoceros; the name "Cyamus Bolge" sometimes given to this species being rejected by Lütken as grounded on the mistaken supposition that the creature is also a parasite in Delphinapterus leonina; 10. Cyamus globipennis, Lk., a species already noticed as possibly new, but not named, by Steenstrup in 1843 [11850], parasitic on the Cacing, or Pilot Whale, Globicephalus melas; 11. Cyamus gracilis, Rouss. de Vanz., from the protuberances of the head of Balena australis and Balena japonica; 12. Platycyamus thompsoni, Gosse, parasitic on the Bottlehead, or Beaked Whales, Hyperoodon rostratus and Hyperoodon laticeps.

The new genus, Platycyamus, instituted to receive Gosse's Cyamus thompsoni, is defined as follows:—
"Corpus valde depressum, laminare fere; pedes primi parisi pedes secundi parisi magnitudine
THE VOYAGE OF H.M.S. CHALLENGER.

fere sequentes hisceque antepositi, annoto primo corporis a capite bene sejuncto; pedes maxillares howl articulati. (Mares feminis minores)

The opinion that Cyamus pacificus may perhaps better be classed as a variety of Cyamus boops, "seems confirmed," Lütken says, "by the fact that young Cyami, taken upon unknown Cetacea, in the Pacific, near the Isles of Tonga and Rarotonga, come extremely near to the species parasitic on the Megaptera of the northern seas, and are probably identical with it."

In addition to the ten well-defined species of the above list, Lütken calls attention to various others less well-known. These are:

1. The species which, according to Bennett, are parasitic on the Cachalot and several Delphinus and Globiocéphali (plusieurs Dauphins et Globiocéphales) of the southern seas. The parasite of the Cachalot, he notes, may possibly be Cyamus pacificus, though Roussel de Vauzème did not find any Cyamus upon the Cachalot.

2. "Cyamus Delphinus," Guérin (from some species of Delphinus in the West Indies), "very near to Cyamus globicéphali, if not identical with it."

3. A Cyamus, also from some unknown Delphinus, regarded by Lütken as certainly a distinct species, though as the specimen is not full grown, and its habitat uncertain, he leaves it unnamed.

4. A whale-louse, which according to a plate published by Dr. Monedero, is, or used to be, parasitic on the Sarde or Basque whale (Nordkaperen eller Sardens Hvallus), instead of which on the plate in question a Pycnogonum is figured.

The species are pretty equally divided between the Mysticete, or Whalebone whales, and the Denticete, or Toothed whales, but hitherto not a single species has been found on a genuine Fin-whale (Balaenoptera). One species of Cetacean may entertain more than one species of these parasites, and the same species of Cyamus, just as the same species of Cirripede, may occur on very nearly related species of Cetacea, especially on species of the same subgenus.

A postscript mentions Dall's new species "Cyamus Scammoni," which lives on the Californian Grey whale, Rhachianectes glaucus, Cope, and which Lütken thinks will stand between Cyamus oralis and "Cyamus Kessleri." Another species, Cyamus suillus, Dall, from the Humpback, Megaptera vicarialis, he considers to come near, perhaps to be identical with, Cyamus pacificus.

1873. Martens, Eduard von.

A synopsis is given of Boeck's Amphipoda, 1870. The name Tryphosa is noted as preoccupied in Leptoptera, but I am informed by Mr. Edward Saunders, the entomologist, that the name as used by Stephens for a genus of Leptoptera has a different spelling, Tryphosa, not Tryphosa, and that without variation so far as he could trace it.

1873. Möbius, Karl, and Metzger, A.

Jahresbericht der Commission zur wissenschaftlichen Untersuchung der deutschen Meere in Kiel für das Jahr 1871. 1. Jahrgang. Berlin, 1873. (With second Title page); Die Expedition zur physikalisch-chemischen und biologischen Unter-
suchung der Ostsee im Sommer 1871 auf S. M. Avisodampfer Pommerania nebst physikalischen Beobachtungen an den Stationen der preussischen Ostseeküste.

Berlin, 1873.

On behalf both of those who have to make catalogues of books, and of those who have to consult them, it is much to be wished that short titles should be used to name rather than to describe a work, and that above all things double title pages should be avoided.

The Amphipoda are catalogued on pages 117-119, with particulars as to the place of capture, depth, nature of ground, and distribution. Fifteen species are named, beginning with "Caprella linearis L.," and "Leptomera pedata Abildg." and ending with "Talitrus lacustris L." To Pontoporia femorata, Kroyer, Pontoporia affinis is made a synonym, with the remark, "Herr Lindström schickte mir Exemplare, die er bei Gothland gefangen hatte, mit dem Namen P. femorata zu; er hat also seinen Speciesnamen affinis selbst zurückgenommen." To "Orchestia littorea Mont.," the remark is appended, "Der Vorsprung am unteren Rande des 5. Glides des 2. Fusspaares ist bei Exemplaren von Stabbenkammer und Kiel kleiner als bei Exemplaren von Greifswald; bei Exemplaren von Sylt fehlt er ganz. Im Uebrigen stimmen alle überein." To this species "Orchestia Euchaeta," Fr. Müller, is assigned as a synonym. Müller's "Orchestia Grapheus" is made synonymous with "Orchestia Deshayesi Savig." In the general observations, Gammarus boreae and Pontoporia femorata are mentioned among those species which occur in the greatest numbers. Gammarus boreae was occasionally found along with the Temora longicornis which made up the chief part of the contents of the stomachs of herrings. In various other fishes, less suited for consuming the Temora, Gammarus boreae was found as one of the constituents of the food.

In the preface, Möbius remarks that "Die Fauna der Ostsee ist ein verkümmerner Zweig der reichen Fauna des nordatlantischen Ozeans und des nördlichen Eissmeeres." One of the conclusions drawn is that "Die Ostsee enthält überhaupt nur eine Auswahl solcher atlantischen und Eisenerthien, welche grosse Temperaturdifferenzen zu ertragen im Stande sind." Such animals are distinguished as eurythermal, in opposition to stenothermal animals, which can live only in warm or only in cold water. All Baltic marine animals can live in water of varying salinity, and are therefore said to be euryhaline. In Section "C. Die auf der Fahrt nach Arndal gefangenen Thiere," on page 153, he mentions, "Caprella linearis l. ; "Protella phasma Mont."; "Amplexis Gaimardii Krüy.;" "Gammarus longimanus Leach."

In this Appendix the Amphipoda are described on pages 173-174. They are fourteen in number. Among them is mentioned "Krigerea arenaria Sp. Bat.". This is no doubt Spencer Bate's Krigerea arenaria, which Boeck calls Krigerea arenaria, and identifies with his Pontocrates norvegicus. "Atylus (Dexamin) Vedlomensis Bat. and Westwood" was dredged "zwischen Helgoland und Spiekeroog." Atylus falcatus and Siphonocetes eucnemis are described as new species, but the descriptions had already appeared in 1871. See Note on Metzger under that date. It is here noted that "Lestrigonus Kinshani Bate," given as a separate species in the earlier list, must be referred as the male to "Hyperia Medusarum Müll. (= Hyp. Galba Montagu)." At page 176 a preliminary list is given of seven species of Amphipoda obtained by the "Pommerania" in the summer of 1872.

1873. Parfitt, Edward.

The opening remarks include observations on the heat and circulation in Niphargus aquilus, Schödte, in which, he says, "the pulsations of the heart are at the rate of 100 in fifty seconds." In the catalogue there are some remarks on the habits of Corophium longicorne, Latr. Eighty-two species of Amphipoda are named; some of the names, however, can only rank as synonyms.

1873. Thomson, Charles Wyville, born March 5, 1830, died March 10, 1882 (John Murray).

The Depths of the Sea. An account of the general results of the Dredging cruises of H.M.S. "Porcupine" and "Lightning" during the summers of 1868, 1869, and 1870, under the scientific direction of Dr. Carpenter, F.R.S., J. Gwyn Jeffreys, F.R.S., and Dr. Wyville Thomson, F.R.S. 1873.

On page 125, Eunirius euspidatus, Kreyer, is figured, and the remark made that it "had previously been known only in the Greenland seas," whereas this specimen was dredged on the third cruise of the "Porcupine" in 1869, among the fauna of the "Cold Area" in the channel between Faröe and Shetland. Fig. 19 is said to be "a large and hitherto unknown species of the genus Caprella." It is named Caprella spinossima, Norman. But Mayer, Caprelliden, p. 35, quotes a letter from Norman saying that this was a mistake on Thomson's part. "It should have been Caprella spinossima, Stimpson. It is = Efgna echinata of Boeck." Judging from a Spitzbergen specimen, which Norman sent as a female of the same species, Mayer inclined to regard the species as new, under the name Efgina spinossima, Norman. This name, however, is preoccupied. The original specimen, which I have had an opportunity of seeing, confirms the view taken by G. O. Sars, 1885, that it is the same species as his Caprella horrida, and since the name Caprella spinossima is preoccupied, Caprella horrida will be the name of the species. The remarkable resemblances between this species and Efgina spinifera, Bell, will easily account for any confusion that has arisen between them, in spite of their belonging to different genera.

1873. Wiedersheim, R.

He records, according to Fries, the finding of an eyeless Gammarus on a stone of the brook at the entrance of the Falkenstein cavern, strikingly distinguished by its milk-white colouring from its brownish companions with well-developed eyes.
1873. Willemoes Suum, Rudolph von, born September 11, 1847, died September 13, 1875 (John Murray).

The new genus Thaumops is thus defined:—

The type is given as "Thaumops pellucida, n. sp. Corpus longitudine 14 [84] mm., latitudine 21 mm., pellucida."

The full description, with plates, was afterwards published in the Transactions, with various corrections, but both genus and species were, shortly after their institution, identified by their author with Guérin's "Cystisoma Neptunus." The "new family, Thaumopidae, belonging to the tribe of Hyperina," which he here proposes to establish, was dropped, and a new family, Cystisomidae, proposed. See Notes on Willemoes Suum, 1874, 1875, 1879.

1874. Bos, Jan Ritzema.

Bijdrage tot de kennis van de Crustacea Hedriophthalmata van Nederland en zijne kusten. Groningen. 1874.

The introduction contains a short historical review of carcinology, and, among other points, suggests that the Hedriophthalmata, in spite of their comparatively small size, are the highest representatives of their class, on account of their dispensing with the nauplius- and zoöa-stages, on account of their including many terrestrial forms, and on account of their late appearance in the strata of the earth, the Podophthalmata having been met with as early as the carboniferous, the Hedriophthalmata not till the Jurassic period.

Descriptions are given of several well-known species, with interesting remarks upon them; the "calceolus" on the antennae of Grammarus pulex is figured and discussed.

1874. Buchholz, Rudolf, died April 17, 1876 (Taschenberg).

This report opens with some occasional remarks on the appendages of the antenna, the eyes, comparative measurements, and classification of Amphipoda.

Valuable remarks are made on the Lysianassidae, with the species Anonyx lagena, Kr., properly Anonyx magus, Phipps; Anonyx littoralis, Kr.; Anonyx planus, Kr., for this and the preceding species the genus Anonyx being adopted in preference to Ondimus, Boeck; the Syrrohiinae, species Syrroci divorce dita, Goös; the Pardaliscinae, species Pardalisca cuspidata, Kr., which, as well as most of the following, is fully described and strikingly figured; the Lencothoinae, species Lencothoe cuspidata, Kr., Amphithoontus aculeatus, Lepechin, identified with Tritropis helleri, Boeck, as well as his Tritropis aculeata; Tritropis (now Rhauchotropis)
fragilis, Goës; the Glicicerinae, species Gliceros boralis, Boeck, retransferred from Monocordes to Gliceres; Gliceros hysterus, Sars; the Pleustine, a new family, species Pleustes panoplus, Kr.; Paramphithoe gracilis, n. g. et s., perhaps the same as Paramphithoe ocyca, Goës, and Paramphithoe glabra, Boeck: the Iphimeline, species Vertmannus serratus, Fabricius (of which the name Vertmannus, White, being preoccupied, has since been changed by Boeck to Acanthontozonina); the Gammarine, species Gammarus locusta, L. (not figured), Anathilla salvinii, Leech, Anathilla plagus, Kr.; the Atyline, species Atylus carinitus, Fabricius, Atylus smithii, Goës (not figured), Acanthone hydræa, Owen, probably, as Miers has pointed out, a new species, distinct from Owen's; Paramphithoe inermis, Kr.; Paramphithoe fabrocinata, Sars; Paramphithoe megabros, n. s.; the Ampeliscine, species Ampelisca eschrichtii, Kr., with the suggestion that Ampelisca macrocephala, Lilljeborg, may be only a local variety; the Podicerine, species Podoceus anguipes, Kr.; the Corophine, species Glauconome kucops, Kr. (not figured); the Hyperide, species Themisto libellula, Mandt; the Caprellide, species Aegina spinifera, Bell, with which he identifies Aegina echinata, Boeck (the name Aegina being probably an accidental slip of the pen for Aegina).

The Syrrohine are said to come near the Glicericine in general form and in the structure of the mouth-organs, although having this distinction that only the left mandible is provided with a processus accessorius. (But this distinction is not universal in the group.)

In the Pardaliscine, Dr. Buchholz corrects the supposition of Boeck that a processus accessorius is wanting to the right mandible. He also considers that Bruzelius and Boeck have both of them confused the joints in the gnathopods of Pardalisca cupulata, that they have taken for the wrist being really the hand, and the finger being, contrary to the general rule in Amphipods, two-jointed. This would be extremely remarkable, and would contravene the rule well laid down by Spence Bate that in the Amphipoda the third (free) joint always underlies the fourth in the gnathopods and overides it in the pereopods, but my own observation of members of the genus Pardalisca compels me to believe that the earlier authors are right, and Dr. Buchholz himself in error. It is in any case clear from the figures that Dr. Buchholz and Boeck are not referring to the same species under the title of Pardalisca cupulata, Kr. The species so named by Buchholz agrees with Pardalisca abyssi, Boeck, a specimen of which was brought home by the Challenger and is figured in this Report.

From the Lencothoina, which he considers too heterogeneous a group, Dr. Buchholz is inclined to transfer the genus Tritropis (since called Rhachotropis by S. I. Smith) to the group containing Paramphithoe.

For the Pleustine, a new family, he mentions as characteristics, the antennae rather short, the lower shorter than the upper (sexual differences not ascertained); the head small, with distinct, well-developed rostrum, the eyes small and lateral; the body frequently carinate, the first four side-plates well developed; the mandibles with broad dentate process but no molar tubercle; the gnathopods large, subulate, the three last pairs of pereopods not much elongated, and the seventh not especially so; the uropods slender, pretty strongly elongated.

It is a little difficult to reconcile the expression "das gänzliche Fehlen des Kauhöckers der Mandibeln" in the above account of the family, with the description "des sehr verkürmerten Kauhöckers" of Pleustes panoplus. This degenerate molar tubeclere is figured by Buchholz himself, as well as by Knyr and Boeck.

The differences in the mouth organs, the absence of a dorsal carina, and the very weakly developed rostrum are thought to justify the establishment of this new genus.

Among the Gammarine, a species taken by von Heuglin at Spitzbergen, is described in a supplementary note, p. 345, as being probably new and coming near to Amathilla pinguis. It is named "Amathilla Heuglini (Buchh.)." The diagnosis is as follows:—"Corpus sat altum, magnum, epimeride crassa, quasi loricatum, dorso rotundato lato, medio tumidum. Oculi nigr, mediocres, reniformes. Antennae superiores inferioribus paullo breviores tertiam fere corporis longitudinem aquaeque; flagello accessorio medii once quatuor articulos praebeat. Epinera anterior media, quartum non itus, postico in spinam validissimam acutam horizontalem productam. Epinera segmentorum abdominalem; secundum et tertium angulo posterior in dentem acutum productum, primam rotundatum, tertium preterea in margine posterior in dentem acutum sursum spectantem productum. Appendix caudalis elongata indivisa, apice incusa, media perparva emarginata. Pedes saltatorii tertii parvis, ramis equalibus compressis, anterioribus non longiores. Color pallide flavus. Long. total. 36 mm."

A full account, illustrated by numerous figures, is given of the differences between the young and adult forms of Amathilla salivini (homari, Fabr.) These, as Buchholz observed, had been already noted by Bruzelius, Skand. Amph. Gam., p. 51. See also what is here said of Grayia imbricata, Spence Bate, p. 332.

Among the Atyline, the genus Paranyphioloe, Bruzelius, is thus limited, to comprise—small, delicate Atyline, thin-coated, with slender bodies, very elongate tailform antennae, slender, elongate feet, gnathopods with linear, weakly-developed, subchelate hands; back rounded, body compressed, rostrum very small; uropods very slender, elongate, the last pair with lancelolate compressed rami; the males uniformly possessing numerous specific appendages to the antennae. The genus, besides including species assigned by Boeck to Pontogencia and Halirages, contains the new species Paranyphioloe megaphos, with the following diagnosis:—"Corpus parvum gracile, tectum, dorso rotundato ubique inermi, oculis permagnis nigris, transverso, ovali-reniformibus, antennis perlongis, subequalibus, longitudinaline totius animalis paullo brevioribus, pedum anteriore manibus parvis ovatis; epinera quattuor anterioribus parvis, illis segmentorum trium abdominalem primorum margine postico fortiter serrato dentatis; pedibus saltatorii elongatis gracilibus. Long. tot. ad 7 mm." The application of the term epinera to the hind margins of the first three pleon-segments cannot, I think, be justified.

In regard to the account given by Buchholz, pp. 375–377, of the Ampeliscine, Spence Bate, and the species, "Ampelisca Eschrichti," Krüger, Taf. XIII. Fig. 1," Metzger, in 1875 (p. 298, note), says of Buchholz's work, "Auf. p. 375 u. ff. ist Ampelisca Eschrichti zum Theil ziemlich ausführlich beschrieben und auf Taf. VIII. Fig. 1. durch Abbildungen erläutert. Beschreibung und Zeichnung weichen ebenfalls von Boeck's Diagnose in verschiedenen Punkten ab; leider hat ausserdem der Verfasser gewisse spezifische Merkmale gänzlich unberücksichtigt gelassen, so dass ich in meiner Hoffnung, hiernach die Richtigkeit meiner Bestimmung zu prüfen, getäuscht wurde. Zunächst muss ich der Behauptung von Buchholz entschieden widersprechen, dass die beiden vorderen Fusspaare nur einfache Krallenfissee seien mit nicht gegen das vorhergehende Glied zurückschlagbarer Kralle, ein Charakter, den Verfasser auf Grund dreier interessierender Individuen sogar der ganzen Familie der Ampeliscineen vindict. Allerdings ist bei allen bis jetzt bekannten Arten der Palmarand nicht deutlich ausgeprägt und geht unmerklich in den Hinterrand über, nichts destoweniger kann aber die Kralle gegen diesen eingeschlagen werden; beide Glieder bilden also das, was man allgemein als manus subcheliformis zu bezeichnen pflegt.—In der Figur 1, Tab. XIII, hat das 7. Bein nur 5 Glieder! Die Centenuren des oberen und hinteren Randes vom zweiten Gliede sind offenbar in der Zeichnung vergessen. Sodann ist auf die Beschaffen-
1858—Chenu and Desmarest, E.

In this work, which should rather have been mentioned under the earlier date, the Crustacea probably, and the Alphabetical Table certainly, should be ascribed to Desmarest alone. Accepting the “Étriphalmas, Leach” as deuxième légion of the “Crustacés maxillés, Edwards,” he makes the “Amphipodes, Latreille,” the premier ordre, p. 46. All the species, he says, are very small, “car on n’en connaît pas qui dépasse une longueur de 0,002.” The “Première Famille, Crevettines, Latreille,” includes two tribes. The first tribe has twelve genera assigned to it, the fifth being given as Philius, Guérin. Of Gammarus, the tenth, he says, “Le type est la Crevette des ruisseaux ou Crevette (Gammarus fluviatilis, Edw.). Longueur, 0°,010 à 0°,015.” “Fig. 27.—Crevette des ruisseaux” has a perfectly smooth back; nevertheless the text says, p. 48, “une espèce que l’on confond souvent avec la Crevette des ruisseaux, ayant les mêmes moeurs, se trouvant dans les mêmes lieux, et n’en différant guère que parce que son abdomen est lisse, est la Crevette puce (Gammarus pusillus, Fabr.)” The second tribe has seven genera, the third being thus given, “Cosmopodia, Templeton (C. obdita, trouvée en mer).”

The “Deuxième Famille, Hypéristes, Edwards,” includes three tribes, the first being “Hypéristes gammaroïdes,” with one genus; the second, “Hypéristes ordinaires” has thirteen genera, among which it may be noted that Lancisca is kept distinct from Hypéristes; to the seventh “Lestrigones, Edw.,” “L. Fabricia” is assigned as the type; Anchylomera is the ninth, and its synonym Hierancum the tenth, while the thirteenth is “Sperchius, Leach,” Sperchius being, in fact, an obscure genus instituted by Rafinesque. The third tribe, “Hypéristes anomales,” receives four genera, the second being given as “Orione, Cocco,” by a substitution of the Italian for the Latin name Orio.

The “Deuxième ordre, Leomodipodes, Latreille” is said to correspond with the “genre Cyane de De Lamarck,” and contains two families, the first Caprelliens, with three genera, Caprella, Leptomera and Naupridia; the second Cyanni, with the one genus, Cyamus.

In the Alphabetical Table Philius, Cosmopodia obdita, Hypéristes gammaroïdes and Leomodipodes are given correctly; “L. Fabricia” becomes Lestrigone Fabricii.” The preface (avis), dated “15 octobre 1858,” thinks that the table, like the body of the work, will be “d’un très-grand secours pour les recherches des naturalistes et des gens du monde.” Yet in 1858 no notice had been taken of Dana’s researches, and in 1874 no hint is given that cardiology had made any advance in the preceding sixteen years.
1874. Dybowski (Dubovsky), Benedict N.

In the Preface, he mentions *Pleciola torquata*, Grube, as a parasite on the branchial plates of species of Gammarus.

In the Introduction, he says that the Crustacean fauna of Lake Baikal consists mainly of Amphipoda, all belonging to the *Gammarina*. Between *Gammarus* *Petersii*, with slender body, long extremities and extremely long antennae, and on the other side *Gammarus inflatus*, with short thick body, short extremities and short antennae, he finds so many gradations of form and combinations of likeness and difference, that he cannot venture under existing circumstances on separating more than a single species from the genus *Gammarus*. This one species he places in a new genus, *Constantia*, a name unfortunately preoccupied among Mollusca in 1860. The accidental misspelling *Costantia* had therefore better be adopted for this genus.

A full table of terminology is given, in which the homologous joints of the appendages receive a needlessly great variety of names.

General remarks on the genus *Gammarus*, Fabr., are concluded by the following diagnosis of it, as applicable to the species from Lake Baikal:—

The species are grouped into two sections, with numerous divisions and subdivisions, and are thus numbered and named in the preliminary review:—"Erste Abtheilung. Die Nebengeissel vielfachgliedrig; zwei- bis vierziggliedrig." 1. *G. Flori*, n. s.; 2. *G. Flori var. albula*, n.; 3. *G. calcarius*, n. s., Taf. vii, Fig. 4; 4. *G. maritilacus*, n. s.; 5. *G. Kieltepski*, n. s., Taf. i, Fig. 1; 6. *G. Stanislaci*, n. s.; 7. *G. pulcr*, De Geer, Taf. viii, Fig. 1; 8. *G. testacius*, n. s.; 9. *G. Sophiv*, n. s.; 10. *G. fuscus*, n. s., Taf. v, Fig. 2; 11. *G. murinus*, n. s., Taf. v, Fig. 1; 12. *G. ahewens*, n. s., Taf. vii, Fig. 2; 13. *G. verrucosus*, Grat., Taf. iv, Fig. 1; 14. *G. lividus*, n. s.; Taf. vi, Fig. 1; 15. *G. hypomorphus*, n. s.; 16. *G. altius*, n. s., Taf. ix, Fig. 3; 17. *G. furcis*, n. s., Taf. ix, Fig. 1; [misprinted Taf. xi, Fig. 1, in the general account]; 18. *G. carneolus*, n. s.; 19. *G. amethystinus*, n. s., Taf. ix,
THE VOYAGE OF H.M.S. CHALLENGER.

Of the new genus Constantia (Costantia), the following diagnosis is given:—"Die beiden Fühlerspere sind zu Locomotionsorganen umgewandelt, die oberen Fühler sind mächtiger und länger als die unteren. Die beiden Endglieder der oberen Stiele etwas flach gedruckt, ihr Innenrand mit einem dichten bürstenförmigen Borstenbesatz versehen. Die Geissel-
REPORT ON THE AMPHIPODA.

429

The type species is named "Constantia Brandichii," n. s., Taf. iii, Fig. 7; var. Alexandri, Taf. iii, Fig. 6, is only distinguished by the greatly developed dorsal spine-process on the first pleon-segment.

1874. GRENAChER, H.

See Note on Grenacher, 1879.

1874. Hoffmann, C. K.

Recherches sur la Faune de Madagascar et de ses dépendances, d'après les découvertes de François P. L. Pollen et D. C. van Dom. 5ère Partie. 2ème Livraison, Crustacés et Echinodermes par C. K. Hoffmann. Leyde, 1874.

1874. Humbert, Alois.

Gammarus pulexus is recorded on p. 114; lists of species from other caves are also given.

1874. Macdonald, John Denis.

A description and figures are given of "a species of Phronima captured in lat. 30° 16' S., long. 176° 27' W."
1874. M'Intosh, William Carmichael.

The habits and special habitats of some of the sessile-eyed Crustacea are noticed. Acknowledgment is made to Mr. Spence Bate and the Rev. A. M. Norman for assistance in determining doubtful forms. In the list of Amphipoda, Allocoristes nilsonii of Bate and Westwood is transferred to *Hyale Nilsonii*, H. Rathke; the species monaculoides, Mont., varicans, "Alderii," Pectinaria, *clypeata*, assigned to Montagna by Bate and Westwood, are here referred to *Stenothoe*, Dana; their *Anonyx denticulatus* to *Anonyx holboellii*, Kröyer, their *Amphessa genuarum* to *Amphissa caryata*, Brasilii, their *Amphissa belliana* to (= *A. macrocephala*, Lilljeborg). "Calliopus blotulatus (n. sp.), Norman, Nat. Hist. Trans. Northumb. & Durham, vol. i. 1865, p. 24," said by Mr. Norman to be not uncommon all along the east coast, is thus described:—"The body is about two-fifths of an inch long, of a pale straw colour, tinted with brownish at the joints and the bases of the limbs. Superior antennae twice as long as the inferior, beautifully banded with red. Eyes irregularly rounded, brownish red or pale brick-red. The first and second gnathopods are nearly equal (the second, however, being larger) and similar in structure. Hand almond-shaped, the palm being furnished with a row of very distinct stout spines, and a row of smaller spines reaching the base of the finger; the latter is long, boldly curved, and regularly divided on the concave side. The first and second pleopods [i.e., pleon-segments] have spines, that of the former, however, being sometimes indistinct. A very characteristic convexity occurs at the junction of the third and fourth pleopods [i.e., pleon-segments]; and the dorsal margin of the latter is concave."

*Eisclusus longicaudatus* of Bate and Westwood is here given as *Heisclusus longicaudatus*, their *Amphithoe littoria* as *Amphithoe podoceraides*, H. Rathke, and distinct from *Amphithoe rubricata*, Mont. "Most of the fine specimens," it is said, "have the hand of the second pair defined by a distinct tooth, as Rathke and Dr. Johnson state." *Podocerus falcatus*, Mont., is given as including *Podocerus paluelUs* and *Podocerus pelagicus* of Bate and Westwood, *Podocerus cariosus*, Leach, as including their *Podocerus capitatus*. "Siphonococcus Whitei," Gosse, is said to be probably the female of "Siphonococcus typicus," Kröyer. The three species, *tuberculosa*, *rimpaquata* and *excavata*, assigned by Bate to *Novia*, are all recorded as found together in the "débris from the coralline ground." *Hyperia medusorum*, O. F. Müller, is given as including *Hyperia galba* of Bate and Westwood, with the remarks "The Lestrigonim Kinahani, Bate, is a sexual variety (male). Some large specimens are found swimming freely on the surface of the water." "Ægina phaena*, Mont.; R. & W. op. cit. ii. p. 45," appears without notice that the authors quoted do not assign it to *Ægina.* "Coprella tuberculata*, Guérin; R. & W. op. cit. ii. p. 68," is said to be common on *Ceramium rubrum* in rock-pools, and in the stomachs of cod and haddock. Mr. Norman's opinion is given that the *Coprella hystrix* of Bate and Westwood is not the *Coprella hystrix* of Kröyer, but rather is *Coprella septentrionalis*. The list includes several other Amphipoda, with occasional notes on colouring.
1874. Marion, Antoine Fortuné.

The Salps are, he says, extremely abundant in some years, and then may not reappear during several springs. They were found in long chains in 1862, with Salpa maxima predominant, which he never took without finding upon it the parasitic Amphipods which he here describes. The first is Vihilia jeanyaritii, Lucas, 1819, of which he considers Vihilia spectabilis, Costa, 1853, and Vihilia multicornis, Claus, Grundzüge der Zoologie, 2d Ed., to be in all probability synonyms. In describing the maxillipeds, “la lèvre inférieure, constituée par la réunion des deux maxillipedes de la troisième paire, appelés souvent pattes-maxioires,” he remarks, “il est très-important de constater que cette lèvre sternoïde est totalement dépourvue d'appendicules palipéiformes, tandis que M. Milne Edwards décrit et figure chez le Vihilia Peronii deux petites tiges rudimentaires représentant ces organes développés dans les Gammarines.” Secondly, Lycxa palex, n. s., is figured and very fully described. It is compared with Lycxa ochracea, Dana. G. O. Sars in 1882 considers that it comes very near the northern species Lycxa (Frydlinka) nubilis, Boeck. Claus in 1879 establishes Lycxa robusta, n. s., but gives as a synonym “L. palex Marion? . . . Junges . . .”

Crustacea. The Zoological Record for 1872; being Volume Ninth of the Record of Zoological Literature. London, m.dccc.lxxiv. pp. 185–204.

Lists are given of the Crustacea taken at the various localities in which dredging was carried on.

"Notes on some of the Species enumerated: by S. I. Smith," include remarks on the following Amphipoda, pages 29 to 35; “Phoxus Krojeri, Stimpson,” “very closely allied to, and probably identical with, the P. Hokholii Kroyer which is found in Greenland, Iceland and northern Scandinavia;” Harpina fusiformis, Smith (Phoxus fusiformis, Stimpson), “this species is very likely identical with the H. plumosus Boeck (Phoxus plumosus Kroyer), which has very nearly the same range as Phoxus Hokholii;” Stenorhynchus peltata, Smith, n. s., Pl. IV [III], figs. 5–8; Syrphus crenulata, Goës, “seems to be an exceedingly arctic form, being found in Europe from Spitzbergen to the western coast of Norway;” Tirion acanthurus, Liljeberg (Syrphus biarplus, Goës; "Thessarops [Testarops] hastata, Norman;" Ediceros lyneus, Sars (Ediceros propinquus, Goës; Monoculodes nubilus, Packard, Mem. Boston Soc. Nat. Hist. i. p. 398, 1867); Monoculodes borealis, Boeck (Ediceros affinis, Goës); Paramphithoe paludita, Brucklitz (Kroyer sp.); Paramphithoe calaphractus, (Amphithoë calaphractus, Stimpson). “this species is apparently a true Paramphithoe, as restricted by Boeck, and closely allied to, if not identical with, P. panopla Bruzelius (Amphithoë panopla Kroeyer). Boeck places Pleustes tuberculatus Bate as a
synonym of Kroyer's species, and if he is correct in this our species is undoubtedly distinct"; *Vertamum serratus*, Göse (Fabricius sp., *Acanthonotus serratus*, Stimpson), "Our specimens all differ from the descriptions and figures given by Boeck and Kroyer in the armature of the posterior margin of the third segment of the abdomen. In our specimens the upper process from this margin is armed with four or five teeth above and at the tip, while the lower process is armed with five or six teeth similarly situated, but with no teeth on the lower margin except just at the tip. In Kroyer's figure (Grönlands Amfiboder, plate ii. figure 8) the upper process is represented as terminating in a single tooth and the lower process as toothed along both sides; Boeck's description agrees with this, except that he says there are two teeth at the tip of the upper process"; Boeck afterwards changed the name to *Acanthonotus serratus*; *Acanthozoa cuvidata*, Boeck; *Byblis gaimardi*, Byblis (Kroyer sp.), "the *Ampelisa Gaimardi* of Dale, and Dale and Westwood, is not this species, but a true *Ampelisa*. All the species of this subfamily are undoubtedly tube dwellers.... In this species, the glands which secrete the cementing fluid are situated principally in the meral and basal segments of the third and fourth pairs of thoracic legs;" *Xenoceca megachir*, Smith, n. s., Pl. IV [III], figures 1 to 4. "*Pedes 3ii et 4i parium articulo Iimo latissimo*" of the generic description would scarcely apply to our species, but in all the other generic characters it agrees perfectly, as it does also with the diagnosis of the subfamily Photine, except that the mandibles each bear six serrated spines instead of the usual number, four." In this species Professor Smith noticed a peculiar "glandular structure filling a large portion of the third and fourth pairs of thoracic legs." "The terminal segment (dactylus) in these legs is not acute and claw-like, but truncated at the tip and apparently tubular." "A large cylindrical portion of the gland lies along each side of the long basal segment, and these two portions uniting at the distal end pass through the ischial and along the posterior side of the meral and carpal segments, and doubtless connect with the tubular dactylus. There can be no doubt that these are the glands which secrete the cement with which the tubes are built, and that these two pairs of legs are specialized for that purpose." In *Ampithoë maculata* the gland is in the middle of the basal segment. Other arrangements with reference to this gland are mentioned for *Cerapus rubricornis*, *Ptilocheirus spinis*, *Byblis gaimardi*, and a species of *Ampelisa*.

1874. Smith, S. I.

The cement-glands are described in *Xenoceca* sp., and noted in *Ampithoë maculata*, *Ptilocheirus spinis*, *Cerapus rubricornis*, *Byblis gaimardi*, *Ampelisa* sp. In the *Cerapus* "the orifice in the dactylus is not at the very tip, but subterminal on the posterior side." In *Ampelisa* and *Byblis* "the remarkable elongation of the two distal segments in the third and fourth pairs of legs is perhaps a special adaptation to enable them to reach back over the deep epimera." See Note on Smith and Harger, 1874.
1874. SMITH, S. I.

At page 645, the account of the Amphipoda begins with the family Orchestidæ, and the new genus Hyatella, thus described:

"First pair of maxillæ with rudimentary, very short, and unarticulate palpæ. Palpus of the maxillipeds composed of five segments; the terminal segment being slender and styliform, and the penultimate broad. Antennæ, antennæ, and thoracic legs much as in Hyale. Telson short, stout, and entire."

"This genus seems to be closely allied to Hyale, but differs from it and from the rest of the Orchestidae in the palpæ of maxillipeds, which has five instead of four segments, showing in this respect a remarkable approach toward the gammaroid group of Amphipoda. From Hyale it differs also in the telson."

For a discussion of the genera Hyale and Hyatella, see Note on Rathke, 1837. Hyatella dentata, n. s., pl. ii. figs. 8–10, is here described. After the description had been sent to the printer, Professor Smith received many additional specimens from Lake Okeechobee, Florida. In some of these, he says, "the dorsal teeth upon the first and second segments of the abdomen are very small; and, in a very few specimens, they are wholly, or almost wholly, wanting." The Amphilithæ azteca, Saussure, "undoubtedly belongs to this genus, and may be called Hyatella azteca." Allorchestæ knudseni of Bate "belongs probably to this genus;" "the palpæ of the first pair of maxillæ, in Bate's species, is figured (perhaps incorrectly) as composed of two segments."

In the family Lysianassidae, "Pontoporeia Hogi," pl. ii, fig. 5, is entered as a new species, with the synonymy, "Pontoporeia affinis" Smith, American Journal of Science, 3d series, vol. ii, p. 452, 1871; and Preliminary Report on Dredging in Lake Superior, p. 1022, 1871. Gammareus Hogi Stimpson, M.S.S., (full-grown male form.) Gammareus brevistylis Stimpson, M.S.S., (female) "Professor Smith had originally regarded his specimens "as specifically identical with the Pontoporeia affinis of the Scandinavian lakes and the Baltic. A subsequent and more minute comparison has, however, revealed some differences, which are apparently constant." "The most remarkable differences are in the peculiar, elongated, papilliform appendages upon the sternal portion of the thoracic segments." These, it appears, are more numerous in the American specimens than in the European, as described by G. O. Sars in 1867. A second new species, Pontoporeia filicornis (Gammareus filicornis Stimpson, M.S.S.), is founded on a single specimen. "This species differs remarkably from all the heretofore known species of Pontoporeus in the excessive elongation of the flagella of the antennæ and antennæ, a character which might be regarded by some naturalists as of generic value. The very close agreement with P. affinis and Hogi in all other parts of the animal, however, seems to indicate a very close affinity with those species, especially the latter; and as this one peculiarity is very likely only a sexual character of the old males of the species, I retain the species in the genus." The detailed account seems to make it doubtful whether the name Pontoporeia affinis would not suffice both for this and the preceding species.

In the family Gammaride, is described Gammareus limnaeus, Smith, pl. ii, figs. 6, 7, (Gammareus lacustris, Smith, 1871), "this species is very closely allied to the Gammareus neglectus of G. O. Sars, which inhabits the lakes of Norway," of which lacustris is a synonym, or...
perhaps rather the rightful name, and from which Professor Smith says that his species, though differing only in minor details, is undoubtedly entitled to be considered distinct. Very large specimens had been obtained in Colorado, from an elevation of 9000 feet. He next describes Gammarus fasciatus, Say. Of Gammarus minus, Say, he remarks that he has "not yet been able to rediscover this species, which is very likely not a true Gammarus." The Gammarus minus of De Kay, he says, "is made up principally of Say’s original description," with a "rude attempt at a figure" apparently from some other species, probably Gammarus fasciatus. He describes both sexes of Crangonyx gracilis, Smith, 1871, and mentions Crangonyx citreus, Packard, 1873, giving under protest as a synonym, "Illypseudonous citreus" Cope, American Naturalist, vol. vi, p. 422, 1872; Third and Fourth Annual Reports of the Geological Survey of Indiana, p. 181, 1872." He describes Crangonyx tenus, n. s., "a slender, elongated species, with very low epimera, resembling more in form the species of *Niphargus* than the typical species of *Crangonyx.*"

In the "Sketch of the Invertebrate Fauna of Lake Superior," four Amphipoda are mentioned, Hyalella dentata, "Pontoporia Hoyi," Gammarus minus, Crangonyx gracilis, with references to the descriptions already given.

In the Section on the "Food of Fresh-water Fishes," "Pontoporia Hoyi," is mentioned as found in the stomach of the White-fish (*Coregonus albus*), at various stations.

1874. Stebbing, Thomas Roscoe Rede, born February 6, 1835.

"Lilljeborgia Normanni" is described and figured as a new species, near to *Lilljeborgia shetlandica*, Bate and Westwood, both species being synonyms of *Cheirocratus sundevalli*, Rathke. A variety of *Iphimedia obesa* is described and figured, as intermediate between that species and *Iphimedia obesa*, with the suggestion that distinction implied by the two specific names may, in fact, be one of sex. The male of *Microcestopus versiculatus*, Sp. Bate, is figured and discussed. This species, in Boeck’s opinion, may be the same as *Antonoc longipes*, Lilljeborg, but the first gnathopods do not suit that view. The alteration of *Microcestopus* to *Microcestocerus*, accepted in this paper, I no longer think necessary. *Microcestopus maculatus*, Norman, is figured, and some notes are given on that species. *Gammarilla breviceps*, Bate, Milne-Edwards, is figured and discussed to show that "Gammarilla Normanni," Bate and Westwood, is in fact the female of Milne-Edwards’ species. This had already suggested by Mr. Spence Bate in the Brit. Mus. Catal., p. 379.

1874. Stebbing, T. R. R.

*Amphilhoe curvicula*, n. sp., is described and figured. *Amphilhoe rubricata*, Montagu, is compared with *Amphilhoe littorina*, Sp. Bate, and the inference drawn that they are varieties only of the same species. *Amphilhoe littorina* is by Boeck identified with *Amphilhoe pseudocerode*, Rathke, but Montagu’s name being still older will take
precedence. Figures and descriptions are given of both sexes of *Sunamphithoe* gammaroides. This I believe to be identical with the partially described *Amphithoe* gammaroides of Spence Bate. Both sexes are described of *Sunamphithoe conformata*, Sp. Bate, with the suggestion that *Sunamphithoe* hamulus, Sp. Bate, is in fact not a separate species, but the female of *Sunamphithoe conformata*. The name of the species, however, should be *hamulus*, although the synonymy, as given both in the Brit. Mns. Catal. and in the Sessile-eyed Crustacea, leads to the (erroneous) inference that *conformata* was the earlier established. As a matter of fact *hamulus* stands first at the original contemporary institution of the two names.

1874. **Stebbing, T. R. R.**

The sessile-eyed Crustacea of Devon. (Read at Teignmouth, July, 1874.)

No new species are described in this paper, which was intended as a supplement to Mr. Parfit's Catalogue, 1873. *Grauia inibrirata*, Sp. Bate, is figured, and notice taken that, contrary to one of the characters assigned to the genus *Grauia*, it has an accessory flagellum on the upper antennae. This species has since been recognised as the young of *Anathilla sabini* (Homari, Fabr.). The suggestion is made that *Sulciator arenarius*, Sp. Bate, is probably the same as the *Lepidactylis* of Say. This surmise has since been confirmed by S. I. Smith. *Phalora kimihani*, Spence Bate, was included in the list by mistake.

1874. **Verrill, A. E., and Smith, S. I.**

Report upon the invertebrate animals of Vineyard Sound and adjacent waters, with an account of the physical features of the region. Extracted from the Report of Professor S. F. Baird, Commissioner of Fish and Fisheries, on the condition of the sea-fisheries of the South Coast of New England in 1871 and 1872. Washington, 1874.

The Amphipoda in this report were identified by Mr. S. I. Smith. At page 19 (313) Mr. Verrill says, "these small crustacea . . . together with the shrimps, constitute a very large part of the food of most of our more valuable edible fishes, both of the fresh and salt waters." The *Orchestia agilis* of Smith, "occurs in countless numbers beneath the masses of decaying sea-weeds." "A much larger species, and one of the largest of all the amphipods, is the *Gammarus ornatus*." "The males are much larger than the females, and sometimes become nearly an inch and a half long." "The only good English name that I have ever heard for these creatures is that of 'seuds,' given by a small boy, in reference to their rapid and peculiar motions." Other species are mentioned, which will be noticed farther on. In a "list of species inhabiting the rocky shores of the sounds and bays," p. 37 (331) eleven Amphipods are named.

Of *Talorchestia longicornis* and *Talorchestia megalophthalma*, of the sandy shores, he says, "when driven from their burrows by unusually high tides or storms they are capable of swimming actively in the water," p. 42 (336). Of the sandy shore species he mentions also *Orchestia agilis*, *Lepidactylis dyliiscus*, *Unciola trivolata*. To the muddy shores six species of Amphipoda are assigned, p. 83 (377). Among the species commonly found on
submerged woodwork six Amphipods are mentioned, p. 98 (392), among which it is curious to note that *Cladula tenebrosa* is not included. Of Amphipods ordinarily found on the bottoms of the bays and sounds, he enumerates for those that are rocky, p. 115 (409), nine species; for those that are gravelly and shelly, p. 128 (422), seven species; for those that are sandy, p. 134 (428), two species, *Lepidastylis dytiscus* being included in this and the two preceding lists; lastly, for those that are muddy, p. 140 (434), "several species" of *Lysianassine*, and eight of genera in other families.

In the section on "free-swimming and surface animals," he says, "several species of Amphipods are also common at the surface. The most abundant were *Callipus larvicola*, of which Mr. V. N. Edwards also took numerous large specimens in February and March; *Gammarus natator*, which was usually common, and occurred in immense numbers August 10 and on several other occasions; and *Hyperia*, which infests several species of large jelly-fishes, and also swims free at will. The *Paronima* is a related genus, but is very remarkable for its extreme transparency, which renders it almost invisible in water." The list, p. 158 (452), mentions "several species" of *Lysianassinae*, and eleven species of genera in other families.

At p. 163 (457), he says, "among the Crustacea there are a few species of Amphipods that are parasitic. One of these, *Laphygusur *sturio*, lives upon the gills of fishes and upon the surface of the body. It was found on the gills of the "goose-fish" (*Lophius*), in Vineyard Sound, and on the back of skates at Eastport." In the list of external parasites, he mentions, besides *Laphygusur *sturio*, "*Hyperia*, species, on jelly-fishes.

On the sandy shores and bottoms of estuaries, three Amphipods are recorded, p. 170 (464); on the muddy shores and bottoms of brackish waters, eight species, p. 177 (471); on oyster beds in brackish waters, four species, p. 182 (476); among eel-grass in brackish waters, eight species, p. 186 (480); on piles, etc., in brackish waters, four species, p. 188 (482); on outer rocky shores, nine species, p. 193 (487); on sandy shores of the open coast, four species, p. 196 (490); on the stony and rocky bottoms on the open coast, nine species, or more, since he says, "species of *Caprella* occur in considerable numbers," p. 200–204 (494–498); on sandy and gravelly bottoms off the open coast, eight species, p. 210 (504); on soft mud and sandy mud off the outer coast, seven species, p. 217 (511).

In the "lists of species found in the stomachs of fishes," pp. 220–227 (514–521), he mentions "Scep; Pogge; (Stenotomum acyprop.). Forty young specimens, one year old, taken at Wood's Hole in August, contained large numbers of Amphipod Crustacea, among which were *Unciola inorata*, *Ampelisca*, sp., etc." "Haddock; (Melanogrammus aeglefinus). . . . A specimen taken at Wood's Hole, November 6, 1872, contained a large quantity of *Gammarus natator.*

"Tom-Cod; Frost-Fish; (Microgalex tom-codin). Several specimens from New Haven Harbor, January 30, contained numerous Amphipods, among which were *Margaris; Gammarus, sp.; Ampelisca, sp.*" others at Wood's Hole, in March, contained "large quantities of Amphipods, especially of *Gammarus angulatus*, *G. natator*, *Callipus larvicola*, and *Micropeltus minax*; and smaller numbers of *Gammarus ornatus* and *G. macronatus*. Another lot of twelve, taken in April at the same place, contained most of the above, and in addition several other Amphipods, viz., *Margaris; Pontogamia inorata*, *Pilbocificus pangus*, and *Caprella. * "Ocellated Flounder; Summer Flounder; (Chelon rhetor cutela), . . . contained . . . Amphipod Crustacea belonging to the genus *Ampelisca.* "Spotted Flounder; (Lophopecta maculata), . . . contained . . . numerous Amphipods, *Gammarus macronatus.*" Sea-Herring; (Glyptus elongata), . . . contained . . . large numbers of an Amphipod, *Gammarus natator.*"

The Systematic Catalogue of the Amphipoda inhabiting the coast between Cape Cod and New York, drawn up by Mr. S. I. Smith, occupies pages 261–273 (555–567). It includes
Orchestia agilis, n. s., pl. iv. fig. 14; Orchestia palustris, n. s.; Talorchestia longicornis, Smith (Talorchestia longicornis, Say, Orchestia longicornis, M.-Edw., and De Kay); Talorchestia megalophthalma, Smith (Orchestia megalophthalma, Bate, Talorchestia quadrijugata, De Kay), "may be based on the female of one of the preceding species, but it is so badly described and figured as to be indeterminable"); Hype littoralis, Smith (Talorchestes littoralis, Stimpson); Leyiocnusae, species; Lepidostylis stygicus, Say; Phoxus kroyeri, Stimpson; Urolpth, species; Monoceloidea, species; Laphygus asperior, Kroyer (Dartenia compressa, Bate); Calliopius levisculus, Bock (Kroyer); Pontogeneia inermis, Bock (Amphithoe inermis and crenulata, Kroyer, Iphionella vulgaris, Stimpson; Athys inermis, crenulata, and vulgaris, Bate; Athys vulgaris, Packard, not Athys (Paramorphite) inermis, Packard, Mem. Boston. Soc. Nat. Hist., vol. i. p. 298, 1867); Gammarus ornatus, M.-Edw., pl. iv. fig. 15 (Gammarus bocuda, Gould; Gammarus pulex, Stimpson); Gammarus ovulatus, n. s.; Gammarus maculatus, n. s.; Gammarus aggregans, Leach; Gammarus muconatus, Say (Gammaracanthus muconatus, Bate, on which Smith remarks, "our species cannot be referred to Bate's genus Gammaracanthus, for the dorsal margin is not distinctly crenated, and the third, fourth, and fifth segments of the abdomen are furnished with fascicles of spines."); Monoceloidea, n. s.; Melita nitida, n. s.; Ampelisca, sp., pl. iv. fig. 17, undescribed; Stylop serrata, n. s.; Philochereus pinguis, Stimpson, which falls to Zaddach's genus Lepchoereus; Microchereus minor, n. s.; Astene, sp.; Amphithoe maculata, Stimpson, pl. iv. fig. 16; Amphithoe calvata, n. s.; Amphithoe longimana, n. s.; Amphithoe empira, n. s.; Pulex furcatus, Smith (Ceropus furcatus, Stimpson); Pulex, sp.; Ceropus rubricornis, Stimpson, pl. iv. fig. 18, which Smith later identifies with Eriochthonus difformis, M.-Edw.; Ceropus unicolor, n. s., presumably Eriochthonus minar, since in 1880, Smith attributes to the genus Ceropus tubularis, Say, as the only species); Ceropus tubularis, Say, subsequently identified without doubt; Ceropus ciliereo, Smith (Ceropus ciliereo, Say, not of Bate); Siphonoscytus capax, n. s.; Uuncia irritata, Say, pl. iv. fig. 19; Hyperia, species, "upon the large red jelly-fish (Cyanea)"); "another species of Hyperia was taken at the surface in company with Saufs," Phronima, species, "closely allied to the P. atlantica of Guérin. According to Professor Verrill's notes it is, in life, translucent, scarcely tinged with yellowish-white, and nearly invisible in the water; the eyes red. Another form allied to the last was taken with it, and is possibly the male of the same species, but differs from it, and from the characters usually assigned to the genus, in possessing well-developed antennae. In life, according to Professor Verrill, it was translucent whitish, the body spotted with dark brown, and the eyes blackish." Thyrocles, species; Caprella geometrica, Say, pl. v. fig. 20, which Mayer identifies with Caprella auctifrons, Latreille; Caprella, species.

In the addenda, p. 451 (745), is given, Themisto, species undetermined. "It occurred swimming at the surface in vast numbers, and was thrown up by the waves in windrows, extending several miles along the shores of Martha's Vineyard."

1874. Willemoes Suhr, Rudolph von.

On a new Genus of Amphipod Crustaceans. Received February 27,—Read March 6, 1873. Philosophical Transactions of the Royal Society of London. For the year MDCCCLXXIII. Vol. 163. London, MDCCCLXXIV. pp. 629-636. Pls. XLIX., L.

Thaumops pellucida, already mentioned in the Proc. R. S., 1873, but here figured and more fully described, was afterwards recognised as Cycloessa neptuni or neptuni, Guérin, 1842,
for which see Note under that date, and compare the account of *Oxinus spinosus*, Fabr., 1775. Some mistakes made in this paper were corrected in an appendix. See the following Note. The specimen was included in a haul made by the Challenger on January 28, 1873, when "the trawl was sent down, in lat. 35° 47', long. 8° 23', to a depth of 1090 fathoms." Among other points of interest Dr. Willemoes Suhm here mentions that the muscles of the thoracic legs are only very weakly developed, from which he infers "that the movements of the animal are not very rapid when it is obliged to walk over the sea-bottom." "The transparency of the body makes it possible likewise to distinguish clearly the cephalic ganglion and the ventral chain, consisting of five thoracic and three abdominal ganglia (Plate XLIX. fig. 1). The cephalic ganglion is situated in the anterior part of the head, more on the dorsal than on the ventral side; it is 3.50 millim. in width, and is horse-shoe-shaped with pointed ends. From the middle of its anterior margin two large nerves run straight to the end of the antenna, while from the opposite side two commissural cords run backwards, traversing the head and, after having encircled the mouth, uniting with the first thoracic ganglion. The nerves passing from the sides of the cephalic ganglion are all employed as ocellar nerves to supply the huge compound eyes. Those of the anterior end are better seen, as they go to the anterior part of the eyes, while those of the posterior end seem to go to the posterior parts.

"The first thoracic ganglion is seated just underneath the ovary in the second segment, and sends out the nerves for the mouth and the genital organs. The two cords then separate till they are united again in the third segment in the second ganglion; thence they run backwards in a single chain and form a ganglion in each of the subsequent segments, sending nerves to the legs. Altogether we find five thoracic ganglia for six segments, and in the abdomen three ganglia for five segments. The last ganglion of the abdomen is more slender than the preceding ones, and seems to send out nerves in different directions, especially to the anus and caudal appendages. In *Phronima* there are ten pairs of ganglia, five of which, as in the present case, are thoracic and five abdominal." Claus, 1879, it will be found, assigns only four ganglia to the abdomen in the Phronimidae.

The exocel appendage of the stomach, described by Claus for *Phronima*, "has, in the present species, assumed so large dimensions as to have replaced the stomach, which does not exist morphologically, but is physiologically represented by the cecum."

"The heart is an elongated tube extending from the second to the fifth segment (Plate XLIX. fig. 3, c). Probably there are three openings in it as in *Phronima*, one in each segment; but of these nothing could be made out.

"The respiratory organs consist of three pairs of small transparent sac-like gills at the bases of the second, third, and fourth pairs of feet (Plate XLIX. fig. 1, br). They are in form and number nearly the same as in *Phronima*.

"Genital Organs.—The single specimen taken is a female. There is a large ovary, distinguished by its rose-colour, occupying the middle portion of the first body-segment (Plate XLIX. fig. 3, or). I suspect that it consists of two ovaries lying close together, and having two excretory ducts leading to the genital papilla." "The genital papilla is an elevation in the centre of the ventral surface of the first thoracic segment between the two limbs [the first pair of ambulatory legs], which, as I have already mentioned, are destined to bear the eggs at their base, as in the females of *Nymphea*. The colour of the papilla is rose, with scattered scarlet points produced by small spines on the surface of the campana. In the centre of the genital papilla there is a large spine (Plate L. fig. 6, c) with a groove leading into a depression (c), in which I believe are seated the apertures of the ovarian ducts. This pit is protected by two soft appendages (Plate L. fig. 6, Ʉ), answering to the valves which are to be found in most females Amphipods, and in which they keep their eggs. In the present species, however, they are only rudimentary, and they do not seem to be
used for that purpose, as I found the eggs attached to the bases of the first pair of ambulatory legs."

The definition of the genus is given as in the "Proceedings," 1873. Willemoes Sulm thinks it nearly related to Phronima, but as "the genital papilla in Thaumops is in the centre of the first thoracic segment, while in Phronima it is in the seventh body-segment," and for other reasons, he thinks it cannot form a member of the family Phronimidae. In mentioning the seventh body-segment of Phronima, instead of the fifth, he was probably thinking not of the female but of the male.

Bovallius, 1886, says, "for my part, I am convinced that the specimen first described as Thaumops pellucida, must be ranged as a distinct species, which still may keep its [specific] name. The males described 1875 (l. c.) [Trans. Linn. Soc.] are perhaps identical with Guérin's species and may be placed there, awaiting a closer examination." This point, and others connected with the specific distinctions necessary to be established in this genus, will be more conveniently discussed later on in this Report.

1874. Willemoes Sulm, Rudolph von.

Since the preceding paper was read three males had been caught, the largest "103 millims, in length, exceeding in length the large female by 19 millims." "These males differ from the females by the absence of the genital openings at the base of the first segment and of the breeding lamelle. The two elongate testes begin just behind the caecum of the stomach, and their vasa deferentia run down to the last segment of the pereion, where they terminate by two simple openings between the last pair of pereiopods." "There is not a trace of a second pair of antennae, either in the male or in the female. In the former, however, the first pair of antennae, the five pairs of ambulatory pereiopods, and the caudal appendages are distinguished by the want of the glandular apparatus. In the females these glands cause an enlargement at the top of each of the appendages in question, and this enlargement is of course also wanting in the male." "The mandibles, which at first I thought were entirely wanting, have now been found. They are very much like those of Phronima, only shorter and not so elongate as in that animal; the palpus, which is present in the mandibles of the male Typhidae, could not be detected in Thaumops. The first maxille are also very small, and differ by their shortness from those of Phronima, but otherwise show the same characters. The second maxille could not be found with certainty; they are either wanting or represented by an organ which I thought was the labium (Plate L. fig. 6, lab). This organ arises from the second joint of a very peculiar appendage, which I have interpreted in my first paper as maxille (Plate L. fig. 6, ma). I am now satisfied, however, that these are the maxillipeds, consisting of three joints. Two of these joints are united together, the first being attached to the oral apparatus, and the second giving rise to a peculiar organ which consists of two chitinous claws united by a thin layer of the same substance, so as to form a sort of plate. I have already mentioned that I am not quite sure whether this is a labium or, as it seems more probable, the result of the displacement and union of the second maxille. This organ is situated at the inner side of the maxillipeds, the third joint of which consists of two strongly denticulated and separate claws. The two appendages (Plate XLIX. fig. 1, ma) which I first thought act as maxille are the gnathopoda of Spence.
THE VOYAGE OF H.M.S. CHALLENGER.

Bate, followed by five pairs of pereiopods. The plepods or swimmerets consist in the male, as well as in the female, of only three pairs."

He still thinks it represents a new family of Hyperidea, to be placed next to the Phronimae. It approaches the Typhida, he says, by "the elongate shape of the head, with the mouth underneath and the claws terminating the gnathopods. On the other hand, however, the want of the second antennae in the male, the elongate slender shape of its first antennae, which show nothing of the enlargement and the olfactory hairs peculiar to the male Typhidae, and the want of the pulps in the male mandible, show that it differs widely from the Typhidae."

He now defines it thus:

"Caput oblongum, ocellis maximis superiorum capitis partem tegentibus. Segmenta thoracica septem, abdominalia quinque. Antennarum in utroque sexu par unum. Mandibulae et maxillae minimae. Maxillipedia par unum conjunctum. Pedum thoracorum paria septem, anteriora duo parva et chells armata. Pedum abdominalium paria tria." There is no doubt, he says, that Thaumops pellucida is a pelagic Crustacean, retreating sometimes to considerable depths, and coming up only in the night.

1874. Willemoes Suhr, R. von.

This is a letter remarking that Thaumops pellucida "has been already described by Guérin-Méneville under the name of Cryptosoma neptun," and that the female caught in the Atlantic "had a length of 84 mm., not of 14 mm., as had been erroneously reported.

1874. Wrzesniowski, Augustus.

The new species is compared with "Callisoma Hopei and C. crenata," which it is said to resemble in the first and second gnathopoda, and in the coxae of the five anterior pairs of appendages, "but those of the fourth pair of pereiopoda considerably deeper than the ones appertaining to the fifth pair." "The basis in the fourth pair" of pereiopoda "considerably broader and higher than in the fifth pair." There are notches on the dorsal surface of the fourth and fifth pleon-segments. "Telson deeply cut, but single."

1875. Catta, J. D.

In this extract, Catta says, "en résumé, des Amphipodes normaux sont déjà représentés, dans le Golfe de Marseille, par une trentaine de genres, dont un au moins nouveau, et par soixante-dix à soixante-quinze espèces différentes. Six espèces nouvelles et deux variétés, de formes surtout adriatiques, donnent pour ainsi dire la physionomie de la faune locale."

The first species mentioned is "Iridium Rissoanum," for which the synonymy is thus established: Iridium jucundum, Grube, 1863, Phoxus rissoanus, Sp. Bate, 1862. Pereionotus testudo, Sp. Bate and Westwood, "ne saurait se distinguer d'I. Rissoanum que par la petite taille de ses yeux et par les dents qui garnissent le bord interne de son antenne supérieure. Ce sont là tout au plus des différences spécifiques; les deux Amphipodes appartiennent donc au même genre, et, comme la publication de Grube est de quelques mois antérieure à celle des auteurs anglais, Pereionotus testudo doit devenir aussi Iridium testudo." Professor Catta had previously said, "si on ne met pas en doute la description de Guerin de Monneville, le genre Phoxus doit rester pour ne renfermer uniquement que le P. servatus, dont le Pléon serait tout-à-fait normal." The question of the telson seems here to be left still in obscurity, unless we may presume that it is present, from the identification of the names given above, since, although Grube's Iridium is described as having "telson nullum," both Phoxus and Pereionotus are described with a telson. In my opinion Phoxus should be accepted as the generic name in preference to Iridium and Pereionotus. But of the two latter, Pereionotus, having been instituted in 1862, has the precedence.

"Pellocoena Marionii" (n. g.) is thus described:—

"Ce nouveau Crustace a été trouvé dans les fonds coralligères de la calanque de Podost. Sa longueur, du bout des antennes à l'extrémité du pléon, n'atteint pas 1 millim. Deux de ses coxas sont énormément développés et forment par leur réunion un véritable bouclier rond, large et bombé. Comme cette disposition se répète des deux côtés du corps, l'animal peut se rouler complètement entre ses deux armoires et ne plus offrir dans cette position que l'aspect d'une lentille microscopique. L'antenne supérieure, courte et trapue, est terminée par un singulier flagellum dont les articles décroissent très-brusquement et très-inégalement de diamètre. Je ne connais rien, chez les Amphipodes, d'analogue à cette antenne ; aussi est-ce avec quelques réserves que je rapproche ce nouveau genre de la famille des Stegocephalidae. Je dédie cette espèce typique à M. Marion." In 1880 Mr. Haswell instituted the genus Cyprioidea, with the species ornata and lineata, to which in 1885 I added an English species, dammonotoides. In 1882 Sars instituted the genus Stegophor, family Amphilocheidae. It is possible, or even probable, that Cyprioidea and Stegophor are synonyms of Pellocoena, but with so brief a description as the above, it is difficult to decide either as to genus or species.

Phoxus erythrourhodon, n. s., is said to come near "P. Hotbaldi de Krüyer," from which it differs, "surtout par la présence d’un œil très parfait de chaque côté de la tête." This eye, he says, does not disappear even when the creature has been long kept in spirit.

"Anonye Brochii," n. s., is said to be near "A. Edwardsii (Krüyer), dont il se distingue par la forme plus ramassée de l'antenne supérieure, par quelques particularités caractéristiques du cinquième siénapogone et par le telson, dont chaque moitié se termine par un poinçon très aigüe."

"Nica Pontica (Rathke oq)," is mentioned as belonging to Nicae, rather than to Hyale, because of Rathke's error in describing the last uropod as bifurcate. But this seems an insufficient reason for cancelling a generic name. It is noted that Czerniavski, though knowing Rathke's species, nevertheless institutes a variety of "Nicae Percevii," under the name of "Pontica."
"Nica Prevostii (H. Milne-Edw.)," is given, with "Amphitrite Prevostii," M. Edw., and "Nica Macrowea," Heller, for its synonyms.

Of Lophotaenia pallida, Sp. Bate, he confirms Sp. Bate's suspicion, that the telson is not only cleft, but double.

Of Microleptopoda anomala (Rathke), he thinks it probable that it is the female of Microleptopoda gyrifotalpa. He mentions Eurythoe erythropthalmus; Liphimella osea, Rathke; Ampelisa bella, Sp. Bate; Lewothoe denticulata, Costa; Lewothoe arenicola, Montagu; Moria truncatipes, Spinola, with which he thinks Heller's Moria sessilimana identical; Moria integrinana, Heller; Lysianassa anomala, Sp. Bate; Lysianassa spinicornis, Costa; and alludes to unnamed species in various other genera of Amphipods, which may be found in the gulf.

1875. Grimm, Oscar.

He collected 350 specimens of Gammarids, belonging to four or five species, some of them colossal forms.

1875. Heller, Camil.

A full description and figures are given of the new species Cleippides quadriceps and Anathillopsis spinigera. Some of the differences pointed out between Cleippides quadriceps and Acanthopus (Cleippides) tricolor, Krüyer, may be due to age or accident; it is highly improbable, for example, that the mandible in the one should possess an accessory cutting-plate and a spine-row, and the other be without them. These would rather be generic differences, of which there does not seem to be any question.

The new genus Anathillopsis has its definition included in the Latin description of the species:

"Corpus compressum, dorso carinato, carina segmentorum in spinas retroversas exuanti; epimeris parvis, rigidis, extrorsum flexis. Antenne superiores inferioribus longioribus, pedunculo elongato, flagello appendiculare brevi. Mandibulae robustae, in spicis dentatae, processu accessorio etiam dentato, palpo triarticulado, articulo tertio breviori quam secundo. Maxillae primi parvis laminae inteiiores lata, longa, in margine anteriore setis sex plumes instructa. Pedes maxillares laminae exteriore brevi, vix ad dimidium articulis palpi secundum elongatum porrecta. Pedes 1° et 2° parvis eadem formae, subcheliformes, non pervallici; articulo quarto et quinto longitudinie fere equalibus, carpo in angulo inferiore postieriore in processum parvum producto, manu ovali in margine inteiiori setis et spinis tenuibus instructa. Pedes trium parium ultiorum articulo primo sat anguste, pedes septimi parvis isidem parium duorum precedentium breviores. Caput rostro frontali
REPORT ON THE AMPHIPODA.

443

brevi instructum, oculi rotundati. Dorsum carinatum, omnis segmenta thoracis et quattuor segmenta postabdominis anteriors carina in margine posteroire in dentes acutos distinci. Angulus inferior posticus lateralis segmenti postabdominis 1st, 2nd and 3rd in dentem acutum productus. Pedes saltatorii ulteriori paris prolatae, rami laminiformibus, in margine spinulosis. Appendix caudalis obovata, usque ad dimidiam partem styli pedem saltatoriorum ulteriori paris recta, in margine posteriore sinuata." It is further remarked that this new genus stands between Amathilla and Gammaracanthus, that it has in common with Amathilla the compressed carinate body, the small similarly shaped subcheliform first and second gnathopods, and the simple emarginate telson, while it is distinguished from it by the elongated upper antennae, the presence of an accessory flagellum, the slender form of the first (femoral) joints of the three last pereopods, the elongate third uropods and the shortened third joint of the mandibular palp. With Gammaracanthus it agrees in the form of the antennae, in the shape of the first joints of the three last pereopods, as well as in the elongated last uropods. It is easily distinguished from it by the short rostrum, the feeble gnathopods, the form of the telson, the structure of the mandibles and mandibular palp, the strongly outward curved lateral edges of the pereon-segments, and the small inferiorly toothed side-plates.

It is rather doubtful whether this genus belongs to the Gammarinae, among which Heller in the above remarks seems inclined to place it. It seems to approach the subfamily Epimineae, Boeck, notwithstanding the minute secondy appendage to the upper antennae, in the presence of which it in fact resembles Amathilla as well as Gammaracanthus. An additional species, Amathillopsis affinis, from Franz-Josef Land, has been contributed to the genus by Mr. E. J. Miers.

Figures and descriptions are given of "Anonyx augenia Kroyer," "Aristias tumidus Kroyer," Onistius littoralis Kroyer," with some notes on "Arothoelepheia Martensii Gois," and some other known species. To Kroyer's Anonyx augenia, "Cancer ampulla Phipps" is given as a synonym, obviously only by a slip for Cancer augenia.

1875. LENZ, HEINRICH.

Seven species of Amphipoda occur in the inlet of Travemünde, Baltic. (Dr. von Martens, Zool. Record for 1875.)

1875. LOCKINGTON, W. N.

Of this paper P. Mayer, Caprelliden, p. 70, gives the following account, "Caprella spinosa. Lockington, from Hakodadi Bay, is distinguished by the considerable length of the male (body exceeding 1 inch, anterior antennae 1 inch long). From the description, however, nothing further can be derived, than that the author does not know the genera with more than five pairs of legs, and also that he takes no account of the mandibular-palp, etc. The species must therefore be considered indeterminate."
1875. Maitland, R. T.

The Amphipoda, pages 241-246, include the names and localities for species of Gammarina numbered 45-60, one of the Hyperina, 61, and Caprellina numbered 62-68. For 
Gammarus fluctuatus, Maitland gives the locality as "Onder steenen in een heelder stroomende vijver buiten de tolsteeg-barriere nabij Utrecht en in't Gein bij Abkoude." Of Gammarus puteus; Fabr., he says, "In groote menigte in bijna alle slooten en staaende wateren onder steenen en bulken, tusschen waterplanten enz. zeer gemene." Lysianassa, Edw., he naturalizes into Ljifjismas. "Amphiloe Jurini, Edw." he gives doubtfully. He retains the name Leptomera in place of the earlier Proto. "Caprella antennata, Edw. III, pag. 108, No. 3. Bate & Westw. II, p. 60," he also gives doubtfully, and likewise "Caprella obesa, v. Bened." Of "Sampylus tristis, v. Bened." he is doubtful. He closes the list with "Cyamus, Lam. 68, etit. Lin. Edw. III, pag. 113, No. 1. Bate & Westw. II, p. 85. Watervisschuis. Op een vinvisch, Balaneoptera rostrata, den 10 Dec. 1862 in 't IJ, nabij Zaandam, gestrand." It would have been interesting to have had some description of this Cyamus, since Lütken in 1873 says that "hitherto not a single species has been found on a genuine Fin-whale (Balaneoptera), although some Fin-whales, for instance B. Sinbaldii, have been the object of fishery, and the opportunity has been used for looking after parasites. See S. Hallas, Vidensk. Medd. fra dem naturhist. Forening for 1867, p. 162."

Among the Isopoda, after Amens is given on page 248, "Pterygocora Latr. 76. arenaria. Latr. Zandpissebed. Slabber, bl. 92, Pl. XI, Fig. 3, 4. Am de kust van Walcheren (Slabber.) N. B. Waarschijnlijk de larve toestand eener Idotea-soort." It is curious that in Slabber's own country he should not have accredited to him the specific name which he gave to this now well-known Amphipod, Haustorius arenarius.

1875. Martens, Eduard von.

Thaumatops is suggested in place of Thaumos as the name of the Hyperid (Cystosoma) [Cystosoma] described as a new genus by Willemoes Suhm. Hesse's Ichthyomyxa, 1873, is criticised.

1875. Metzger, A.

V. Zoologische Ergebnisse der Nordseeufahrt... X. Crustaceen aus den Ordnungen Edriophthalmata und Podophthalmata. Bearbeitet von Prof. Dr. A. Metzger in Münden. Hiezu Abbildungen auf Kupfertafel VI. pp. 277-310.

A list of Amphipoda is given, pages 278 to 281, numbering eighty-three species, with particulars as to place of capture, depth, nature of ground and geographical distribution. Species previously taken by Leuckart or by Metzger himself, even if not observed on the present expedition, are included. On *Amphithoe gibba*, R. Leuckart, the note is given, “Von späteren Forschern nicht wieder aufgefunden, oder doch nicht erkannt. Die L. c. [Frey und Leuckart, Beiträge p. 162] gegebene Beschreibung ist zu unvollständig. Nach der Übereinstimmung mit A. Rathkei zu urteilen, gehört die Art wahrscheinlich der Gattung Calliopus an.” See Note on Frey and Leuckart, 1847. Of *Gammarus elongatus*, Leuckart, he says, “Später, wie es scheint, noch nicht wieder aufgefunden.” He notices Boeck’s opinion that it may be *Mюрa longinana*, Thompson. He here gives Kröyer *arenaria*, late, with Boeck’s *Postorates norvegicus* as a synonym.

Fuller notes and descriptions of new species are given on pages 296-300. *Dulichia monacantha*, n. s., Tab. vi. fig. 8, is thus described:—

"Caput antice paulum productum et rotundatum. Epimerum primum in spinam longam productum, epimerum secundum margine posteriori rotundatum, margine interiore recto et parum modo productum. Pedes secundi parum multo longiores quam latiores, dentibul duobus instructae, dente postico longiore et acuminato. Pedes quinti et sexti parvis articulis terci longitudinem quarti et quinti junctorum vix superant. Pedes septimi parvis articulis quarto longiore quam quinto, articulo tercio prolongo, longiore quam primo. Pedes salutorii ulteriori paulum pedunculo vix diminutum longitudinem rami inferioris asquanti. Longitudine animalis c. 5 mm." It comes, he says, very near to *Dulichia pocata*. Of another *Dulichia*, spec. dubia, he had only a single defective specimen, a female with eggs. This he describes, as also the female of *Heda montrosa*, Boeck, in which his two species showed the first gnathopods larger than the second, having the hand curved, not with three, but only two teeth. He describes the tubes of *Siphonocrates eapitatus*, Metzger, as apparently very fragile.

*Bythid cruscorinis*, n. s., Tab. vi. fig. 9 is thus described:—

according to Buchholz, it is probably the young of *Tritropis aculeata*, Lepechin. He comments on *Stenoleuca marina*, Bate, *Stenoleuca monoculoides*, Montagu, *Metopa pollexiana*, Bate. He retains the last name, though agreeing with Bate and Westwood (vol. ii. p. 499), in the view that Kroyer’s *Lencoleuca elypeata* is probably the female of *Metopa pollexiana*. *Leureloperatum*, Bate and Westwood, distinguished, he says, from *Orchomenes*, Boeck, only by the want of an accessory flagellum, should find its place in Boeck’s arrangement of the *Lysianassina* just after *Orchomenes*. To supply defects in the original description of the genus, he gives the following:

“Alle Mundtheile von dem seitlichen Kopflappen und der erste Epimere bedeckt. Mandibeln viel länger als breit, an der Ellenförmigen oder flach-helmformigen Spitze ungefährth; Palpus sehr lang und schlank, 2gliedrig, Sörmig geschwungen und weit hinter dem elliptischen, nicht sehr hervortretenden Kaulpokker eingekeilt. Innere Lade (lohus interior) des ersten Maxillenpaares kurz und schmal, am Ende mit zwei Borsten; äussere Lade kräftig, an der Spitze mit ungleichen und unregelmässig zweiwöllig gestellten Zähnen; Palpus zweigliedrig mit feinähnlichem Endrand und hinter demselben schwach gerief. Maxillen des zweiten Paares mit schmälen und nicht sehr langen Läden, die äussere unbedeutender länger als die innere, beide nach den Enden zu mit Borsten bewehnt. Die hintere oder äussere Lade der Maxillarfüssse, welche eben über das dritte Glied des Palpus reicht, hat einen eonuierten Innenrand und ist hinter der Crenulation bogenförmig geriff; innere oder vordere Lade viel kürzer und schmäler, nur bis zum Ende des ersten, verhältnismässig starken, Pulpagliedreich, an dem schief abgestutzten Ende mit einigen kleinen zahnartigen Vorsprüngen und am Innenrande mit spärlichen Borsten bewehnt.” This is followed by a description of the species *Lepidoleperum curinatum*, Bate and Westwood.

*Callisoma krejci*, Bruzelius, was found in great numbers within dead specimens of *Echinocardium corvatum*.

Section III. is “Ueber die Crustaceenfauna der Nordsee diesseits und jenseits der Doggerbank,” pp. 306–309. From the Deutsche Bucht, 97 Crust. *Podophthalmata* et *Eidophthalmata* were known, of which 46 species were Amphipoda, from Northumberland a total of 167, of which 89 were Amphipoda, and of this 89, 41 were common to both districts. The five Amphipoda not known to occur from the Northumberland side were *Amphileuca gibba* and *Mylius flabellus*, from Heligoland; *Orchomenes pinguis* from the west coast of Norway; and the southern species *Medita palmata* and *Orchestia deshayesi*. Various speculations are entered into, to account for the facts of distribution so far as ascertained. The districts compared were “von Texel (Holland) bis Blavandseluk (Jütland)” and the Nordseegebiet “zwischen dem westlichen Abhang der Doggerbank und den Küsten von Yorkshire bis zum Firth of Forth.” Among the important relations of temperature it is said that “alle Wasserschichten der Nordsee diesseits der Doggerbank, oder, um die Lage genauer zu fixiren, diesseits einer Linie etwa von Scarborough bis zu südlichen Eingang in den Skagerrack oberhalb Honsholmen und Hirschal, im Monat August von der Oberfläche bis zu 20 bis 30 Faden nahezu eine gleichhohe Temperatur besitzen, während jenseits dieser Linie die tiefere Wasserschichten erheblich kühler bleiben als diejeniger der Oberfläche.” Among the species, six in number, named as likely still to be found in the Deutsche Bucht, “*Novia caudata*” is given, perhaps by mistake, for *Novia tuberculosa*, Sp. Bate, as it is accompanied by “*Novia multata*,” and Spence Bate’s two other species of *Novia* are recorded as actually found.

1875. The Micrographic Dictionary. London, MDCCCLXXV.

An article on *Gammarus* mentions the species *pales* and *flavialites*, adding that “there are twenty-three species of *Gammarus*, many of them marine.” It also names *Talitrus*
saltator as belonging to the Gammarina. The bibliography refers to Desmarest, Milne-Edwards, Gervais, Westwood, Bate and Westwood in the Annals and Magazine of Natural History.

1875. Miers, Edward John, born 1851 (E. J. M.)

"Lysianassus Kergueleni," n. s., is described. This species was subsequently transferred by Mr. Miers to the genus Ammoe. It was again found by the Challenger Expedition.

A new genus Paramora is thus defined:—"Superior antennae exappendiculate, but little longer than the inferior. Gnathopoda subequal, well-developed; dactylytes closing along the inferior margin of the palm. Posterior pair of pleopoda with the rami very unequal, the inner rami short or rudimentary. Telson cleft nearly to the base."

"This genus will apparently include Melita Fresnelii, Audouin, and Melita tenuicornis, Dana, which latter species is placed by Mr. Spence Bate provisionally in the genus Miera." The type species is Paramora australis.

In the August number of the Annals, p. 117, Mr. Miers changes the name of Paramora australis to Atylus australis, and in the Phil. Trans. Royal Soc. for 1879, he says, "it is probable that a separate genus will eventually have to be formed for the reception of the two species just mentioned [Atylus australis, Miera, and Atylus (Iphimedia) fischeri, Dana], and A. australis, Spence Bate. They differ from the normal species of the genus Atylus, as restricted by Boeck, in being destitute of dorsal carination, and in some other particulars. For A. australis I originally founded a new genus Paramora, allied to Melita in having the inner rami of the posterior pair of pleopoda short or rudimentary, but differing from it in the absence of an accessory appendage to the upper antennae. A subsequent examination of a series of younger examples showed, however, that my original types had sustained injury, the rami in question having been broken off and lost, and that in reality the inner rami are as well developed as the outer in A. australis. Yet though the genus Paramora is unavailable for A. australis, it will hold good for the reception of Melita tenuicornis, Dana ?., and Grananora Fresnelii, Audouin, mentioned at the time of its publication as apparently included in it; unless, as is probable, there be some error in the figures and descriptions published of these species."

In a letter dated October 19, 1885, Mr. Miers says, "I suppose the genus Paramora will hardly stand." The species Atylus australis is, I think, without doubt the same as that described by S. I. Smith, under the title Atylus (?) australis, Miers (?), of which Mr. Smith has very obligingly sent me specimens, which will be further noticed later on in this Report.

Podoerms ornatus, n. s., is briefly described, the length given being ½ inch, which is probably a misprint, as the length mentioned in the subsequent fuller report is 13 mm.

1875. Norman, A. M.

Among the animals found attached to the Falmouth-and-Lisbon telegraph-cable laid in June 1870 and taken up for repairs in the autumn of 1874, Mr. Norman mentions four Amphipoda; Amphithopsis lotipes (Sars), giving reasons for using this name in preference-
to *Calliope obsiana* or *Calliope jingalli*, Bate and Westwood; "*Gammaropsis erythrophthalmus*, Liljeborg = *Eurythros erythrophthalmus*, B. & W.;" "*Probolium* (=Montagna, Bate): fragment"; and "*Eupia phasma* (Montagna) = *Protilia phasma*, Bate."

1875. **Packard, A. S.**

At page 599, speaking of the embryo in *Oniscus* and *Aselbros*, he says, "The abdomen is curved up and backwards, while in the Amphipods it is bent beneath the body, as in Fig. 254, and this is really, as Fritz Müller observes, the only important difference between the embryos, at an early stage, of the two groups. The embryo Isopod at the time of hatching closely resembles the adult, there being no metamorphosis.

"The development of the Amphipods or beach fleas, is nearly identical with that of the Isopods. The eggs of certain species undergo total segmentation, while those of other species of the same genus (Gammarus) partially segment, as in the spiders, and in a less degree the insects, showing the slight importance to be attached to this matter, and that Haeckel's term *Morula* when used for the total segmentation of Crustacea is of little significance, how [ever] much it may be in the lower animals."

"Summary of changes:—

1. Segmentation of the yolk, partial, or total (Morula).
2. Nauplius state in the egg.
3. Larva hatching in the form of the adult with the full number of feet; no metamorphosis."

He refers to the works of E. van Beneden, Dohrn, Rathke, and Bobretzky, all concerned with the embryology of Isopods.

1875. **Powell, Ll.**

This species will be considered later on in this Report. It bears a strong general resemblance to *Phronima scolenterax*, Forskål, the distinction between the two being based on characters which are not very striking at first sight.

1875. **Rougemont, Philipp de**, born 1850, died 1881.

*Questio inauguralis; Die Fauna der dunkeln Orte*. München, 1875. 13 pp.

The author bases an argument on the relationship between *Gammarus pulex* and *Gammarus puteanus*. He makes the pungent observation that the errors which zoologists have made in the establishment of species during the last fifty years it will take a hundred years to correct.

1875. **Rougemont, Ph. de.**

The general structure of the Gammaridae is described and the sensory appendages discussed. The cylindrical appendages to the flagellum of the upper antennae are recognised, in
agreement with Leydig and contrary to the view of Spence Bate, as organs of smell. The fact that they are longer in the blind *Gammarus pulex* and *Asellus* from the wells than in *Gammarus pulex* and *Asellus aquaticus* is regarded as a natural compensation made to the former for their want of sight. To the plumose hairs at the base of the upper antenna, which Sara and others accept as auditory organs, like those described by Hensen for the Decapods, Rougemont disallows this function, on the ground that to the web-and cave-shrimps hearing would be of no particular service, and that in Amphipods neither auditory vesicle nor otolith has been discovered. He regards the hairs in question as ministering to the sense of touch, and were there any word to express something intermediate between the senses of touch and hearing, he would be willing to adopt it for the function of these organs.

He agrees with some earlier writers in ascribing to the cone of the antennary gland a sense of smell, and supposes, while the cylinders of the flagellum smell more distant objects, the cone takes cognizance of food approaching the mouth, an ingenious but highly probable suggestion. He mentions that Felix Plateau, who like Spence Bate recognised eyes in *Gammarus pulex*, briefly described these organs as "dreieckig mit sphärischen Winkeln, klein und pigmentlos." But de Rougemont himself had never been able to find any Krystallkörperchen, and is convinced that these animals cannot see and distinguish objects, though the light, penetrating their transparent skin to the culmen of the optic nerve, may produce a disagreeable impression, which leads them to prefer a safe obscurity.

1875. Schiodte, J. C.

Schiodte considers that the structure of the mouth in the Amphipoda offers three principal types, best distinguished by the connections which determine the movements of the mandibles. The first type belongs to the *Gammarus-Cavellina*-forms. Here the mandibles are short, three-sided, with broad triangular base, the outer angle of which is socketed by a short process in the pleural border of the head. On this process and the outer side of the shaft they have an oscillating movement, but being free from the special arrangements for regulating their movements which are found in the other two types, he calls this group Eltherognatha, defined by the formula, "Mandibula trigona, conchilo articulatorio antico curvato. Labrum planissculum, transversum, simpliciter." The lower lip he describes as having four comparatively soft cushion-like lobes and two more strongly chitinized and calcified horns directed backwards, stiffer than the cushions, yet yielding towards their free ends, so as to constitute a spring stiff enough to hold the mandibles up for their oscillation, yet elastic enough to yield to pressure, and which he therefore designates as "processus mandibularis labii inferioris."

The second type includes most of the *Lysianassina*, Dana. Here, in addition to the arrangements above mentioned, "from the front end of the shaft, on the upper side, in front of the palp, there issues a club-shaped, articular process, rounded at the end, which fits into a corresponding cup on either side of a saddle-shaped process on the palate, close behind..."
the upper lip, descending into the mouth-cavity." It is this arrangement in connection with the development of the upper and lower lips, that determines the scissor-like movement of the mandibles in this group, which he therefore calls Trocholognatha, thus defined, "Mandibulata producta, condylo articulario instructo antico, acetabulo epipharyngis accommodato. Labrum crassum, conicum, simplex." Of this group he considers that there are, as suggested by Kreyer, only two principal types, Anonyx and Opis, and as the first group correspond with the Oatesi, as defined by Schiodte, so this with the Circulans under the same limitation.

The third type includes the Hyperina, and because the outer lobes of the mandibles are pressed into a transverse furrow of the upper lip he calls this group Piezognatha, thus defined, "Mandibulata producta, condylo articulario antico carinato, mandis exterioris fossae transverse lobri accommodata. Labrum planiscatum, transversum, duplex."

As abnormal among the Eleutherognatha, the mouth-organs are described of Stegocephalus, Cyamus and Laphystius. The illustrations are taken from "Caprella septentrionalis Kr. sp."; "Laphystius Sturioni Kr. sp."; "Cyamus ovalis Ronn. de Vaux. sp."; "Anonyx Lagena Kr. sp."; "Stegocephalus Ampulla Kr. sp."; "Themisto libellula Mandt. sp."; "Anephyloma sp. sp."

The English reader will be glad to know that there is a translation of this highly important paper, "partly condensed with the sanction of the author," in the Annals and Magazine of Natural History, for September, 1876. The beautiful and elaborate plates of the original do not, however, accompany the translation.

1875. Simon, Eugène.

He enumerates and shortly describes several species of Crustacea living in caves, among them, "Niphargus subterraneus (Leach) = puticatus (C. Koch) aquilex and styxius (Schiodte), Carniolia, also in wells." (Dr. von Martens, Zool. Record for 1875.)

1875. Smith, Sidney I.

"Hyalella, genus nov." is here defined as in 1874, except that the penultimate segment in the maxillipod-palma is here said to be "longer than broad." Hyalella dentata, pl. i. figs. 3-6, is again described as "sp. nov." Hyalella inermis, n. s., pl. i. figs. 1-2, is described, "closely allied to the last species, but wholly without teeth upon the dorsal margin of any of the abdominal segments." On this, Faxon in 1876 says, "after an examination of a large number of Hyalella dentata and H. inermis from Utah, I am satisfied that they are but varieties of one species." The policy of coining, or retaining, names for varieties is open to question. Where the variation is not sufficiently important to be regarded as specific, it might well, in my opinion, be left without a special name. In the present instance it seems highly inconvenient to have a species named from a particular character, and a variety named from the absence of that very character. If it is impossible to retain both
names as specific, this would seem to be one of the rare cases in which original names might justifiably be changed on account of their inappropriateness. The difficulty, however, will not arise, if, as already suggested, the names may be considered synonyms of Hydella alvina, Philippi, 1860. Gammarus limnus, Smith, pl. ii. figs. 13–14, from "Lake near Long's Peak; elevation, 9000 feet," is described, and Gammarus robustus, n. s., pl. ii. figs. 7–12, from Wahsatch Mountains, Utah.

1875. Smith, Sidney I.

The Crustaceans of the Caves of Kentucky and Indiana. From the American Journal of Science and Arts, Vol. IX., June, 1875.

Stygoharum vitreus, Cope, from Mammoth Cave, is said to be really a Crangonyx, which should stand as Crangonyx vitreus (Cope). Crangonyx vitreus, Packard, from Indiana, is very different from Cope's species, but closely allied to Crangonyx gracilis, from Michigan, Lake Superior, etc., differing principally in the structure of the eyes. Since Packard's species in any case must yield its specific name, one is led by Professor Smith's account to regard it as a synonym of Crangonyx gracilis.

1875. Stebbing, T. R. R.

Bathyporeia pilosa, Lindström, is figured and described, with an argument to show that Bathyporeia pelagica, Sp. Bate, is the adult male, and "Bathyporeia robertsoni," Sp. Bate, a younger form of the male, of the same species of which Bathyporeia pilosa is the female. G. O. Sars, has expressed the opinion that Bathyporeia robertsoni is a distinct species. H. Blanc accepts my view.

1875. Stebbing, T. R. R.

In this paper a new species is described under the name Dexamine antarctica. This in November 1878 I transferred to Atylus on the ground of its likeness to Atylus gibbosus, Sp. Bate, and of its residing, like that species, in a sponge. Atylus gibbosus, however, having no palp to the mandibles, belongs not to the Atylinae, but to the Dexaminæ, and is made by Boeck the type of a new genus Tritata, which name he derives from the Greek Τριτάτα, without explaining why he introduces an additional letter into the Latinized form of it. My species will become Tritata antarctica, and will probably include as synonyms, Polycheira tenuipes, Haswell, from Port Jackson, and Polycheira obtusa, Thomson, from New Zealand.

Another new species, described and figured as "Seba Saundereii," is said to come from Algoa Bay, South Africa. In 1883, a new genus and species from New Zealand was described by Mr. Chilton under the name Tectaticum typicum. This is probably the same as my Seba saundereii. A specimen brought home by the Challenger was taken in the Strait of Magellan, so that the range of this little species in the south would seem to be very extensive.
1875. Willemoes Suhm, R. von.

In this letter, dated "H.M.S. Challenger, Cap York, in September 1874," under the heading "Die Thiere der Oberfläche," he says, "Die Crustaceen traten namentlich auf der Fahrt von den neuen Hebriden nach Cap York massenhaft auf, doch fangen die Euphausiden, die bei den Fidschi-Inseln noch geheim waren, an, seltener zu werden.—Namentlich schön war die Ausbeute an Stomatopoden Decapodenlarven und an Hyperiden. Von letzteren waren diesmal nicht nur Hyperia, Phronima, Cylopus, Cyprisoma, und Ozycephalus sondern auch Rhabdosoma vorhanden, die abenteuerliche langgestreckte Typhida, die wohl zu den seltensten Bewohnern der Oberfläche gehört, da es uns bisher noch nie gelang eines Exemplars derselben habhaft zu werden."

1875. Willemoes Suhm, R. von.

The part of the paper referring to the Amphipods is on pp. 24–26, under the heading "On Cystisoma Neptunus (Thaumops pellucida)." (Pl. XI. figs. 4–8). Willemoes Suhm here objects to supposing that the antennæ in Cystisoma represent the second pair, an opinion which he wrongly attributes to Guerin-Meneville. "Against a union of Cystisoma with the Hyperhids may be advanced," he says, "besides the form of the head (which is more Typhida-like) and the absence of the second antennæ in both sexes, the absence of a palpus on its mandible. (Pl. XI. fig. 6). The palpus is always present, according to Claus, in Hyperids, but is wanting in Phronimidae." (But on this last point see Note on Claus, 1879.) "The male," he says, "differs by the absence of glands at the top of nearly all the appendages, especially in the last pair of pereiopods, which, according to this, have not the same clumsy appearance as in the female. The two testes begin just behind the stomach (fig. 5, t), and send vasa deferentia to the last segment of the perizon, where two simple genital openings are to be seen between the last pair of legs (fig. 5, a, g)." He further says somewhat mysteriously, "probably (as in Phronima) the full-grown male is somewhat smaller than the female; it seems that Cystisoma Neptunus can attain a very considerable size; for the last and largest male which we got in the trawl has a length of 103 millim. This male is the largest specimen of Cystisoma as yet on record, so that the probability that the female grows still larger seems to be but slight. The figure 4, apparently of this specimen, is drawn rather less than life-size, although the "Explanation of Plates" gives it as "Nat. size."

1876. Bate, C. Spence.

Referring to his earlier report, in 1855, Mr. Spence Bate says that in the present report he is desirous "to show—that the epimera, as sectional pieces in a theoretical construction of a
somite, cannot exist; that the so-called epimera are portions only of the integumentary structure of the appendages of the animal, and that the apodema are formed out of this structure, more or less thinned out by lateral pressure and internal arrangement; and that the head of the lower types and carapace of the higher are homologically the same, the carapace being a monstrous development intended for the covering and protection of the more complicated branchial appendages of the higher types" (p. 47). On page 41 it is stated that "the third pair of maxillipeds in the Brachyurous Crustacea are identical with the first pair of walking-legs in the Stomatopoda, Amphipoda, and most of the Isopoda." But, at least as regards the Amphipoda, second gnathopods must have been intended instead of the first pair of walking legs.

1876. Boeck, Axel.

A preface in French by Hakon Boeck explains that, when Axel Boeck died in May 1873, he left his Manuscript almost complete, but the figures not in all cases named. This deficiency Hakon Boeck had to supply to the best of his ability. In regard to the synonymy he was obliged to depend in part, he says, upon the data supplied by Bate and Westwood. His editorial task must have been one of no slight difficulty, and he deserves the gratitude of the student for his labours.

At page 190 is given Opies, new genus, thus defined:—
"Mandibulae palpo profundiis quam tuberculo molari affixo. Maxille 1mi pars lamina interiore angusta, non longa, in apice sutas duas plumosas gerenti. Maxille 2di pars laminis angustis, non vero longis. Pedes maxillares laminae exteriore elongata, angusta, in margine interiore denticulata instructa; fore ad lineam articuli palpi brevis 3ti orrecta; articulo palpi 4to unguliformi. Pedes 1mi pars manu permagra, inflata, in angulo inferiore antico producta et acute. Appendix caudalis prolongata, profunde fissata." Krøyer's name for this genus, Opis, was preoccupied.

For Opis leptochaeta, Bate and Westwood, 1868, Boeck here proposes a new genus, to be called Leptochelea, of which he says, "I Munddeleens Bygning afviger deu ikke saa meget fra slegten Anonyx, men dog iar derved, at Kjøbeføderernes ydre Padder ere temmelig smalle og væbnerde med smaa Tænder istedetfor Knuder paa den indre Rand. Springføderne ere forlængede, og Halvedehaaget er særdeles langt, dybt klovet." By the structure of the first gnathopods it approaches, he says, the Oeclerineae. Besides that Leptochelea contravenes the rule against adopting a specific name as generic, it falls as a synonym to the earlier Eunymp, Norman, 1867.

The Iphimellae are accidentally introduced at page 235, as Subfamilia V. of the Gammaridae, instead of coming later as Subfamilia VII. of the Lecithideae. Among these the first genus is Acanthostrœma, A. Boeck. This name supersedes the earlier Acanthonous of Owen and Vertmann of White, both of which are preoccupied. Acanthostrœma itself might have been presumed to be an accidental misspelling or misprint for Acanthostoma, but that it occurs several times without variation. It is thus defined:—
"Lobium superior proelongatum. Maxille 1mi pars palpus 2articulato; articulo 1mo longo; laminae interiore per magna, triangulares, multis setis plumosis instructa. Pedes maxillares palpo robusto; articulo palpi ultimo parvo. Pedes 1mi et 2di pars graciles, manu subcheliformi destituti; articulo 5to 1mi pars prolongato, gracili; ungve in margine postico perserrato. Corpus compressum; epimeris magnis, rigidis."
In the Subfamily Dexamines, for his genus Lampra, 1870, a preoccupied name, Boeck now gives "Tricera. n. g." It is thus defined:—

"Pedes maxillares lamellis exterioribus angustioribus, valde curvatis et modo in summo dimidio spinis punciis validis armatis; laminis interioribus latioribus et longioribus quam apud genus Dexamine, spinis multo curvatis et gracilibus armatis. Epimera minima; epimera quattuor anteriores uno non aliora, in margine inferiore armata. Pen quinque parium ultirernum articule 4to et 5to perbrevibus; uagve parvo." The type is Mythis gibbusus, Sp. Bate.

In his notice of the genus Hoploos, Liljeborg, Boeck says, "Hos denne Slægt fandt jeg først og nøjagtig undersøgt den ciendommelige Halsring, eller rettere Øjophagingsring, som ligger indenfor Løberne og er saaleden den indernste og en constant Del af Tygeapparatet."

1876. Catta, J. D.

From some Algo attached to a vessel, which had come from India round the Cape of Good Hope into the harbour of Marseilles, were taken a group of Crustacea. Among others there were specimens of Probolium polygryon, A. Costa, and Amphithoe penicillata, A. Costa. Professor Catta gives a full description and figures of Probolium polygryon, showing that Probolium megachelis, Heller, cannot properly be distinguished from it. He applies the rather inconvenient nomenclature of 1st, 2d, 3d, 4th, and 5th siagonopodes respectively to the first and second maxilla, the maxillipeds, and the first and second gnathopods. Both in the description and figures, however, it is clear that the premier siagonopode represents the second maxilla, and the deuxième siagonopode the first maxilla. The "saille très-volumineuse, arrondie et surmontée d’un long pêl cylindrique" given as part of the "premier siagonopode" is probably the base and inner plate of the first maxilla. The palp or "pièce exténe" of the "deuxième siagonopode" (first maxilla) should no doubt have been represented as two-, instead of one-jointed. The species should moreover have been assigned to Stenothoe, Dana, as the mandibles are without palp.

Under the heading, Amphithoe penicillata, Professor Catta investigates the relationship between "Amphithoe Dermarestii," Sp. Bate, and Amphithoe penicillata, as described first by Costa and then by Heller. He points out that the figures given by the Italian and Austrian authors do not correspond with their descriptions. Carefully figuring and describing the second gnathopod of his own specimen, he decides that the species "Dermarestii" of Bate must be united with penicillata of Costa. In my opinion the name must be carried back a step further to "Amphithoe Valiantii," Lucas, 1849, in which the hand of the second gnathopods "est profondément échancré à son bord inférieur, et qui, à la naissance de cette échancrure, est armé d’une épine forte et très-saillante." Costa describes this mand "col dorse prolongato un poco al di là della inserzione dell’unghia; il margine unguicolar assai obliquo ed a curva rientrante; il margine dorsale ornato di lunghi peli, che all’estremità formano un folto pennello." Sp. Bate gives it in his species, "ovate, the upper margin furnished with four or five fuscunci of hairs; palm oblique, deeply concave, defined by one or two short spines." When it is remembered that in the species of Amphithoe, the second gnathopod varies with age and sex, but little confidence will be felt in the multitudinous species at present established on subtle distinctions, referring to the shape of the gnathopods, the length of the antenna, the colouring of the animal, or perhaps even the locality in which it was captured.
1876. Claus, C.

1876. Faxon, Walter.

Of the Crustacean fauna of the lake, Mr. Faxon says, “excepting a species of Cypris, all the specimens collected belong to one amphipodous genus, Allorchestes, which had hitherto afforded but one or two authentic fresh-water species, ranging from Maine to Oregon and the Straits of Magellan. Seven new species are described in this paper from Lake Titicaca. Several of them are remarkable among the Orchestidae for their abnormally developed epimeral and tergal spines. Some are also noteworthy as comparatively deep-water forms of a family commonly regarded as pre-eminently littoral.”

The genus Allorchestes is thus defined:—“First maxille with small unarticulate palpi. Palpus of the maxillipeds composed of four segments, the distal segment usually bearing a movable spine at its apex. First antennae shorter than the second antennea, longer than the peduncle of the second antennae. First and second thoracic legs subcheliform. Propodite of second pair larger than propodite of first pair, and much larger in the male than in the female. Telson short and entire.” Hyalella, Smith, 1874, is given as a synonym. My reasons for preferring Hyalella to Allorchestes are given in Note on Ratske, 1837. Mr. Faxon describes Allorchestes armatus, n. s., figs. 1-18; Allorchestes echinus, n. s., figs. 19-21; Allorchestes longipes, n. s., figs. 22-25; Allorchestes lucifugus, n. s., fig. 26; Allorchestes latimanus, n. s., figs. 27-28; Allorchestes longipalume, n. s., figs. 29-31; Allorchestes capreus, n. s., figs. 32-34. He also figures Allorchestes dentatus, var. inermis, fig. 35, for Hyalella inermis, Smith. Of his specimens he says, “they differ from specimens from the United States in having a firmer and less transparent shell, and a little differently shaped propodite to the second pair of thoracic legs in the male; hardly enough to warrant the establishment of a new species when one considers the variability of the species within the limits of the United States.”

In a note Mr. Faxon says, “Among the Crustacean collected by the Thayer Expedition in Brazil are two species of Allorchestes. One is represented by a unique female specimen taken from a canal at Campos by C. F. Hartt. It differs from A. dentatus, var. inermis, only in the second pair of antennae, which are half as long as the body only and twice as long as the first pair; flagellum composed of thirteen segments. Length of body, 4 mm. In the absence of more specimens, I would consider this a variety (gracilicornis) of Allorchestes dentatus,” fig. 36. “The second species is represented by several specimens. It may be called Allorchestes longistilus, sp. nov.” Fig. 37. “Differs from A. dentatus, var. inermis, in its slenderer body, longer antennae, and especially in the length of the third pair of caudal stylets.”

Records Crangonyx macronatus, n. s. See Zool. Record.

1876. Fries, S.

1876. Giard, Alfred Mathieu.

"Urothoe marina presents a strongly marked sexual dimorphism. The most striking character of the male sex is the length of the inferior antennae, which greatly exceeds the superior ones. It is well known that it is a character of the same kind that distinguishes the male Hyperia (Lestrigon) from their females." Judging from the antennae, as figured by Spence Bate, he argues that "Urothoe Bairdi and Urothoe elegans must be regarded as representing male individuals; while Urothoe brevicornis and Urothoe marina are, on the contrary, figured from the female sex."

1876. Hoek, P. P. C.

In all seven Amphipoda are enumerated, none new.

1876. Humbert, Alois.

Humbert assigns the first discovery of well-Amphipods to the year 1835, in point of time, and for the persons, to Gervais and Koch, but Leach's Gammarus subterraneus, which he after-
REPORT ON THE AMPHIPODA.

wards mentions, is earlier. Schielote followed with his Niphargus from the caverns, and then new species of Niphargus and even new genera allied to it were discovered in wells, caverns, and in the sea. "Finally, in 1869 M. F. A. Ford indicated for the first time the existence of blind Gammaridae (Niphargus) in the depths of the Lake of Geneva, and in 1873 he found the same animals in the Lake of Neuchâtel."

After mentioning the different species belonging to Niphargus and its synonym Eriopis, and the Crangonyx subterraneus of Sp. Bate, he reviews the work of de Rongemont, with whose conclusions he is unable to agree. He has himself found forms agreeing with none of the six described by de Rongemont. One of these, from the Lake of Geneva, he calls "Niphargus putucus, Koch, var. Forelli"; the other from a well at Onez, in the environs of Geneva, he calls Niphargus putucus, var. mediocres. In the species of Niphargus he has examined, he has "been unable to perceive the least trace of eyes or even of a deposit of pigment."

He minutely describes, and gives the name of sensitive capsules to, the very small organs on the dorsal parts of the segments already noticed by de la Valette. These he finds also along the anterior margin of the head and on the first two joints of the peduncle of the superior antenna. On the antenna he enumerates sensitive setae, olfactory cylinders, sensitive capsules, olfactory setae, and hyaline bacilli. The last he describes; he says that they "perfectly resemble those figured by Sars upon the joints of the outer branch of the superior antenna of Mysis ornata. He thinks that Jarschinski may refer to them in his paper (in Russian) On the Leydigian organs of the antenna of the Crustacea Amphipoda, 1868.

As to the idea of practically making Gammarus pulex one and the same species with those assigned to Crangonyx and Niphargus, he points out that, "in the Gammarus proper the last pair of saltatory feet are biramous; Gammarus pulex even has the two branches nearly equal. The Niphargi have these branches very unequal, but both of them still exist. In Crangonyx, on the contrary, there is only a single branch." Also the telson "is double in Gammarus, of a single piece but deeply cleft in Niphargus, and completely entire in Crangonyx." He believes that Niphargus is an ancient genus descended from a form now extinct.

1876. MAITLAND, R. T.

Determinatie der dieren beschreven en afgebeeld in de werken van JOB BASTER en MARTINUS SLABBER. Tijdschrift der Nederlandsche Dierkundige Vereeniging. Tweede Deel. 'S Gravenhage & Rotterdam, 1876. pp. 7–15.

For Baster's work he gives in 1st Deel, "Tab. IV. Fig. II. Caprella linearis, Latr.," in II Deel, "Tab. III, Fig. VII. VIII. Orchestes litoreus. Leach." For Martinus Slabber, he gives "Tab. X, Fig. I. 2. Leptoneura pedata. Mull.," and "Tab. XI, Fig. 3. 4. Pterygoeca arenaria. Latr. (door v. d. Hoeven de soort ongedetermineerd gelaten)." See Notes on Baster, 1759, 1762, and Slabber, 1769.

1876. MAITENS, EDUARD VON.

(zool. chal. exp.—part lxvii.—1887.) XXX 58
1876. **Miers, E. J.**

**Catalogue of the Stalk- and Sessile-eyed Crustacea of New Zealand.** London, 1876.

Dana’s classification, with some slight alterations and additions, is adopted in the catalogue. The Amphipoda occupy pages 117–130. The genus *Paramorpha* is provisionally retained for Dana’s *Melita tenacicornis*. No new species are described, but, as was reasonable to expect, and as Mr. G. M. Thomson recognises, the publication of the Catalogue gave an impulse to the study of local zoology in New Zealand which has produced many excellent results.

1876. **Miers, E. J.**

The species in question is named “*Talitrus Gulliveri*” after Mr. Gulliver who found it.

1876. **Norman, A. M.**

No new Amphipoda are recorded, but Tables are given showing that the “Valorous” brought home from Greenland and Davis Strait 39 species of Amphipoda, of which 12 were previously known as North-American, 32 were known as European, 9 were known as British, while the total number of species brought home by other British Arctic Expeditions had been 18. 6 species were brought by the “Valorous” from the North Atlantic, its total of Amphipod species being 42.

1876. **Rougemont, Ph. de.**

See Notes on Rougemont, 1875.

1876. **Sars, G. O.**

The new Amphipods here described are:—103. *Liljeborgia aquicornis*; 110. *Pensione eucanthus*, with the observation “P. pulchello Kr. affinis sed diverso dorso toto carinato et spinoso, spinis multo majoribus,” subsequently called *Paramphithoe eucantha*; 116. *Halirages quadridentatus*, with the remark “H. tridentato affinis, sed major et diversus spinis dorsalibus 4, oculis multo majoribus, antennis et pedibus magis elongatis, segmento 3°
postabdominis in margine postico non serrato;" 117. Amphithopsis pulchella, "A. latipedi M. Sars affinis sed diversa segmentis postabdominis non carinatis nec spinosis, antennae superioribus longioribus, pedibus angustioribus;" 119. Muria tenella, a name preoccupied by Spence Bate for the still smaller Gammarus tenuellus of Dana, and since changed to Muria tenella; 134. Dalichia birthisoriae. 131. Glaucomone planipes, Norman. is given, with the following notice, "Unciola planipes, Norman, Report of deep-sea dredging off the coast of Northumberland and Durham," pg. 3, Pl. VIII. fig. 9–15.—Specimina observata a forma typica differente manu pedum 2° paris elongato-quadrangulari carpi longitudinem aequante adyve apicem fero ad lineam rectam truncata, antennae inferioribus maris structura valde singulari, articulo pedanueli penultimo et antepenultimo insolito modo dilatatis et complanatis articulationem mobilissimam inter se formantibus." This, in 1879, is given as a distinct species, Glaucomone petalocera, and in 1885 is renamed Unciola petalocera. 137. "Caprella borrida, n. sp. (= Caprella spinosiissima Norman, non Stimpson)" has been already mentioned in the Notes on Stimpson, 1854, and Wyville Thomson, 1873. It is clearly not an Aegina, since Sars expressly describes it as having "Mandibulae palpe carinatos." In 1885 he names it Caprella spinosiissima, Norman. For his reasons see Note on his work of that date.

1876. Smith, Sidney I.

The Amphipoda include Hyale villorum, n. s.; Lysianassa kibleri, n. s., in which "the antennule, mandibles, second maxille, maxillipeds; and posterior uropods are more like some of the species of Orchestes than they are like the species of Lysianassa, as described and figured by Boeck, and the characters assigned to Lysianassa by this author would require considerable modification to admit our species." Lysianassa kergueleni, Miers, "is quite a different species, and not a Lysianassa," having the first gnathopods subchelate. Lastly, Professor Smith describes "Atlus (?) australis, Miers (?)," with references to Paramura australis, Miers, and ? Atlus australis, Miers. Dr. Kidder's specimens have "minute secondary flagella upon the antennule." "This species cannot be referred to the genus Atlus as restricted by Boeck." It will be discussed among those brought home by the Challenger.

1876. Stebbing, T. R. R.

The species here figured and described as new, under the name Microdeuteropus bidensatus, is probably at most not more than a variety of Austroco longipes, Lilljeborg. Notes are made upon Acidostoma obovatum, Lillj.; Krügerina arenaria, Sp. Bate.; Lilljeborgia normanni, which is a synonym of Cheirocratus sandevalli, Rathke; Melida glutiosa, Sp. Bate.; Proto goodforsir, Sp. Bate. It is remarked that the last species possesses two pairs of styliform appendages of the pleon, not a single pair as Spence Bate had stated. It is further suggested that Proto goodforsir is a form of Proto pedata, Leach. This suggestion is confirmed by Mayer, who unites them as synonyms of Proto ventricosum, O. F. M.
1876. Stebbing, T. R. R.

The species named in the Brit. Sess. Crust., "Allochrestes Nilsonii," Rathke, and "Nicea Lubbockiana," Sp. Bate, are here called respectively "Hyale Nilsonii," and "Hyale Lubbockiana," Böeck's view being accepted that *Allochrestes* and *Nicea* are both synonyms of the earlier *Hyale* of Rathke. Böeck's opinion that the two species in question are also identical is rejected. I am at present inclined to believe that *Hyale Lubbockiana* is a synonym of *Hyale pontica*, Rathke. Under the heading "Anonyx serratus*, Böeck," the suggestion is made that *Orchomene pinguis*, Böeck, *Orchomene serrata*, Böeck, and *Orchomene minutus*, Krøyer, are but one species, which might be retained in the genus *Anonyx*. It is proposed that "Anonyx Edwardsii" and *Anonyx minutus* of the Brit. Sess. Crust., i. pp. 94, 108, should fall to the same name. G. O. Sars decides, in 1882, that *Lysianassa longicornis*, Sp. Bate, and "Anonyx Edwardsii," Sp. Bate (non Krøyer), are respectively the male and female of one species, which he names "Orchomene Batei;" but the first gnathopods of the species which Spenke Bate accepts as *Lysianassa longicornis*, Lucas, will not admit of this identification. The male specimen which I have described in this paper is no doubt "Orchomene Batei," Sars.

"Probolium Spence-Batei," n. sp., is described and figured, but as nothing is said about the mandibles, and the specimen itself has perished, the true position of this species must remain indefinite. It may possibly belong to *Amphilochus*, rather than either to *Stenothoe* or *Metopa*, to one or other of which species of *Probolium* are generally synonymous.

Some notes on *Urothoe* are given.

1876. Stebbing, T. R. R.

*Amphilochus constrictus* is described as a new species, but as subsequently explained in the Annals for November 1878, it is probably identical with *Amphilochus mansulcns*, Sp. Bate, though differing to some extent from that author's account of his species. Meinert records it from Storebelt. *Danaia dubia*, Sp. Bate, is figured and described. *Calliomerus acutifolius* is described and figured as a new genus and species, but this is subsequently cancelled in the Annals for November 1878, as being a synonym for *Amphilochus mansulcns*. *Eunana stilipes*, Norman, 1868, and *Cratippus teniiipes*, Sp. Bate, 1882, are compared, the conclusion drawn being that the genera are the same. No doubt the species are also identical. *Calliomerus pusilla*, a new genus and species described by Grube in 1861, bears a strong resemblance, and in regard to the generic name, *Calliomerus* supersedes both *Cratippus* and *Eunana*.

1876. Willemoes Suhr, Rudolf von.

Preliminary Report to Professor Wyville Thomson, F.R.S., Director of the Civilian Scientific Staff, on Observations made during the earlier part of the Voyage
of H.M.S. Challenger; and on Crustacea observed during the cruise of H.M.S. Challenger in the Southern Seas. (Read March 16, 1876.) Proceedings of the Royal Society of London. Vol. XXIV. London, MDCCCLXXVI. pp. 569–592.

On page 576 he refers to the capture of "a large female of Cystisoma Neptunus," on the way from Gibraltar to Madeira. In the "List of the land animals collected in the Tristan d'Acuña group," for Crustacea, he gives, p. 585—

"1. Oniscus, everywhere under stones; 2. Gammarus, everywhere under stones."

After describing, page 587, a gigantic ostracod brought up by the deep-sea dredging between

Prince Edward Island and the Crozets, he says, "this is not the only example, however, of gigantic forms in the deep sea, for the same trawlings brought up two specimens (from 1375 and 1600 fathoms) of a Gammarid Amphipod, the larger of which has a length of 60 millims, and a height of 35 millims. Though we now know that certain Hyperids (Cystisoma Neptunus, both sexes of which we found in the Atlantic, and described in the Phil. Trans. 1873; see also Trans. Zool. Soc. 1875, 2nd ed. Zool. i. p. 24) attain the considerable length of more than 4 inches, these transparent and elongated animals do not make such an impression as the Gammarids, which are besides in no way peculiar, being perfectly normal, and approaching perhaps most the genus Typhimedia. I shall therefore give later a more accurate description of them, and here only direct attention to the fact that in the deep sea, as well as in the sedimentary strata, animals are found which, compared with their relations living now-a-days, and in shallow water, are of a very considerable size; and I may perhaps best in this place add that in this dredging of 1375 fathoms a Nymphoid (Pycnogonid) was got measuring nearly two feet across the legs." The Gammarids referred to I have described under the name Andania gigantea. The genus Typhimedia is probably an error for Iphimedia.

On page 589 he says, "In Kerguelen Island, where we stayed nearly a month, much shallow-water dredging took place in the different harbours, most of which was done by Professor Wyville- Thomson himself, while I was on shore collecting the land animals of the place. There is no Gammarus with terrestrial habits nor any Oniscus to be found in these barren islands, animals which still exist on the Tristan d'Acuña Islands." Nevertheless, for Amphipods found on the rocky heaths of Kerguelen, see Note on S. I. Smith, 1874.

On page 590, he says, still referring to Kerguelen, "the Crustacea inhabiting the shallower water are several species of Serolis, Spharoma, Arturus, some Gammarids, several species of Caprella, one of which has a very slender and long manus, and some Pycnogonida. There is scarcely anything interesting to be found in that zone [going from a few fathoms down to forty]. In the second zone [40–120 fathoms] of deeper water (though not deep-sea fauna, which we scarcely ever have found in less than 500 fathoms) we had a richer harvest; Tanais and Pronus, very curious Amphipods, Mysids, and Nebalia are the inhabitants, about which I shall now say a few words."

The long-handed Caprella is no doubt the species since named Dodosea elongata.

In this second zone, with a larger species of Serolis, "an Amphipod occurred, a Gammarid, distinguished by a bright red frontal prolongation of the head and having no eyes. These I first thought might be discovered in some form or other in the red prohoscis; but my expectations were not justified by the results of the dissection. The organ is divided by a line along its top into a right and left portion. The chitinous layer has got no facets, and the whole organ is filled by a finely granulated red pigment. What its function may be I cannot say, having never met with anything like it." This is no doubt the species named Ediceropsis vestreata, in the Annals and Magazine of Natural History for March 1883, but transferred to a new genus, Ediceroidal, in this Report.

On page 591 he says, "between Kerguelen and Heard Islands we dredged in 150 fathoms, but
got only a Scalpellum, an Arcturus, and a spiny Amphipod, which is the corresponding
form to the Gammarus borealis of the North. Near Heard Island, in 75 fathoms, we
found the same animal and a Sphaeroma, but no other Crustacea at all." The spiny
Amphipod is named in this Report Acanthochinus tricarinatus. I have seen no second
specimen of this striking species, but as Iphimelia pulchridentata was dredged in 75
fathoms near Heard Island, it is probable that on a cursory inspection this species was
mistaken for the other.

1877. Bate, C. Spence.

Report on the present state of our knowledge of the Crustacea. Part I. On
the homologies of the dermal skeleton (continued). [From the Report of the
British Association for the Advancement of Science for 1876.] London, 1877.
Plates II. & III. pp. 75–94.

At page 81 Mr. Spence Bate says, "the fact that the supposed side-plates, or epimera, were
merely the first joint of the normal legs or appendages has been satisfactorily demonstrated
in the Edriopthalinae, as far as relates to the somites of the pereion; but hitherto the
relation of the side-plates of the pleon to the normal condition of the mobile appendages
had not been demonstrated until the structure of the dermal anatomy of the genus Apsenodes
had been made out. [Hist. Brit. Seaside-eyed Crust., vol. ii, p. 146 (Apsenodes)]; that 'one
interesting and, as far as we know, unique feature in these Crustacea yet remains to be
noticed. The segments of the pleon have the lateral walls (long known as the epimera
of Milne-Edwards, called also the pleura by many authors) existing as articulated appendages,
demonstrating two important features in the homologies of these parts: 1st, that they are
all really portions of the appendages, being the first joint or coxae of the pleopod . . .
and 2nd, that, since the peduncle consists of three joints, the second branch in the appendages
of the pleon, as in other parts, is shown to take place invariably at the extremity of the
third joint.' " It seems to me, however, that the force of this argument is weakened or
destroyed, by the fact that numerous species of Apsenodes have now been examined and
described by various authors, and in regard to no one of the species has any author followed
Mr. Spence Bate in speaking of the epimera of the pleon as articulated.

As a curious fact in comparative carcinology, Mr. Spence Bate observes, that "contrary to a
possible condition of all other appendages, the coxal joint of the first pair of antennae is never
absorbed into or fused with the sternal portion or ventral arc of the somite to which it
belongs" (p. 85). Numerous allusions to the Amphipoda occur, as might be expected, in
different parts of this memoir.

1877. Chatin, Joannes.

Recherches pour servir à l'histoire du batonnet optique chez les crustacés et les
Paris, 1877.

A list is given of earlier works bearing on the subject. In regard to the cône, "cette pièce
généralement brillante et réfringente qui surmonte le batonnet optique dans les Arthropodes,"
he says, "La forme du cône est, de tous ses caractères, celui qui présente les variations les
plus nombreuses et les plus considérables. Il est en général prismatique chez les Tylon,
Epineria, Lichomolgyus; ovoide dans les Eupagurias, Paguristes, Caprellia, Notopterophorus;
pyramidal chez les Cypriolina et Lysianassa; claviforme chez les Isza; cylindro-conique dans certains Squilla, etc."

1877. Hoek, P. P. C.

No new Amphipoda are reported.

1877. Huxley, Thomas Henry.

The Edriophthalmia are described on pages 359 to 367. "These resemble the Podophthalmia in never possessing a greater than the typical number (20) of somites, though, in some members of the group, the body is composed of fewer somites, in consequence of the abortive or rudimentary condition of the abdomen." The genus Amphithoe is chosen for special description, but it is not easy to see why this name should have been chosen for the animal figured, which has a large rostrum, the back carinate and almost every segment dentate, the fifth side-plate shorter than the fourth, and the upper antenna showing a secondary flagellum, suggesting, therefore, Gammaracanthus boractus rather than any Amphithoe. The head proper, in Professor Huxley's view, has only five pairs of appendages, the sessile eyes not being counted. These are the antennules, antennae, mandibles, and two pairs of maxillae. The first pair of thoracic appendages "are applied against the mouth, and form a large lower lip. "The 'head' of Amphithoe, therefore, is formed by the coalescence of the seven anterior somites of the body; but I believe that the tergum of the seventh (or first thoracic) somite is obsolete, as in a Stomatopod, and hence that the tergal surface of the head of the Edriophthalmia corresponds exactly with the cephalostegite (or that part of the carapace which lies in front of the cervical groove) in Podophthalmia. Mr. Spence Bate has shown in his valuable 'Report on the Edriophthalmia,' that in the Crustacea at present under discussion, a strong apodeme arises on each side from the posterior part of the sternal region of the head, and passing inwards and forwards meets with its fellow, to form an endophragmal arch, which supports the oesophagus and stomach and protects the nervous commissure between the first and second sub-oesophageal ganglia, which runs under it. The discoverer of this structure conceives that it represents the terga of the three somites immediately preceding the mouth; but I cannot see that it is other than the representative of the precisely similar mesophragm formed by the anterior apodemes in Astacus. In fact, the correspondence in structure between the head of an Amphithoe and the cephalic portion of the cephalo-thorax of Astacus is not a little striking. There is the same sternal flexure, the same relative position of the stomach, and of the insertions of the mandibular muscles. The great difference lies in the abortive condition of the ophthalmic appendages." In treating of the embryology the remark is made that "in certain Amphipods (Gammarus locusta and Desmopilus) the vitellus undergoes complete division; while, in closely allied forms (Gammarus fluviatilis and pulce), and still more completely in those Leopoda which have been studied, the part of the vitellus which divides into blastomeres, becomes more or less completely separated from the rest immediately after ecdration, and the so-called partial yolk division, take place." A note gives a reference to "E. van Beneden, Recherches sur la Composition et la Signification de l'Oeuf, 1870." By consulting this work Mr. W. E. Hoyle has found for me the clue to the mysterious
word *Desmophillus*. In the first place it is a misprint for *Dermophilus*, which should have been noticed under the date 1870. In that year Beneden and Bessels, in their Mém. sur la Formation du Blastoderme chez les Amphipodes, etc., p. 26, footnote, say, "Nous avons en l'occasion de constater le portiment total du vitellus et un mode de formation du blastoderme tout à fait identique à celui que nous avons reconnu chez le *Gammarus locusta*, dans un groupe d'Amphipodes tout nouveau, dont nous proposons de donner prochainement la description.

"Les crustacéens remarquables vivent en parasites sur le *Lophius piscatorius*, et les modifications qu'ont subies les caractères du groupe auquel ils appartiennent, par l'influence de leur vie parasitique, sont d'un haut intérêt à divers points de vue. Nous proposons pour cet animal le nom de *Dermophilus lophii*.

"On connaîtra bientôt des parasites dans tous les groupes de crustacés. On connaît des cyrripèdes parasites en grand nombre; certaines espèces de tâlámies en sont littéralement couvertes; les Lernéens sont véritablement des Céphalopodes parasites; on connaît depuis longtemps des Isopodes parasites; enfin nous venons de découvrir un parasite qui, anatomiquement comme embryogéniquement, est un véritable Amphipode."

E. van Beneden, in the paper to which Professor Huxley refers, says at p. 132, "L'épithélion envoie souvent à l'intérieur des tubes ouvrant des prolongements, en forme de cloisons transversales . . . ; quelquefois comme dans le genre *Dermophilus* (Ed. van Ben. et Em. Bess.), ces prolongements sont de véritables lames cellulaires qui séparent complètement dans le vitellogène deux œufs voisins." At page 136, a footnote gives a reference, in regard to this genus, to Édouard van Beneden et Émile Bessels, Mém. de l'Acad. roy. de Belg., t. xxiv, "by error for t. xxxiv." It is obvious that van Beneden applies the term *parasite* to any creature which lodges upon another, whether it feeds upon the carcass of its host or not. It is probable that the *Dermophilus lophii* here mentioned is the same as the *Ichthyomyzonus lophii* of Eugène Hesse, 1873, while Hesse's *Ichthyomyzonus* appears to be partly, if not entirely, identical with Kroyer's *Lophius*, 1842. See additional Note on Hesse, 1873, in Appendix.

For the comparative anatomy of the Crustacea, the English student will do well to read what Professor Huxley has to say in this volume on all the groups, or to study his work entitled, *The Crayfish*, an introduction to the Study of Zoology.

1877. Martens, Éduard von.

Crustacea. The Zoological Record for 1875; being Volume twelfth of the Record of Zoological Literature. London, m.DCC.LXXVII. pp. 213–234.

The following account is given of M. Hesse's curious new genus:--

"Piscicolae. A new family proposed for the reception of *Ichthyomyzonus*, g. n.; 3 anterior pairs of feet directed forwards with hooked claws; the 4 posterior longer, with nearly straight claws; abdomen composed of 2 or 5 segments; respiratory organs in the form of a double cylindrical multianulated hairy rod on the under side of the abdomen; end of the abdomen two-branched, each branch terminated by several leaflets. This family connects the Amphipoda with the Isopoda. *I. ornatus, morrhæus, lophii*, and *squatina*, spp. mm., living as parasites on the cod, toad-fish, and angelfish on the Atlantic coast of France. Hesse, Ann. Sci. Nat. (5) xvi, pp. 1–16, pl. iv. [The description is not quite satisfactory; according to the position of the respiratory organ, this genus should be placed rather with the Isopods than with the Amphipoda.]" There seems here to be some misconception in the account of the abdomen. The pleopods also, to which Hesse attributes respiratory functions, are, according to his description, of the character usual among the Amphipoda, not like those of Isopoda. Compare the Note on Hesse, 1873.

A list of Crustacean literature is given, pages 58 to 68. The discussion of the Amphipoda begins at page 91. Meinert prefers to reinstate Montagu’s specific name for *Hyperia gallina*, on the ground that O. F. Müller’s account of *Cancer melunarum* is too indefinite, and not like Montagu’s, supported by figures. But Montagu’s figure is of so little service for specific distinction as to constitute but a weak reason for displacing the older and well-established name *melunarum*. Meinert includes in the synonymy *Hyperia obliqua*, Kroyer, and *Lestrigonus oswedalii*, Sp. Rete, in regard to which compare Note on Thomas Edward, 1868. Meinert also prefers the name *Orchestia littorea*, Montagu, to *Orchestia gaumarellus*, Pallas, on the ground that the figures and descriptions in Pallas are “insufficient to distinguish his O intestus Gaumarellus from his O. Loenusa.” But the Notes on Pallas, 1766, 1772, will, I think, show that this opinion is erroneous.

*Pontoporeia ferruginea*, Bruzelius, is kept distinct from *Pontoporeia femorata*, Kroyer, on the ground that Kroyer could not possibly have overlooked the striking furcate process on the back of the fourth pleon-segment. But it seems that Kroyer did not do so, although in his specimen it may have been weakly developed. It is figured in the “Voy. Scand. Crust., t. xxiii., f. 2, a–y;” to which Meinert himself refers under *Pontoporeia femorata*, Kr.

To *Bathyporeia pilosa*, Lindstrøm, are assigned synonyms “*Bathyporeia Robertsonii* Sp. Bate,” and “*Bathyporeia pelagica* Sp. Bate,” both as male forms. *Bathyporeia tenuipes*, n. s., is thus defined: “Antennae superiores subquadrate, flagello appendiculare biarticulato. Antenne inferiores articulo tertio et quarto longis atque temibus. Angulus capitis acutus, protubentia. Pedes omnes tenues, modice hirsuti; pedes saltatorii ultimi paris setis simplicibus instructi.”

*Urothoe marina*, Sp. Bate (♂), and *Urothoe brevicornis*, Sp. Bate (♀), are accepted, in accord with Bate and Westwood’s suggestion, as the two sexes of one species.

*Paramphithoe platys*, Boeck, and *Paramphithoe bicuspis*, Kroyer, are the names given to two species which Boeck, in his latest work assigned to *Pleustes*.

Of *Callipus norvegicus*, Rathke, Meinert remarks that it is by no means easy to distinguish it from *Callipus brevicornis*, in which I quite agree with him. He thinks it may be no more than a variety of *brevicornis*. Of *Gammarus hovesta*, Linn., he says that the young differ from the adults in having the eyes small, round or oval, and the rami of the last uropods often of different lengths. He agrees therefore with the general view in making *Gammarus pereirurus*, Rathke, a synonym of *hovesta*; but he also thinks that *Gammarus marinus* is only a shallow water variety.

In the synonymy of *Gammarus pulex*, Pennant, he places *Gammarus pulex*, of Hocinus and others, “*Gammarus Roselli Gervais*,” *Gammarus fluvicollis*, Milne-Edwards, *Gammarus lacustris*, G. O. Sars, *Gammarus neglectus*, G. O. Sars. Between *Gammarus pulex* and *Gammarus neglectus* he has met with the intermediate gradations. If Sars’ species is maintained, he thinks that the earlier name for it should not have been altered, in which also I agree with him.

*Pallasia*, Sp. Bate, he spells *Pallasia*, but this improvement must be avoided, as with it the name is preoccupied.

(Zool. Chal. Exp.—Part LXVII.—1887.)
"Amathilla sabini" Leach, is considered to include as a variety, Gammarus angulosus, Rathke, and Anathina carino-spinosa, Sp. Bate. Zaddach's Leptocheirus is (not rightfully) made a synonym of the later Ptilocheirus, Stimpson. To the species Leptocheirus pilosus,

"?Protomeleia hirsutimanus" Sp. Bate," is given as a synonym. Eischius longicaudatus, Sp. Bate and Westwood, is retained as a separate species under the name Pholis longicaudata. To Protomeleia fasciata, Kroyer, are assigned as synonyms Autonoe macronyx, Lilljeborg, and "Microleptocheirus Webster," Sp. Bate.

Under Gammaropsis erythroplhalmus, Lilljeborg, he mentions that a specimen from Nyborg was labelled "Autonoe Karmonensis Bock." "Without doubt," he says, "hereby a new species is designated, which, however, I have not found described by Bock. I found no difficulty in determining it as above."

With "Siphonornatus Colletti, Bock," he found one of Bock's labels bearing the name "Corephius steentrupii," and with "Glaucomeone steentrupii," Bock, he found a label, "Harphius Kroyer, B." The localities and synonyms of various other species are given in this work, but without descriptions, as indeed is the case with most of those above-mentioned.

1877. Miers, E. J.

No new species are here recorded, but for Lysianassa (Anonyx) lagena, Kroyer, is substituted the name Anonyx mugax, Phipps, with the remark, "Phipps's figure of this common Arctic species is quite recognizable; and his name must therefore be adopted for it." Lysianassa bidenticulata, Sp. Bate, 1888, which its author had in 1862 transferred to Cancer (Lysianassa) mugax, Phipps, and which Bock identified with Gammarus mugax, Owen, under the name Sowernes eubli, Kroyer, is here re-established as Anonyx bidenticulatus, Spence Bate, being "distinguished by the form of the third segment of the pleon, which has a second tooth on its posterior margin above that of the postero-lateral angle," instead of being "valle rostral" as in Sowernes eubli. Sars, in 1885, calls it Sowernes bidenticulatus, Sp. Bate. Acanthozone (Acanthosoma) hystrix, Owen, is re-established, with the observation, "This species has been referred by Bock to the Oniscus cucullatus of Lepchind (Acta Acad. Sci. Petrop. p. 249, pl. viii. fig. 3, 1780); but the species figured by that author differs in having vertically projecting spines upon only the first four segments of the pleon. The species figured by Buchholz (Zweite deutsche Nordpolar. Zeol. Crust. p. 362, pl. xi.) as Acanthozone hystrix differs from that figured by Owen in the more numerous and closely placed spines upon the posterior margins of the base of the perioiopods, and in the form of the rostrum, and is, I think, distinct."

The account of the Crustacea "is confined to the species collected between lat. 78° and 81° N."

"The most northerly species collected is Anonyx rugas, one of the commonest and most abundantly distributed of the Arctic Amphipoda, and first made known to science a hundred years ago by Théppis." At page 56 a table is given of "the Geographical distribution of the Crustacea collected by the Arctic Expedition north of lat. 78° N." This includes 12 species of Amphipoda, common to Greenland and Spitzbergen, 9 of them being also Scandinavian, 5 or 6 of them belonging to Arctic America, 3 to Iceland, 4 to Britain, 2 to north-east Asia. A species of Amphipod, "perhaps belonging to the genus Phronusa," is mentioned as having been collected by A. C. Horn, Esq., while on board the yacht "Pandora."

On Anonyx rugas, Théppis (Anonyx lagem of Sp. Bate, Boeck and Buchholz), Miers says, "my observations scarcely agree with those of Hr. Buchholz and other authors as regards the rare occurrence of the males of this very common and well-known Amphipod." The far longer flagella of the inferior antennae distinguish the males. The largest male taken measured ⅓ inch, the largest female 1 inch 9 lines.

For "Anonyx galosus? Pl. III. fig. 2," the synonymy gives Anonyx galosus, Kröyer, Sp. Bate, and Boeck; Anonyx norvegicus, Liljeberg, and Anonyx holobolii, Sp. Bate, Brit. Mus. Catal., p. 75. The description is followed by these remarks, "I have referred the specimens collected by Mr. Hart with some doubt to the Anonyx galosus of Kröyer, as the antero-lateral margin of the head is less broadly rounded, and the accessory flagellum is longer than that of A. galosus according to Boeck's diagnosis. In the form of the first and second pairs of legs and of the terminal segment they agree well with the descriptions of A. galosus, and particularly in the presence of a tooth on the inner margin of the dactyl, which is mentioned by Liljeberg as characteristic of that species. From A. panuus they differ in the shorter antennae, and in the absence of a tooth on the posterior margin of the fifth postabdominal segments."

"Onesiinus Edvardsii. Pl. III. fig. 3," has for synonymy, "Onesiinus Edvardsii, Kröyer,"
"Lyssianassa Edvardsii, Goös," and "Onesiinus Edvardsii, Boeck." After the description, Miers says, "the specimens collected differ from Boeck's diagnosis in one particular, the third segment of the postabdomen is slightly produced upwards at the postero-lateral angle. Nothing is said of the form of this segment by Kröyer in his description of the species or in the Latin diagnosis that follows. In Kröyer's figure of the species in the Atlas of the 'Voyage en Scandinavie,' the postero-lateral angle of this segment is represented as not produced upward, but acute. There is, however, a manifest inconsistency between the diagnosis of Boeck and the figures in the Atlas referred to; e.g., in Onesiinus panulus the third postabdominal segment is described by Boeck as 'sursum productus acutus,' but figured by Kröyer as broadly obtuse and rounded at the postero-lateral angle. Onesiinus edvardsii has been recorded from Greenland, Spitzbergen, and Britain."

Notes are given upon Atylus carinatus, Fabr. To Acanthozone hystric, Acanthozone hystric, Owen and Ross, Bell; Amphithoe hystric, Kröyer, M. Etw.; Pararaphtoidea hystric, Brindley, Sp. Bate; Acanthozone eapitata, Boeck, nec Lepechin; Acanthozone hystric, Miers, Ann. and Mag. Nat. Hist. (ser. 4) xix. p. 137 (1877); with the remark, "in the elaborate plate that illustrates this species in the 'Zweite deutsche Nordpolarf.', [1874], the rostral spine is represented as conical, straight, and acute, and the bases joint of the sixth and seventh pairs of legs as armed with four strong spines upon its
THE VOYAGE OF H.M.S. CHALLENGER.

posterior margin. In all the specimens of both sexes that I have examined the rostral spine is laterally compressed and bent near its base, projecting horizontally forwards, and there are but two spines upon the posterior margins of the basal joint of the sixth and seventh pair of legs. It is probable, therefore, that a distinct species is figured by Buchholz in the plate referred to. *Halirages fulvocinctus*, Sars, is next mentioned, followed by *Gammarius locusta*, Linn.; *Gammarius cristatus* loricatus, Sabine; *Anathilla pinguis*, Kroyer. *Eusirus cuspidatus*, Kroyer, is thus remarked upon, "The single example in the collection is fully adult and bears ova. Length 1 inch 7½ lines (41 millims.)."

"The basal joint of the sixth and seventh pairs of legs is considerably narrowed to its distal extremity. The second and third segments of the abdomen have the posterior margins rounded and very finely serrated. This species has been described at great length and figured by Buchholz, l.c.; but either the figure is carelessly executed as regards many details, or it represents a very distinct species. The rostrum is represented as much longer than in the specimens I have seen; the exca of the fourth pair of legs with its inferior margin straight (not rounded as in the examples I have examined), the second and third segments of the abdomen with the posterior margins strongly angulated, &c."

Notes are given on "*Trilopros oculata*," chiefly referring to the development of the ovigerous lamelle in the females.

*Egina spinosissima* is given with references to *Egina spinosimima*, Stimpson, *Caprella spinifera*, Bell, *Egina echinata*, Boeck, *Caprella spinosissima*, Stimpson, Bate. "The largest specimen, length nearly 2 inches 2 lines (54 millims.) is very robust, of a green colour, and with but very few small spines and many indistinct very small tuberous; the second pair of legs has the hand armed upon its inferior margin with two very strong teeth, and a third small tooth close to the distal extremity; the finger is strong and very much curved; the first joint of the first pair of postabdominal appendages is short and much broader than the second joint.

"The smaller specimen, length a little over 11 lines (24 millims.), is of a whitish colour, purplish brown at the bases of the spines, which are numerous, especially on the back. The hand of the second pair of legs is nearly of the same form as in the preceding, but the finger is less areuate; the basal joint of the second pair of legs not broader than the second joint.

"In the specimens I have before me the teeth on the inferior margin of the palm of the second pair are not only much larger than in *E. echinata*, but the palm itself is not tuberculated as in that species, as figured by Boeck (l.c.) [pl. 38, fig. 6. 1876]. It is possible that the two forms are distinct; but the variation in the spines of the body and its limbs are known to be very great in some species of the genus.

"Probably the specimens referred by Ross in Parry's 3rd and 4th Voyages to *Caprella scolopendroides*, and which he describes as having 'a great number of small spines along the back,' should be referred to *Egina spinosissima*. They were collected at Port Bowen and Low Island.

"This species has been recorded from the coasts of Greenland, Spitzbergen, and Norway; and if, as I believe, the species of Stimpson is identical, from the Grand Manan at the entrance of the Bay of Fundy."

1877. STALIO, LUIGI

The preface briefly reviews the literature of Adriatic carcinology. The Edriophthalmia are divided into three orders, Amphipoda, Lemnodipoda, Isopoda. Among the characters of the
Amphipoda, p. 162, are included "a pair of mandibles with two palps," although on the same page, in the first family, the Orchestide, the mandibles are rightly said to be without palps. In the second family, the Gammaride, the mandibles are said to be provided with palps; but that is not the case with two of the genera here mentioned, Probolium and Decamene. The only other family assigned to the Amphipoda is the Corophiide. No new species are described or mentioned. Probolium polygnon, A. Costa, is given without explanation as a synonym of the later Probolium megacheles, Heller. Elasmopus rapax, A. Costa, is given as a synonym of Podocerus longimanus, Heller, although Heller himself points out that the last uropods and telson of Elasmopus rapax do not admit of its inclusion in the genus Podocerus, where nevertheless J. V. Carus has since placed it under the name Podocerus rapax.

In the Leuolidipoda, according to the definition here given, "the mouth is furnished with a circular labrum, with two maxille strongly dentate and without palps, and with a pair of maxillipeds provided with palpiform branches." It is possible that by the "due mascelle fortemente dentate e prive di palpi," not maxille, but mandibles are intended, but "mandibole" is elsewhere used for mandibles, which in many of the Caprellide are furnished with palps, though not in the genus Caprella, which alone claims Stailio's notice. In the Caprellide he says "l'apparato orale ha la medesima conformazione dei Gammaridi saltatori," probably by this phraseology intending to intimate that in Caprella as in Orchestia the mandibles are palps.

1877. Streets, Thomas H.

The lower antennae and "posterior styles" which were missing in Dana's specimen of Clydonia longipes are here described. Lestrigonss rubescens, Dana, is reported. Hygeria tricuspidata, n. s., is described, in which the first gnathopods have "the meros produced antero-inferiorly," "carpus broad, produced inferiorly, but not anteriorly," while "the second pair has none of the joints produced." "When the animal is at rest, the inferior antennae are evidently folded up, . . . in the concavity of the front of the head." At the end of the description the opinion is urged that the genus Lestrigonss should be retained, instead of being regarded merely as the male sex of Hygeria, but the argument seems to rest entirely on the account given of the inferior antennae in the male of the so-called Hygeria tricuspidata, which, however, with its folded antennae, cannot be a Hygeria, but must belong to the Platyscelida. Phronima pacifica, n. s., is described from the "North Pacific Ocean. Latitudes 4° and 21° north; longitudes 127° and 151° west." "This species is distinguished from P. sedentaria by the broadly-quadrate form of the carpus of the third pair of thoracic feet, and by having the carpus of the gnathopoda less produced anteriorly. In other respects they are similar. The shape of the hand more nearly resembles the hands of P. custus and P. bornensis; but it is distinguished from both of the latter, by the character of the anterior surface of the carpus and of the propodus. In the latter both the carpus and propodus are furnished with a cunulated tubercle; in custus the tubercle is single and tooth-like. There is a striking resemblance between the propodus, and the anterior surface of the carpus of the third pair of thoracic feet, of the smaller specimens of pacifica, and the corresponding parts of P. atlantica, which is said to be the female of sedentaria; the broad hand, however, separates them. It is a remarkable fact, that in all the species of Phronima
that have been described, even from widely-separated localities, the variation is very slight indeed." See also Note on Streets, 1882.

Anchylonyx, new genus, is thus described:—"Head moderately large, broad and rounded at the top, tapering inferiorly to the oral apparatus, and excavated in front. Eyes on the lateral and dorso-scapular surfaces of the head. Both pairs of antennae present, long; base of the superior pair long and stout, three-jointed; inferior pair slender, four-jointed. Flagellum very attenuated and elongated. Thorax broad, somewhat compressed; segments six. Abdomen narrow. The gnathopoda not subchelate, nor much reduced in size, when compared with the following feet; the first and second pairs of thoracic feet long, slender; carpus and merus linear. The third pair enlarged; carpus and merus dilated, with the anterior margin armed with teeth; propodus flexes on the carpus, impinging against the teeth on its anterior margin; dactylus fused with the propodus. The fourth and fifth pairs of feet subequal, shorter than the preceding. The three posterior pairs of abdominal appendages biramous, lanceolate; rami pointed." In the additional observations it is noted that "the mandibles are without appendages," and that, as in Platymus, "a pair of wing-like plates exist at the base of the dactylus of both pairs of gnathopoda."

The type species is Anchylonyx hamatus, but in 1882 Dr. Streets makes it a synonym of Plironima elongata, Claus, 1862, and Plironima elongata, Claus, 1872.

Anchylonyx thyropoda, Dana, is reported, with the additional observation that "the inferior distal angles of the propodos of the third and fourth pairs of thoracic feet is produced, and when the joint is flexed this projection impinges against the antero-inferior angle of the carpus."

Platyscelus batei, n. s., is described, with the remark that "this species is closely related to P. rissoinæ; the differences are chiefly in the structure of the gnathopods, and of the third and fourth pairs of thoracic feet. The gnathopoda bear a striking resemblance to those of the young of P. servatus, but as the rest of the structure of the animal shows no evidence of immaturity, this is undoubtedly their normal adult condition." Yet, as the length is given as "0.12 of an inch," and the inferior antennae are said to be short, the specimen could scarcely be full-grown, and the independence of the species is therefore very doubtful. Platyscelus servatus, Bate, is regarded by Claus as a synonym of Tymiis acutidens, Risso, and Platyscelus rissoinæ as perhaps a synonym of his own Eutyphio armatus. Dr. Streets' work does not seem to have come under the notice of Claus. Amphiproné servulata, n. s., is described, and Ozzycephalus taberculatus, Sp. Bate, a species which Claus identifies with Ozzycephalus piscator, Milne-Edwards.

The new genus Leptocelis is thus described:—"Animal long and slender. Head large and produced anteriorly into a rostrum; narrowed behind the eyes; the constricted portion short, and not narrower than the thorax; under surface excavated anteriorly on each side for the reception of the superior antennae. Superior antennae short, sickle-shape. Inferior antennae five-jointed, folded upon themselves four times, and concealed beneath the head; first and second joints distally enlarged. An elongate mandibular appendage. Gnathopoda short, and complexly chelate. Third and fourth pairs of thoracic feet having the coxae dilated; the fifth pair small. Fourth and fifth abdominal segments fused into one; sixth small. Caudal appendages long, biramous. Telson cylindrical, long." The type species, Leptocelis spiniferus, is described in detail.

This genus, Dr. Streets says, exhibits a remarkable blending of the characters of Ozzycephalus and Rhabdoloma. Much the same is said by Claus of his species Ozzycephalus tenuirostris, 1871, to which, in 1887, he makes Leptocelis spiniferus, Streets, a synonym, without explaining why he rejects the genus Leptocelis. Streets here speaks of "a long, acute spine, pointing upward, on each side of the fifth segment of the abdomen. In 1878, he says nothing of this, but describes "the first three segments of the abdomen subequal,
inferior margins finely serrated, the third segment with the postero-inferior angle produced into a long, spinous process; the angle of the first and second segments square behind, not produced." Claus, on the other hand, for his species gives "die Seitenflügel der Abdominalsegmente unbewaffnet," yet he figures the postero-inferior angle of the third pleon-segment produced into a sharp point, the same angle on the two preceding segments being well rounded.

1877. Théel, Hjalmar.
Relation de l’expédition Suédoise de 1876 en Yenissei. Upsala, 1877. p. 33.
"Gammarus puteus found in lakes of the Tundra, near Doudino, Siberia, at 69° N. lat." (Dr. von Martens, Zool. Record for 1877.)

1877. Thomson, C. Wyville.

There is but one passage specially referring to the Amphipoda (pages 129–132). On January 28, 1873, the trawl was employed successfully "at a depth of 1090 fathoms, about 90 miles to the south-east of Cape St. Vincent." "The trawl on this occasion contained a single example of the female of a very large amphipod crustacean, briefly described under the name of Cystosoma neptunii by Guérin-Méneville from a single specimen obtained in the Indian Ocean. We have since taken several specimens at different stations in the Atlantic; and as a small male was in one case captured in the towing-net, there can be little doubt that, like Plironima, to which genus it is allied, Cystosoma is a pelagic animal, probably retiring during the day to a considerable depth, but occasionally coming to the very surface of the water. The male example figured (Fig. 27), which is 103 mm. in length, was taken in Lat. 1° 22' N., Long. 26° 36' W., a little to the east of St Paul's Rocks, where the depth was 1500 fathoms.

"The animal presents a very remarkable appearance. It is absolutely colourless and transparent, so that by transmitted light the internal organs can be perfectly seen through the test—the cephalic ganglion with the nerve-fibres running to the antennae and the eyes; the ganglia of the double ventral cord with the filaments passing to the appendages; the heart, an elongated tube with three openings; the stomach, a large sac with a small intestine leading from its base to the excretory opening in the telson; in the female two large rose-coloured ovaries, the oviducts passing to an opening covered by two small lamellae, at the base of the first segment of the pericranium; in the male two elongated testes, their ducts opening between the appendages of the seventh segment.

"The head is large and greatly inflated, and its upper surface is entirely occupied by two enormous faceted eyes, reminding one of the eyes of Aegina among trilobites. There are two rows of spines along the lateral borders of the head, and some spines are placed round the mouth, which is in the usual position at the base of the cephalic segment on the lower surface of the body. The first pair of antennae only are developed in either sex. The antenna consists of two joints, and is attached to the anterior margin of the head.

"The parts of the mouth and the maxillipeds are very small; the two gnathopods are terminated by claws as in the Typhidae, and act functionally as second and third maxillipeds.

"The pleon consists of seven segments; and the pleon of five, to the two last of which the
caudal appendages are attached. The five pairs of ambulatory legs are long and slender, and the three pairs of "swimmerets" are normal. The eggs are large and few in number; some of these observed contained embryos in which nearly all the appendages were developed, showing that the young undergo no metamorphosis.

"Dr. von Willemoes-Suhm, who has carefully described this singular form, has proposed to establish for the genus a family Cystosomidae, holding a place intermediate between the Typhide and the Phronomidæ."

A casual allusion to Amphipods occurs on p. 388.

1877. Woodward, Henry.

A Catalogue of British Fossil Crustacea, with their synonyms and the range in time of each genus and order. London, 1877.

The notices of Amphipoda in this work are as follows:—Intro. p. vi. "The order Amphipoda has one representative in the Upper Silurian (the Xerogrammarus Salteyi, H. Woodw.); it is represented by Gymnocyclus in the coal of Rhenish Prussia, and by the genus Prosoponiscus in the Permian of Durham. Other (Secondary) species occur in Bavaria, etc. The living genus of Amphipoda are abundant, both marine and freshwater; and some species are even terrestrial in their habits."

The table of genera and species, etc., on p. viii., assigns but one genus and one species to the British fossil Amphipoda.

Page 62 gives "Order V. Amphipoda.

"Prosoponiscus, Kirkby, 1857.

"Trilobites, Schlotheim. 1820, Petrefact. p. 41.

"Distribution. Permian.

"Prosoponiscus problematicus, Schlotheim. sp. 1820. Magnesian Limestone, Durham.

"Trilobites problematicus, Schlotheim. 1820, Petrefact. p. 41.

In regard to the above, see Notes on Schlotheim, 1820, 1822; Schauroth, 1854; Kirkby, 1857; Woodward, 1871.

1877. Wrzesniowski, August.

Synurella petonica, a new genus and species, is here introduced, but not described, since the account of its circulation can scarcely stand either for generic or specific description. The name Synurella was afterwards, with perhaps unnecessary purism, changed to Goplanus. The change indeed would have scarcely been legitimate, had Synurella at its first introduction been attended by sufficient description to give it a status in scientific nomenclature. The interesting details in regard to the heart, etc., were subsequently repeated with improvements. Reference is made to "Cullesoma Brunnichii," earlier described, and to "Hyale Jettskii" described subsequently.
1878. Bate, C. Spence.

Two new Crustacea from the coast of Aberdeen. Annals and Magazine of Natural History for May, 1878. p. 411. Fig. 2.

The new species Lestrigonius spinidorsalis, closely resembling Lestrigonius crusulans, differs from any species of the genus known to Mr. Spence Bate in having the last two somites of the pereion and the first three of the pleon produced in the median line of the dorsal surface posteriorly to a sharp-pointed tooth or spine. [Surely this is Paralambocephalus compress (Goes) 1865.]

1878. Bate, C. Spence.

The name Lestrigonius spinidorsalis is here altered to Hyperia (Lestrigonius) spinidorsalis, since Hyperia is the older name, and Lestrigonius is probably founded not on specific but sexual differences, containing the male forms, as suggested in the British Museum Catalogue, 1862.

1878. Bate, C. Spence.

The Crustacea in Conch’s Cornish Fauna revised and added to by C. Spence Bate, F.R.S. 1878. Reprinted from Part II, No. XIX. Journal Royal Institution of Cornwall.

The Amphipoda, pages 43 to 62, are not a revision of Conch’s work but an addition, taken from Mr. Spence Bate’s own writings. On page 47 the genus Grayia is given as Groga. There is reason to believe that this only represents the young of Amathilla homari. Acanthonotus owenii is here said to have been taken from Maia squinado, but the remark properly applies to Isxæ montagni, Milne-Edwards, as may be seen in the Brit. Seas. Crust., i. p. 216. Siljeborgia is printed by mistake for Liljeborgia.

1878. Bate, C. Spence.

In discussing the first pair of antennæ, Mr. Spence Bate remarks that “in Amphipoda there is never more than one secondary appendage, and that is always of a rudimentary character, and frequently only determinable in the very young stage of the animal and obsolete in the adult.” Dybowski, however, among the Gammari of the Baikal found the secondary appendage sometimes consisting of forty articulations, and therefore scarcely to be called rudimentary. “As we descend,” Spence Bate observes, “in the scale of Crustacean forms the antennæ naturally become simplified; but as they lose their internal structural character they increase their external functional arrangement. Thus in Amphipoda the auditory chamber and otoconia are wanting, but in all the aquatic normal forms the

(zool.shall.exp.—part lxxvii.—1887.) Xxx 60
filaments are long, and richly studded with those membranous organisms that I have named auditory cilia." The discovery by Claus of ooliths in the Oxycephalidae is not noticed.

In speaking of the second pair of antennae, Spence Bate says, "in the Amphipoda this antenna is simple and normally well defined, the five joints of the peduncle and the flagellum being separate and distinct." But according to my experience the two first joints of the peduncle are as a rule more or less fused together.

"Among the Hyperidea," he further says, "the [second] antenna is considerably impoverished, and in many genera it is rudimentary, while in Phrosina it appears to be absent." In regard to Phrosina, however, I may state that I have just received (June 27, 1887) from Dr. Bruce specimens taken at Malta, of Phrosina semilunata, Risso, c, in which both pairs of antennae are well developed with long flagella.

The three sections of this paper are headed respectively "Correlation of Appendages," "On Exuviation," and "On Renewal of Appendages."

It has been shown by S. I. Smith that the names Sulcator, Sp. Bate, 1854, and Pterygoecera, Latreille, 1825, must yield to the earlier name, Lepadactylus, Say, 1818, but in my opinion the name Hanstorfius, proposed by P. L. S. Müller in 1775, has the preference over all its competitors. The elaborately and beautifully illustrated notes by Bovallius (in English) open with an account of the adventures of Slabber's species, not however taking into account Lepadactylus dytiacus of Say. A chronological list of the literature is given, with a corresponding omission. A new subfamily is created, Pterygoecrina, thus defined:

"Cephalon rostrum fereus minimum, articulum primum antennarum non tegens.
"Labium superius breves, apice rotundatum.
"Mandibulae magna, palpo elongato, articulo palpis secundo tertio longiore.
"Maxillae primi paries parvae, palpo biarticulato.
"Pedes maxillares palpo laminari.
"Antennae superiores flagello appendiculari instructae.
"Gnathopoda primi paries dactylo unguiculato, secundi paries dactylo minus duplici.
"Pereiopoda primi et secundi paries articulis ultimis ligulas formantibus.
"Pereiopoda sequentia dactylo carentia.
"Telson simplex.
"Corpus non valde compressum.

"The family Pterygoecrina is distinguished from the Pontoporeiinae and Phoxinae by its general form as well as by the abnormal structure of the dactyls of the gnathopoda. Another remarkable character is presented by the peculiar form of the corpus and propus of the first and second pairs of the pereiopoda, which I have thought proper to denote as spoon-shaped 'ligualiformis.' Pterygoecera differs, moreover, from the Phoxinae by the second joint of the mandibular palpus being larger and longer than the third, and also by the telson not being bifid, but simple and only incised."

In the very full and detailed account of the species it is mentioned that "with the age of the animal the size of the eyes diminishes also, and in the oldest they are discovered only with difficulty. The pigment is red, the eye-lens short, thick, bluntly conical, the surface of the eye irregularly faceted."
1878. Catta, J. D.

The Amphipod in question has been only found in a well at La Ciotat (Bouches-du-Rhône, France), a hundred yards or so from the Mediterranean. The water of the well becomes brackish in summer. Professor Catta observes that in the corpus and propodus of the first pereopod his new species has, with exaggerated development, a character common also to Gammarus pulex and Gammarus locusta, in that these joints are “garnis d’immenses pois plumeux disposés par rangées transversales et entremêlés de piquants.” From the sweeping movement of these setae he formulates the name “Rhipidiophorus (περιβόης, balai de plumes).” The first pereopod in this species, he says, is much longer than the second; the first uropods are much shorter than the second; the third are enormous, whether compared with those that precede or with the size of the animal, and have one branch rudimentary; the other branch “garnie de nombreuses rangées de grandes soies et de piquants, est composée de deux articles dont le dernier est assez réduit.”

An argument follows to show that the genus Niphargus ought to be again merged in Gammarus. It is urged that in Gammarus pulex, and in Gammarus neglectus, Sars, one ramus of the third uropod is biarticulate, as in Niphargus; that Humbert’s “Niphargus pulexus, var. Forclii” has “des poils et des pelionps sur le bord postérieur des derniers Somites,” as in Gammarus; that the presence or absence of eyes is not of great importance; and that the telson is practically alike in the species assigned to both genera. As to the dorsal hairs and prickles, he says, “G. Rhipidiophorus qui est Niphargus par les antennes, le cinquième Siagonopode et le Pléon, porte aussi ces poils et ces piquants.” It may, on the other hand, be argued that in Niphargus aquilex the biarticulate ramus of the third uropod is strikingly distinguished from that in any species of Gammarus by the length which the second articulation attains, as well as by its cylindrical shape. The discovery of transition-forms between two genera will always cause some difficulty, but as such forms have probably existed in innumerable cases where they have not been discovered, it is a question how far the discovery of them should be allowed to interfere with well-established distinctions either of genera or species. When Niphargus aquilex and Gammarus pulex are side by side, it is rather the difference of the facies than the likeness which attracts attention.

1878. Chatin, Joannes.

Accounts are given of the eye in Lysianassa spinicornis, Costa, fig. 24; Isra nicea, Thor., figs. 25, 26; Caprella acanthifera, Leach, figs. 28, 29; Epimera, nov. sp., Catta, figs. 30–34. This new species lives parasitic upon Sabireta donumcula, Nardo. The pigment-sheath is rouge vif, while other species of Epimera have it brown, and others again almost black. The genus, he thinks, requires a complete revision.
1878. Claus, C.

He here notices the two lateral pairs of arteries belonging to the heart of Phronima, which he had at one time supposed to be merely strings of connective tissue. The same pairs of vessels, he says, are found also in Phronimella, and in two new Mediterranean Phronimidae from Messina, for which he institutes the new genera Phronimosia and Paraphronima. In the latter genus there is a third pair of arteries in the fifth peraeon-segment. This he finds also in Phronia, Hyperia, Oxycephalus, Thanysis, Platyscelus (Typhis) and Vitilia. He is inclined to consider three pairs (in the third, fourth, and fifth segments) the normal number for the Platyscelidae and Oxycephaliuae, especially as three is the prevailing number for the pairs of venous ostia (in the second, third, and fourth segments) in the Phronimidae and Gammaride. Sometimes the first pair of ostia is wanting, and sometimes the third pair of arteries. “Two pairs,” he says, “of lateral slits, which then uniformly belong to the third and fourth peraeon-segments, I find in almost all Platyscelide, e.g., Typhis, Lyceopsis, n. gen., and in Oxycephalus, Vitilia, and Hyperia.”

He assigns three pairs of lateral ostia (in the second, third, and fourth peraeon-segments) alike to the Gammaride and Caprellide. In the genus Tanais the elongate heart is, he says, quite Amphipod-like in its relations, but has only two lateral openings in the third and fourth very elongate peraeon-segments.

The heart as a rule runs from the beginning of the first to about the middle of the sixth peraeon-segment, but in Oxycephalus the cephalic aorta begins at the beginning, and in Typhis and Lyceopsis at the end of the second segment. The two pairs of valves are described which are found at the origin both of the cephalic and abdominal aorta, and some other details are entered into.

1878. Dezsö, Béla.

The general results only of Dr. Dezsö’s investigations are given in the following terms:—

“Bei Crustacea, die ihre Kiemen als Körperanhänge an der Bauchseite des Abdomens und Postabdomens haben, kommen ebenfalls so viele Paare von Spalten am Dorsalgewebe vor, wie viele Paare von Kiemen existiren.

“Bei Crustacea, die ihre Kiemen unter der Thoraxschale beherbergen, kommen am Herzen so viele Paare von Spalen vor, wie viele Paare von Kiemen sich unter der Thoraxschale vorfinden.”

These results do not seem to tally with those arrived at by Fritz Müller, Claus and Delage, with regard to the heart in the Amphipoda, among which five pairs of branches are commonly combined with three pairs of lateral slits in the heart.

1878. Forel, F. A.

In respect to the general conditions of life in a fresh-water lake he distinguishes three regions, “die littorale, die pelagische und die tiefe Region.” The deep fauna is tolerably rich in
species and in number of individuals; most types of fresh-water animals have their representatives there (mit Ansahme der Najaden und der Spongien). In this region in the Lake of Geneva he found, among others, "Niphargus pulexius, var. Forelli, Al. Humbert." References are given to Professor Forel's earlier writings on lake-fauna.

The investigations were made on "Caprella aquilibrata Sp. B. (9)." Its food Gamroth considers to be the larvae of Bryozoa and perhaps the adult Bryozoa likewise. The work is one of importance, discussing the whole organisation of the creature in question, but it has been to some extent superseded by the later labours of Paul Mayer and Delage. Mayer points out that Gamroth erroneously attributes only one joint, instead of two, to the flagellum of the lower antennae in Caprella aquilibrata; that he figures on the first maxilla an inner basal plate (Kaudale) with setae, as found in the normal Amphipoda, but not present in any of the Caprellidae with which Mayer is acquainted; and that he leaves unnoticed the want of symmetry in the mandibles, and makes no mention of the Paragynith (lower lip). He calls the hairs on the lower antennae "Strudelorgan," a term which Mayer considers appropriate, as well as Haller's "Ruderhaare," and "Fangorgan" which would suit Gosse's description. The "Frontal organ" or "Nackenorgan," which Gamroth discovered, one on either side the median line of the body, in front of the brain, and above the origin of the upper antennae, is considered by Mayer to be a gland rather than, as Gamroth suggested, an organ of sense. His mistake in supposing that the colouring matter was in the epidermis instead of under it, is explained by Mayer by the fact that the Chromatophores do push excrescences in between the cells of the epidermis, giving an appearance as if the epidermis were itself pigmented.

1878. Gegenbaur, Carl.

Grundriss der vergleichenden Anatomic. 2te Aufl. 1878.

Elements of Comparative Anatomy. By Carl Gegenbaur, Professor of Anatomy and Director of the Anatomical Institute at Heidelberg. Translated by F. Jeffrey Bell, B.A., Magdalen College, Oxford. The translation revised and a preface written by E. Ray Lankester, M.A., F.R.S., etc. London, 1878.

The Arthropoda occupy the fifth section, pages 228–305. The Crustacea are divided into a) Entomostraca, b) Malacostraca. The latter are divided into 1. Thomeostrea (Pycnophthalmus), and 2. Arthrostraea (Hedrophothalma). The latter are exhibited as follows:—

Amphipoda. Gammarus, Orchestia, Hyperia, Pagonia.

Lanodipoda. Caprella, Cyamus.

Isopoda. Bopyrus, Cymothoa, Sphaeroma, Onisens, Asellus, Bathsea."

In the preface, pages xiii–xx, there are some important remarks on "Nomenclature of the Parts of the Digestive Tract." Mr. Lankester proposes "to distinguish the primitive digestive space which develops from the endoderm (in fact the gastrula stomodae) as the 'enteron.' The anterior passage leading into this from the mouth, and formed by an ingrowth of
ectoderm," he says, "I have termed the 'stomodeum,' and the corresponding passage leading from the anus I similarly propose to call the 'proctodeum.' These three primary factors of the alimentary tract are most equally developed in the Arthropoda and some Mollusca."

In Professor Lankester's Classification the Arthropoda are the "Branch. Gnathopoda" of the "Appendiculata," which "include animals with lateral locomotive appendages, and usually a segmented body," a group, "excepting that it has the addition of the Rotifera, nearly coextensive with the Annelida" of Huxley's Classification in 1869.

1878. GODET, PAUL.

Gives measurements. See also Note on Godet, 1873, in Appendix.

1879. HALLER, GOTTFRIED OTTO, born May 30, 1853, died May 1, 1886 (Mlle. A. Haller).

Short descriptions are given of the following species, Protella major, n. s., subsequently recognised by Haller as the male of Protella phasma, Montagu; Caprella liparotensis, n. s.; "Caprella Halleri," n. s.; "Caprella Dobreni," n. s.; Caprella elongata, n. s., for which, and for the two preceding, see the next Note; Caprella antennata, n. s., identified with Caprella acanthifera by Mayer, who notices that Haller himself does not again mention this species; and lastly, "Podalirius Krügeri," n. s.

1879. HALLER, G. O.

Of the genera Podalirius, Proto, Protella, and Caprella, Dr. Haller found Protella most, Podalirius least, suited for his anatomical investigations. His discussion of the nerve-system should be read under the light thrown by Mayer's later investigations. In the section headed "Sinnesorgane," Haller denies the existence of the "trichterförmige Frontalorgan" which Gamroth discovered lying immediately behind the origin of the upper antenna. But the existence of this frontal- or nuchal-gland is reaffirmed by Mayer. After the discussion of various hairs destined for sensation, Haller gives in his third section, "Einige mikroskopische Beobachtungen über Haargebilde, welche theils zum Ergriffen und Festhalten, theils zum Schwimmen dienen." While, he says, the upper pair of antenna is "stets uud überall Sinnesorgan," and therefore beset with all sorts of hairs for purposes of sensation, the hinder pair does not always agree with it in this purpose. It often loses almost entirely the importance of an organ of sense, and by way of compensation becomes destined to support the organs of locomotion. Hence arise swimming-antennae, as among the Copepoda. In the genus Caprella it is possible to form two subgenera, one with the lower antenna acting as organs of sense, the other in which they have become swimming organs. In this
latter case they have the whole under side closely set with long stiff hairs, arranged in two simple rows. These swimming-bristles are movably socketed, and on each joint increase in size from behind forwards. Their peculiar structure is described. The structure, positions and uses of various spines are investigated.

Sections of the work are devoted to the heart and circulation, the organs of reproduction, the apparatus of nutrition and glands of the intestine, a gland in the head of the second gnathopod of some Caprellidae (e.g., *Caprella dokerti* and *Protella phasma*), remarks on large connective-tissue cells in the bodies of the Caprellidae, sexual differences, adaptability, mode of life, epizoic plants and animals, classification.

*Proto pedata*, Fleming, and “*Proto Goodairi*,” Spence Bate and Westwood, (Figs. 23–25), are given as distinct species, but the better opinion unites them under *Proto ventricosa*, O. F. Müller. *Proto brunneovittata*, n. s., is described and figured. Remarks are made on the genus *Protella*, Dana, and the species *Protella phasma* (Fig. 26). *Caprella*, Lamarck, is defined, and in “Subgenus I. Caprellen, deren unteres Fühlerpaar Ruderborsten trägt,” he places 1. *Caprella equilibrata*; 2. *Caprella acutirons*; 3. *Caprella liparotensis*, n. s. (Figs. 41, 42), which is described in detail; 4. “*Caprella Helleri*,” n. s. (Fig. 43), which Mayer considers to be the young form of some *Caprella* which cannot be determined.

In “Subgenus II. Die unteren Antennen sind Sinnesorgane.” Here are placed, 5. *Caprella linearis*; 6. “*Caprella Dokerti*,” n. s. (Fig. 44), which is given by Mayer as a synonym of his subsequently published *Caprella grandinana*; 7. *Caprella acanthi/era*, Leach; S. *Caprella elongata*, n. s. (Fig. 45), which Mayer considers to be a smooth variety of *Caprella acanthi/era*.

Of *Podalirius*, Kröyer, two species are given, *Podalirius typicus*, Kröyer, and *Podalirius kröyeri*, n. s. (Figs. 46–49), both species being described in detail.

In the conclusion, Haller draws out the following genealogical tree of the Caprellidae, which he regards as probably Crevettina metamorphosed by a parasitic mode of life.

```
Crevettina
        (Amphithoe)
          |  Proto
          |  Protella
          | (Protella gracilis Dana
          | Protella phasma Mont.)
     Cyamidae.

           |  Caprella
           |  Podalirius
```

1878-HAYEK, GUSTAV VON.
1879.

Von Hayek divides the “Untereich, Arthropoda, Gliedermusser,” into four classes, Crustacea, Arachnoiden, Myriopoda, Insecta. In the higher forms, he says, the body is clearly divided into three principal sections, constituting the head, thorax, and abdomen, but “bei den Krebstieren, als den niedern organisirten Gliedermussern, ist eine derartig ausgesprochene Sonderung niemals zu bemerken, sondern eine mehr oder weniger weitgehende Verschmel-
zunächst den Kopfes mit den folgenden Segmenten, und wäre es auch nur das vorderste des Bruststückes, der sogenannten Prothorax, zur Regel geworden.” He divides the Crustacea into seven orders, the Amphipoda standing sixth, between the Isopoda and Decapoda. At page 89 he defines the Amphipoda (Flöhrkrebse), as “Getrennt-schechteleiche Krebsthiere mit entwickeltem Bruststücke, von den Seiten her zusammengedrücktem Leibe, und kiemenlosen Postabdominal-Gliedmassen.” The illustrations are taken from “Amphithorak Jurini.” M. Edw.; Gammurus neglectus, Lilij.; Gammurus locusta, Montagu; Caprella linearia, L.; and Phronima solventaria, Forsk. Fig. 10–14, “Gammurus neglectus, Lilij. Partie eines sehr vergroßerten Embryos,” exhibits the heart with six “visceral Spaltöffnungen.” Of the eyes it is said, “Die zusammengesetzten, sitzenden Augen werden von der zu einer Hornhaut umgewandelten, ganz glatten, niemals facettierten Körperdecke überzogen.”

“Caprella nova-zealandiae, sp. nov.,” is described. It is said to approach “C. geometrica, Say, from which it differs, however, in the form of the spine on the cephalon, in the length of the antennæ, and in the articulation and arming of the second pair of gnathopoda.” Mayer considers that this, together with Caprella candelis, G. M. Thomson, is probably a local variety of Caprella equitiva, Say. A second species is described as “Caprella lobata, Guérin.”

In Notes on Some New Zealand Crustacea, [Read before the Wellington Philosophical Society, 11th January, 1879], Trans. N. Z. Inst. Vol. xi. pp. 401–402, Mr. Kirk mentions the capture of Podocerus cylindricalis, Say, and Plesistes panopodes, Kriyer, at Worsor Bay. He says, “these are both Arctic species, and their occurrence on our coast is somewhat remarkable.” It has since been suggested that the Plesistes is a variety.

1878. Leydig, Franz.

On the antennæ of the Amphipoda, Leydig distinguishes:
1 Gewöhnliche Borsten. These ordinary bristles, for most of their length dark-rimmed, but with bluish ends of finer, clearer structure, and often a fine hair given off some way short of the termination, are found on other parts of the body as well as the antennæ.
2. Fiederborsten. These plumose bristles, spoken of by Humbert as “capsules sensitives,” may, Leydig says, be sensitive, but they are not capsules, they are modified pores (Hautepilules). For the explanation of the like in other Crustacea and in insects, he refers to his own work Über Geruchs- und Gehörorgane der Krebse und Insecten, Archiv f. Anat. u. Physiol., 1860. Between this and the preceding class he places a sort of Haftfieberborsten, such as are found on the rim of the head and the back of Gammurus petenaeus.
3 Cylinder oder Keulen. In these cylinders or clubs, the end swelling into a sort of knob
REPORT ON THE AMPHIPODA.

shows a pale, fine structure, but no opening. They may be seen on the flagellum of the lower antenna of *Gammarus pulex*.

4. Riehnzapfen. These olfactory tubes are on the flagellum of the upper antenna. They have a narrower dark-rimmed stem and a paler, broader body, in which there is a slight indentation at about midway. A cloud of fine granular substance may sometimes be seen issuing from the terminal aperture.

5. Schuhartige Anhänge. Calceoli. These shoe- or slipper-like stalked appendages are supposed to belong only to the lower antenna of the male, but it is now known that they occur on both pairs of antennae and in both sexes.

In the ordinary bristles, called by du Rougemont tactile bristles, Leydig could not find a nerve, though inclined to regard both the bristle and still more the fine offshoot near the tip as the sheathing of a nerve-end. That Claus should have seen the nerve in other Crustacea [the Argulidae] he thinks open to doubt. This doubt Claus criticizes in "der Org. d. Phron. p. 10–11, n. 1. The plumose bristles Leydig had always regarded as tactile bristles, having in other subjects shown how they were placed upon indubitable ganglia. If the view of recent observers, that these are auditory hairs, be justified, the sense of sound, Leydig infers, must be distributed over a considerable portion of the surface of the body, a conclusion not of necessity to be rejected.

He defends his attribution of an olfactory function to the "Riehnzapfen" against the objections of Graber in 1877. In the lower animals he considers that the different senses are not necessarily very sharply distinguished, so that one and the same nerve-end-apparatus may serve for the sense of touch, taste and smell, may even not be quite inaccessible to light and sound. He illustrates his meaning by the popular use of the German word "Wittern" (compare English "savour") employed sometimes of taste and sometimes of smell.

In *Gammarus fluvialis* and *Gammarus pulex* he thinks the eyes are pretty much alike in shape. In both the cornea is smooth and without facets. The crystal cone, he says, consists of four pieces, which can scarcely be correct; see Note on Grenacher, 1879. In view of the very varying statements of authors on the eye of *Gammarus pulex*, he made investigations from which he determines that the optic ganglion is present, but not the eye, though pigment-spots mimicking the eye have led some observers to believe that an eye existed in fact.

Under the heading, "Über die Schalendrüse," Leydig reminds us that in his Naturgesch. d. Daphniiden, 1860, pp. 28, 29, he had described his discovery in *Gammarus* of the homologue of the "green gland" in Astacus; but when he says that O. Sars seven years later only knew of the presence on the lower antenna of "un procés conique dirigé en bas et appelé l'épine olfactoire," he is very much in error as to the state of Sars' knowledge.

See Note on Sars, 1867. Claus, in 1873, objects that the name "Schalendrüse" has no sense when applied as by Leydig to the gland in the base of the antenna, "sondern jaest lediglich für das in die Schale gerückte Drüsennar der Phyllopoden, welchens der Kieferregion gehört." The pair of glands corresponding to the shell-gland is entirely wanting, he adds, in all developed Malacostraca, and has hitherto been made out only during the larval life in Sergestes and Euphausia, while on the other hand in the Phyllopoda and many other Entomostraca the antennary gland corresponding to the green gland of *Astacus* only exists in the larval stage, but afterwards becomes completely degraded (Der Org. d. Phron., p. 13).

On the digestive system, Leydig recalls the investigations he had described in 1855 in regard to the stomach, histological structure of the intestine, liver and adipose body. He here remarks that the fat-drops are always colourless, and that in the fatty body of the body cavity, round the intestine, there are besides the fat-drops also layers of those concretions

(zool. chall. exp.—part lxvii.—1887.)

XXX 61
which he had formerly pointed out as existing in *Asellus aquaticus*, and in some insects and Myriapods. On the term Kaumagen here employed for the stomach, Claus says that in the general use by authors of this terminology obviously borrowed from the Decapoda, we must not lose sight of the fact that for the Amphipoda "die Kauorganisation des Vormagens bislang keineswegs bewiesen worden ist." In fact, he continues, the importance of the supposed Kaupplatten (triturator organs) at least in the Phronimide appears to be limited to a closing apparatus (as in a lobster-pot), whereby the food that has passed into the Vormagen (cardiac portion of the stomach) is restrained on the one hand from returning into the oesophagus, and on the other from passing over too rapidly into the Magendarm (pyloric portion of the stomach) (Der Org. d. Phron., p. 25).

On the circulation, Leydig calls attention to the presence (observed apparently in *Gammarus puteanus*) of a sharply defined aorta proceeding from the anterior end of the heart, with a furcate division in the head. Also, he says, in the antennae and pleopoda the arterial course is so definitely distinguished from its surroundings that the expression vessel (Gefäss) is more appropriate for it than lacuna. I do not therefore understand the criticism of Delage (p. 89) upon this paper by Leydig that "ce n'est plus le lieu de faire avancer la question, reproduit, au contraire, une erreur ancienne en niant absolument que les courants sanguins des membres possèdent des parois."

Remarks are made by Leydig on the distribution of, and distinctions between, *Gammarus pulex*, de Geer, *Gammarus fluviatilis*, Rösel, and *Gammarus (Niphargus) puteanus*, Koch. Adopting the view of de Rougemont that *Gammarus pulex minutus*, Gervais, is identical with Koch's *puteanus*, he says that this last was made known by Koch and Gervais at the same time. "Wenn man freilich, wie es ihn und wieder geschieht, zu Koch citirt: 'Fauna insectorum Germaniæ initia, 1798; so käme die Beobachtung von Koch weit vor der Gervais'; allein das erste Heft des Koch'schen Werkes, welches als Fortsetzung der von Panzer beginnenden und bis zum 109. Heft fortgeführten Fauna insectorum Germaniæ auftritt, erschien 1835, nachdem zuvor Herrn-Schiffer die Hefte bis zum 132. herausgegeben hatte. Dieselbe Jahreszahl, 1835, trägt auch der Band der Annales des sciences, welcher die Beobachtungen von Gervais bringt."

Leydig in this work gives a summary of his earlier investigations on the structure of *Gammarus*, which may be quoted in his own words, "So habe ich die histologische Beschaffenheit der Haut schon im Jahre 1855 erörtert und später im Jahre 1860, da ich früher die Cuculæ als nicht verkalzt bezeichnet hatte, aufmerksam gemacht, dass doch auch bei *Gammarus* nach Essigsäurezusatz die Haut Luftbläschen entwickelt. Ferner wurde, was oben noch einmal zur Sprache kommen soll, die Schalendrüse nachgewiesen, auf die Anwesenheit eines Kaumagens hingedeutet, und die histologische Beschaffenheit des Darmes, der Leber und des Fettkörpers dargethan. Endlich habe ich bereits im Jahre 1848, also um 20 Jahre vor E. van Beneden's Arbeit über die Furchung der Amphipoden, den Furchungsproces von *Gammarus* beschrieben und abgebildet."

Crustacea. The Zoological Record for 1876; being Volume thirteenth of the Record of Zoological Literature. London, M.DCCC.LXXVIII. pp. 1–18.

An analysis is given of Claus' "Untersuchungen zur Erforschung der genealogischen Grundlage des Crustaceen-Systems. Wien, 1876." "Nebalia and Branchiopæs among the living forms may give an approximate idea of those primordial forms, from which the Decapods, Stomopods, Amphipods and Isopods are to be derived."
1878. Mayee, Paul, born July 20, 1848 (P.M.).

The first chapter is "über die Drüsen in den Beinen der Phronimiden," the second discusses "die Gehäuse der Phronimiden" (Gerstanek).

This paper, according to Haller, explains in great detail the gland in the grasping-hand of Phronima solenaria, pointing out its position, form, number of outlets, microscopic constitution, and suggesting that it is either a poison-gland, or more probably emits a secretion necessary for dissolving the interior of the creature used by the Phronima as a nest or nursery.

1878. Miers, E. J.

The account of the Crustacea appeared in the Annals and Magazine of Natural History in 1877. See Note on Miers, 1877.

1878. Schmidt, Oscar.

This paper raises certain objections to the views of Exner and Grenacher on "mosaic vision," which are met by Grenacher in an appendix (pp. 168–170) to his great work on the subject, Untersuch. über das Sehorgan, 1879.

1878. Stebbing, T. R. R.

Caprella fretensis, n. sp., is described and figured, from two specimens found at Salcombe in South Devon, at which place the estuary yields Prodo ventricosa, O. F. M., and many other Amphipods. Meyer accepts Caprella fretensis as a distinct species, but considers it extremely close to Caprella septentrionalis, Krzyer. It is abundant at Ilfracombe, and very variable, some specimens coming far nearer than others to the published accounts of Krzyer's species just mentioned.

The correlation between the spines on the palms of the hind legs, die Einschlagdornen, in the Caprellidae, and the generic divisions of that family, is noticed. Mayer, die Caprelliden, p. 13, remarks that it would be difficult to carry through the employment of this character for generic division, since Caprella acanthifera, for example, would then have to be transferred to another genus. This indeed is on other grounds suggested by Boeck, who thinks that Caprella acanthifera may belong to his genus Echinella. Of Stimpsonia
There is no text in the image.
REPORT ON THE AMPHIPODA.

485

evolved, triangular rostrum; constricted behind the eyes into a short, narrow neck. Superior antennae with the peduncle three-jointed; in the female straight. First and second pairs of thoracic legs small, chelate, the fourth joint broad and long, the fifth short and narrow. The last three pairs of legs with the basal joint narrowly dilated; the seventh pair diminutive. The sixth segment of the abdomen long and narrow. Caudal appendages long and linear. Telson short, triangular." The type species, Calamorhynchus piliceps, n. s., is described from a female specimen, the head and second thoracic foot being figured. Rhabdosoma whitei, Sp. Bate, and "Rhabdosoma armatum (Edw.), Adams and White," are figured and described, two species which Claus unites as identical. Rhabdosoma armatum, Sp. Bate, is curiously treated by Dr. Streets as a separate species, to which he gives "provisionally the name Rhabdosoma longirostris (Bate)," although he recognises that Spencer Bate took his description and figure from the same specimen that furnished White's figure.

1878. Uhler.

Two Amphipods (Gammarus sp. and Caprella geometrica, Say), along with other Crustacea, observed at Fort Wool.

1878. Woodward, Henry.

1878. Zaddach, G.

Zaddach here expresses the opinion that the epimera or side-plates of the Amphipoda are parts of the segments, an inheritance from the unarticulated pleura of the Trilobites, and a higher development of these. For the first joint of the leg after the epimera he adopts the term Hülle, for the second and third Dreigelenk and Schenkel, for the fourth and fifth Schienenglieder, and for the sixth Tarsus. He gives a table to show the differences between the eight species which he has to describe, namely, Talitrus locusta, Gammarus locusta, Melita palmata, Callope tessiscala, Protomedeia pilosa, Pontoporeia fenarata, Bathyporeia pilosa, Corophium longicorn. In 1843, he says, specimens of Corophium longicorn and Protomedeia pilosa were taken by Rathke in lake Geserich. Zaddach himself had not been able since to find them in that, or hear of them in any other, inland water of Prussia. In describing the family Orchestidae, he calls attention to the "endophragmal arch," which is wanting in other Amphipods, with a reference to Bate and Westwood, i. p. xvii, fig. 3; he says that the maxillipeds bear not two, as in the Gammaridae, but three laminar processes on the three lowest joints, and that they are only five-jointed, because the claw-shaped terminal joint is wanting; the telson, he says, is wanting. But the telson, though small in Talitrus, is not wanting in this or any other known genus of the Orchestidae; and the fourth joint of the maxilliped-pulp, though rudimentary or obsolete in Talitrus and Orchestra, is developed in Hymet and Hyalela; while, lastly, it is not correct to give as a family
characteristic that the three lowest joints of the maxillipeds are expanded, since alike in *Talitrus, Orthogammarus* and *Talorhynchus* it is not the first but the second joint of the palp that has an expansion, nor is that one of such a laminar form as to be properly comparable with the plates attached to the two joints below the palp. The remark that the palp is wanting to the first maxillae also requires qualification, since in *Talitrus locusta*, for example, one is present though rudimentary in size.

In describing *Talitrus locusta* (Taf. 1) Zaddach affirms that there is no trace of a mandibular palp; he says that the function of the mandibular spine-row is obviously to pass on the morsels bitten off by the cutting-edge to the molar tubercle. What is commonly called the under lip should, he thinks, be called the tongue, both from its function and from its answering morphologically to the tongue of many insects. He considers that Linnaeus in the description of his *Cancer locusta* in the Fauna suecica could not have intended any other species of Amphipoda than this.

In describing the family Gammaride, Zaddach maintains that the peduncle of the lower antennae has but four joints, not admitting the composite character of what he calls the first joint. In the description of *Gammarus locusta* (Taf. 2) he points out that young specimens (Taf. 3) differ from the adults in the size and shape of the eyes, in the number of the joints of the antennary flagella, in the rami of the third uropods, and in the telson. He argues that Linnaeus in the Fauna suecica, No. 2041 and No. 2042, by *Cancer pulex*, which gnaws the fishing-nets, meant only *Gammarus locusta*, and by *Cancer locusta* meant only *Talitrus locusta*, since that alone by its leaping, its powerful head and long antennae, was fit for comparison with a grasshopper or locust. At the same time he considers the name *Gammarus locusta* too firmly established for alteration. He here recognises that the Amphipoda in amber, *Pulsoamphipus sambiensis*, which he described in 1864, may belong to the genus *Gammarus*, or come very near it.

In describing *Melita palinura* (Mont.) Lesch, (Taf. 4), Zaddach mentions that the side-plate of the sixth peraeon-segment in the female, and not as Boeck states in the male, is prolonged downwards at the front angle and bent upwards into a blunt hook, destined, he thinks, to provide the large claw of the male with a holdfast. (Bruzelius had already, in 1859, rightly ascribed the peculiarity in these side-plates to the female.) *Amphitoe norvegica*, Rathke, he does not consider distinct from *Calliope laevicauda* (Kroyer) Kroyer, which he figures (Taf. 5) and describes.

It may be noticed that in this paper Zaddach accepts the name *Protomeidea pilosa* for the species which he himself in 1844 named *Leptocheirus pilosus*, but Boeck maintains that *Leptocheirus, Zaddach*, is a genus quite distinct from *Protomeidea*, Kroyer.

1879. BRANDT, A.

In a letter to the editor, dated from Dorf Elenowka am Goktschai, den 26. Juli 1879, Dr. Alexander Brandt reports that in the Goktschai there were swarms of Gammarids, especially on the shore. Those discovered were very uniform, corresponding in size and habit to *Gammarus pulex*. Individuals brought up from a depth of 34 fathoms showed a brighter colouring than those from the upper waters. He remarks that their eyes are not dark or continuously pigmented, but offer only lighter pigment-flakes of a roundish stellate form, so that at first sight he could fancy them destitute of eyes. Have we, he asks, by any chance here to do with a blind variety in statu nascendi?
1879. Claus, C.

Der Organismus der Phronimiden. Mit. 8 Tafeln. Wien, 1879.

Following Milne-Edwards, Claus here sets the Typhide or Platyscelidæ (Hyperina anomala), distinguished by a marked sexual dimorphism as well as by the zig-zag antennæ of the male, over against the Hyperina with normal antennæ. In the latter group he arranges, in three families, the Phronimide, Hyperide and Vibliide. The Vibliide are easily distinguished by the general form resembling the Gammaride, the small size of the head and eyes, as well by the short dilated anterior antennæ. The border line is less easily marked out between the other two families. He characterizes them as follows:—

"Phronimide. Head of considerable size, generally with strongly prominent snout, and divided pair of eyes extending over almost the whole surface of the head. The antennæ in both sexes with multiarticulate peduncle, in the female without or with rudimentary, in the male with long multiarticulate, flagellum. Gnathopods frequently armed with weak clasper (Greifhand); the rest of the thoracal-limbs end with simple claw and are formed like one another (Hyperin), those of the fifth (Themisto), and sixth pair (Cythopus, Cystosoma) are sometimes considerably elongated, those of the seventh or last pair only as an exception (Cythopus) rudimentary.

"Phronimide. Head of considerable size, generally with strongly prominent snout, and divided pair of eyes extending over almost the whole surface of the head. The antennæ in both sexes with multiarticulate peduncle, in the female short and without flagellum, in the male long with multiarticulate flagellum. The antennæ of the second pair in the male like those of the Hyperide, in the female reduced to the coxal-joint coalescent with the cephalic integument and accompanied by the antennary gland. The thoracal legs partially (principally the fifth pair) armed with powerful chelæ (Greifzange), often of different form and size. Elongate backward directed liver-tubes absent from the stomach (am Magendarm fehlen)."

The Phorminæ, Claus here says, are to be referred to the Typhide. The Phronimide he subdivides into two subfamilies thus:—

"1. Phrosina. Form of body broad and compact. The three pairs of uropods broad-leaved with fin-like rami. Besides the powerfully developed fifth pair of legs of the peræon (Primmo Guér.), generally also the third and fourth pairs (Anchylomera Edw. = Hieraconyx Guér.), as well as the sixth (Phrosina Risso = Daetylocera Latr.) armed with powerful claspers (Greifhand).

"2. Phrosina. Body slender and extended, with the last segment of the person elongate. The three pairs of uropods elongate stiffform, with narrow lanceolate rami. Thoracal legs extremely varied, those of the fifth pair [third peræopods] often armed with broad or more elongate (compound) chelæ."

The genus Phrosina, Latr., is thus defined:—

with hohem, gewölbtem Scheitel, Scheitelmündung sehr verlängert. Die zwei vorderen Brustsegmente ohne Grenzen verschmolzen. Mandibeltaster fehlen auch dem Männchen. Zunge der Unterlippe (Maxillardfusspaar) auf einen warzenförmigen Höcker reduziert. Die beiden Gnathopodenpaare schmächtig mit schwacher (zusammengesetzter) Greifhand. Das dritte Beinpaaar etwas weniger, das vierte stark verlängert. Das fünfte Beinpaaar endet mit sehr langgestreckten (zusammengesetzten) Greifhand. Drei paare von Kiemenschläuchen am 4., 5. und 6. Brustringe." Phronimella elongata is the type species, with which Dr. Streets has identified his own Anchylonyx hamatus. In fact, as Streets has already observed, there are in the male three pairs of uropods, and I find that a rudiment of the middle pair is, at any rate sometimes, persistent in the adult female. The first pereopod (das dritte Beinpaaar) is longer than the second, not vice versa. The error in the generic definition was made by Claus in his original account of "Phronima elongata," but corrected by Claus himself in the same year, 1862.

Phronimopsis, n. g. (figs. 1-3), is thus defined:—

Paraphronimella, n. g. (figs. 4-10), is thus defined:—

From page 8 to page 78 the investigation is conducted which is indicated in the title of the paper. The principal results are thus summarised by the author himself:—

1. The two new genera Phronimopsis and Phronimella prove that the armour of the fifth pair of legs [third pereopods] with a chelate hand (Scheerehaut) is a character only of generic value.

2. The females of the Phronimidae possess a rudiment of the second pair of antennae, which is generally reduced to the spherically protuberant coxal-joint containing the coiled antennary gland.

3. In front of the mouth lies a rudiment of the upper lip, an atrium bounded by the side-plates of the mandibles and the lower lip (Paragnathen), into which cavity flows the secretion of powerful glands when food is being taken.

4. These glands are complexes of four gland-cells with long emission-ducts, and lie partly in
the periphery of the oesophagus, partly in the maxille, in which in point of form and structure they repeat the leg-glands.

5. The function of these glands is the preparation of the ferment (Enzyme), which is mixed with the food at its entrance into the oesophagus, to facilitate the digestion of starch and albuminoid substances.

6. The alimentary canal (Darmcanal) is devoid of every form of gland-cells. To the muscular oesophagus of complicated structure, lined with chitinous Intima, succeeds the oesophageal stomach (Schlundmagen, Vormagen), with two ceca (Nebentaschen), stretching into the crop (Magendarm). In this digestion is carried out. The crop which surrounds it, situate in the head and the two first pereon-segments is, like its two forward-directed pairs of so-called liver tubes, lined with a deep cylindrical epithelium, which repeats the structure of the epithelium of the mid-gut (Dünndarm-epithel), and serves for resorption. The narrow intestinal tube (Darmrohr), is lined with a polygonal pavement epithelium, and in the sixth pleon-segment passes over into the short rectum (Afterdarm), which is fastened to the integument by means of dilators. [At page 23, in the Monehlarm of Phronima three sections are distinguished as Mundhöhle, Schlundkopf and Schlundrohr or oesophagus.]

7. The annular muscles of the intestinal tube correspond to single muscle-cells, the nuclei of which follow one another in a median row on the dorsal side of the intestine.

8. The heart stretches from the boundary of the head to the middle of the sixth pereon-segment, and possesses, besides the three pairs of ostia provided with valves and the two aortas, two pairs of lateral arteries.

9. Each artery arises over an oblong slit bounded by two side-flaps (Seitenklappen) while at the base of each aorta lie two obliquely set ostia with a pair of flaps (valve-opening) to each.

10. The obliquely transverse muscle-rings of the heart are developed from two lateral rows of cells, between which a dorsal and ventral median suture remains.

11. Under the heart, adjoyning the ventral wall of the heart, there stretches across through the body-cavity a septum composed of large cell-plates. Besides this there is a second septum which occupies a similar position in regard to the intestine, so that the space of the body is divided into three blood-channels bounded by connective-tissue, and communicating with one another by definite openings. Besides these main channels, which are continued on into the head, there exist a number of more peripheral accessory channels, likewise bounded by connective-tissue, which represent the blood-courses of the regular circulation.

12. The ventral ganglionic chain contains, excluding the suboesophageal ganglion-mass, nine ganglia, of which five belong to the pereon, four to the pleon. The last pereon- (thoracic) ganglion, just as the last pleon- (abdominal) ganglion, follows the next preceding ganglion immediately. The last pleon-ganglion has arisen out of the concretion of three ganglia for the fourth, fifth and sixth pleon-segments, these ganglia in the embryo being separate.

13. The suboesophageal ganglion-mass corresponds to six ganglionic nuclei, or to seven if we take into account the ganglionic centre belonging to the commissures which provides for the nerves of the second antennae. Besides the nerves of the second antennae also all the maxillary nerves are derived from the cephalic commissure, to which their place of origin has shifted itself.

14. The peripheral nerves are rooted, not in the so called “Punktsubstanz” [Dietl’s Marksubstanz, p. 57, myeloid substance, Packard], but derive their fibres from ganglion-cells partly of the corresponding ganglion—as well crossed as uncrossed fibres—partly of the preceding ganglion, partly from the brain.

15. The fibre-tracts of the so-called esophageal commissure which enter the brain pass partly to the ganglion-layers of the same half of the brain, partly in crossed converse to those of the
opposite side. In the brain there exists a powerful commissural system, from which portions reach laterally into the powerful optic-ganglia.

16. The ganglion-cell-layers are thickenings of the superficial layer. Inner ganglionie nuclei do not exist. The small-celled ganglion formation of the cap-shaped hinder lobe answers to the fungus-like structure on the brain of the higher Crustacea and insects.

17. The optic-fibres of the lateral eye and of the frontal eye run in planes that cross at nearly a right angle.

18. Each eye is surrounded by a firm sheath, the continuation of the outer nerve-sheath of the brain, which also wraps itself over the front surface, and before each complex of two crystal cone-cells between the rounded vesicles of their nuclei contains two flat oval nuclei.

19. The cuticular cornea is not derived from the crystal cone-cells, but from a special hypodermal-layer separated from those cells by the eyesheath, and is renewed at the time of exuviation.

20. The eye continuously increases in extent with the growth of the body, by the formation of new peripheral elements.

21. The objection to the possibility of mosaic vision based on the form of the crystal cone is thoroughly untenable. [At p. 73, Claus expresses his agreement with Grenacher's opinion, that the Hyperidae are not dim-sighted.]

22. At the ovary there is a special germinal layer. The geniculate terminal section of the ooviduct ends with a sack-like expansion in a seminal pocket.

Of parasites, Claus found in the crop of Phronima and Phronimella almost constantly a little oval Gregarine, free or encysted; more rarely, in the body-cavity of Phronima, embryos of Echinorhynchus, and sometimes in the brain a young Nematode, spirally rolled.

To judge by the short list of literature on page 81, Claus was unacquainted with the papers on the pelagic Amphipoda by Dr. T. H. Streets, which are dated 1877 and 1878.

1879. Claus, C.

This work, which has been since its publication the leading authority on the group with which it deals, is practically embodied, though with a few modifications, in the larger and finely illustrated work by the same author published this year (1887).

It is noticed that in external form the Platysceliden show an astonishing number of gradations from the egg-like Typhidæ to the rod-like Oxycephalide. The common features are to be found in the structure of the antennæ in the male and of the fifth and sixth thoracal legs (third and fourth pereopods) in both sexes. Five families are established, in two divisions, division A., containing the Typhidæ and Scelidæ; division B. the Prooideæ, Lyceideæ and Oxycephalideæ. In 1887 the Lyceideæ form a separate division.

The Typhidæ contain five genera:—1. Eutypis, taking the place of Typhis, Risso, preoccupied, and having in the synonymy "(Thyropyus, Dana, Sp. Bate δ = Dithyurus Dana, Platyscelus Sp. Bate ♀)," of which names Dithyurus, Dana, must take precedence of Eutypis. In this genus both pairs of gnathopods have compound chelae, the two end-joints of the hinder antennæ in the male are very much shorter than the two preceding joints, and the lobes of the maxillipeds (Unterlippe) are slightly concave on the inner edge. The species assigned to it are—1. ovoides, Risso (including Platyscelus sericus, Sp. Bate ♀), and Thyropyus ovoides, Sp. Bate (♀); 2. armatus, n. s.; 3. serratus, n. s.; 4. globosus, n. s. In 1887 Claus adds "E. inermis Cls. (Dithyurus Faba Dana)"
2. *Hemityphius*, n. g., thus defined:—

("Die Oberlippe bildet eine helmformig gewölbte Klappe mit zwei schief vorragenden Flügeln," 1887.) *Hemityphius tesnimanus*, n. s., and *Hemityphius crustulatus* (crustulatus, 1887), n. s., are described.

3. *Paratyphius*, n. g., thus defined:—

4. *Tetrathyphrus*, n. g., thus defined:—

Type *Tetrathyphrus forcipatus*, n. s.

5. *Amphithyphrus*, n. g., thus defined:—

("Unterruppe zu einer kurzen Saugrohre umgestaltet," 1887.) The species described are *Amphithyphrus bifasciatus*, n. s.; *Amphithyphrus sculturatus*, n. s.; *Amphithyphrus similis*, n. s.

The remaining genera must be described in the less detailed form, which is given in advance of the fuller definitions.

The second family, Scelichi, contains:—

Type *Euceltus robustus*, n. s.

2. *Schizoceltus*, n. g., in which "Das vordere Gnatopodenpaar endet klanenförmig, das
THE VOYAGE OF H.M.S. CHALLENGER.

hintere mit zusammengesetzter Scheere. Femoralplatte des sechsten Beinpaares mit langer sichelförmig gebogener Längs spitze.” Type, Schizosecles ornatus, n. s.

3. Tanyscelus, n. g., in which “Beide Gnathopodenpaare enden klauenförmig. Femoralplatte des sechsten Beinpaares sehr lang gezogen und vorn verkleinert mit taschenförmiger Grube der Aussenseite. Endglied der hinteren männlichen Antenne kurz. Uropodenäste flossenförmig verbreitert.” Type, Tanyscelus pteromus, n. sp. (Thyroplus diaphanus Dana).”

The third family, Proneida, contains:

2. Eupronoe (Pronoe, Dana, ex parte), in which “Das hintere Gnathopodenpaar mit zusammengesetzter Scheere, vordere Antennen des Männchens mit dreigliedrigem Geißelaschirm. Hintere Antennen lang, zickzackförmig gefaltet, mit sehr kurzem Endglied. Doppelsegment des Abdomens (5 und 6) relativ kurz. Aeste des letzten Uropodenpaares sehr lang, flossenförmig” with the species Eupronoe marculata, n. s.; Eupronoe armata, n. s. (Pronoe brunnea, Dana, hypothetically); Eupronoe minuta, n. s. For the opinion that this genus is a synonym of Orio, Cocci, see Note on de Natale, 1850; to the small female specimen from Lagos there mentioned, Claus in 1887 gives the name Eupronoe serrata, n. s.

3. Parapronoe (Amphipronoe, Spence Bate, §), which resembles the preceding genus, except that it has “Doppelsegment des Abdomens ungewöhnlich verlängert. Aeste des letzten Uropodenpaares kurz.” This has the species Parapronoe crastulata, n. s.; Parapronoe pareri, n. s. Spence Bate assigns to Amphipronoe, “first pair of gnathopoda complexly subchelate; second pair not subchelate.” On the supposition that the words “first” and “second” in this account ought possibly to be transposed, Claus gives Amphipronoe as a doubtful synonym of Parapronoe. Amphipronoe serrula, Bate, 1877, has the gnathopods described in accordance with Spence Bate’s generic account.

The fourth family, Lyceidae, contains:

1. Thamyris, Spence Bate (with Brachyseles, Spence Bate, §, and Schuchagensia, Claus, for synonyms). In this genus “Beide Gnathopodenpaare enden mit zusammengesetzter geracketcher Scheere. Stiel des ersten Uropodenpaares kaum länger als die Aeste. Fünftes Beinpaae mit dem sechsten ziemlich gleich lang.” It receives the species Thamyris parax, Claus (Schuchagensia parax, Claus, 1871), and Thamyris aolica, Claus. Claus has also examined a female specimen of a much smaller and perhaps distinct form. Independently of this, and another larger specimen of some species of Thamyris of unknown locality, Claus describes in 1887 two fresh species, Thamyris Irvingi, n. s., and Thamyris mediterranea, n. s. Whether Spence Bate’s Thamyris aolica and Thamyris (Brachyseles) crassula are separate species he cannot determine with certainty; in 1887 he thinks it probable that they are.

2. Lynca, Dana, in which “Beide Gnathopodenpaare enden mit scharfgerader zusammenge- setzter Scheere. Das erste Uropodenpaar stiefelförmig verlängert, mit kurzen Aesten. Fünftes Beinpaae stark verlängert.” Species, Lynca unatua, n. s.; Lynca similis, n. s.; Lynca serrata, n. s.; Lynca robusta, n. s.; Lynca pales, Marion (§). To the description of Lynca robusta in 1887 Claus adds, “Hier schliesst sich die von Marion beschriebene Lynca pales an, von welcher lediglich jugendliche Individuen in der
REPORT ON THE AMPHIPODA.

493

Athemöhle von Salpen gefunden wurden," without explaining why he does not in that case adopt Marion's earlier specific name.

3. Simarophybus, Claus, in which "Das vordere Gnathopodenpaar endet einfach klaunenförmig, das hintere mit halber Scheerenhand. Stiel des ersten Uropodenpaares so lang als die Aeste. Fünftes Beinpaa nur wenig verlängert," with the species Simarophybus antennarius, Claus. In 1887 Simarophybus rapax, Claus, is given as a synonym, with a reference to the Untersuchungen, 1871, but this is probably an accidental confusion with Schuhagenia rapax, the synonym of Thamyrus rapax.

5. Paralycyas, n. g., in which also "Beide Gnathopodenpaare enden einfach klaunenförmig," while it has "Fünftes Beinpaa stark verlängert. Stiel des ersten Uropodenpaares so lang als die Aeste. Siebentes Beinpaa mit dünnen, gebogenen Femoralplatten und rudimentären Anhang." Type species, Paralycyas gracilis, n. s.

In 1877 Claus remarks that Phorbus, M.-Edw., belongs to the Lycyas, while he no longer definitely includes Lycyas in that family. Among other exceptional characters of that genus, he notes that there are only two pairs of branchial vesicles. These are on the third and fourth pereopods.

The fifth family, Oxycephalidae, contains:

1. Oxycephalus, Milne-Edwards, in which "Beide Gnathopodenpaare enden mit zusammengesetzter Scheere. Körper massig gestreckt, Stirnschnabel nicht merklich länger als der Kopf, die Femoralstäbe des fünften und sechsten Beinpaares sind ziemlich hohe Platten." The species assigned are Oxycephalus pisator, M.-Edw., with Oxycephalus oceanicus, Guérin, and Oxycephalus tuberculatus, Sp. Bate, as synonyms (to which in 1877 Oxycephalus tuberculatus, Streets, 1875, is added); Oxycephalus similis, n. s.; Oxycephalus latirostris, n. s.; Oxycephalus tenirostris, Claus, 1871 (to which in 1877 Lytorchis spinicauda, Streets, 1878, is given as a synonym); Oxycephalus porcellus, n. s.; Oxycephalus longiceps, n. s.; Oxycephalus typboiclus, n. s. (to which in 1878 Oxycephalus Bulbosa, Streets, 1878, is assigned as a possible synonym). For the suggestion that Oxycephalus typboiclus might be the Ornithorhynchus coscoi of de Natale, see Note on de Natale, 1890. De Natale's species is clearly an Oxycephalus, but further than this its identification perhaps cannot be carried.

1879. EDWARD, THOMAS.

The list of Amphipoda extends from page 432 to page 435. Some notes are given on the colouring of various species, and on the times of the year at which specimens were taken with eggs. The colouring of the eggs of sundry species is also noticed. To Nematobranchia the note is appended, “With eggs in December. The female has the palms of the two first pairs much narrower than the male.” After the names Lestrigonus exulans and “Kinahani,” Hyperia galla and Hyperia obligia, the observation is made, “These are the only species of this family which I have ever found on the Meduse. I consider Lestrigonus Exulans to be the male of Hyperia Galla, and L. Kinahani the male of H. obligia.” After the names “Hyperia transversa, n. s.,” “prehensilis, n. s.,” “cyaneo, n. s.,” he writes, “All these three new species were first taken at Banff by T. E.; the males and females of all three being procured. The males differ but little from the females, except that they are somewhat larger.” No notice is taken of the name Hyperia nuda, which he spoke of in 1868. Of Dulichia porrecta and Dulichia fulcata he says, “I look upon these as being male and female of the same species.”

The list, like the rest of Mr. Smiles’ entertaining book, is disfigured by numerous misprints. Pliocus is given for Pliucus, Zetlwandica for Shetlandica, Bullomensis for Volumnesis, Plierus for Plierus, grandulaculis for grandulaculi, Hora for Aura, Megamnora for Megamoera, Siphonocetes for Siphonocetes, Protomedia for Prote, the last being perhaps due to a slip of the pen on the author’s part.

1879. Fries, S.

The occurrence of well-shrimps in the slightly brackish wells of Heligoland and in England is discussed, and the view advocated that they must have existed in these localities before the islands were separated from the mainland. Fries has examined specimens from the above mentioned wells of Heligoland, from the Falkenstein caverns, from the springs running out of the caverns, from the Hilgerhäuser caverns, and from the depths of the Lake of Geneva. In all he finds no greater differences than would justify the naming of varieties. He therefore adheres to the view of Rougemont in uniting the various so-called species of the well-shrimp, and considers that the name Gammarus puteanus, as the earliest and best known, should be retained, though appearing unduly to restrict the distribution of the species to wells. Humbert’s definition of the genus Niphargus, he considers, may be applied to the specific definition of Gammarus puteanus. The addition, however, to “Oculi nulli” of “vel rudimentarii” must be struck out. In the second maxille, which according to Humbert have the setae of the inner lobe only at the apex, specimens from the Falkenstein spring show three bristles somewhat further down the inner rim than is the case in Humbert’s drawing, Pl. VI, Fig. 8a. A constant character in all specimens of Gammarus puteanus examined by Fries is, that the secondary flagellum of the upper antennae has only two joints, not four or three as in Gammarus pulex 5 and 9 respectively. At pages 129-134 he discusses the Isopod “Asellus caudatus,” Schödel (in litt.) (= Asellus Sieboldii,
REPORT ON THE AMPHIPODA. 495

Rougemont)." He has uniformly found this in company with \textit{Gammarus pulex}, which, according to Rougemont, is its mortal foe. He agrees with Rougemont in considering that \textit{Asellus cavaticus} is related to \textit{Asellus aquaticus} very much as \textit{Gammarus pulex} is to \textit{Gammarus pulex}.

At p. 309 other localities are mentioned for the occurrence of \textit{Gammarus pulex} and \textit{Asellus cavaticus}.

1879. GRENACHER, H.

Preliminary notices of these investigations were given in the Göttinger Nachrichten, 1874, Nr. 26, and in the Klinischen Monatsblätter für Augenheilkunde, supplementary number for May, 15th year, 1877.

The elaborate and exquisite illustrations to this work seem to show all that is at present known as to the organs with which the book is concerned. Grenacher maintains "the theory of Mosaic Vision," propounded by Johannes Müller in 1826, and gives references to numerous works more or less opposed to or agreeing with his own views. In pages 109-114, and on Plates IX. and X., he treats of the eyes of the Amphipoda, referring especially to \textit{Gammarus locusta}, \textit{Talitrus saltator}, \textit{Gammarus neglectus}, \textit{Hyperia galba}, \textit{Phanomis sedentaria}. Fig. 99 gives a "Schnitt, parallel der Längsaxe des Thieres und senkrecht auf die Längsaxe der Gesammtauges, von Gammarus locasta." Fig. 100 shows a single ocellus from the same animal with the "nuclei of Semper" on the surface over the crystalline cone, composed as usual of two longitudinal segments. Fig. 102, A. and B., shows two ocelli of \textit{Talitrus locusta}, one from the middle, the other from the rim of the eye. Fig. 103 shows the "Zellkerne der Retinula" on either side of the inner end of the crystalline cone of one of these ocelli. Fig. 104 shows the "Krystalkegel mit Retinula aus dem Auge von Hyperia galba (H. Latreille). Der Krystalkegel aus dem peripherischen Theilen des Auges ist von einer weiten Hülle umgeben, deren Kerne vorn gelegen sind. Besondere Zellen, um das Hinterende des Krystalkegles. Das fein quergetreifte Rhabdom hat in seinem Innern einen deutlichen Canal." Fig. 105, a.b., is a "Querschlitze durch den Krystalkegel desselben Thieres in verschiedene Höhen, um das Verhalten desselben zu seiner Hülle zu zeigen." Fig. 106, a.b.c., shows "Querschlitze durch die Retinula desselben Thieres in drei verschiedenen Gegenden. An allen ist die Zusammensetzung der Retinula aus fünf Zellen, an den beiden ersten auch die des Rhabdoms aus ebensoviel Stübschen, sowie der centrale Canal desselben zu erkennen."

1879. HOEK, P. P. C.

The work contains five chapters:—

I. On the anatomy and classification of the Caprellidae.

II. Contributions to the knowledge of the Corophidae. Dr. Hoek here goes into detail to confirm the opinion of A. M. Norman that "Corophium Benelli," Bale and Westwood, is the female of \textit{Corophium crassipenne}, Brazelius. He unites, in agreement with Axel Boeck,
On an *Gastroclonus* from terra firma. The *Gastroclonus* in question was found in a walled garden in the town of Zalt-Bommel in the province of Gelderland, many miles from the sea, and is identified by Dr. Hoek with *Gastroclonus canaamus*, Heller, taken on Olympos in Cyprus at a height of 4000 feet.

On some insufficiently known Gammaridae. These are—1. *Atylus scammonianus*, Milne-Edwards; 2. *Callopinus brevisculcs*, Kröyer, on which Dr. Hoek observes that the genus *Callopinus* is intermediate between the Atylinae, to which Bock assigns it, and the Gammarinae; 3. *Melita obtusata*, Montagu, as to which he adopts Norman's statement that *Melita proxima*, Bate and Westwood, is the most frequent form of the male of *Melita obtusata*, and *Meganemora alaeri*, of those authors, its female; 4. *Cheirocratus brevicornis*, n. s., which, however, is the same as *Cheirocratus antennatus*, Rathke, and has also been described under the names *Liljeborgia saltwadiica*, Sp. Bate, and *Liljeborgia normalis*, Stebbing, though some of its characteristic points were first clearly brought out by Dr. Hoek; 5. *Ampelisca equicollis*, Bruzelius, is distinguished from *Ampelisca laticollis*, Liljeborg; *Tetromus typicus*, Sp. Bate, later incorrectly identified by Sp. Bate with *Ampelisca garnavi*, Kröyer, and by Norman and Bock and Hoek considered synonymous with *Ampelisca carinata*, Bruzelius, and by Sars with *Ampelisca terticornis*, Liljeborg, is here attached, in accordance with Norman's suggestion, to *Ampelisca equicollis*, Bruzelius, as the male form. But Bate's species is distinct, and is entitled to the name *Ampelisca typicus,* if a species which is not the type can lawfully be called *typicus;* see discussion in Note on Sars, 1882.

V. Short anatomical notes on Gammaridae, referring to the structure of the antennae with their "calcari," etc., and to the branchiae of *Atylus scammonianus*.

1879. JOSEPH, GUSTAV.

In regard to the *Niphargus puteanus* from Venice, it is shown that their introduction into the carefully covered wells (Pozzi) of Venice is best explained by the transport of water from the mainland to replenish these wells in the dry season.

1879. MAERTENS, EDUARD VON.

1879. Miers, E. J.

Only an incidental allusion to the Amphipoda is here made.

1879. Miers, E. J.

The description of Talitrus gulliveri from Rodriguez is here repeated. In the account of the Kerguelen Amphipoda, notice is taken of Hyale villosa, Smith; Lysiannassa hilderti, Smith; Lysiannassa kergueleni, Miers, is transferred to Anonyx, and will be discussed further on in this Report. This species, together with Astylus australis and Podocerus ornatus, is figured and more fully described than when first published.

1879. Pagenstecher, H. Alex.

Compare the Note on Willemoes Suhm, 1876.
1879. Sars, G. O.

1879. Smith, Sidney I.

Occurrence of Chelura terebrans, a crustacean destructive to the timber of submarine structures, on the coast of the United States. Proceedings of United States National Museum. pp. 232–235. Fig. 1.

The synonymy is given, as well as a description, and other notes. Compare Note on Verrill and Smith, 1874, p. 436.

1879. Stebbing, T. R. R.

Sessile-eyed Crustacea of Devonshire. Supplementary List. (Read at Ilfracombe, July 1879.) The Transactions of the Devonshire Association for the Advancement of Science, Literature, and Art. 1879. 9 pages.

A suggestion made by the Rev. A. M. Norman is here mentioned that *Grayia lubricata*, Sp. Bate, is the young of *Anathilia salinia*, Leach. It is proposed to unite the species *Nesia excavata*, Sp. Bate, with that author's *Nesia rinalpinauna*.
1879. Stebbing, T. R. R.

These names I now regard as synonyms of *Hyale pontica*, Rathke.

1879. Studer, Th.

Lists are here given both of the literature of the subject and of the species of animals. The Amphipoda are enumerated at page 126. They are named as follows:—*Atylus australis*, Miers; *Atylus*, n. s.; "Ammon Kerguelenii," Miers; "Lysiana Kidderii," Smith; *Hyale villosa*, Smith; *Leucos sp.; Podocerus ornatus*, Miers.

In the "Vertheilung der Meeresthiere," I notice also, at p. 136, among Crustacea, "Eusirus? 150 Faden Sandschlaum." *Atylus australis*, Miers, is noted as approaching *Atylus fissicantula*, Dana, from Valparaiso.

1879. Thomson, George M., born 1848 (Chilton).

Of "*Talitrus ? nova-zealandia*, Dana (*Orchestoidea ? nova-zealandia*)," Mr. Thomson remarks, "This species is certainly the female of *Talorchestia quoyana*," M.-Edw. "The males of the *Talitrus*, and the females of the *Talorchestia*, have never yet been described as such."

The new species described are *Nicca nova-zealandia; Nicca fluviatila; Nicca rubra; Decavum pacifica; Atylus danai; Phorura nova-zealandia; Calliope dioctaeta; Calliope fluviatila; Gammarus barnesianus; Planepus interlinearis*, with the remark appended, "I have named this species as above, from the fact that it is almost intermediate between the only two species hitherto described—*P. rissoinae*, Bate, and *P. serratus*, Bate?; *Caprella caudata*, recorded by Mayer as a near relation, if not a local variety, of *Caprella equilibra*, Say; *Caprellina nova-zealandia*, according to Mayer identical with *Caprella longirostris*, Nicolet, the genus only, not the species, being new.

*Caprellina*, new genus, is thus defined:—"Bony cylindrical. Cephalon confluent with first segment of pereion. Pleon rudimentary. Gnathopoda subchelate; branchiae attached to second pair. First two pairs of pleopoda represented by the branchia attached to their respective segments; third pair feebly developed; two posterior pairs well developed, subequal. First and second pairs of pleopoda rudimentary in the male, not obsolete."

"This genus appears to be intermediate between *Ceratops* and *Caprella*. From the former, it differs in not having the pleopoda developed, but agrees with it in having branchia attached to the second gnathopoda. In respect to this latter character it differs from its nearer ally *Caprella*, and also in having the third pair of pleopoda feebly developed." Mayer, instead of placing the genus between *Ceratops* and *Caprella*, sets it next to *Proto*, in common
with which it has a mandibular palp, the flagellum of the lower antenna consisting of more than two articulations, branchial on the second, third and fourth peraeon-segments, and a pleon with two pairs of appendages in both sexes.

The three species of *Nicaea* may be assigned to the genus *Hyale*, as in each the telson is deeply divided; for the species of *Calliçe*, the altered generic name *Calliopis* has since been adopted; *Gammarus barbinus* has been recognised as identical with *Corophium longentebulki*, Chilton, 1883, and by Thomson and Chilton, 1886, called *Corophium barbinum*, with *Haplocheira typica*, Haswell, in the synonymy; but the right name will, I think, be *Haplocheira barbinus*; *Platycopius intermedius*, if really distinct from *serratus*, which Claus identifies with *oroides*, will become *Dithyurus intermedius*. For the species described as *Lysianassa kroyeri*, Spencer Bate (*Ephippiphora kroyeri*, White), see Note on Miers, 1884, and Note on Thomson and Chilton, 1886; *Paramera tenuicornis*, Miers, Mr. Thomson says "must be replaced in the genus proposed by its original describer, Dana, viz., *Melita*.

The sexes and young of *Themisto antarctica*, Dana, are described, but specimens which Mr. Thomson has had the kindness to send me, with this name attached, belong, I believe, to the genus *Parathemisto*. The minute illustrations to this paper by no means fairly represent Mr. Thomson's own drawings, for "instead of lithographing the plates, the draughtsman traced them on to a large sheet, from whence they were photo-lithographed."

1879. Thomson, George M.

A short description is given of Mr. Thomson's earlier paper in the New Zealand Inst. Trans., and four more species are added to the local fauna:—"1. *Ampithyonotus levis*, sp. nov. (Pl. XVI. figs. 1–4)."

"Though agreeing closely in generic characters, this species is very distinct in appearance from A. *Edwardsi*, as figured in the British Museum catalogue, and also apparently from A. *spinaeulina*, Costa," in regard to which it must be observed that, of the two species compared, the former belongs to the genus *Haplocheira*, the latter to *Decamure*; "2. Aora typica, Kröyer," in which "the superior antennae were about as long as the animal; the propodes of the first gnathopoda, as well as the last four joints of the second gnathopoda, were very hairy; telson quite smooth"; "3. *Microdeutopus maculatus*, sp. nov. (Pl. XVI. figs. 5–8)," accepted by Thomson and Chilton, 1886, as the female of Aora typica, Kröyer; "4. *Cyrtophium cristatum*, sp. nov. (Pl. XVI. figs. 9–15)."

"This species differs from the generic characters of *Cyrtophium* in possessing an appendage on the superior antennae; but as it agrees in every other respect, I do not feel justified in placing it in a new genus. It comes nearest to *C. brasilienne*, obtained by Dana in the harbour of Rio Janeiro." Dana's species here referred to is *Platycopius brasilienne*.

1879. Wrzesiński, August.

This paper, the first of an important series, is on new Peruvian species of the genus *Hyale*, Rathke, which genus, in the wider sense accepted by Boeck and Stebbing, he thinks may be conveniently divided into two subgenera, the one *Allorchestes*, Dana, with telson simple
REPORT ON THE AMPHIPODA.

501

rim entire, the other *Hyale* sensu strictiore (*Nicea*, Nicolet), with the telson more or less divided. Professor Wrzesiński does not appear to have seen Faxon's paper, dated June 1876, on the Fauna of Lake Titicaca, which discusses the genera *Allorchestes* and *Hyale*, and also shows that the species of *Hyale* here described from the fresh-water springs of the Peruvian Cordilleras are not the first of their genus or subgenus known from fresh water, as the Professor supposes.

In the remarks common to all the species it is stated that, in the side-plates of the last six or five pairs of feet, above the branchiae, are inserted cylindrical structures, closed at the point, which are considered to be accessory branchiae (Nebenkiemen). To "*Hyale Jelshii*" he assigns, "Nebenkiemen am 2-5. Fusspaare einfach, von vorn nach hinten immer an Länge zunehmend, am sechsten Fusspaar am längsten und doppelt, am siebenten Paar fehlend." "*Hyale Labemirski*" has "Nebenkiemen einfach, am 2-7. Fusspaare eingefügt. Am zweiten Fusspaare erscheinen sie ganz rudimentär, an den zwei folgenden etwas grösser, doch immer sehr klein, an den drei folgenden Fusspaaren länger als die eigentlichen Kiemen." "*Hyale Dybowskii*" has "Nebenkiemen am 3-7. Fusspaare, einfach."

To the subgenus *Hyale*, "Telson mehr oder weniger gespalten," are assigned the new species, "*Hyale Starckou*" "keine Nebenkiemen," found under stones on the sea-coast, and as its nearest relatives, *Hyale* (*Nicea*) *plumicornis*, Heller; *Hyale* (*Nicea*) *fasciculata*, Heller; *Hyale* (*Nicea*) *multicornis*, Heller; *Hyale* (*Nicea*) *narcograf*, Heller; *Hyale* (*Nicea*) *carpomyza*, Heller; *Hyale* (*Nicea*) *schmidlii*, Heller; *Hyale* (*Nicea*) *rudis*, Heller; *Hyale* (*Orchestra*, *Allorchestes*) *pererti*, Lucas, Grube; *Hyale* (*Allorchestes*) *rubricata*, Bate, Stebbing.

1879. Wrzesiński, August.

The name *Gopla* is said to designate in Polish a water nymph. The genus is thus defined:— Upper antennae longer and stronger than the lower and provided with a short accessory flagellum. First and second gnathopods subcheliform, subequal. Last uropods one-branched. Telson simple, emarginate. The three last pleon-segments co-joined.

The last character is said to be its chief distinction from *Crangonyx*, Sp. Bate. A description of the species and its habits follows, containing some sufficiently remarkable particulars.

On the second gnathopod and first peraeopod of both sexes on the front rim of the flabby part of the side-plate are seated a pair of cylindrical accessory branchiae; to the fourth and fifth peraeopods and to the front rim of the first abdominal segment similar but simple accessory branchiae are attached. They are entirely wanting on the second and third peraeopods. [In the original some errors have crept into the printing, which I have ventured to correct according to what I suppose to have been the author's intention.] In the male from the
second gnathopod to the fifth peraeopod lamellate appendages are present, homologous according to their position and structure to the lamellae of the female brood-pouch. In copulation the considerably smaller male attaches itself with its subcheliform gnathopods to the back of the fifth or sixth peraeopod-segment of the female so that its body forms almost a right angle with that of the female. Then it bends its body in an arc towards the abdominal surface of the female, the point of its tail remaining at a good distance off from her. Spasmodic movements are made by the male from time to time. As a rule two suitors attach themselves at the same time to the female. The brood-pouch of the female at this period appears always to be filled with eggs.

_Goplana polonica_ generally progresses with an upright walk, and even climbs the smooth walls of a glass aquarium. It swims on its back, but not with facility; at the bottom of the water it hops about in an agile manner.

_Gammarus ambulanus_, Friedrich Müller, is a near relative of this fresh-water species, and is therefore renamed _Goplana ambulanus_. It may well, I think, be questioned whether _Goplana polonica_ is more than the adult of Müller's species.

---

1879. **Wrześniewski, August.**

"_Lada Chaubééktii_" is described, a new genus and species from shore-pools in the Gulf of Chimbote, Peru. It is distinguished from the hitherto described species of _Melita_ by the absence in the male of a finger on the first gnathopods, and by the peculiar structure of the hand, in which the front and upper edge forms a short, thick, hook-formed, downward-curved process. The finger in the second gnathopods closes against the inner surface of the hand, as is the case with _Melita palnata_, Leach, and the Brazilian species, _Melita messulina_, F. Müller, and _Melita insatiabilis_, F. Müller. The author is rather doubtful whether to insist on a new genus for his species, or to regard it as a subgenus of _Melita_, in close relationship with the species just mentioned.

_Lada_ in the Slav mythology represents the goddess of love.

The females are distinguished from the males by shorter antennae, differently formed hands of the gnathopods, the first not being fingerless, and by a hooked process on the antero-inferior edge of the coxa of the fourth peraeopod. It is remarked that a similar process in _Melita palnata_ is wrongly attributed by Boeck to the male instead of the female.

"_Mera Micri_," a new species collected by Herr J. Stolzmann together with _Hyale stolzmanni_ and _Lada chaubééktii_, belongs to the division of the genus _Mera_ which is made by Sp. Bate to form a separate genus _Megemoera_. The differences between the two appear so slight that Wrześniewski follows Heller and Boeck in re-uniting them.

_Callisoma Branickii_, a new species briefly described by Professor Wrześniewski in 1874, is here compared with _Callisoma kroyeri_, Bruzelius. The latter species is stated to have, in common with _Callisoma branickii_, _Callisoma evaeta_ and _Callisoma kropig_., on the back of the fourth pleon-segment a saddle-shaped depression, the existence of which is not noticed by Bruzelius, and expressly denied by Boeck. The distinctions given between _Callisoma branickii_ and _Callisoma kroyeri_ refer to measurements of the eyes, antennae and hand of first gnathopods, to the number of joints in the flagella of the upper antennae, and to the armature of the inner rim of the finger of the first gnathopod. To my mind they together barely amount to the value of specific difference. In regard to the saddle-shaped depression on the fourth pleon-segment, it may be noted that this is extremely common among the Amphipods, but that, even in species which have the character well developed, it is often
concealed beneath the preceding segment. The telescoping of these two segments is facilitated by the depression, and is of obvious importance for the bending and unbending of the pleon.

1879. Wrześniowski, August.

Also in a Separat-Abdruck, 24 pp.

These valuable contributions to the anatomy of the Amphipoda are based chiefly on *Goplana polonica*, *Palussea cancellus*, *Callisoma branickii*, and two varieties of *Gammarus pulex*. The matrix or hypodermis is shown to be completely distinct from the adipose tissue, the former, as examined in *Palussea cancellus*, presenting a typical stratified cylindrical epithelium, having its small granular cells provided each with a nucleus and nucleolus, the latter consisting of relatively large, rounded and somewhat angular, very pale cells connected together without intercellular substance. This latter forms a sheath for the alimentary canal, and fills the space between it and the heart, for which it forms the serous covering, intercellular substance here making its appearance. By flat or string-like offshoots it connects the various internal organs with one another and with the external covering of the body. On various parts of the inner surface of the matrix it forms a layer of connective tissue to which the offshoots above-mentioned are fastened. The fat-drops, which are met with most constantly between the alimentary canal and the heart, are rare or almost entirely wanting in fasting Amphipoda, but abundant in well-fed specimens.

The muscular system in *Goplana polonica* is thus described. The flexors of the back present two separate systems. The one consists of oblique muscles running from above and behind obliquely forwards and downwards. Each muscle begins halfway up the segment and inserts its lower end on the ventral surface of the preceding segment. These are wanting in the first four segments of the body, but present from the fifth to the tenth, the three following segments, which in *Goplana polonica* are coalesced, possessing a common very strong oblique flexor. The other set of flexors is thus constituted. On either side in the lower part of the segments run, from one segment to the next, and interfaced, pairs of muscles parallel to the ventral surface of the body. These muscles are united at the places of insertion, so that they form elongated links. These Wrześniowski calls longitudinal flexors of the back. The regular arrangement of these prevails from the fourth to the ninth segment of the body. Only the upper muscle enters the tenth segment. The three coalesced segments have a single very long longitudinal flexor. In the front part of the body these muscles run without interruption from the hinder rim of the head to unite at a common place of attachment in the fourth segment of the body.

The extensors, which are considerably stronger than the flexors, form strong tracts on either side, extended between the front rims of neighboring segments. The front divisions of the extensors and flexors raise and lower the head.

The abdominal feet are moved by a complicated system of muscles. The first basal joint of each foot possesses an extensor and a flexor, which draw the whole foot forwards and backwards. The two terminal branches of the foot have each a very thin and broad extensor and flexor, running from the upper rim of the basal joint to the commencement of the corresponding branch. Each branch has its own abductors and adductors, the outer
possessing two abductors and a very strong, thick and long adductor, the inner branch having simple and very weak muscles.

Notes are given (pp. 465-6) on the nerve-system as displayed in Goyplana polonica and the varieties of Gammarus pulex. The "auditory hairs" on the upper antenna of Callisoma branickii are minutely described, and from their likeness in structure and nerve-apparatus to the auditory hairs and auditory nerves of the Decapods, as described by Hensen, it is argued that a like function may be reasonably attributed to these organs in the Amphipods, notwithstanding Leydig's doubts on the subject. The plumose hairs of the last uropods are not considered to have anything in common with the function of hearing. A detailed account is given of the antennary nerves in Callisoma branickii.

In describing the so-called "calceoli," the author refers to the work of Dybowski as showing in agreement with his own observations that these organs are to be found sometimes on the upper as well as the lower antenna, and in the female as well as the male sex. He thinks it clear that the "trumpet-mouthed auditory cilia" on the upper antennae of Gossea microdentata, Sp. Bate, and the oval "auditory cilia" on the upper antennae of Bathyporeia robertsoni of the same author, are really "calceoli."

In Callisoma branickii the calceolus presents a thin-walled, flattened, pedunculate vesicle, nearly of the same form as figured for Gammarus pulex and Gammarus neglectus by de la Valette, G. O. Sars and Leydig. A large circular ganglion-cell lies close to the base of the calceolus, but the entrance of the nerve into it could not be made out. In the peculiar lanceolate calceoli of Goyplana polonica, nerve-fibrille were traced right to the sharpened rims of these organs, with a fan-like distribution. The calceoli are here regarded as apparatus for smelling in agreement with the view of G. O. Sars. [This view had earlier been advocated by de la Valette and by Bate and Westwood, Brit. Ses. Crust., vol. i. p. 87, 1863; H. Blanc would refer them to the sense of hearing.]

In Hyale jelskii, the author found on the front rim, both of the outer and of the inner lobe, of the second maxilla three rows of bristles, each row consisting of differently formed bristles. In the uppermost row no connection was found with the nerves, but in the lowest and middle rows this connection was made out, and the suggestion is offered that the lowest row are perhaps organs of touch and the middle row organs of taste.

Numerous observations are given (p. 511 f.) on the intestinal canal and its appendages. The whole length of this organ appears to be sheathed in a layer of the adipose tissue (Leydig's serosa). The muscular covering of the mid-gut consists chiefly of transverse threads, that of the hind-gut of an outer layer of transverse, and of inner, thick, separate, longitudinal muscles. The membra propria of the mid-gut is very thin, that of the hind-gut thick, consisting of a transparent, homogeneous matrix, including groups of spindle-shaped cells which run out into thin, long processes at both ends. In the central part of the mid-gut he believes that no cuticula or intima exists. [In the Caprellide Mayer (p. 147) finds, apparently throughout, a fine, not chitinous, intima.] Between the mid- and hind-gut is an outer projection and an inner, ring-shaped flap or valve, with its free edge directed backwards, so that what is passing through the body can easily go from the mid- into the hind-gut, but not easily on the reverse route. In Pallasca cancellus the hind-gut has six rows of dilators (not to be confounded with sphincters).

The appendages of the intestine are next discussed. The cecal diverticulum behind the stomach is designated neck-gland (Nackendrüse.) To this expression Mayer takes exception as not very appropriate. Mayer also remarks that in the Caprellide there are at this part of the intestine not one diverticulum only, but a pair. The muscles, cells and vesicles of the liver-tubes are minutely described. The cylindrical glands, opening, according to the author, at the beginning of the hind-gut, close behind the above-mentioned valve, are called rectal-glands (rectaldrüsen.) The view of G. O. Sars that these cylindrical glands are homologous
with the Malpighian vessels of insects is accepted. Mayer maintains that these structures which lie on the borders of the mid- and hind-gut belong morphologically to the former, the mid-gut and the cecal appendages being sharply distinguished from the hind-gut by an interruption of the epithelium, and by the absence from the former of the chitinous intima. He agrees with Nehesi that, whatever their function, they cannot be morphologically compared with the Malpighian vessels of insects. In addition to the other appendages, in Gopliona polonica Wrésniowski finds a previously undescribed gland, which lies in the telson, and has a round opening in the terminal part of the hind-gut just before the anus. This he calls the anal gland (Adferdrüse).

A description is given (p. 537) of the windings of the antennary gland in Gopliona polonica, and of the structure of its tissues. A very accurate account follows of the circulation of the blood, mostly already published in 1877. For a summary of the results see Note on Delage, 1881. Wrésniowski justly gives de la Valette the credit of having observed the three pairs of venous ostia of the heart in the second, third and fourth segments of the peraeon respectively, with their oblique direction, on the right side from above and in front downwards and backwards, and on the left side from behind and above forwards and upwards, so that in each pair the slits cross one another at an acute angle. The heart extends from within the hinder limit of the head to the middle of the sixth peraeon-segment in Gopliona polonica, to nearly the end of the fifth in Palliacea caneculus. In each segment of the peraeon it is fastened to the hack by a pair of upper, and to the sides of the body by a pair of lower, wing-shaped muscles; the front end in the head has only the upper pair.

The arterial ostia, one in the hindermost part of the head, the other in the fifth or sixth peraeon-segment, are provided with a complicated valve-apparatus. In each a membrane-like diaphragm is extended, with a simple slit in the centre. The edges of the slit are provided with a sphincter-like muscle, and in the whole surface of the diaphragm the author thought he could perceive annular, very delicate muscle-threads. From the edges of the diaphragm on either side ascends a muscular membrane, finding attachment to the dorsal wall of the heart. During the systole the lateral muscular membranes contract energetically, opening the slit in the diaphragm; in the diastole they relax, while the muscle-threads of the diaphragm contract, and act as sphincters to close the slit, so that the cavity of the heart is now completely shut off from that of each aorta. To prevent the valves bulging in into the cavity of the heart, a pair of trabeculae are fastened, on one side to the rims of the diaphragm-slit, on the other to the ventral wall of the heart. The lateral, venous ostia have each an inwardly projecting valve, with its outer and inner lips provided with sphincter-like muscles. The sphincter of the outer lip is formed by muscles of the wall of the heart, which at the lower angle of the slit separate, to reunite at the upper angle. The inner lips are provided with a separate sphincter. At the systole first the inner and then the outer slit of the ostium closes.

Lateral arteries are not found in the Gammaride, so far as observed by Wrésniowski, Claus, [and Delage], although in the Hyperina two or three pairs have been found by Claus. The anterior aorta clings to the upper wall of the stomach, bends sharply down over its front upper edge, descends the front wall of the esophagus and ends abruptly close to the floor of the head. During this course, in Gopliona polonica, three branches are given off on either side. The uppermost branch originates just in front of the geniculate bend of the aorta, and provides for the upper antennae. The middle branch goes down from the bend of the aorta and runs to the eye, where it appears to end. The lowest branch separates from the main stem close to its termination, and provides for the lower antennae. [In Talitrus locusta, Delage describes three arteries proceeding from the anterior extremity of the heart, centrally the upper aorta with a valve, on either side facial arteries, in which he could not discover valves, though for all that they might exist. The facial arteries run at first upwards and
The unite, fifth branches posterior. The very ring. From rings, stomach, cavity. at ring. approaches forwards aorta. On rings, visceral cavity. Almost oxidised blood-current of the intestine opens. The heart, blood-current at the thoracic void, while venous current ascends the opposite side in each set. Between the four first and the three last feet of the pereon, there is a similar diversity in the direction of the currents. See Delage, 1881, and Claparède, 1863; Wrzesiński gives a reference also to Claparède, Études sur la circulation chez les aranées du genre Lycosa, 1875.) Into each foot of the pereon two arterial currents enter, but only a single venous current returns. All these streams pass special openings in the articulation between the side-plate (coxa) and the segment, as well as in that between the side-plate and the first joint of the limb (coxa and basis). Each foot possesses a common venous sinus, lying in the under part of the segment above the side-plate, and bounded by the flexors and extensors of the foot. Into this sinus gathers all the blood running back from the foot and its appendages towards the heart. In each branchia the arterial current traverses the hinder rim and passes over by means of numerous transverse currents into the venous current which pursues its course on the front rim. The venous current of each branchia opens into the common venous sinuses of the foot, so that the blood oxidised in the branchia flows direct to the heart, without contributing to the nourishment of the foot.
In each foot of the pereon the arterial blood courses as well by the anterior as the posterior rim of the side-plate. In the four first pairs the anterior stream supplies the side-plates and the accessory branchiae (where such exist). The cavity of the side-plate is formed into three longitudinal canals, which on the lower rim unite, and besides communicate with one another by numerous cross canals. The arterial current flows down in the front and middle canals, while the venous current ascends in the hinder. The hinder arterial current of the foot passes partially into the branchiae, partially into the foot itself, and partially into the lamella of the brood-pouch in the female or its homologue in the male. In the three last pairs of pereopods the front arterial current provides for the foot and its accessory branchia, the hinder sends its secondary currents into the branchiae, the side-plate and the marsupial lamella. In the side-plate the current runs round the rim. [With this account should be compared Dr. Delage's account of the circulation in corresponding parts of *Talitrus locusta*.]

From each appendage of the pereon and pleon a single venous current proceeds. All these take their way to the dorsal side of the body-cavity and debouch in a spacious venous sinus, bounded below by the intestine and its adipose-tissue, on the sides by the muscles of the back, and above by the back of the animal. [This Delage calls the pericardial sinus, and assigns it a bounding membrane of its own, open only to the thirteen pairs of pericardial vessels.] In this sinus, which lies over the hinder aorta and over the heart, a hinder and an anterior current are to be distinguished. The former flows from the hinder end of the body forwards to the third pereon-segment, the other has a backward direction and reaches the same segment. In the hinder current debouch the venous currents of the five last pereon-segments and of the whole pleon, to the anterior belong the venous currents of the antennae, the head and the two first pereon-segments.

At the diastole the blood collected in the (pericardial) sinus passes through the gaping ostia into the heart. This movement is helped by the upper wing-like muscles, as by their contraction the sinus in its horizontal and perpendicular diameter is contracted, and its two streams in this way are pressed towards the third pereon-segment, and rush with greater energy through the slits, the heart acting like a suction pump. The front slit takes only the blood of the front current, the hindmost of the hinder, the middle the leavings of both.

It thus appears that the arterial currents from the two aortas and their branches wash various organs of the body, as the intestinal canal and the nerve-centres, and then in full tide press into the articulated appendages, finally to quit them as venous currents and pass into the dorsal sinus. Wrzesiński found no direct bending round of the hinder arterial current into the dorsal sinus, such as Clams has described in *Phronima sedentaria*. The whole blood-content of the venous dorsal sinus passes, he says, direct into the heart, without previously traversing the branchiae as Spence Bate states, Sessile-eyed Crustaceon, i. p. xxxii. On the contrary the branchiae receive their blood from the same arterial streams which supply the feet, and the contents of the venous dorsal sinus present a mixture of the blood returning from all parts of the body, which has been subjected not only in the branchiae, but, at least partially, also in the antennae, side-plates and legs, to oxygenation. A separation of the arterial and venous blood is therefore not arranged for.

The blood-plasma in young specimens of *Goplana polonica* appears of a yellowish-red colour, in adults of more or less greenish, sometimes even emerald-green hue. The body becomes paler, when the blood is drained away. The blood-corpuscles in this species are of considerable size, consisting of a soft, granular protoplasm, in which clear, pseudopodial-like processes sometimes make their appearance. More or less numerous fat-drops in the plasma of the blood circulate with it throughout the body.
1880. Asper.

In some of the lakes a Gammarid was met with, which strikingly reminded Dr. Asper of the common Gammarus pulex. The lake-form, however, was smaller and of a glassy transparency. Specimens from depths of 140 and of 60 metres possessed beautiful organs of vision, with clearly observed crystal-cones. At Widensweil, at a depth of 40 metres, along with seeing forms were found blind specimens agreeing in the smallest detail with "Niphargus Foreli" from the lake of Geneva. Specimens from Oberrieden Dr. Asper regards as intermediate forms between Gammarus pulex and the "Foreli" variety of Niphargus pulicans.

1880. Claus, C.

Vilibilia meliternana, Claus, is retained. At page 605 it is said that "die ältesten bis jetzt bekannt gewordenen fossilen Podophthalamen sind langschnäuzige Decapoden und Schizopoden aus der Stein Kohlen-formation (Palsoceramon, Palsoceras, Pygocephalus)." Palsoceramon, however, is an Amphipod, but with a misleading name. See Note on von Schaueroth, 1854.

1880. D'Urban, W. S. M.

The Crustacea brought home from the "Willem Barents" expedition by Mr. W. J. A. Grant, were sent by Mr. D'Urban to the Rev. A. M. Norman and Professor J. O. Westwood, and the Amphipoda are named as follows "Anonyx unguis (Philips), Acanthosomatosoma inflatum (Krüger), Gammaracanthus toreyanus (Sabine), Amphithoe leviuscula, Bell, Acanthostephia Malugreni (Goës). Tritropis Helleri, Boeck, Unciola leucophae (Krüger), Hyperia cyanesc (Sab.)." The dates, latitude and longitude, and depths, of the "finds" are given.
1880. Grimm, Oscar.

Dr. Grimm says, "Gammaracanthus caspius, mihi, from a depth of 108 fathoms in the Caspian, Boeckia spinosa, pasusta, and hystrix, mihi, from depths of 70–150 fathoms in the Caspian, and various species of Mysis from the same sea, and from depths down to 500 fathoms, all have well-developed, large, prominent, and black-pigmented eyes. This sufficiently proves that at the depths indicated the visual organ can be and is made use of, as here absolute darkness does not prevail, but only a dark night." "In the Caspian Sea, at 0° 12' E. long. (from Iakuv) and 39° 51' N. lat., I obtained in a single cast of the dredge ten new species of Gammaride (namely Gammarus panzillus, G. crassus, G. Gregorowici, G. portentosus, G. coronifer, G. thaumops, Pandora cecia, Iphigenia abyssorum, Gammaracanthus caspius, and Amathilina cristata), all of which are furnished with eyes, but in very different degrees of development: thus Gammaracanthus caspius has very large round eyes, Gammarus coronifer and Amathilina cristata long but narrow eyes, Gammarus thaumops triangular unpigmented eyes, and Pandora cecia small unpigmented eyes, which can hardly be endowed with the faculty of sight. A still better example is furnished by the following new Amphipoda discovered by me in the Caspian Sea:—

<table>
<thead>
<tr>
<th>Onesimus caspius</th>
<th>from the depth of 75–250 fathoms,</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;pomposus&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>&quot;platyurus&quot;</td>
<td>&quot;40 and 48&quot;</td>
</tr>
<tr>
<td>Pantoporeia microphthalmal</td>
<td>&quot;80–90&quot;</td>
</tr>
<tr>
<td>Niphargus caspius</td>
<td>&quot;35–90&quot;</td>
</tr>
</tbody>
</table>

of which the last two species, together with Onesimus caspius, were also taken in one cast, and, indeed, at a depth of 80–90 fathoms, at 0° 26' E. long. and 41° 6' N. lat. Pantoporeia microphthalmal and Niphargus caspius possess pigmented but small eyes; of the species of Onesimus some possess red, others (On. caspius) perfectly unpigmented eyes, which, in the last-mentioned species at least, are deprived of the faculty of sight; and with these more or less blind species there live Mysis, the large, convex, and black eyes of which certainly absorb a sufficiency of light even in the darkness of the depths."

While taking the quotations from Mr. Dallas's version, I have not followed him in altering his author's Gammarus coronifer into Gammarus coronifer. It may be observed that the generic name Boeckia is preoccupied, having been used by Malm in 1870, when it forthwith lapsed as a synonym of Leptochirus. Pantoporeia, if it be not intended for Pantoporia, is inconveniently near it. Iphigenia makes an even closer approach to Iphigenia, a genus of molluscs. Pandora is preoccupied over and over again.

Of Niphargus caspius, Grimm says, "from this species N. puteanus is probably derived. It is possible that it is identical with N. ponticus, Czer.; unfortunately I have been unable rightly to determine the latter, as the description which Hr. W. Czemajowski has given of it appears to be very defective. (See his 'Materialia ad zoographiam ponticam comparatam 1868.') It must, however, be remarked that our N. caspius differs in many respects from
the other species of Niphargus, and, indeed, from N. puteanus, as in its shorter antennæ, the different formed hand of the last pair of limbs, etc.; so that, perhaps, our species may be regarded as the representative of a new genus between Niphargus and Gammarus.”

This, however, he does not establish, but remarks that “Niphargus cospius is very probably the ‘extinct Gammarid’ (see Leydig, Ueber Amphipoden und Isopoden, Zeitschr. f. wiss. Zool. xxx. p. 249) which the other species of Niphargus have as their ancestor.”

Defective eyes, Grimm explains, are compensated for by other sense-organs; for example, in the male of Niphargus cospius the five-jointed main flagellum of the upper antennæ has on its first four joints very large olfactory cylinders, with an aperture at the free extremity of each, "from which, perhaps, as Leydig states, thin hairs may actually be exerted; and from within a nervous branchlet penetrates into each cylinder, and forms a cellular inflation (in the cylinder itself) only to disappear immediately afterwards, as I have observed still better in living examples of another species, namely Gammarus priscus, mili, at Krasnovolch." The species of Onesiimus being mud-burrowers "have no sense-organs on the antennæ and other external parts of the body, as in Niphargus," but, on close examination, "we find very highly developed, although concealed, sense-organs on the outer lamelle of the maxillipedes, which have already been described or figured by different authors. These are short thick stumps with rounded ends, which stand in corresponding cyindrical depressions of the lamella, from which they usually have only the rounded portion projecting. Some of them, however, appear much longer, inasmuch as they project more and also have the extremities more acute; these are the two cylinders standing at the apex of the lamella, which present a transition towards the ordinary setæ, and thus also prove that we have to do with chitinous setæ metamorphosed for a particular purpose.” These he proposes to call "taste cylinders.”

1880. Grobben, Carl.

Die Antennendrüse der Crustaceen. Separat-Abdruck aus den Arbeiten des zoolog. Instituts zu Wien, Tom. III. Heft 1. 18 pp. m. 1 Taf. 1880.

The antennary gland, originally discovered by Leydig, Naturgeschichte der Daphniden, 1860, is described as consisting of two histologically distinct parts, a terminal pocket, Endstückchen, and a convoluted tube, Harnkanälchen, which, for the Amphipoda, opens in the well-known generally cone-shaped process of the compound basal joint of the lower antennæ. In Gammarus marinus, Grobben says, the terminal pocket lies in the dilated basal-joint of the lower antennæ, quite close to the integument, connected with it by trabeculae. Its shape is reniform; at the hinder end, comparable to the hilus of the kidney, rises the renal tube, which at first runs a short space back, then bends forward, at the same time inclining towards the middle, presently turns upward, again turns back downward, and now in a great arc winding close to the terminal pocket, after a short geniculation runs into the antennary cone, in the apex of which the gland has its outlet. The terminal pocket is lined by an epithelium, the cells of which are arched forwards into the interior of the pocket. The protoplasm is coarsely granular. The exterior is sheathed in a delicate supporting membrane. The protoplasm of the cells lining the renal tube shows a finely fibrous structure, as already noticed by Weismann. The nuclei are oval; towards the cavity the cells were covered by a noticeable cutícula. The terminal section of the tube is formed by cells which completely agree with the matrix-cells of the skin, and which also develop a chitinous cutícula, which passes direct into the cutícula of the skin. This terminal section, which in structure does not agree with the renal tube, but shows the
REPORT ON THE AMPHIPODA.

511

same structure as the skin, he designates Haruleitor. The expressions Haruleitor and
Harunactlilien sufficiently indicate Grobben's own opinion that the gland in question has
a renal function.

1880. Haller, G.

Miscellanea anthropologica. Beschreibung zweier neuer Caprellen. Zeitschrift
für die Gesammten Naturwissenschaften. Dritte Folge. 1880. Band VI. Berlin,

Haller says that he gave the name Caprella gigantea to a new species from the North Sea, which
he here describes and figures, on account of its great length, 30 mm., before he was aware
that Hock had observed a specimen of Caprella linearis 25 mm. long. He likewise
describes and figures the male and female of Caprella dentata, n. e., from Isehia.

He refers to "Mittheilungen der schwed. entomolog. Gesellschaft. No. 10. Jahrgang 1880,
pag. 671 nebst Tafel," for a preliminary notice of Caprella gigantea.

1880. Haswell, William A.

On Australian Amphipoda. From the Proceedings of the Linnean Society of

The new species described and figured are Tolidus epiplatus; Talorchestia diemenensis;
"Orchestia Macqueyana;" Allorchestes rupicolus; Allorchestes longicornis; Allorchestes crassicorneis;
Stegocelatus latus; Amorphyllis macrophthalmaus; Amorphyllis brevicorneis, evidently
the same as Amorphyllis macrophthalmaus; Neobate oligota; Lysianassa nitens; Lysianassa
affinis, not distinguishable from Lysianassa nitens; Glycera longicornis; Ampelipes
australis; Phoros eptes; "Phoros Batei;" Phoros levis; Leucothoe commensalis;
Leucothoe diemenensis; Leucothoe gracilis, recognised later, together with Leucothoe
dimenensis, as falling under Leucothoe commensalis; Melita australis; "Melita (?)
Ramsayi," afterwards transferred to Mera rubromaculata, Stimpson; "Meganacerina
Mastersii;" Meganacerina diemenensis; Mera spinosa, afterwards identified with Mera
rubromaculata, Stimpson; Amphidrillohis cinerea, to which probably the two described but
unfigured species, Amphidrillohis grandimanus and Amphidrillohis setosa, must be united; Micro-
dentorhynus australis; Nemcechira fusciata; Haplocheira typica, probably the same as
Haplocheira barbimanus, Thomson, sp.; Cypridium parasiticum; Tolidus australis; "Proto
Novo-Hollandiae;" Protobota australis; Caprella tenax, a species since relinquished by its
author. Besides these, Talorchestia quadrivina and Mera rubromaculata are described
and figured as synonyms respectively of Orthorhitha quadrivina, Dana, and Gammarus
rubromaculatus, Stimpson.

In this group are included five new genera; in the family Gammaridae, subfamily Stego-
cephalidae, the genus Amorphyllis, thus defined:—

"Superior antennae with a well-developed appendage. Mandibles with a palp. Maxillipeds
with well-developed squamiform plates. Anterior gnathopoda sub-pediform. Posterior
gnathopoda imperfectly subchelate. Rami of the fourth and fifth pleonpods styiform;
those of sixth pair broad-lanceolate. Telson squamiform, eleft.” This genus differs from
Stegocelatus by the possession of a mandibular palp, and cannot, I think, for that and
other reasons, stand in the same subfamily with it.

The genus Nephele is thus defined:—"Superior antennae simple. Mandibles without an
appendage. Maxillipeds with a squamiform process on the bases only. Gnathopods subchelate; second pair the larger; coxae of anterior pair well-developed. Fourth pair of coxae wide, excavated behind to receive the anterior part of the fifth pair. Posterior pleopods biramous. Telson squamiform. Neobate was subsequently transferred by Mr. Haswell to the Orehestide, and perhaps is synonymous with Hyale, Rathke.

In the subfamily Lysianassidse, the genus Glyceria is defined as follows:—"Superior antennae slender, rather long, provided with an appendage. Mandibles with a palp, the incising edge not toothed; no accessory plate; anterior margin with a prominent tubercle. Maxillipeds with large squamiform processes on the basal joints. Four anterior pairs of coxae deeper than their respective segments, the fourth pair slightly produced inferiorly and posteriorly. Gnathopods filiform, slender; anterior pair smaller than the posterior, imperfectly subchelate; posterior pair subchelate. Posterior pleopods biramous; the ram broad-lanceolate. Telson double." The name Glyceria, being preoccupied, was subsequently changed to Glicercia.

In the family Corophiidea, subfamily Podocerides, the genus Xenocheria is thus defined:—"Body slender. Coxae small. Superior antennæ very long, longer than the inferior pair, with a secondary appendage. Mandibles with an appendage. Both pairs of gnathopods non- subchelate, armed with very long hairs; carpus of posterior pair broad, plate-like, applied to the anterior (dorsal) border of the merus. Posterior pleopod subchelate. Telson simple."

The genus Harpocera is thus defined:—"Body not much compressed laterally. Upper and lower antennæ subequal; superior pair without an appendage; inferior subpediform. Both pairs of gnathopods simple, fringed with long hair. Posterior pleopods biramous, with unequal rami. Telson single."

1880. Haswell, William A.

The new species described, and in almost all cases figured, are, Allorchistes niger (not figured); Cyprioides ornata; Cyprioides lineata, not improbably female or young form of Cyprioides ornata; Lysianassa australiensis, to be placed with Lysianassa nites, Haswell, as at most a variety; "Montagia Miersii," Montagia longicornis (in which, as in the preceding species, the mandibles not being described, the genus remains doubtful between Stenothoe and Metopaj; Elicerus latrans; Elicerus aenicola, perhaps, according to Haswell, identical with Elicerus fosor, Stimpson; Stenothoe pinguis; Iphimeidea ambigua; Atylus monoculoides; Atylus nigrus; Lencothoe nov-hollandiae; Harmanotus crassipes; Ensiris [really Liljeborgia] dubius; Morra [Paramenia Chiltoni] dentifera; Morra hamigera; Morra viridis; Morra approximans, probably to be united with Morra [Paramenia?] dentifera; Megamora subcarinata; Megamora suensis; "Megamora Boeckii;" Wycella longimanus; Amphithoe quadriramus; Poloceras australis; "Microlepturus Mortoni;" Microlepturus tenipes (this being in Chilton's opinion the female, and the preceding species the male, of Awa typica, Krøyer); Microlepturus elifer; "Colonastis Brasilius;" Cyrtophium dentatum (in 1886 re-named Dextraessel dentatum); Cyrtophium minutum; Ictius punctatus, afterwards identified with Ictius australis; Polycheria [properly Tritata] tenipes; Polycheria [Tritata] breccicornis, unfigured and probably a form of the preceding species; Caprella echinata, since transferred to Protella; Caprella cornigera, referred later
on to Hircella; Caprella inequina, a preoccupied name for a species almost beyond doubt identical with Caprella durdevskii, Czerniavski, 1888; Caprella obesa, also a preoccupied name, the species itself being recognised by Mayer, and accepted by Haswell, as identical with Caprella aquilinna, Say.

The new genus Cypridella, in the family Gammaridae, is thus defined:—"Body broad. Pleon and pleon of equal length. Coxae of gnathopoda very small. Coxae of the first and second pairs of pereiopoda enormously developed; and cemented together to form broad and deep lateral shields, concealing almost entirely the gnathopoda and pereiopoda, and extending forwards to the sides of the cephalon, and backwards as far as the posterior border of the sixth segment of the pleon, excavated posteriorly for the amalgamated shallow coxae of the third and fourth pereiopoda. Coxa of the last pair of pereiopoda very small. Antennae subequal, superior without an appendage. Mandibles with a palp. Maxillipeds unguiculate; both bases and ischiium armed with small squamiform plates. Gnathopoda subcheliform. Pereiopoda slender. Posterior pleopoda biramous. Telson single." Mr. Haswell subsequently discovered that the coxae of the third and fourth pereiopoda were not amalgamated, but that the coxa "of the fourth pair is entirely rudimentary and covered by that of the third." This character does not apply to the closely related European species Stegoplex longicaudis, G. O. Sars, or to Cypridella harmonicae, Stebbing. The genus Pollicora, Catta, briefly described in 1873, is perhaps the equivalent both of Cypridella and Stegoplex.

The genus Harmonia (misprinted Harmonia on p. 330, but given correctly on p. 349), is defined as follows, "Coxae not so deep as their respective segments. Superior antennae with an appendage. Inferior antennae longer than the superior pair. Mandibles with a palp. Maxillipeds unguiculate subcheliform, provided with a squamiform plate on the basos only. Gnathopoda subchelate, unequal, posterior pair very large. Pereiopoda stout. Posterior pleopoda biramous, the rami short, conical. Telson single, elongate." Mr. Haswell further remarks of this genus that it "has affinities with Euryxenus and Amathia, but is distinguished from the former by the form of the telson and the stoutness of the pereiopoda, and from the latter mainly by the large size of the posterior gnathopoda." For a different view adopted later, see Note on Haswell, 1885.

The description of the genus Wygillia gives "Coxae scarcely so deep as their respective segments. Superior antennae shorter than the inferior pair, appendiculate. Mandibles with an appendage. Maxillipeds exunngiculate, squamiform processes rudimentary. Gnathopoda subchelate, posterior pair very large. Posterior pleopoda uniramous—the rami large. Telson simple, undivided." The description of the species Wygillia longicaudus, speaks of the "posterior pleopoda with the outer ramus broad," as though there were more than one ramus. The figure which Mr. Haswell gives much resembles Ischyrocerus (Polycherus) anguipes, Kroyer. Mr. Chilton supposes that the description given of the pleopods is the result of an oversight, and that the genus must be cancelled in favour of Polycherus. It must, however, be observed that Mr. Haswell's description of the maxillipeds is quite inconsistent with this conclusion.

As a genus incertae sedis is given the genus Polycheria, with these characters, "Pereion broad; pleon compressed, more or less carinate. Antennae subequal; superior pair without an appendage. Mandibles exappendiculate. Maxillipeds with well-developed squamiform processes. Gnathopoda small, subchelate. Pereiopoda all prehensile, with narrow bases. Posterior pleopoda biramous with equal rami. Telson double." This genus is evidently synonymous with the genus Tritata, Boeck, included in Boeck's subfamily Dextriniae. It will probably be right to include Polycheria tenipes, Haswell, Polycheria brevicornis, Haswell, Polycheria obtusa, Thomson, and Dextrina antarctica, Stebbing, all under the name of Tritata antarctica.

(Zool. Chall. Exp.—Part LXVII.—1887.)
1880. Haswell, William A.

"Between the amphipodous fauna of Temperate Australia," Haswell says, "as exemplified in Port Jackson and that of tropical Queensland, a well-marked dividing line may be drawn." The characteristic Australian Amphipoda are to be found on and near the shores of the temperate latitudes; within the tropics they are comparatively few and not characteristic. "The Orchestidea, however, are quite as abundant on sandy and stony beaches in the tropics as in temperate latitudes."

Descriptions are given of the new genera _Cyproidia, Amaryllis, Glyceria, Polycheira, Xenochira, Haplocheira_, for which see Notes on Haswell, 1889, pp. 511–513. From the present paper the following quotations may be given:—

"Probably nearly allied to _Eusurus_ and _Idana_ is a new generic form, which I have named _Macleayia_. It has the superior antennae appendiculate, shorter than the inferior pair; the mandibles are provided with an appendage; the maxillipeds are exaquinulate, with the squamiform processes rudimentary; the gnathopoda are subchelate, the posterior pair being very large; the posterior pleopoda have one large ramus; and the telson is small and undivided." [The same definition (see p. 513) is given for _Wycilites_, the name _Macleayia_ being dropped without explanation.]

"In _Chloris_ (mihi) the antennae are well developed, the superior pair shorter than the inferior and provided with an appendage; the mandibles are palpigerous; the maxillipeds unguicate, subpediform, provided with a squamiform process on the basal joint only; the gnathopoda are subchelate, unequal, the second pair being very large; the posterior pleopoda are biramous, with short, conical rami; and the telson is single and elongate." The same definition is given for _Harmonia_ (see p. 513), the name _Chloris_ being dropped, no doubt for the sufficient reason that it was preoccupied.

1880. Haswell, William A.

This paper includes figures and descriptions of _Talitrus assimilis_, n. s.; _Talorchestia tinaea_, n. s.; _Talorchestia terre-regina_, n. s.; _Talorchestia (?) marmoreata_, n. s.; _Talorchestia praedactylis_, n. s.; _Talorchestia quadririma (Dana), var._; _Aegidophoreia dienemesis_, n. s.; _Atylus microdactylus_, n. s.; _Atylus megalophthalmus_, n. s.; _Phronia australis_, n. s.; _Mera crassipes_, n. s.; _Cytrophium (?) hystric_, n. s. In the Australian Catalogue, 1882, _Talitrus affinis_ is given, apparently by mistake, for _Talitrus assimilis_, and in 1885, Mr Haswell makes _Talitrus affine_ a synonym of _Talitrus sylvestris_, Haswell. _Cytrophium (?) hystric_ he subsequently named _Laxanophius hystric._

The new genus _Aegidophoreia_ is thus defined:—"Coarse of the posterior gnathopoda, and of the first and second pairs of perseiopoda greatly expanded, deeper than the respective segments; those of the third last pairs of perseiopoda small, that of the third pair bilobed—the posterior lobe larger than the anterior. Antenna simple; the superior pair shorter than the inferior. Mandibles without an appendage. Maxillipeds with a pointed dactylos. Gnathopoda subchelate—the posterior pair much larger than the anterior. Posterior pleopoda uniramous.

See Note on Joseph, 1879.

1880. Jourdain, S.

M. Jourdain concludes that the cylindres à bâtometes so commonly met with on the upper antennae (antenne interne) of Crustacea, both pedipalpal and digonath, are certainly organs of sense; but, relying only on anatomical structure apart from physiological experiment, we have no right to affirm that these cylinders "sont affectés à l'olfaction."

In the order Leuconodipoda, pages 126–128, Kossmann describes "Protella Danae," n. s., Taf. xii. Fig. 1–7, and Protella subspinosa, n. s., Taf. xii. Fig. 8, 9. Both of these are considered by Mayer to be young forms of Protella phasina, Montagu.

In the order Amphipoda, pages 129–140, he first of all observes that he cannot acquiesce in that accentuation of small, and generally merely sexual, distinctions in the form of the gnathopods, which has led to the separation of the genera Talitrus, Orchestia, Orchesodilea and Talorchestia. He prefers to group in the genus Orchestia all forms of the family with short upper antennae and without ungues on the maxillipods. He then describes Orchestia fissaipinosa, n. s., Taf. xiii. Fig. 1–5, from a form probably female, in which the first gnathopod is not in the least cheliform, the second gnathopod has a daethylus which ends in a pointed spine, and also has fine spines on the whole inner rim, while the rest of the rim is quite bare. The figure shows a band, terminally rounded, projecting much beyond the daethylus.

It must here be observed that, if the four genera above-named are united, Talitrus takes precedence of Orchestia, and, in fact, if they are kept separate, Orchestia is the only one of the four in which Kossmann's species cannot stand. Provisionally it may be called Talitrus fissaipinosa, but the possibility remains that a single specimen 5 mm. in length may be the young of some previously known species.
Professor Kossmann uses the term *first pereiopod* as an alternative for *first gnathopod*, thus adding one more to the many confusions in the nomenclature of one subject. It is surely of the first importance in scientific language that as far as possible one word should be restricted to one meaning. Since the inventor of the term *first pereiopod* applied it to the limb behind the *second gnathopod*, it is open to other naturalists to reject the term altogether as inconvenient or erroneous, but not to apply it to the limb in front of the second gnathopod. For other confusions in nomenclature see the Note on Wrzesniowski, 1881.

In the family Gammaridae, to the genus *Edicerus*, Krøyer, Kossmann assigns the synonyms *Westwoodilla*, Spence Bate; *Monoculodes*, Stimpson; *Krøyera*, Spence Bate. To show the close connection of the four he gives the following table:

"Zweiter Gnathopoden:

<table>
<thead>
<tr>
<th>A. scheerenförmig</th>
<th>Krøyera, Spence Bate</th>
</tr>
</thead>
<tbody>
<tr>
<td>B. subeheliform, Carpus</td>
<td></td>
</tr>
<tr>
<td>a. bis gegen den Daetysus verlängert</td>
<td><em>Monoculodes</em>, Spence Bate</td>
</tr>
<tr>
<td>b. nicht bis gegen den Daetysus verlängert</td>
<td><em>Edicerus</em>, Krøyer</td>
</tr>
<tr>
<td>C. weder subeheliform, noch scheerenförmig</td>
<td><em>Westwoodilla</em>, Spence Bate</td>
</tr>
</tbody>
</table>

The other distinctions, he says, depend only on the proximity or separation of the eyes. For *Edicerus* he offers the following diagnosis:

He describes *Edicerus affinimus*, n. s., Taf. xiii. Fig. 6–8, in which, he says, the eyes appear to be separate; the pigment was no longer visible, but there were two lateral faceted cornece to be seen.

*Leuctroë cassisimana*, n. s., Taf. xiii. Fig. 9–10, is probably, as suggested by Miers in his "Alert" Report, 1884, a synonym of *Leuctroë spinicarpa*, Abildgaard. Kossmann’s largest specimen was a female with eggs, 7 mm. in length. Under *Mera* (properly Mera), he describes *Mera erythrea*, n. s., Taf. xiv. Fig. 1–8, which he says is very like Dana’s *Gammarella bosiliensis*. That species, he thinks, Sp. Bate ought to have placed in the genus *Mera*, not in *Gammarella*. It may indeed be noted that the description of the antennae does not agree with Sp. Bate’s own definition of *Gammarella*. Meantime Kossmann’s species does not well agree with *Mera*, but suits very fairly with *Elasmopus*, Costa, as defined by Broek, both in respect of the mandibles, antennae, uropods and telson. It may well stand at present as *Elasmopus erythrea*.

*Mera masaccensi*, n. s., Taf. xiv. Fig. 9–11, is described as belonging "to that subdivision of the genus *Mera* of which *M. tenella*, Dana, is typical. It would perhaps not be impossible to characterise it as a new genus. Apart from the slenderer habit, its characters are the presence of a double claw on the pereiopods (see Dana, Expl. Exp. Crust., Atl., pl. 65, fig. 747) and the peculiarity, that the second joint of the upper antennae is much longer and thinner than the preceding.” It is perhaps by some oversight that Kossmann describes "the hinder pleopods" as quite like those of the preceding species, although with less numerous, finer spines. This is, with little doubt, a species of *Mera*, and in that genus the last uropods have long rami projecting beyond the first and second pairs.

In the family Podocioidae he mentions *Amphithoë filosa*?, Savigny’s species, and *Amphithoë erythrea*, n. s., Taf. xiv. Fig. 12, 13, with the “general form quite as in *Amphithoë filicornis*, Dana; stellate pigment distributed over the whole body.” I do not think this species can be separated from "*Amphithoë Vaillantii*,” Lucas, 1849.

REPORT ON THE AMPHIPoda.

517

Nebenast, while Dana says expressly ‘Antenne prime non appendiculate,’ and Spence Bate does not attribute an accessory flagellum to a single one of his 39 species of Amphithoë. (Compare Note on Huxley, 1877.) Kossmann having found a form, in other respects near to Amphithoë, but with an accessory flagellum, not without show of reason institutes a new genus for it, which he regards as a link between Cymarurus and Amphithoë. The Podocerus longicornis, Heller, and Podocerus longipalpis, Heller, 1867, which Nebeski, 1880, transfers to Amphithoë, although they have an accessory flagellum, should perhaps rather be placed in Kossmann’s genus *Amphithoë*, unless that itself should yield to *Gruvia*, Czerniavski, 1868.

The type-species, *Amphithoë* *longicornis*, n. s., is not figured. The upper antennae are as long as the animal. The second joint of the peduncle is more slender and somewhat longer than the first; the third much shorter. The principal flagellum consists of twenty-two (with the terminal rudiment twenty-three) joints distally increasing in length; the accessory flagellum, consisting of one long and one short joint, does not attain the length of the first joint of the principal flagellum. The mouth-organs answer to Dana’s figures for *Amphithoë*. Other particulars are given, but it is a great disadvantage that the establishment of a new genus should be unattended by illustrative figures. The specimens did not exceed a length of 4 mm. In the two-jointed accessory flagellum and the last uropods this species agrees with *Podocerus monodon*, Heller, 1866, but the principal flagellum of the upper antenna is quite distinct.

In the family Corophiidae, he notes that *Colomastix*, Grube, is earlier than either *Eucopina*, Norman, or *Cratippus*, Spence Bate. He describes *Colomastix hamifer*, n. s., Taf. xv. Fig. 1–10, which seems to be separated by very fine distinctions from *Colomastix pusilla*, Grube, as *Cratippus tenuipes*, Sp. Bate, by equally subtle differences from Grube’s species. In *Colomastix hamifer* the second gnathopod, however, is described as having the second, third and fourth joints very short; this probably indicates that the specimen was a male form.

In the tribe Hyperina, family Synopiidae, Kossmann describes *Synopia orientalis*, n. s., Taf. xv. Fig. 11–13. Only the first peronopod, part of the second, and the maxillipeds, are figured. In many respects the species is stated to agree with Dana’s *Synopia ultramarina*. The mouth-organs obviously remove this genus, as has been pointed out by Claus, from the Hyperina.

1880. Markham, Albert Hastings.

On the 11th of May, 1876, within about 400 miles of the North Pole, in a depth of 71 fathoms, “a bread bag, filled with the scrapings of our pannikins and a little pemmican, was lowered to the bottom, and, having been kept there some hours, was hauled up, and to our great joy was found to be almost alive with numerous small crustaceans and foraminifera; specimens of which were, of course, collected and preserved, being the most northern animal life yet discovered.” A footnote to the word “crustaceans” says, “Among these, a fine adult male example, and several smaller ones. The length of the largest specimen is 1½ inch. This species is one of the commonest and most abundantly distributed of the northern
Amphipoda. It was discovered by Captain Phipps in 1773, and is found along the shores of Arctic America, in the White Sea, on the coasts of Greenland, Iceland, Spitzbergen, Norway, and in the Sea of Okhotsk" (p. 309). On the following day Captain Markham with his party, by a walk of about a mile, reached latitude 83° 20' 26" N., 399½ miles from the North Pole.

Crustacea. The Zoological Record for 1878: being Volume fifteenth of the Record of Zoological Literature. London, m.dccc.lxxx. pp. 1–47.

1880. Mayer, Paul.

1880. Miers, E. J.

No new Amphipoda are reported.

1880. Nebeski, Otmar.

The first section is on the unicellular glands in the first and second peraeopods of the Corophiidae. Counting seven joints to the leg, the gland-cells are found as a rule in the second, third, fourth and fifth joints. Each single element of the gland presents itself as one cell, with a special cuticular duct, hence the epithet chosen. There are two kinds of cells, the opaque and the clear; the former found only in the second joint, the latter both in this and the three following.

In the unguis there is a little reservoir into which the ducts of the glandular apparatus open to let out the house-building secretion at the point of the finger. The form of the glandular complex varies, but for the same species, or even genus, is constant. Nebeski found the secretory apparatus in all Corophiidae which he was able to examine; "these were species of the genera Microbentopus, Microprotogus, Amphithoe, Podocerus, Ceraurus and Corophium. The genus Cyrtophium, which hitherto has been included among the Corophiidae, but which is devoid of the glands and so appears to be an exception, differs in many respects essentially from the Corophiidae, and on the other hand stands so near to the Dulichidiidae that it ought to be reckoned in this family, and so the exception is only apparent." In Orchesta the arrangement is different; in the Gammaride, he says, the glands are, so far as he knows, entirely wanting. He considers that the possession of the secretory apparatus in the first and second peraeopods may be regarded as the characteristic mark of the Corophiidae.

"It has been long known," he says, "that species of the genera Ceraurus, Siphonoccales and Unciola, Say (=Microbentopus, Costa) through cementing sand, mud, particles of wood, etc., by means of a secretion hardening in water, form tubes into which they withdraw"
REPORT ON THE AMPHIPODA.

519

when disturbed.” He refers to the method, mentioned by Sp. Bate, adopted by species of Orehestia of wrapping themselves about with sea-weed. This he observed in the case of Orehestia penicillata, Costa, and also in Heller’s two species of Podocerus, which he names Orehestia longicornis and Orehestia kerimana. (See Note on Kossmann, 1880.) The Corophiinae adopt a third mode of using their secretion, in lining the walls of the channels which they burrow in the mud.

The second section treats of the unicellular glands in the genus Orchestia. Here the gland-cells are distributed in different places over the whole body, but principally “in the coxal-plates and the analogously formed lamellar expansions which are found on the bases of the three hinder peraeopods of both sexes and on that of the second pair of gnathopods of the female.” Small groups are found in the other joints of the legs, and in small numbers the cells are found in the antennae, mandibles, maxillipeds, last uropods, and elsewhere; in the last pleon-segment they form a large dorsal complex, reaching into the telson. The outlets are not as in the Corophiidae by numerous tubes of various lengths, often uniting into a bundle before reaching the common exit, but by short courses to independent pores opening in the chitinous walls of various parts of the body. They are found in both sexes of Orchestia, of terrestrial habit, but in Nicae, more attached to the water, they are wanting, and may hence have the function of preventing too rapid evaporation of moisture.

Comparing his own observations with those of others, Nebeski concludes “that in the Phronimidae and Caprellidae three to five or more gland-cells are united in the formation of a secretory element and from this proceeds a cuticular emission-duct, while in the Crevetinna this formation of a complex does not occur, inasmuch as the secretory element coincides with the histological, that is with the cell, and so a special cuticular passage belongs to each cell. The Hyperida seem to possess both types of glands, so that in this respect they occupy an intermediate position; at least Paul Mayer mentions that in the Amphipoda ‘in opposition to the Phronimidae the complex-formation only occurs in a limited degree or is entirely wanting,’ which would consequently betoken a nearer approach to the Crevetinna.”

The section on the renal glands attached to the intestine of the Crevettina is of considerable interest. Nebeski cannot confirm Spence Bate’s view that in Gammarus and Mxra there is but one gland-tube, at least he himself always found two in Gammarus marinus and Gammarus brevicaudata, and with this the statements of Wrześniewski on Gammarus pulce agree, although in Gophsa pulvina the right gland suffers degradation in course of development. In Melita Nebeski found the gland unpaired. In all the Corophiidae, he says, we have two small tubular or vesicular structures which rise obliquely from the intestine. Among the Gammaridae they are small in Mxra, but in most they stretch in adult specimens through more than three segments. For these the peculiarity is characteristic, that at their origin they bend forwards, and, lying close to the intestine, run forwards more or less far. In Cyrtophium they pass backwards through the long fourth, to the beginning of the fifth, pleon-segment. In Nicae to begin with they turn backwards, but again bend forwards and end just over the place of origin. In Orchestia they differ both in size and position. While in all other forms, where the rectum quite uniformly occupies the three last pleon-segments, the tubes are placed on the intestine at the boundary between the third and fourth pleon-segments, in Orchestia they arise in the seventh pleon-segment at the sides of the intestinal canal, and with gradual elevation run backwards; between the third and fourth pleon-segments they lie dorsally on the intestine and here form the same flexure which Nicae exhibits. The difference between Nicae and Orchestia is shown to depend on the modification which the rectum has undergone in Orchestia. That the glands belong to the mid-gut is a point on which Nebeski is in agreement with Mayer, 1882, and Baldwin.
Spencer, 1885. In regard to the concretions found in the gland-tubes of *Orchestia* he is also corroborated by Spencer, who found such in *Talitrus locusta*, though apparently of a somewhat different chemical composition.

A section is devoted to the rectum of *Orchestia*, and another to a comparison of its bristle with those of other Crevetts. A further section discusses the production of ova in the *testes of Orchestia*. The curious fact is affirmed that the males of *Orchestia* produce, not, as the Cymothoidea, at one time spermatozoa and at another time ova, but both sexual products in parallel development at one and the same time, although the eggs are never laid, and there is no broad-pouch for hatching them if they were.

In the section headed “Beobachtungen über die Crevettenfauna des Triester Hafens,” under *Orchestia cordiama*, Heller, Nebeski remarks that this, which was originally regarded by Heller as a fresh-water form, must really be considered, like *Talitrus*, a land-Amphipod, since it soon dies whether placed in fresh or salt water.

In the Gammaridae, subfamily Stegocephalinae, Nebeski gives *Probolium tergestinum*, n. s. (fig. 39), “Artcharaktere: 3. Glied der Maxillarfisse bedeutend verlängert. 6. Glied des ersten Füseparres länglich viereckig, vorne abgestutzt, 4. und 5. Glied vorne in nach unten vorspringende Lappen ausgezogen.” It is said to be very near *Probolium monocoloideus*, nor am I inclined to separate it from that species (*Stenothoe monocoloideus*, Montagu), even as a variety. The figures given by Nebeski seem to me to agree with those given by Boeck with even more than the usual exactness to be found between authors figuring quite independently of one another.

In the subfamily Gammarinae, under *Dexamine*, Leach, he notices the large comparative size of the first three pleon-segments as well in this genus as in *Atylus, Pherusa* and *Calliope*, giving room for powerful muscles to work the relatively large pleopoda of these capital swimmers. He gives *Dexamine dolichonyx*, n. s. (fig. 40), “Artcharaktere: 1. Glied der oberen Antennen kurz und gedrungen, ohne Zahnfortsatz; das breite Handglied des zweiten Gnathopodenpaares am Männchen am Oberrande tief ausgebuchtet; Klauen der Thoraxbeine sehr lang; das 2., 3. und 4. Segment des Abdomens am dorsalen Hinterrande in einem spitzen Zahn ausgezogen.” The deep narrow cavity in the back of the hand of the second gnathopod was only found in the two male specimens, not in the females. A specimen of this curious species, from the Clyde, sent me by Mr. David Robertson, of Glasgow, shows in the pereopods a short hand and wrist preceded by a very long joint, which is characteristic of Boeck’s genus *Triteta*. The species should, I think, be named *Triteta dolichonyx*. The bristle have lateral dilations.

Nebeski gives "*Pherusa bipinosa* (= *Atylus bipinonos* Sp. B.)," with the remark that “this species, as long as the artificial separation of the genera *Pherusa* and *Atylus* is maintained, must be referred to *Pherusa*, as it possesses a completely lanceolate telson, which is precisely the character that differentiates *Pherusa* from *Atylus." He seems unaware that Boeck has already named it *Halirages bipinosa*.

*Gammarus Eduardisi*, Sp. Bate, is described by Nebeski as undoubtedly not more than a variety of *Gammarus locusta*.

In the Corophiidae, subfamily Podocerinae, he discusses the connection of the telson and the last nannopods with the mode of life. He thinks that *Aera* and *Stimponia* will probably have to be transferred to the Podocerinae, in which Heller has already placed *Microleptopus*.

*Very near to Amphithoe penicillata*, Costa, which is among the commonest Amphipods of Trieste Harbour, he places *Amphithoe longicornis* and *Amphithoe largiana*, placed by Heller in the genus *Podocerus* because of the unarticulate secondary flagellum, although in other respects, Nebeski says, they clearly belong to *Amphithoe*. The four so-called species of *Podocerus*, named variatus, pelagius, pulchellus and falcatus, he unites into one
species, the females, and especially the younger specimens, agreeing with *Podocerus pelagicus*, Sp. Bate, the adult females having often the *variegatus* form; the males being either of the *palpebellus* or *falcatus* form. Boeck and Hoek, he thinks, were wrong in regarding these two latter as stages of growth, for they attain an equal size, and series of the two forms do not seem adapted for passing one into the other. *Podocerus occlus*, Sp. Bate, he regards as quite distinct.

To *Corythus abalites*, Templeton, he assigns *Derochoë punctata*, M.-Edw., as the female, but without giving reasons.

In *Cyrtophilum* he points out that the 1–2-articulate accessory flagellum has been overlooked. He considers that the genus should be transferred from the Corophiidae to the Dalichidae. The species *Cyrtophilum darwini*, Spence Bate, to which Nebeski is referring, ought no doubt to be placed in Dana’s genus *Platophilum*, which Dana himself distinguished from *Cyrtophilum* by the presence of an accessory flagellum.

Pages 47–48 contain the list of “Literatur.” Fig, 41 refers to *Microdeutopus grylotolpa*, Costa; Fig. 42 gives the telson of *Podocerus falcatus*, *Amphithoe longicornis*, *Amphithoe longimanus*, *Amphithoe penicillata*, *Microdeutopus*, *Amphithoe bicuspis*, *Microprotopus*. Fig. 42 refers to *Podocerus falcatus*; Fig. 43 to *Podocerus occlus*. The earlier figures illustrate the anatomical details given in this important paper.

In the Arthropoda, Class I. Crustacea, has in this work, p. 302, Subclass IV. [III., sec p. 283], Malacostraca (Thoracipoda, Woodward), in which Division A. Edriophthalmata, is split up into three orders, Lecmodipoda, Amphipoda, Isopoda. In the definition of the Lecmodipoda, they have “The first two segments of the thorax amalgamated with the head and carrying legs,” which is no doubt a theoretically accurate description, if the maxillipeds are regarded as legs, but in the account which follows the statement is retained from earlier editions that “the first thoracic segment is amalgamated with the head, and the limbs of this segment appear to be inserted beneath the head, or, as it were, beneath the throat; hence the name given to the order.” Here the first thoracic segment is the second thoracic segment of the definition. The mandibles are stated to be without palps, which is not the case in all, or even most, genera of this order. A figure is given of “Caprella plasma,” which belongs to a genus possessing mandibular-palps. The species is known as *Protella plasma*, Montagu, and has rudimentary pereopods, which are not indicated in the figure.

The second order, Amphipoda, is exemplified by *Talitrus locusta*, which is figured, and *Gammarus pulex*. It is remarked that “all the Amphipoda are small,” a rather indefinite statement, scarcely indicating the actual range from about a tenth of an inch to something over four inches.

The statement that “the earliest known Isopod is the *Prosoponiscus* of the Permian rocks” is a mistake obviously due to the miscasting name *Prosoponiscus*, which is as unsuited as its predecessor *Palaeoniscus* for a genus of fossil Amphipoda.
1880. PARONA.

"Niphargus puteanus" (Koch). Variety from a cavern in Monte Fenere Val Sesia, Piedmont; with historical account of that species generally." (Dr. von Martens, Zool. Record for 1880.)

1880. SMITH, SIDNEY I.

Professor Smith gives a full description of Cerapus tubularis, Say, which he partially figures. It is, he thinks, "not congeneric with any described species, and the genus cannot properly be placed in any of the numerous subfamilies defined by Boeck, though it is probably most nearly allied to his Podocerinae." He proposes for it a new subfamily, Cerapinæ, thus described:—

"The single known genus differs from the Podocerinae and allied groups in the following characters. There are only three pairs of branchial lamellæ, which are borne on the third, fourth and fifth segments of the prosome, and only three pairs of ovigerous lamellæ, which are borne on the second, third and fourth segments. The second and third pleopods are much smaller than the first, and their inner lamellæ are rudimentary or very small. The second and third uropods are uniramous and nearly alike, the distal segment in each being short and terminating in a hooked point.

"The only known species inhabits unattached, portable tubes, and, as in many allied genera, has large cement glands in the bases of the first and second peraeopods."

Professor Smith at this date regards Cerapus tubularis as the only species, without, however, taking Cerapus abditus, Templeton, into account. For other species that had been referred to Cerapus, he adopts Ericthonius, M.-Edw.

Unciola irrorata, Say, is stated to have precedence over Glaucome leucopis, Kröyer. Lepidactylis, Say, is preferred to the other names which compete for the designation of Slabber's Oniscus arenarius.

1880. STOSSICH, MICHELE.

This paper, included in P. Mayer's list, 1882, I have not been able to obtain.

1880. STUXBERG, ANTON.

Evertbratfauna i Sibiriens Ishaf. Förelöpande Studier grundade på de zoologiska undersökningarna under Prof. A. E. Nordenskiölds Ishafs-expedition
At pages 62-66 Stuxberg enumerates one hundred and fifteen Arctic Amphipoda, which we met with in various localities in the numbers and proportions exhibited by the following table:

1) Grönlænd 74 arter = 64,3 %
2) Spetsbergen 73 = 63,6 %
3) Skandinaviens N. och V. kust 69 = 60,9 %
4) Sibirien Isaf 60 = 52,2 %
5) Murmanska och Hvitafjord, Jugor schar 31 = 26,9 %
6) Matoschkin schar 30 = 26,1 %
7) Arktiska Amerika 25 = 21,3 %
8) Britanië 24 = 20,9 %
9) Island 23 = 20,6 %
10) Danmark 22 = 19,1 %

b) Øfriga danske sund 20

c) Danmarks vestkust 11

11) Østersjøen 4 = 3,5 %

"Weyrechtia. Novum genus Amphipodum, ex familie Gammarinorum Boeck, inter congeneres valde insignis est et ab ipsis bene diversum, neque cum aliis ejusdem familiae generibus similidinalem praebet quam eum genere Amathillarum."

THE VOYAGE OF H.M.S. CHALLENGER.

latior; supra funem pedunculi pedum ultimorum parvis spuriorum parallelae, succum paullo curvata, non fissa, margine postico 3 sinibus haud profundis, quorum medius latus, laterales acuti, setis singulis præditi. Integumenta cephalocornis et canes nitida, punctis impressis rotundis confertissime collatis.—Corpus longituæ 51°, latituæ maxima 17,5°, altituæ maxima 11°. Longituæ antænnorum superiorum a) pedunculi 5°, b) flagelli primarii 10°, c) flagelli accessorii 3,5°. Longituæ antænnorum inferiorum a) pedunculi 7,3°, b) flagelli accessorii 17°.

"Habitat in Mari Sibiricæ Glacialis inter promontorium Vankarens et Fretum Beringianum fundo arenoso, orygarum 4—6 profunditate."

No doubt the word "accessorii" is applied to the flagellum of the lower antennæ in the above account by an accidental mistake in writing.

1880. Thomson, George M.

The observations refer to the Crustacean fauna of Dunedin Harbour, the maximum depth of the bay being probably about 3 fathoms. Under "Amphipoda Normalia. Fam. Gammarides. Subfam. Stegocephalides," there is instituted the new genus Panoploea, thus defined:

"Coxa of the four anterior segments well developed, those of the second pair of pereiopoda excavated on the upper part of the posterior margin. Antenne subequal, without a secondary appendage. Mandibles with an appendage. Maxillipeds with a squamiform process on the ischium. Gnathopods feeble, almost chelate. Three posterior pairs of pereiopoda double-branched. Telson simple, squamiform." Mr. Thomson says, "I have formed this genus to include two species which appear to me to be the southern representatives of the arctic genus Plesistes. It differs from Plesiastes only in the well-developed squamiform plate on the ischium of the maxillipeds, and in the gnathopods being slender and more or less chelate. In the general appearance of the species, however, there is a very perceptible difference." The new species, figured Pl. I. figs. 2, 3, are named Panoploea spinosa and Panoploea debilis. Of these, through the kindness of Mr. Thomson, I have been able to examine specimens, and it appears to me that Panoploea spinosa is certainly an Iphimedia, while Panoploea debilis has numerous points of resemblance to Amphiploës longimana, Böeck, but as the species has three dorsal spines, it may be more correct to place it in the closely allied genus Halirages, Böeck. It cannot be generically united with Panoploës (Iphimedia) spinosa. In "Subfam. Phoxides. Genus Amphiploches, C. Spence Bate," is described "Amphiploches squamosus, n. sp. (Pl. I. fig. 4.)" In "Subfam. Gammarides. Genus Euirus, Kröyer," is described "Euirus cuspilatus, Kröyer, var. antarcticus, n. var." Of "Melita tenuicornis, Dana (Mora tenuicornis, Sp. Bate, Paramura tenuicornis, Miens)," it is said, "the females are remarkable for possessing a hook-like process on the exal lamella of the fourth pair of pereiopoda, almost exactly similar to that figured and described by Fr. Müllcr (Facts for Darwin, p. 27) as occurring in M. insulatilis." In "Genus Megamona, Spence Bate," "Megamona fasciculata, n. sp. (Pl. I. fig. 5)," is described. In "Fam. Corophidiæ. Genus Corophium, Latr." a description is given of Corophium contractum, Stimpson.
1880. **Uljanin, B.**

The results of the investigation are here given in summary. There is a notice of this paper by P. Mayer in Zool. Jahresber. (1880), II. Abt., pp. 53, 54. 1880. An account of the investigation was published in extenso in 1881. See Note on Uljanin under that date.

1880. **Weber, Max.**

"M. Weber has examined histologically and chemically, and described the so-called liver of terrestrial, freshwater, subterraneous, littoral, and truly marine species of different orders, viz.:—several *Oniscidae*, including the blind *Typhlonus steini*, *Aeolus aquaticus*, and the subterraneous *A. caricibus*, *Gammarus palus*, *fluviatilis*, *puteanus*, *marinus*, and *locusta*, *Talitrus* and *Orchestia*, and *Astacus fluviatilis*. He comes to the conclusion that in the *Decapoda*, *Amphipoda*, and *Isopoda*, this gland is tubular and contains at least two sorts of cells, one of which secretes a fluid acting as a ferment (enzyme) on albuminous substances, and the other a pigment allied with a fatty substance and cholestearin, serving for the emulsion for fat. He calls the first ferment-cells, the second liver-cells, and the whole organ 'hepato-paucereus,' as it combines the function of the liver and that of the true digestive glands of the Vertebrates. During the embryonal stage the liver is developed and active in the *Crustacea*, as in the *Vertebrata*, which proves that its function is not only digestion, but also excretion. In some Amphipods and Decapods, there is a third sort of cells, probably reserve-cells, which are destined to supply, if necessary, the others." (Dr. von Martens, Zool. Record for 1880. He says there is an abstract also in the Journal of the Royal Microscopical Society, iii. p. 424.)

1881. **Buckley, Arabella B.**

In a popular account of the Crustacea, pp. 153–177, the expression "insects of the sea" for these animals is approved and adopted. The figure, 57. C, to which the name *Caprella* is assigned, really represents *Prote ventricosa*, O. F. Müller.

1881. **Delage, Yves.**

This admirably lucid essay discusses the subject successively in regard to the Isopoda, Amphipoda, *Laeomodipoda*, and *Tanaidae*. An account is given of the ingenious methods of
Dr. Delage confirms the view of Fritz Müller that the number of lateral slits in the Amphipodan heart consists, with rare exceptions, of three pairs [without, however, noticing that la Valette had already in 1857 plainly stated this fact in regard to Gammarus pulex, and that Spence Bate, Sessile-eyed Crustacea, vol. i. p. xxxii., 1868, describes the course of the blood in the Amphipoda returning to the heart, "which it enters by three lateral pulsating oblique apertures"]; he gives G. O. Sars the credit of having first clearly indicated the existence of a posterior aorta with definite walls; he finds that Wrześniowski has recognised the existence of the hinder cardio-aortic valve; has described exactly the lower aorta with its termination in the hinder part of the ventral sinus by three openings, two lateral and one terminal; has described the course and branches of the upper aorta, but without seeing the valve that separates it from the heart, or the pericerebral vascular ring; has been the first to recognise that the blood which circulates in the appendages is contained in true vessels, and, lastly, has had a glimpse of the pericardium, since he speaks of a venous cavity above the heart. [In the Zoologischer Anzeiger for 1879 Wrześniowski very minutely describes the valve apparatus at both extremities of the heart.] Delage believes himself to have proved by injections that, in the principal joints of the legs, instead of occupying half the total breadth, leaving the other half to the venous current, the arterial vessels wind, perfectly rounded and defined, between the muscles, only communicating here and there with the corresponding venous vessels, which are also on their part perfectly individualised. He therefore rejects the view that the cavity of each limb is simply subdivided into two compartments by a single longitudinal membrane. His further discoveries concern the existence of the anterior cardio-pericardiac valve [already known to Wrześniowski], a pericardium with perfectly definite and continuous walls, a peri-cephalagran vascular collar formed by two branches of the anterior aorta, and a vascular ring formed by the aorta round the brain, a ring characteristic alike of the Amphipoda and the Lemodipoda. His observations were made principally on Talitrus locusta, Latr., Gammarus locusta, Fabr., in both of which the lateral orifices of the heart are found in the second, third and fourth segments of the person; on Montagia monocoloides, Sp. Rate, in which he could not discover an orifice in the second segment; and on Corophium longicorne, Latr., in which there is but one pair of lateral orifices, situated in the fourth segment. The Corophines are separated from the (other) Amphipoda, not only by this distinction, but also by the absence of two vessels proceeding from the upper extremity of the heart and designated "facial arteries," as well as by the absence of a vascular ring round the so-called "renal organ," and by the circumstances that the lower aorta is not terminally divided, and that the pericardium, instead of occupying the whole length of the body, is limited to the person.
In the Caprellina, observations based on Caprella acanthiifera, Leach, Caprella acutifrons, Latr., "Protella phasma (Sp. Bate)," "Proto pedata (Flemm.) et P. gosseiri (Sp. Bate)," show an absence of the peri-osophageal collar, though the blood-current pertaining to it exists in the usual place. The three pairs of lateral orifices in the heart are present, but the two first pairs are narrow and wanting in activity, especially in Caprella acutifrons, thus indicating an affinity between the Caprellina and the Corophinae, in which the two first pairs of orifices have completely disappeared. They agree with the Corophinae also in the circumstance that the hind limbs receive their blood from the aorta and return it to the ventral sinuses, and do not, as in Talitrus, receive it from the ventral sinuses and return it to the pericardium.

Of the Tanaida Dr. Delage examined more particularly Paratanais savignyi (Tanais savignyi, Kroyer), in which the heart has two pairs of lateral orifices, situated in the third and fourth segments, Tanais eiliatus, Lillj., with a single pair in the fourth segment, and Apunodes latreillii, Sp. Bate. He thence tabulates the affinities of the Tanaida with the Isopods, Amphipods and Decapods respectively. He connects them with the Amphipods by the form and position of the heart; by the absence of arteries springing from the heart with the exception of the aortas; by the small number of arterial ramifications; by the fact that the ventral sinuses is arterial and not venous; by the pericardiac vessels; by the loose peri-osophageal vascular collar not giving origin to a ventral median vessel, and, above all, by the peri-cerebral vascular ring characteristic of the Amphipods.

For the Hyperina, which he had no opportunity of examining, he refers to Pagenstoeker's account of Phronima sedentaria, 1861 (on p. 90 misprinted 1761), and various treatises by Claus, who has shown that in the Hyperina the heart has three pairs of lateral orifices besides two aortas with valves, the lower aorta communicating with the heart by a double opening, showing perhaps an indication, Dr. Delage suggests, of a tendency to the bifid arrangement actually found in the Isopods and in the two abdominal aortas of the Tanaida.

For the whole subject, compare Note on Wrześniowski, 1879; for the Tanaida, Note on Blanc, 1884.

1881. Gordon, G.

Mr. William Robertson, residing in Shetland, having procured specimens of Phronima sedentaria from Urrafirth, and kept them alive for some time in confinement, informed Dr. Gordon "that the tail of the crustacean was the sole moving power that carried both itself and dwelling round the sides of the vessel; that the Phronima often left and returned to its Beroe; that hundreds of them were cast ashore about the same time, January 1880, at Ronas Voe." Of the young, two or three days after their birth, he says, "these young crustaceans kept to the surface of the water, but if it was stirred, they then sank to the bottom, lay on their backs, and kept constantly working with their tails. The adults lay the same way when they were out of the Beroes." The way in which the Beroe is spoken of in parts of this paper might easily produce the impression that it was a still living animal, in which the Phronima was ensconced.
1881. Hartwig, G.

Among the "Edriphthalma" he mentions, page 247, "the saltatorial sandhoppers (Talitrus)," "the ill-famed Chetura," "the parasitical Cyami which gnaw deep holes into the skin of the whale." Figures are given of *Chetura teredora* and a "sandhopper," presumably *Talitrus borealis*. The frequency of the sandhoppers on the shores of the Arctic seas is illustrated by Holboll's account of his experiment with bait in an open basket let down to a depth of seventy-five fathoms. It is scarcely necessary to remark that the Amphipods taken in that instance were not the sandhoppers of the shore.

1881. Leslie, George, and Herdman, William A.

The Crustacea extend from page 42 to page 52. "In the arrangement and nomenclature of the Amphipoda and Isopoda," the authors say, "we have followed Bate and Westwood's 'British Sessile-eyed Crustacea,' a work from which we have derived the greatest assistance." They enumerate only sixteen species of Amphipoda, without any descriptions. The "Caprella nigeras (Linn.)," may probably be the same as the "C. lobata (Müll.)," which they identify with "the C. lavis of Goodier." This will reduce the number of species to fifteen, of which five are Caprellidae. It will be tolerably safe to say that such a list gives no idea whatever of the Amphipod-fauna of the Firth of Forth. Six out of the ten species of normal Amphipoda are given on the authority of Metager.

It is here noted that Glycera, Haswell's name for a new genus in the Lysianassine, is preoccupied in Annelides.

Crustaceae. The Zoological Record for 1880; being Volume seventeenth of the Record of Zoological Literature. London, m.dccc.lxxx1. pp. 1–61.

It is noted that the name Chloris, used by Haswell for a new genus among the Gammaridae, is twice preoccupied in Aves, and once in Botany.

1881. Mayer, Paul.

1881. Miers, E. J.

There is here only an incidental allusion to the Amphipoda.

1881. Miers, E. J.

On Acanthostepheia pulchra, n. s., is figured and described, with a comparison between it and Acanthostepheia malmgreni, Goës. Amathillopsis affinis, n. s., is figured and in like manner compared with its near ally Amathillopsis spinigera, Heller.

1881. Miers, E. J.

Crustacea, in Markham's Polar Reconnaissance, 1881.

No new Amphipoda reported. Compare Note on Markham, 1880.

1881. Miers, E. J.

The only Amphipod included in this account is Ampelisca tenuicornis, Liljeborg, of which a detailed description is given.

(zool. chill. exp.—part lxvii.—1887.) XXX 67
1881. Moseley, Henry Nottidge.

At page 204, Mr. Moseley says that “in nearly all the mesenterial cavities [of *Stephanopylella formosisima*] were found one or two small crustaceas (a Gammarid?), which must apparently live as commensals within the cavities of the living coral.” Three specimens of the coral were obtained at “Station 192, off the KI Islands. Lat. 5° 42′ S., long. 132° 25′ E. 129 fathoms;” and several specimens at “Station 203, off Zebu, Philippine Islands. Lat. 18° 10′ N., long. 123° 55′ E. 95 fathoms.”

As I have not found any Gammarids in the Challenger collection from the stations here mentioned, there is little doubt that the Crustacea referred to belonged to the Hyperinna.

1881. Packard, A. S., Jr.

“Many miles of galleries have been explored, and no end has yet been reached” of this cave on the southern boundary of Tennessee. The Isoped, *Cerolaxa nickajackensis*, Packard, n. s., is not uncommon in the waters of the cave. “The second crustacean discovered swimming about in the subterranean stream, was a species of Amphipod belonging to the genus Crangonyx, and which may be called *Crangonyx antennatum* Packard.” The description of pl. vii. fig. 2, gives *Crangonyx antennatum*. “It is a large and purplish species; the first antennae very long; the flagellum with 20–24 joints; the entire antenna being over one-half, and nearly two-thirds as long as the body; the last joint of the peduncle being slightly more than half as long as the penultimate joint.” A comparison of it is made with *Crangonyx gracilis*, Smith. “It is very different from *C. citrins* Cope, of Mammoth Cave, and from *C. packardii* Smith, differing in its distinct eyes, and larger, more numerous jointed antennae.”

1881. Smith, Sidney I.

Among the Amphipoda, pages 447–452, is described “*Neohela phasma*, sp. nov.—*Neohela*, nom. nov., vice *Hela* Boeck, provoc.” “This species is apparently very closely allied to *N. monstrosa* Boeck, but has well-developed eyes, and the propodus in the second pair of gnathopods is different in form, besides other slight differences.” Altogether seven species of Amphipoda are here recorded.
1881. Smith, S. I.

"Few species of Amphipoda were found; but the Arctic species, Stegocopehalus ampulla, Haploops setosa, and Epimeria loricata, G. O. Sars, occurred, the last in abundance."

1881. Ulianin, B.

After explaining his methods of investigation, Ulianin refers to eight authors, who have previously treated the same subject. Of H. Rathke’s Reise bemerkungen aus Turien, 1837, he says, “Enthält Beobachtungen über Entwicklung der Amphithöö. pieta, Gammarus gracilis, Amathis carinata und Hyale pontica.—Die Beobachtungen von Rathke haben Bedeutung nur in historischer Hinsicht.” Of Meissner’s paper in 1885, he says, “Enthält die ersten sehr dünften und grässentheils unrichtigen Angaben über das kugelförmige Organ,” and at p. 451, “Nach dem von Meissner veröffentlichten Abbildungen zu urtheilen, untersuchte er ein zerstörtes Organ, das an Lappen der zerriessenen Cuticularhaut hing. Die Einstülpung der Cuticula in das kugelförmige Organ wurde von ihm als eine Öffnung in der Cuticula, nämlich als eine Micropylöffnung erklärt. Da er die Membran, in der er eine Mikropyloöffnung zu finden glaubte, irthümlich für die Dotterhaut hielt, so zog er den Schluss, das die Befruchtung des Eies der Amphipoden noch im Eierstocke vor der Bildung des Chorions geschehe.” In Müller’s Für Darwin, 1864, he says, “Das Vorhandensein der Larvenhaut bei Amphipoden-Embryonen wird zum ersten Male gezeigt.” He finds the statements of de la Valette on the first developmental stages in Gammarus pulex very like what he has himself observed in the eggs of species of Orchestia, but 1. the latter undergo “wenn auch einer sehr oberflächlichen und kurzen doch einer echten Furchung;” 2. “bei den Orchestien . . . treten aus dem Inneren des Eies nur vier grosse amoböse Zellen, die nur nach mehrfacher Theilung und Wanderung auf der Oberfläche des Eies in ruhende Blastodermeuben übergehen; während der Wanderung der amobösen Zellen auf der Oberfläche des Eies wird ausserdem die Nahrungsslotter wieder einer Art oberflächlicher Segmentation unterworfen;” 3. “bei den Orchestien ist es möglich gleich nach der ersten Theilung der vier grossen aus dem Inneren des Eies angetretenen amobösen Zellen den Pol zu unterscheiden, an welchem das Blastoderm angelegt wird und der später der Bauchfläche des Embryo entsprechen wird.”

In Besse’s paper in 1869 and Dohrn’s in 1870, Ulianin says, “das kugelförmige Organ wird mit dem Rückenstachel der Zoë homologisirt,” but, he thinks, without good reason. Sars’ opinion that the organ in question was of service for the nourishment of the embryo, he considers quite untenable. He himself agrees with those who regard it as an inherited organ, having no special physiological function, but of high morphological importance. It is, he says, “als eine lokale Einstülpung des Ektoderms angelegt; die Zellen dieser Einstülpung scheiden eine Cuticula aus, die mit der zur selben Zeit von der Oberfläche
des Embryo ausgeschiedenen Cuticularhaut im Zusammenhange steht.” It has, he continues, the most striking resemblance to “der sogenannen Schalengrube der Mollusken.”

Having previously observed that, “vorausgesetzt das bei den Orchesten, ähnlich dem, was bei anderen Crustaceen beobachtet wurde, die das Zerfallen des Dotters in Dotterschollen hervorrufenden Zellen zum Auflauf des Mittel-darmes verbraucht werden, nimmt das Entoderm seinen Ursprung von dem Zellen des kugelförmigen Organes,” Ulazin thus concludes:—“ähnlich wie bei anderen Crustaceen entsteht bei den Orchesten das Mesoderm durch Zersplitterung des Blastodermus, während das Entoderm aus vom Ektoderm abstammenden und in den Dotter einwandernnden Zellen zusammengesetzt wird. Die Thatsache, dass die in den Dotter einwandernnden Zellen von den Zellen des kugelförmigen Organes abstammen, kann uns auch nicht sehr befremden; das kugelförmige Organ ist, wie oben gezeigt wurde, ein ererbtes verknümmertes Organ, das seine frühere Bestimmung mit der Zeit verloren hat und dem im Laufe der Zeit neues Funktionen bei der Bildung des Entodermus aufgelegt wurden.”

1881. Wrześniewski, August.

Goplana polonica nowy rodzaj i gatunek skorupiaka obniesiego z okolic warszawy opisal August Wrześniewski. Warszawa, 1881.

A very useful comparative table is given of the terms used by nine authors in describing the mouth-organs and external parts of Amphipoda, omitting mention, however, of the labrum or upper lip. The labrum or lower lip is called langue by G. O. Sars, zunge by Dybowsky, Paraphaet by Claus, masillipeds. Dybowsky is here said to call the uropoda Schwimmeibe and Springibeine, but that does not quite accurately represent him, since in reality he calls the three pairs of pleopoda Schwimmeibe, the first two pairs of uropoda Springibeine, and the last pair das Steuerbein. It is a mistake also to say that Dybowsky gives metacarups as an alternative for the “Handwurzel” or wrist of the gnathopods; in fact he gives the word carpus, as might be expected, though for the corresponding joint in the first two pairs of pereopods he gives “Afterhandwurzel (pseudocarpus),” and in the last three pairs “Fusswurzel (metatarsus).” According to the lists here given, tarsus is used by Claus and Heller as an alternative for carpus, by Dybowsky as an alternative for Fusstück (the name which he gives to the hand in the last three pairs of pereopods), and by Milne-Edwards, in the form tars, as an alternative for doigt or dactylopodite.

The structure of Goplana polonica is illustrated by Plates X. and XI. of which the explanation is given in French as well as in Polish.

1882. Chilton, Charles, born 1860 (Chilton).

Art. XXIV. points out the resemblance of the first gnathopods of Microdeutopus maculatus, G. M. Thomsen, to those of Aoro gracilis and Aoro typica. Art. XXV. describes and figures the new well-shrimps Callopanecae compactus, Callopanecae subterranea, and Gammarnus fragilis.

This important work gives in the Introduction a general account of the structure of the Amphipoda. The accounts of Mr. Haswell's own species are reproduced from his earlier publications already noticed. Among the addenda et corrigenda at the end of the volume, he remarks that "the species on which the genus Noblate was founded belongs to the Orchestidae, and is allied to the form afterwards named by me Asphalophoreus." He had previously placed Noblate in the subfamily Stegopodidae. The name Glycerina is now altered to Glycerina, Glycerina being preoccupied. The species Icillus punctatus is recognised as only a variety, and therefore a synonym, of Icillus australis.

Crangonyx lucifugi, n. sp. "a small, rather elongated species, that was obtained from a well in Abingdon, Knox county, Illinois," "appears to resemble C. tenuis Smith, but is evidently different. In that species, as described by Prof. S. I. Smith, the first pair of feet are stouter than the second, and have the palmar margin of the propodite much more oblique. The reverse is true of the species I describe. Nor do I understand from the description of C. tenuis that the posterior caudal styles each consist of a single segment. There are some minor differences. From C. sitifera, judging from Prof. Cope's description in American Naturalist, Vol. vi. p. 422, it must differ in the caudal styles. 'Penultimate segment, with a stout limb with two equal styles,' is a statement that will not apply to my species, whichever the 'penultimate' segment may be."

Mr. Hay next describes "Crangonyx bifurcus, n. sp.—General form and appearance those of the Western variety of C. gracilis." "This species," he says, "differs from C. gracilis more particularly in the form of the telson, and in the length of the outer rami of the posterior stydes as compared with the peduncle. From C. antennatum Packard (American Naturalist, 1881, p. 880), it differs in the form of the telson, and in the much greater size of the eyes." Found in a rivulet at Mason, Miss. "The three species, C. gracilis, C. bifurcus and C. lucifugi present an interesting gradation in the form of the posterior caudal stydes. In the first-named the outer rami is twice the length of the peduncle, and the inner rami is present, but rudimentary. In C. bifurcus the outer rami is but two-thirds as long as the peduncle, while it is doubtful whether there is anything whatever to represent inner rami. In C. lucifugi both the outer and inner rami are absent, and the peduncle itself is much reduced."
1882. Hoek, P. P. C.

The part concerning the Amphipoda, beginning at p. 41, describes the new species, *Socarnes ozalis*, Taf. III. fig. 29-29r., given as a link between *Socarnes* and *Ichnopus*, but recognised by G. O. Sars, in 1885, as a synonym of *Socarnes bilenticulatus*, Sp. Date (sp.); *Anonyx debriquiti*, Taf. III. fig. 30-30x., noted as having much in common with *Anonyx ampulla*; *Haploops tavis*, Taf. III. fig. 31; *Podocerus tuberculatus*, Taf. III. fig. 32. Brief observations are made upon *Omanimus leucopis*, G. O. Sars; *Tryphosa horingii*, Boeck; *Acanthozon cuspidata*, Lepechin (with criticism of the figure given by Bachholz, in 1874); *Gammarus locusta*, Linn.; *Amphelisca esrichti*, Kröyer, and others. A short appendix refers to Stuckberg's recently published Evertebratfaunen i Sibiriens I saf. There is a Literatur Verzeichniss, pages 71-73.

A species closely resembling Hoek's Arctic *Podocerus tuberculatus* was taken by the Challenger near New Zealand.

1882. Lenz, Heinrich.

On pp. 174, 175, *Corophium longicorne*, Latr.; *Bathyporeia pilosa*, Linstr.; *Calliope lacrimosa*, Krey.; *Melita palmata* (Mont.); *Gammarus sabinei* (Leach); *Talitrus locusta*, L., are mentioned, with notes as to their occurrence, and on p. 178, in a summary of the investigations in this region, nine Amphipoda are recorded.

Crustacea. The Zoological Record for 1881; being Volume Eighteenth of the Record of Zoological Literature. London, m. DCCC.LXXXII. pp. 1-38.

1882. Mayer, P.

It is safe to affirm that for a long time to come this work will be absolutely indispensable to every genuine student of the Caprellidea. The scope and comprehensiveness of it may be inferred from the principal headings in the long table of contents. Under "Systematik,"
are given, historical review; special classification; alphabetical table of the genera and species. These are followed by "Geographische Verbreitung." Under "Anatomie und Histologie," are given, general form of the body, segments, limbs; integument; glands; nervous system; organs of sense; muscles; connective tissue; organs of respiration; circulatory apparatus; organs of nutrition; sexual organs. Next come "Entwicklungsgeschichte," "Biologie," "Phylogenie," under which the structure of the Cyamidje is considered, and lastly "Literaturliste." The various topics are handled with great thoroughness, and the opinions of earlier writers are minutely and carefully criticised.

Mayer thus defines the family Caprellidae:

Up to the date of Mayer's treatise there had been established eight genera, for the arrangement of which various useful tables are given. Cercoops, Proto and Caprellina agree in having branchiae on the second, third and fourth segments; the rest have them only on the third and fourth. Proto and Caprellina have more than two joints to the flagellum of the lower antennas; the rest have only two. Caprella and Polatirius are without the mandibular palp, which is present in the rest. Proto stands alone in having seven pairs of complete limbs on the person; Protella has five pairs complete and two pairs rudimentary; Cercoops, Egnia, Egnivella, Caprella, have only five pairs; Caprellina and Polatirius have four pairs complete and one pair rudimentary. In Cercoops the pleon has five segments, in Protella two, in the rest only one. In Egina, the abdominal feet are jointed, in Egnivella not jointed. But of Cercoops and Egnivella Mayer does not speak from his own observation.

Within the genus Caprella, the species may be divided, as pointed out by Haller, into two groups, those in which the lower antennas carry "Raderborsten," and those in which they carry "Sinnisborsten." They may be otherwise divided into two groups, according as in the male the basal joint of the second gnathopod is very long or is short.

To Cercoops is assigned the single species "Cercoops Habiab, Krüger." Proto, Leach, has the synonymy, Leptonera, Latreille; Namperlia, Latreille; Namperlia, Milne-Edwards; Proto, Desmarest. The species assigned to it are, vasticea, O. F. Müller; brumneovittata, Haller; "Novo-Holmrioge," Haswell; and "Prots cornigera," Haswell, for Caprella cornigera, Haswell. This last species has three pairs of branchiae arranged as in Proto, but the first three pairs of pereopods have not been observed, only the muscles of the body going to them are so little developed, as to produce the impression that the limbs themselves may be rudimentary, in which case Mayer would place the species in a new genus, Hircella, a name adopted by Haswell in 1884, without further observation of the appendages in question.

The genus Caprellina, Thomson, has the one species longicollis, Nicolet, with "Novo-
Zealandiae," Thomson, and brevicollis, Nicolet, for synonyms.

Protella, Dana, has the species phasana, Montagu; gracilis, Dana, with australis, Haswell, as a possible synonym; echinata, Haswell, for Caprella echinata, Haswell; and "Haswelliana," Mayer, n. s., in which the last two segments of the person are confluent. Haswell, in 1885, says of his Protella australis that "it is a very well-marked species and quite distinct from P. gracilis of Dana, to which Mayer is inclined to unite it, both in the form of the head and of the gnathopoda. The gnathopoda are not unlike those of P. dentata [10. dentata] but in other respects the two species are quite different." Mayer remarks
THE VOYAGE OF H.M.S. CHALLENGER.

that if Boeck's \textit{E"gina echinata} should prove to be a \textit{Protella}, Haswell's \textit{Protella echinata} might be renamed \textit{echinatina}.

To the genus \textit{E"gina}, Kr"oyer, Mayer assigns \textit{E"gina longicornis}, Kr"oyer, with \textit{E"gina levis}, Boeck, for a synonym; and \textit{E"gina echinata}, Boeck, with the synonymy, \textit{E"gina spinosissima}, Stimpson; \textit{Caprella spinifera}, Bell; \textit{Caprella spinosissima}, Bate, and \textit{1 Caprella spinosissima}, Norman. Of these, however, the first three represent \textit{E"gina spinosissima}, Stimpson, 1854, and the fourth is \textit{Caprella horrida}, Sars (see Note on Sars, 1885). As doubtful species of \textit{E"gina} are mentioned Dana's "\textit{A.f. acutata}" and "\textit{A.f. tenella}," from the Sooloo Sea, of which Dana thought the former might be the female, the latter the male, of one and the same species. \textit{E"gina}, Boeck, distinguished from \textit{E"gina} only by having the appendages of the pleon unjointed, has the solitary species \textit{E"gina spinosa}, Boeck, also marked out by the strong dorsal spine at the beginning of the first proen-segment. A spine on this segment is to be noted also in \textit{Caprella spinulata}, Couch, 1852.

In regard to the genus \textit{Caprella}, Lamarck, Mayer calls attention, as Kr"oyer had already done, to the great variability in the species, which has led to the introduction of many needless specific names. He lays down a sort of canon, that "a single specimen of small size can only be determined with any certainty under favourable circumstances." New species ought not as a rule to be established without an opportunity of examining an adult male specimen. Of about ninety named species Mayer has been able to refer ten to other genera of \textit{Caprellidae}, about ten he has had to leave uninvestigated; of the remaining seventy he has been able to recognise ten as undoubted species, the remainder consisting partly of synonyms, partly of species perhaps good and tenable, partly of such as are absolutely indefinite (unbestimmbar). His ten well-ascertained species are thus classified:

\begin{itemize}
  \item \textbf{A.} Hinter"fu"hrer mit Sinneshaaren. Dimorphismus bedeutend.
    Stamm vollig glatt; 2. Arm des erwachsenen \textit{M"annchens} lang,
    Hand desselben ausserordentlich gross und dick . \textit{C. granulifera}, n. s.
    Stamm entweder auf allen oder wenigstens den drei letzten
    Segmenten mit paarigen oder unpaaren dorsalen H"ackern
    oder Dornen; 2. Arm des erwachsenen M"annchens kurz,
    Hand desselben im Verh"altniss nicht so stark entwickelt
    wie bei der vorigen Art . . . \textit{C. acanthifera}, Leach.

  \item \textbf{B.} Hinter"fu"hrer mit Ruderhaaren. Dimorphismus wechselnd.
    Stirnstachel fehlt.
    K"orper ungemein bestachelt. 2. Arm kurz . \textit{C. tuberculata}, Bate and
    Westwood.
    \begin{itemize}
      \item dorsal ganz glatt. 2. Arm kurz . \textit{C. aquilifera}, Say.
      \item nur auf Segment 5-7 bestachelt. 2. Arm des
        erwachsenen M"annchens lang . \textit{C. linearis} (Linn"e) Bate.
    \end{itemize}
    Stirnstachel vorhanden.
    2. Arm des erwachsenen \textit{M"annchens} kurz.
    Geissel des Vorder"fu"hrers mit 14 Gliedern.
    \begin{itemize}
      \item rund. 5. und 6. Segment glatt . \textit{C. acutifrons}, Latreille.
    \end{itemize}
    2. Arm des erwachsenen M"annchens lang.
    2. . . . ungew"ohnlich lang \textit{C. inornis}, Haswell.”
\end{itemize}

To this table I have added the names of the authors of the species from the accounts given by Mayer further on.
To his new species, *Caprella grandimana*, Mayer assigns the earlier "Caprella Dohrnii," Haller, as a synonym, apparently rejecting Haller's name on the ground of some uncertainty connected with his species, and what seems to be an error in the description. It must be observed also that the name *Caprella inermis*, Haswell, requires to be changed, having been already used by Grube for a different species. As it appears to be undistinguishable "from *Caprella Doniavskei,*" Czerniavski, it may as well be known by that name. With *Caprella tuberculata*, Bate and Westwood, Mayer suggests the possible identification of de Quercie's *Puce de Mer arpenente*, Fig. A., B. (1780), which in my opinion is quite out of the question.

The genus *Podalirius*, Kröyer, receives three species, distinguished in the following table:

1. Palmarrand der Grossen Greifhand beim Männchen mit einem
   kleineren proximalen und einem größeren medialen Fortsatz. *P. typicus*, Kröyer.

2. Palmarrand der Grossen Greifhand ohne den medialen Fortsatz:
   Hinterbeine kurz, Palmarrand mit Einschlaghaken. *P. minutus, n. s.*

Traces of the first and second pereopods are stated to be present in "*Podalirius Kröyeri.*" To *Podalirius minutus* is assigned as a synonym *Podalirius typicus*, Hoek.

Under the head of Phylogenie, at page 192, the following hypothetical table of genealogy is given:

One hundred and thirty-one works are mentioned in the Literaturliste and Nachtrag, pages 194–201, which, with a few unavoidable exceptions, have been carefully studied and are here minutely criticised by Mayer.

Taf. i., a double plate, gives figures, lateral and dorsal, of both sexes of the following species, *Proto ventricosa, Proletta phasma, Podalirius kröyeri, Podalirius minutus, Caprella* (Zool. Chal. Exp.—Part LXVII.—1887.)
538

THE VOYAGE OF H.M.S. CHALLENGER.

gammarus, Caprella acanthifera, Caprella equilibra, Caprella dentata, Caprella acutifrons, all found in the Gulf of Naples. The remaining nine plates give numerous and important details of the structure both external and internal of various species. There are also various illustrations interspersed with the text.

Attention may be called to the section on the salivary gland, as Mayer says, p. 145, that "Alle Autoren ohne Ausnahme schweigen von den Speicheldrüsen."

1882. SARS, G. O.

A list is given of 294 species of northern Amphipoda, 8 of them Hyperina, 268 Gammarina, and 18 Caprellina. The Gammarina are distributed among 22 families, the subfamilies of Boeck being dropped. Forty new species are figured and described, namely; 95. Cypionia borealis, rather to be called Tyro borealis; 97. Lysianella petaloceora, a new genus, of which the special characteristic is said to be the peculiar development of the penultimate joint of the peduncle of the lower antennae, "insolito modo dilatatum, laminari, facie interna seriis numerosis transversis cilium exornata." The undivided telson brings it near to the genus Lysianassa, from which it is distinguished by the antennae, the first maxille "lobo incisivo angusto spinis minutis crebris armato, palpo brevi, lobo interno angustato, biseto," and the first gnathopods "sat breves, distincte subcylindrom, manu carpo parum longiore leviter atenuato, apice oblique truncato;" 98. Ichneumus unbonatus; 99. Orchomene pectinatus, said to be distinguished from Orchomone serratus, Boeck, by the pale, narrow, subsigmoid eyes, the high, compressed gibbosity on the fourth pleon-segment, and other details; 100. "Orchomone Butel," "= Anonyx Edwardsii Sp. Rite, (no Kr0yer) = Lysianassa longicornis Sp. Rite &." Professor Sars says that Boeck seems not to have had this form under his notice, otherwise he could not have identified it with his Orchomone serratus, which is very distinct and the same as Lysianassa etepata, Goës. As it is not the same as Kr0yer's Anonyx Edwardsii, with which Rite had identified it, Sars renames it Orchomone butel, which, however, cannot rightly, I think, be made to include the species which Sp. Rite calls Lysianassa longicornis, Lucas; 102. Trepheus eiliata, apparently very near to Trepheus nova, Kr0yer; 104. Normania latina, provisionally referred to the genus Normania, but without examination of the mouth-organs; 110. Phoroxus flagellus, "= Phoroxus simpliz Boeck non Sp. Rite," the name proposed for this species (already described by Boeck, but by him incorrectly identified with Rite's species), referring to the characteristic form of the rostrum; 112. Stegopnephalus gibbosus, said to be easily distinguishable from the two other northern species by the "Epimera 4ti paris permagna, antecedentibus juntis plus duplo majora, postice valde producta et sequiliert rotundata, distincte latora quam altiora" and by the "segmentum 5ium corporis postica supine in giberum acutum desinens, epinaeris in medio marginis posterioris processum aminsum leviter recurvum formantibus, angulis inferioribus obtuse rotundatis;" 113. Stegopnephalus auratus, said to resemble Stegopnephalus christianseni, Boeck, but to be distinguishable by its smaller size, a broad orange stripe over the back, and the structure of the fifth peraeopods with "articulus basalis permagna, laminari, ceteris juntis multo longior, ad marginem posticum dense serratus et deorsum in angulum valde prominentem et ultra articulum 4ium porrectum excurrens;" 114. Andania pectinata, said to be near Andania nordmanni, Boeck, but to
be distinguished from it by the first gnathopods “ungue terminali spinis 4 pectinatim ornato,” the second gnathopods, “ungue terminali spinis 2 armato,” the “epimera 4th paris antecedentibus junctis cinctis circaulis, oblique triangulares, postice obtuse products, margine inferiori parum aractu,” and by the “pedes ultimi paris articulo basali subellipptico deosum rotundato-producto, margine posteriori lavi; articulo 3th qvam in A. nivalicrus minus dilatato;” for the relationship of this species to Stegocophalus, see Note on Aurivillius, 1883; 115. Amphilochus inermis, said to be very like AmphiLochus manuelens, Sp. Bat, but having the hand of the first gnathopods “angulo anterio nec in spina producto,” and distinguished from Amphilochus ornatus, Boeck, by the second gnathopods, in which the hand is much larger than in the first pair, “apicem versus dilatata, acie aractu calce carpi angusta et elongata ad aciem manus perrecta,” and by the very elongate telson;’’ 116. Stenothoe longirostris, new species of a new genus, of which Sars says “this curious little Amphipod obviously belongs to the Family Amphilochidae, but is so different from the forms hitherto known that it must be made the type of a new genus. The chief characters are the enormous development of the third and fourth pairs of side-plates, and the rudimentary structure of the two first pairs, also the narrow linear form of the basal-joint of the third and fourth peraeopods, by it which it recalls the genus Stegocophalus.” It is very near to, if not synonymous with, the earlier genus Peltoecon, Catta, 1875, and the genus Cygnosia, Haswell, 1880; see Notes on Catta and Haswell under those dates; 117. Stenothoe tenella, distinguished from the two other northern species of Stenothoe by the less strongly built body, the thin antennae and peraeopods and light-coloured eyes; 118. Stenothoe brevicornis, like Stenothoe monocalicles in the very short antenne, distinct in the much less developed side-plates; 119. Metopa rubriscillatora, recognised by Sars as standing very near to Metopa aberti, Sp. Bat, but distinguished from it by its far smaller size, the antenne of uniform length, the hand of the second gnathopods, thus described, “pedes 2th paris robusti, manu magna, oblonga, acie brevi, fere transversa, subilicus serrulata, inferne processu dentiformi sat prominente apici quum basi multo propiore definita;” and the colouring, “corpus pelliculum fascis transversis angustis ex parte interruptus colore intense purpureo ornatum;” 120. Metopa leptocarpa, “pedes primi paris forma insolita, tenissimi, fere filiformes, carpo valde elongato et angusto, manu apicem versus leviter dilatata, acie transversa et inferne distinctissime definita;” 122. Metopa boralis, synonyms with Metopa bruxelli, Boeck, non Goës, being distinguished, Sars says, from Metopa bruxelli, Goës, by its more considerable size, shorter antenne, first gnathopods “articulo 3th inferne parmi producto, manu medio leviter dilatata carpi longiudivinem sequunt,” and by the second gnathopods in which the palm is more coarsely serrate and the lower angle more prominent; 123. Metopa calcarata, distinguished by the relatively large oval eyes, the much dilated and downward produced third joint of the hinder peraeopods and by the second gnathopods in the male, which are “permagni, manu valde elongata, subarcuata, margine inferiore dense ciliato et antice eminientem serratam praebente, ungue terminali fortissimo margine altero ciliato;” 124. Metopa gregaria, the hand of the second gnathopod in the male “valde prolongata, subarcuata, margine inferiori toto dense ciliato in medio dentibus 2 et prope apicem eminientem subilicus serrata armato, acie non definita, ungve terminali validissimo manu longiore in margine interno ciliato;” 128. Brouzia tuberculata, near Brouzia serrata, but distinguished from it, Sars says, by want of any proper dorsal carina, though all the segments are raised above into protuberances, also by the blunt lateral carina, and by the lower hinder angles of the third pleon-segment, which are “acuminati et valde sursum curvati margine inferiore serrato;” 129. Edicerus micros, near Edicerus lynceus, M. Sars, but scarcely half the size, with a shorter, less inflated rostrum, smaller eyes, second joint of upper antenne linear, hands of the first and second gnathopods more elongate, third uropods very long; 131. Halimecon
THE VOYAGE OF H.M.S. CHALLENGER.

megatopus, distinguished by the uncommonly thick arched rostrum and large, confluent eyes; 132. Haliccreon (?) crotipes, only provisionally referred to Boeck's genus, as Sars recognises that the third uropods are not longer than the second, which is the case in the typical species, Haliccreon longicaudatus, and that the proportions of the first four pairs of percepods in the two species are very different; 133. Paramphitla brevicornis, with a general resemblance to species of Meteo, to be distinguished from its own allies by its small size, pale colour, and unusually short antennae; 134. Paramphitla armilla, nearest to Paramphitla glabra, Boeck, but distinguished by the eyes, "magni, rotundato-triangularis," the "spinae posteriores medicae, dente anguli infero-posterioris ferro obsoleto," the two gnathopods "mano elongato-ovata in 2° pari paulo majora, acie bene definita, obliqua, margine inferiore spinis nonnullis et fasciulis pilorum ornato," and the considerably greater length of the percepods; 135. Iplinodra minuta, distinguished from Iplinodra obseta, Rathke, by Professor Sars by its having no spine on the first joint of the upper antenna and by the different form of the two pointed processes at the lower hinder angle of the third pleon-segment, as well as by its small size and very different colouring; distinctions of somewhat doubtful specific value, that of colour above all being untenable in face of the numerous variations which Iplinodra obseta undoubtedly presents; 137. Atyssus minutus, very like Atyssus scammonieni, M.-Edw., but distinguished by the very remarkable first percepods "structura singulari, organa valida affinis formantes, articulo first brevissimo, cupuliformi, 5to nato et curtato ad basin fasciculati 2 spinarum armato, ungu terminali fortissimo, falciformi," a species which appears to be synonymous with Atyssus fulcatus, Metzger, 1871; 138. Halirages megatopus, distinguished from its ally Halirages tridentatus, Buenechus, by the enormously developed eyes and the "segmenta 2 prora corpris postici supina medio in processus singulos acutos producta; segmentum 3iium ad angulum infero-posteriorum truncatum et fortiter serratum; 139. Halirages incerti, to be recognised by its slender body, want of dorsal processes, thin, elongate percepods, and the sides of the head produced downwards into conical processes; 141. Ampelisca melifera, distinguished by a pair of tubercles on the back of the first, and another pair on the back of the second, pleon-segment; 143. Tritropis inflata; 144. Tritropis arivontris, which, with the preceding species, must be transferred to Rhachotropis, S. I. Smith; 147. Melita pellucida, "corpus pellucidissimum abscire pigmento. Longit. 5°mm."; 149. Ampelisca gibba, in the form of the last percepod said to be very like Ampelisca larvata, Liljeborg, but clearly distinguished by the different form of the head, although nothing in the figures and descriptions given respectively by Sars and Boeck of Ampelisca gibba and Ampelisca larvata seems to justify the separation of the former from the latter; 151. Ampelisca anomala, a species of importance as a link between the two genera Ampelisca and Bythid, even without links sufficiently close. In the general form of the body and development of the sides-plates, the new species, according to Sars, is a genuine Ampelisca, whereas the two basal-joints of the lower antennae are quite uncovered as in the genus Bythid. The last uropods extend indeed beyond the others, but still are far from being as strongly developed as is usual in species of Ampelisca; 153. Bythid crythrops, distinguished from Bythid gaimaridii by smaller size, red eye-pigment, longer upper antennae, and by the penultimate joint of the peduncle of the lower antenna being distinctly shorter than the last joint; 154. Photis longicornis, the antennae shorter and thinner than usual, sparsely pilose with short bristles, the palm of the first gnathopod obliquely excavate, of the second "basinuate"; 156. Gammairopis melacoca, "=G. crythrops Boeck, non Liljeborg," distinguished by Sars from Liljeborg's species by the shorter secondary flagellum of the upper antenna, the acute antero-lateral angles of the head, and the also acute infero-posterior angle of the third pleon-segment, while, further, the eyes in this species are black, not red, as required by the
very name of Lilljeborg's species; 157. *Podocerus minutus*, a minute form distinguished by Professor Sars from *Podocerus falcatus*, Montagu, on the ground of its far smaller size, the eyes considerably larger, the slighter unciliated lower antennae, the slenderer pereopods and the different colouring. As to the last point, "color flavescens fusco variegatum" would often precisely describe specimens of *Podocerus falcatus*. The difference in the second gnathopods of male and female is just what is found in the *palpellibus* and *variegatus* forms of *Podocerus falcatus*. Boeck speaks of having taken *Podocerus falcatus* at 20 fathoms depth, so that the occurrence of *Podocerus minutus* at a depth of 20 to 30 fathoms will not be, as Sars appears to suggest, an additional evidence of its distinctness. May it not be the *Ischyrocerus minutus* of Lilljeborg, 1851; 159. *Siphonocetes pallidus*, said to be distinguished from *Siphonocetes typicus*, Kr., and *Siphonocetes collotti*, Boeck, by its small size, pale colour, and the antennæ thus described, "1i paris dimidio corpore longiores, articulis pedunculi sensim magnitudinie decreascentibus, flagello articulis pedunculi 2 ultimis junctos longitudine aequante vel paulo superante, 6-articulato; 2di paris valde corporis longitudinem excedentes, margine utroque valde setoso, articulo ultimo pedunculi penultimo nominil brevior;" 165. *Caprella citata*, the second gnathopods as figured and described corresponding so exactly in form and ciliation to those often met with in *Caprella acanthifera*, Leach, as to raise a presumption that Sars' specimens may belong to that very variable species. The elongate flagellum of the upper antennæ, the only other distinctive mark to which Sars himself draws attention, is likewise proper to *Caprella acanthifera*. On the other hand, the figure does not show the globose head so notable in that species, to the distinctive shape of which Sars himself calls attention in noticing *Caprella acanthifera*, and the hands of the pereopods are described and figured with "seis prope basin dente minute armata," whereas in *Caprella acanthifera* the place of insertion of the principal spines, which defines the palm, is not, as in many Caprellæ, near the base of the hand but some way down its margin. In regard to the ciliation or hairiness of the hand of the second gnathopod, a doubt arises whether it may not be merely an adventitious growth; like the hairs depicted by Tate and Westwood on the second pereon-segment of their *Caprella tuberculata*, "die aber nichts Anderes als Pilzthymien sind," in P. Mayer's opinion.

Besides describing new species, Professor Sars makes important observations on many old ones. He regards *Tauria abyssorum*, Boeck, as a synonym of 91. *Tauria medusærum*, Fabr., so that, combining Sars' view as to the species with that of Boeck, the *Fabricius'* species should be called *Hyperia abyssorum* (Boeck); 92. *Parathamnida abyssorum*, Boeck, is obviously identical with Tate's *Hyperia obturia*, but as this is distinct from Kreyer's *Hyperia obturia*, which = *Hyperia galata*, Montagu, Boeck's name is retained. *Trophana malnii*, Boeck, is referred to Dana's genus *Lycxa* as 94. *Lycxa malnii*. *Lycxa pater*, Marion, 1874, from the Mediterranean, is said to come very near the northern species. *Lysianassa planosa*, Boeck, is said to be undoubtedly the male of 96. *Lysianassa costæ*, Milne-Edwards; *Lysianassa unia*, Goës, which Boeck gives as *Orchomene unio*, is considered by Sars as belonging to the genus *Leptodiporeus*, Sp. Bate. *Pontoporeia furcigera*, Bruzelius, is considered to be scarcely distinct from 105. *Pontoporeia fenorata*, Kreyer, since Kreyer figures the peculiar process on the fourth pleon-segment which has suggested the name *furcigera*. The curious 107. *Argiopa typica* of Boeck is said in some degree by its general habit to recall the Ampeliscæ, and to be slower in its movements than other members of the family Pontoporeidae. 108. *Bathy-poreia robertsoni*, Sp. Bate, is held by Sars to be a distinct species from the closely allied *Bathyporeia pilosa*, Lindström, in which I cannot agree with him. *Montaguia* (*Probolius*) *pollucius*, Sp. Bate, is mentioned as 125. *Metopus pollucius*. *Crasia schüeizi*, Boeck, is stated to be a synonym of 126. *Danaia dubia*, Sp. Bate. 130.
Monoculodes carinatus, Sp. Bate, is distinguished from Monoculodes affinis of Boeck [which J. S. Schneider thinks may = Monoculodes stimpsoni, Sp. Bate]; 142. Leucothoe furina, Savigny (Sp. Bate), is thought to be easily distinguishable from Leucothoe spinicarpa, Abildgaard, by its slenderer body, a somewhat different form of the gnathopods, and difference of colouring. It may be doubted, notwithstanding, whether any or all of these distinctious suffice to establish the specific difference in question. Halice granulicornis, Boeck, is undoubtedly, Sars says, the male of 146. Halice abyssi, Boeck. Bate's Ampelisca gaimardi (originally Tetronatus typicus) is stated to be undoubtedly the male of 148. Ampelisca tenuicornis, Lilljeborg, not a separate species, Ampelisca typica, as Boeck makes it. But here neither Sars nor Boeck can be right, for the anterior part of the back, both in Ampelisca tenuicornis and in Boeck's description of Ampelisca typica, is round, while in Spence Bate's species "the anterior half of the animal is much more compressed than the posterior, and narrowed to an angle upon the dorsal surface, the angle increasing anteriorly to the extremity of the head." Boeck is probably right in adopting Norman's suggestion that Ampelisca carinata, Bruzelius, is the male of Ampelisca equicorina, Bruzelius, but again neither Norman nor Boeck can be right in uniting Ampelisca gaimardi, Sp. Bate, to Ampelisca carinata, Bruzelius, for that species has the front part of the back rounded. The name Ampelisca typica (Bate, non Boeck) will therefore belong to Ampelisca gaimardii (Bate, non Kroyer), while Ampelisca typica, Boeck, is united to Ampelisca tenuicornis, Lilljeborg. The question, however, remains, whether the specific name of Tetronatus typicus can with propriety be retained, when the species to which it refers has been found to belong to a previously established genus. 158. Corophium bonelli, M.-Edwards, is distinguished from Corophium crassicornis, Bruzelius, by the rounded side-lobes of the head and the far weaker form of the lower antennae both in male and female. Siphonocetes crassicornis, Sp. Bate, under the title 160. Cerapus crassicornis, is referred without doubt to the genus Cerapus, Say, as characterised by S. I. Smith. It constructs, out of particles of mud, small, regularly cylindrical tubes, which it carries about with it. The species referred by Boeck to Cerapus belong to Erichthonius. The females of 163. Dulichia monacantha, Metzger, are said to be very like the females of Dulichia porrecta, Sp. Bate, while the males are clearly distinguished by the development of the side-plates of the second pair into long forward-directed spine-like processes.

1882. Streets, THOMAS H.

Dr. Streets is of opinion that Claus combines in his description of Phronima sedentaria more than one species. Phronima sedentaria itself Dr. Streets had not had any opportunity to examine. He points out that to Claus is due the discovery that such and such a species known in the female had a male form presenting characteristic differences. He upholds Phronima atlantica, Guérin (fig. 1, 1a, 2), as a good species, against the researches of Claus, and also Phronima pacifica, Streets, fig. 3, 3a. In regard to the genus Phronimella, Claus, he says, 'Claus states that there are 'only two pairs of styloform caudal appendages.' This is true of the female, but not of the male. In one of his plates, where the caudal extremity of a male is given, the three pairs of styloform appendages are very clearly represented.' Description and figures (4, 4a, 5, 5a) are given of Phronimella elongata, Claus, with which Dr. Streets identifies his own Anchlyonyx hamatus, 1877.
1882. Stuxberg, Anton.

E. von Martens in the Zoological Record for 1883 says that Stegopycathus kessleri, sp. n., from the northern coast of Asia, is figured but not described (p. 713). Of Acanthostephia malayreni (Goës) a woodcut is given and an account of its general occurrence in the Siberian glacial sea (pp. 724, 729). *Atyles caricatus* (Fab.) is mentioned (pp. 723, 729) for its occurrence in the same sea. "Weygrecchia, g. n., for *W. mirabilis*, sp. n., 51 mm. long. Description of the species, but no generic characters given." (See Note on Stuxberg, 1880.)

For the views explained in this paper see Note on H. Blanc, 1884.

In this list of Amphipods from the west coast of France, forty species are mentioned, the habitat being specified from which each was obtained. The determination of the species was made with the assistance of Bate and Westwood's well-known work, and includes "*Gossea microdentata* S. Bate," but this M. Chevreux has since informed me was entered in mistake for *Caliopius norvegicus*, Rathke.

1883. Chilton, Charles.

The new species described are *Nicca eleganta*, *Cypridoida* (?), *crassa*, *Micra incerta*, *Podocerus frequens*. *Cypridoida* (?) *crassa* differs so much in the form of the coxae from the other three species belonging to Haswell's genus *Cypridoida* that, as Mr. Chilton himself suggests, it will probably have to find a generic place elsewhere.

Article III. describes and Plate IV. figures *Phreatocetus typicus*, a singular well-shrimp, of a new genus and species, which appears to be an Isopod with some remarkable Amphipodan affinities. The genus is thus defined:—"Body long, sub-cylindrical, laterally compressed. Upper antenna short, lower long, with flagellum. Mandible with an appendage. First pair of legs subchelate, others simple; first four pairs articulated to body at the anterior ends of
their segments and directed forwards, last three articulated at posterior ends of their segments and directed backwards. Abdomen long, of six distinct segments, last joined to telson. Sixth pair of pleopoda biramous, styliform. Telson large, subconical." See Note on Thomson and Chilton, 1886.

1883—Gerstaecker, A.
1884.

This work contains a full and clear account of the organisation and development of the Amphipoda, compiled from all the best authorities, and illustrated by figures given in facsimile from the original works. There is an introductory account of the history of the subject, and a list of authors in a chronological order determined by their first publications about the Amphipoda.

In most cases names of genera and species have been accepted from authors without criticism, it not being within the plan of the work to rectify minor details of classification. The transfer, however, of the Tanaisi to the Amphipoda is made without reserve. See further, Note on Gerstaecker, 1886.

The blind Nyphurus orcinus recorded from the caves of Potis Kawez and Mrzla jama, Carniola, 51 mm. long. (Zool. Record.)

1883. Marion, A. F.

In the "Description des Faunes," the occurrence of Gammarus locusta in several localities is recorded, and of other well-known Amphipods at different points. In the "zone émergée," of the littoral zone, it is noticed that Gammarus marinus "une livrée brunaire, parfaitement en rapport avec la teinte des débris décomposés de zostères. Souvent, lorsque la vague accumule des débris d'algues vertes (Ulves et confères), ces Crustacés changent, par mimétisme, de coloration" (p. 42).

At page 84, in a footnote, Professor Marion says, “Les Amphipodes sont excessivement abondants dans nos graviers conglomérés; ils se rapportent pour la plupart à des formes nouvelles qui devraient être le sujet d’un mémoire spécial, mais qui n’ont été décrétées jusqu’ici que d’une manière préliminaire (voy. Catta: Note pour servir à l’Histoire des Amphipodes du golfe de Marseille, Revue des Sc. naturel., t. IV, n° 2, septembre 1875).

“L’espèce la plus commune est le Meri truncaitus, Spinn., à laquelle sont associées les Meri integrimana, Heller, Lysianassa Andromedusia, Sp. F., Lysianassa spinicornis, Costa, Melita palmata, Leach, Leuconoë articulosa, Mont., Ampelisca Belliana, Bate, Iphimedia oseba, Rathke, Liljeborgia pallida, Bate, Microleptopus anomalous, Rathke, Protomedia hieruntana, Sp. Bate, Icriidium Rissoamum, Gruet et Bate; et quelques Isopodes, Sypharoma curtum, Leach, Ancus forculatarius, Risso, Prania ventricosa, Risso, etc.”

1883. Marion, A. F.

From the “Sables vaseux au sud de Maire, profondeur = 65 à 70 mètres; et vase sablasse de 75, 80 et 90 mètres, par le travers de Rieu,” Lysianassa longicornis, Lucas, is recorded (p. 16). Among the species dredged by the Travailleur between Marseilles and Corsica were Leuconoë denticulata and Lysianassa ciliata, and at the deepest station, “234 à 250 mètres,” “Ichnopus taurus, Ichnopus calceolatus, Ampelisca Gaymardi.”

It is noted that Iphigenia, G. M. Thomson’s name for a genus among the Corophidæ, is twice preoccupied in Mollusca.

1883. Schneider, J. Sparre.

A list, accompanied by short notes, is given, pp. 27–30, of thirty-five Amphipods, none described as new, including two littoral forms, Cyamus boops parasitic on Meagurta boops, and the rest from depths between five fathoms and thirty.

1883. Schneider, J. Sparre.

Bidrag til en noierce karakteristik af de ved Norges kyster forekommende Arter af familien Oediæeridae. Separataftryk af Tromsø Museums Aarshefter VI. Tromsø. 1883. 44 pages. 3 Pl.

The subfamily Oedicorina, Liljeborg, 1865, Oedicorinae, Boeck, 1870, was called by G. O. Sars, in 1882, the family Oedicoride. This change is here accepted. Great weight is laid on the (ZOOL. CHALL. EXP.—TART LXVII.—1887.)
stilliform character of the finger or last joint in the fifth pereopods, as a distinctive mark in this family. A general description is given of the head, side-plates, mouth-organs, limbs and telson. This is followed by a conspectus of the Norwegian genera and species which the family includes.

Pontocrates norvegicus, A. Boeck, is identified with Krogera altamurhina, Sp. Bate, instead of with Krogera arenaria, Sp. Bate, with which Boeck himself made it synonymous. On this see further, Note on J. Sparre Schneider, 1885. Monoculodes affinis, A. Boeck, is thought to belong rather to Monoculodes stimpsonii, Sp. Bate, than to Monoculodes carinatus, Sp. Bate. A relationship is suggested between Monoculodes graeci, A. Boeck, and Monoculodes longicorne, of the same author. A species is described under the title Halimedon squamulii, A. Boeck; with the authority of Professor G. O. Sars for its being so entitled, but it is said not to agree well with the figures and description by Boeck, and both in appearance and in the structure of the mouth-organs to be unlike the genus Halimedon.

1883. Smith, Sidney I.

In the “List,” sixteen species of Amphipoda are recorded, none of them new. To Rhachotropis aculeata, Lepechin sp., is appended a note, “Póxis et τρόποι, nom. nov., vice Tritripis Boeck, præc.”

The review takes into account Professor Packard’s papers:—“A list of the animals dredged near Caribou Island, southern Labrador, during July and August, 1880,” (Canadian Naturalist and Geologist, viii., pp. 401–429 (1–29), December, 1863), and his “View of the recent invertebrate fauna of Labrador” (Memoirs Boston Soc. Nat. Hist., i, pp. 292–303, pls. 7, 8, 1867). Professor Packard’s Amphipoda had been determined by various authorities, and much confusion had arisen, which Professor Smith in this paper sets himself as far as possible to correct. “In determining Professor Packard’s species I have been greatly aided,” Professor Smith says, “by a set of his specimens collected in 1864 and labeled by him for the Museum of Yale College.”

“Anonyx producta, fide Boeck,” Packard, 1867, is referred to Anonyx pavitus Lilljeborg; Monoculodes madalatus Packard, 1867, to Ωδιερος lyreus M. Sars; Amphithomatus cataphractus Packard, 1867, to Plesodes pavitus Bate (Kröyer); Atylus vulgaris Packard, 1867, to Pontogenea inermis Boeck (Kröyer); “Atylus (Paramphitoe [—theo]) inermis (Kröyer, fide Boeck),” Packard, 1867, to Halirages fulcrocinctus Boeck (M. Sars); Gammarus mutatus Packard, 1863, to Gammarus locusta Fabricius; Gammarus purpuratus Packard, 1863, and Gammarus dentatus Packard, 1867, both to Melita dentata Boeck (Kröyer); Amphithomatus Ediroldii Packard, 1867, to Rhachotropis aculeata Smith (Lepechin); Amphithoe pelagica Packard, 1863 and 1867, to Amphithoe macrocephala Lilljeborg; Amphithoe Gaulardi Packard, 1867, to Byakia Gaulardi (Kröyer); Amphithoe maculata Stimpson, 1853, Packard (Amphithoe), 1867, Smith, 1874, to Amphithoe protecorades Ibach, 1843; Orinus rubicorius Stimpson, 1853, Packard (rubicorius), 1867, to Eriothontias difformis Milne-Edwards; Glaconome leucops Kröyer, to Ureola tigrina, Say.
1883. STEBBING, T. R. R.

A few of the more striking forms among the new Amphipods brought home by the Challenger, which had been entrusted to me in the summer of 1882, are here briefly described:—in Boeck's subfamily Oedicerotinae, Acanthostepheia ornata, n. sp., since transferred to a new genus as Oediceroides ornata, and Oediceropsis rostrata, n. sp., now called Oediceroides conspicius, the specific name rostrata having become inappropriate in the change of genus; in the subfamily Epimerinae, Epimeria conspicius, n. sp., with the remark that it may prove to be only a variety of Epimeria loricata, G. O. Sars, of which I now consider it a synonym, and Acanthosome tricarinata, n. sp., since transferred to a new genus as Acanthochilus tricarinatus; in the subfamily Gammarinae, Amathillopsis australis, n. sp., nearly allied to Amathillopsis spinigera, Heller, and Amathillopsis affinis, Miers; in the subfamily Stegocephalinae, Andania gigantea, n. sp.; in the subfamily Iphimeleinae, Iphimeleia pulcherribentata, n. sp., and Iphimeleia pacifica, n. sp.; and lastly, in the family Caprellidae, Dodecus elongata, n. g. et sp.

The new genus Dodecus is thus defined:—"The mandibles having an elongate triarticulate palp. Six pairs of feet attached to the pleon, the fourth segment having none. Branchial vesicles at the base of the second gnathopods, the first pereiopods, and attached to the footless fourth pereon-segment, the rudimentary pleon having two pairs of biarticulate appendages."

Heller placed his new genus Amathillopsis between Amathilla and Gammarocanthus, two genera of the Gammarinae. In accordance with this arrangement I placed the new species, Amathillopsis australis, in that subfamily, but in view of the elongated palps of the maxillipeds I am now doubtful as to the propriety of this classification.

1883. WOODWARD, HENRY.

The Class Crustacea, page 196, has for its first division the Thoraetipoda, with two legions, 1. Podopodhaltiniae, containing two orders, 2. Eupodhaltiniae, also containing two orders, the Isopoda and Amphipoda. The latter, pages 212-213, include the Laemodipoda as an aberrant group. No mention is made of the Hyperina. The statement that the body-rings of the Amphipoda are compressed laterally requires some limitation in regard to such genera as Lajestius, Isinia, and Corophium. The illustrations given are "Orchestia Darwinii," male, and "the spectre, or skeleton shrimp (Caprella)" ♂ and ♀. The Orchestia is evidently taken from Fritz Müller's Facts for Darwin, the Caprella from Rete and Westwood's Caprella tuberculata.

1884. BELTRÉMIEUX, ÉDOUARD.

"Cite les cinq espèces suivantes: Phronima fuicola Leach, Talitrus gammarellus Lam. (Orch. littorea Leach), Talitrus saltator Edw., Corophium longicorne Latr., Hyperia Latreillii Edw." (M. Chevreux in litt.)
1884. Blanc, Henri.

According to Dr. Blanc the Amphipods of the Bay of Kiel forcibly illustrate the remark of Professor Möbius that the invertebrates of the Baltic are a degraded branch of the rich fauna of the North Atlantic and Arctic oceans.

The introduction discusses briefly the external structure, sexual differences, places of abode and length of life of Amphipods, and assigns their colouring to chromatophores in some species, and oil-drops in others, spread about in the body.

A special account of the "Calceoli" reviews the opinions of earlier writers upon them, describes their structure, and gives a preference to the view that they may be organs of hearing, rather than of claspers and smell. The occurrence of the apparatus in the females as well as the males is urged against the suggestion that they are organs of claspers. In favour of Dr. Blanc's own view the circumstance is mentioned that the apparatus is met with in species which live in small depths, and that the number of the calceoli is greatest in those species which live on the surface, where enemies threaten most. The parts of the organ in question are the stem, the cup-shaped base with a central opening above carrying a circle of very fine hairs, and, seated with its broader end in the cup, an ovoid bladder-like structure extremely thin-walled and marked with concentric stripes. Professor Blanc could not discover any termination of a nerve in the Calceolus or connection with the antennary-nerve, but a dark stripe within the stem he considers to be a sensory nerve-mass carrying the circle of hairs. The so-called Rieszhäppchen (bâtonnets hyalins) he finds on the upper antennae of both sexes of the Amphipoda, but Hoek's account of them on the lower antennae of Cheirocratus brevicornis he is unable to corroborate.

Excellent figures and descriptions are given of the following species, with remarks of value upon them:—Hyperia galla, Montag; found in late summer lodging in Medusa aurita and Cymene capitata, commonly free in winter; Orchestra littorea, Montag, with two forms of the male, on which light has since been thrown by Faxon's observations upon Canthus; Pontoporeia femorata, Kröyer (with Pontoporeia affinis, Lindström, in the synonymy), and Pontoporeia furciger, Brandt, which, however, should probably be named respectively Pontoporeia affinis, Lindstr., and Pontoporeia femorata, Kröyer (see Sars, Oversigt, p. 83, 1882); Bathyporeia pilosa, Lindstr.; Dromine spinosa, Montag; Atlulas blepharon, Sp. Bate, which Boeck calls Habrocyclus blepharon; Callitopus leviusculus, Kröyer; Gammarus locusta, Linné, found in almost fresh water as well as in salt water everywhere; Cheirocratus brevicornis, Hoek, the synonymy of which seems to be Gammarus sundevallii, Rathke, Lithoborgia shetlandica, Sp. Bate, Pseudodelia ritchei, Sp. Bate, Lithoborgia normanni, Stebbing, so that its proper designation is Cheirocratus sundevallii, Rathke; "Anathylla Sabini," Lesch; Microdonto crus gyllotlapis, Costa, referred in accordance with Heller to the family Corophidae, subfamily Podocopina; Amphithoe podocorodes, Rathke; Podocerus falcatus, Montag; Corophium longicornus, Fabricius; Proto ventricosa, Müller, and lastly Caprella lineari, Linné, including therein, in agreement with Hoek and contrary to the view of Mayer, Caprella hystrix and Caprella acuminifera of Sp. Bate.
1884. BLANC, HENRI.

Dr. Blanc agrees with Lilljeborg in referring the two species Tanais rhyncites and Tanais bulatius of Fr. Müller, as respectively male and female forms, to the older Tanais oerstedii, Krøyer. The description which he proceeds to give bears on the disputed question, whether the Tanais should be reckoned among the Amphipoda. In Tanais oerstedii, he says, the heart extends along the back from the last thoracic ring to the hinder rim of the cephalothorax. In this species, as in Tanais savignii, it possesses only two pairs of ostioles (venous orifices), whereas for Tanais dubius? Müller reckons three pairs, and Delage only one pair for Tanais sittatus. The ostioles are situated in the second and third free segments of the peraeon. Besides these, the heart has five arteries, the cephalic artery and two abdominal arteries described by Delage, and in addition two thoracic arteries as large as the cephalic, arising, opposite one another, from the ventral part of the heart, below the two ostiules in the second free thoracic segment, and running a ventral course to the first thoracic feet.

In conclusion Professor Blanc says, “the characters which bring the Tanaisæ near to the Isopods are more numerous [than those which connect them with the Amphipoda and other groups]. The general form of the body is that of the Isopods. The body is flattened, the sixth and seventh segments of the pleon are, as in the Isopods, soldered together and form a caudal lamella, while in the Amphipods these two segments are distinct. The number of ganglia in the ventral chain of Tanais Oerstedii is the same as in certain Isopods, as Cymothoea, Ligia; in the Amphipods the number is less considerable, the abdominal ganglia being reduced to four or three. The five pairs of abdominal feet, as in Anceus, are all alike; since they play a part in the act of respiration, they are not the biramous feet of Amphipods. In the latter group, the urinary secretion is situated in the antennary glands and the glandular appendages of the rectum [of the midgut, according to P. Mayer]; these glands are wanting in the Tanaisæ as in the Isopods, in which the urinary secretion is situated in the fatty body. Lastly, the absence of the seventh pair of feet in the embryos of the Tanaisæ and the Isopods is an important character which distinguishes these Crustacea from the Amphipoda, of which the embryos are born with the same number of appendages as they have when adult.”

One point in this argument loses some of its force from the fact that the sixth and seventh abdominal segments are occasionally soldered among the Amphipoda, in the tribe Hyperiina. The absence of lateral arteries was considered by Delage to show a nearer connection of the Tanaisæ with the Amphipoda (Gammarina) than with the Isopods, but this point of resemblance can no longer be relied on since Professor Blanc’s discovery of the lateral arteries in Tanais oerstedii, nor yet on the other hand can the presence of these arteries be relied on as any special link between the Tanaisæ and Isopoda, since Claus finds lateral arteries in many genera of the Amphipoda (Hyperiina).

Gerstaeker, 1886, is by no means convinced by Professor Blanc’s arguments, and, as will be seen, retains his conviction that the Tanaisæ ought to be classed among the Amphipoda.
1884. Chevreux, Édouard.

Forty-four species of Amphipods are here enumerated in addition to the forty recorded by M. Chevreux in 1883. The actual number of distinct species in the list will be rather smaller, when allowance is made for the instances in which separate names have been given to the different sexes of the same species. This will be understood in most cases from the notes which M. Chevreux has appended.

1884. Chilton, Charles.

Of a whale-ouse, found on Euphyi1etes potts, a species said to be “identical with Viagia breviceps of the northern hemisphere,” Mr. Chilton writes, “I can find no important character by which these specimens can be distinguished from Cyamus seti, as described and figured by Bate and Westwood. The penultimate joints of the last three pairs of legs are not quite so stout as shown in their figure, but this is evidently a character liable to variation according to age, etc. The young taken from the pouch of the female closely resemble those figured by Bate and Westwood on page 90.”

Wyillea longimanus, Haswell, is identified by Mr. Chilton with Podocerus cylindricus, Kirk, and renamed Podocerus longimanus, figured pl. xvii. fig. 2, in regard to which see Note on Haswell, 1880.

A new genus, Teraticum, is thus defined:—“Body small. Eyes two. Coxae of first four segments as deep as their respective segments. Antenne with short flagella; upper antenna with a small secondary appendage. Mandible with an appendage. First gnathopod larger than the second, subchelate; second slender, chelate. Posterior pair of pleopoda uniramous. Telson single, undivided.” This must, I think, yield to Soba of A. Costa. The type species, Teraticum typicum, seems to be identical with “Soba Saundersii,” Stebbing.

A new genus, Paramania, is thus defined:—“Antennae subequal, superior with a secondary appendage, both with multiarticulate flagella. Appendage of mandible with three broad setose joints, as in Podocerus. Maxillipeds with well-developed plates on isochs and meros. Gnathopoda subchelate, first small in both sexes, second small in female, very large in male. Last pair of pleopoda biramous, rami styliiform. Telson single, ending posteriorly in two conical projections.” This genus was instituted to receive Paramania typica, n. sp. pl. xix. fig. 1, Paramania longimanus, n. s., pl. xx. fig. 2, and Maria dentifera, Haswell, pl. xxi. fig. 2. Of these the first and third have the coxae of the third pereon-segment in the males “large, and produced along the inferior edge of the second segment.” In the females and in the other species the coxae are normal. In describing the genus Gammaropsis, Lilljeborg, Boeck does not choose the same characters as those used by Mr. Chilton, but when the description of Boeck’s Gammaropsis erythroghthalamus (melanops, G. O. Sars) is added to that of the genus, and in like manner Mr. Chilton’s specific descriptions are added to that of his genus, it becomes, I think, clear that Paramania cannot be separated from Gammaropsis.
The mouth-organs and pleon seem to be in minute agreement, while the antenna and gnathopods have a full generic correspondence.

_Corophium lewedenfeldi_, n. sp., pl. xx. fig. 1, is next described. This, however, cannot stand in the genus _Corophium_, since it has a secondary appendage on the upper antennae, the first gnathopods are not subchelate, the second gnathopods are without the characteristic prolongation of the third joint, and the third uropods are biramous. The species is, moreover, now recognised as identical with _Cambarus barbimanus_, G. M. Thomson, 1879, which no doubt belongs to Haswell's genus _Haplocheira_. _Panopyra transtvrcans_ n. s., pl. xxi. fig. 3, is next described, as closely related to, and taken in company with, _Panopyra debilis_, Thomson, for which see Note on Thomson, 1880.

The new genus _Birecena_ is thus defined:—“Body broad, coxae very shallow. Antennae subequal, upper without a secondary appendage. Mandibles without an appendage. Maxillipeds with well-developed plates on both bases and ischias. Gnathopods equal, not subchelate. Last segment of pleon and its appendages rudimentary. Telson simple, not divided.” The type species is _Birecena fideus_, n. s., pl. xxi. fig. 1 (Birecena fideus at p. 265). Mr. Chilton thinks it may come near _Philas_, but he is very uncertain.

1884. Chilton, Charles.

In this paper Mr. Chilton proposes the specific name "_Conoecus_" for a variety of _Allorchestes crassicorius_, Haswell, pl. 46. fig. 1. But this variety according to Haswell is not _Allorchestes_ crassicorius, but the female of _Edriophthalmus quadrirrinalis_, Dana. He describes _Glycerina affinis_, n. s., pl. 47. fig. 1., which "closely resembles G. [hasilicornis], Haswell"; _Miera festiva_, n. s., pl. 46. fig. 2., which, according to Mr. Haswell, belongs to _Miera rubromaculata_; gives notes on _Megamora (Miera) rubromaculata_, Haswell, to which he finds that _Miera petrii_, Thomson, is a synonym, and on _Amphithoe setosa_, Haswell; discusses the relations of _Microdeuteropus mortoni_, Haswell, _Microdeuteropus tenuipes_, Haswell, _Microdeuteropus maculatus_, Thomson, with one another and with _Aora typica_, and suggests the possibility that _Pararwsnia typica_, Chilton, is the same as _Miera appalachianus_, Haswell.

Mr. Chilton further suggests that the genera _Aora_ and _Microdeuteropus_ will eventually have to be combined.

He transfers _Montagna miersii_, Haswell, which he had previously renamed _Montagna miersii_, to Costa's genus _Probodanum_, but without saying whether it has or has not mandibular palps, so that it remains uncertain whether it should be placed in the genus _Stenothoe_, Dana, of which Costa's _Probodanum_ is a synonym, or in _Metopa_, Boeck.

1884. Chilton, Charles.

Arguing that similar variations may arise independently, where animals of the same family are separately subjected to new but similar conditions of life, Mr. Chilton says, "We know that this is true to a certain extent at any rate, for the terrestrial Amphipoda and Isopoda have without doubt arisen independently, and yet in both the inner antennae have become very small—rudimentary in the Isopoda, nearly so in Amphipoda,—and in both the mandible
has lost its palp.” He also remarks that “the Amphipoda appear to be only now developing terrestrial forms, and a splendid series could be made out of existing species, from *Neces*, living wholly in the water, through *Altorchestes*, etc., which live in rock-pools, but can walk and live (lap, MS. correction) on land with great agility, *Talorchestia*, etc., living just above high-water mark, and only occasionally splashed with salt water, to species of *Orchestia* and *Talitrus*, such as *O. Sylvecola*, which live far away from the sea.”

1884. Chilton, Charles.

This note identifies *Meca petrii*, G. M. Thomson, with *Megamorxa (Meca) subcarinata*, Haswell, the latter name having the priority.

1884. Claus, C.

At page 405, the Arthropoda are defined as “Laterally symmetrical animals with heteronomously segmented body and jointed segmental appendages; with brain (supraoesophageal ganglia) and ventral nerve cord (ganglionic chains).”

At page 411, Class I.—Crustacea are defined as “Aquatic Arthropoda, which breathe by means of gills. They have two pairs of antennae; numerous paired legs on the thorax, and usually also on the abdomen.” It is observed that “some forms, however, can live on land, and possess respiratory organs adapted for breathing air.” “The mandibles are simple but very rigid and hard masticating plates, which are usually toothed and correspond morphologically to the coxal joint of a limb, the following joints developing into a palp-like appendage (mandibular-palp).” “The delicate hairs and filaments of the anterior antenna are probably olfactory organs.” “The so-called shell glands of the lower Crustacea are regarded as urinary organs, as are also the glands opening at the base of the posterior antenna in the Malacostraca. In the Entomostraca the latter are only preserved during larval life. Short tubes, which correspond to the Malpighian tubes of the Tracheata, may also be present on the rectum (Amphipoda).” [This correspondence, however, is denied by P. Mayer, 1882, and W. B. Spencer, 1885.]

The Crustacea are divided into four groups, Entomostraca, Malacostraca (“the higher Crustacea characterised by a definite number of segments and appendages”), Leptostraca (for Nebatia), and Gigantostraca. The Malacostraca include the two orders, Arthrostraca (Amphipoda and Isopoda), and Thoracostraca.

At page 449, the Arthrocostraca are defined as “Malacostraca with lateral sessile eyes, usually with seven, more rarely with six or fewer separate thoracic segments, and the same number of pairs of legs. Without a reduplicature of the skin.” “The head bears four antennae, the two mandibles, four maxillae, and a pair of maxillipeds; in all six pairs of appendages. A small bilobed plate, distinguished as the underlip, behind the pair of mandibles, marks the boundary of the primary region of the head. The two pairs of maxillae as well as the maxillipeds are secondary cephalic appendages derived from the thoracic region of the body.” I do not know how this last statement is to be reconciled with the previous
description of the Malacostraca, p. 447, "the head includes in all cases, behind the mandibular segment on which two paragnathi form a kind of underlip, the segments of two pairs of maxillae. The latter preserve more or less the character of phyllopod feet. The head, therefore, consists of five segments, each with its pair of appendages, viz., two pairs of antennae, one pair of mandibles, and two pairs of maxillae. It is followed by the thorax, which is composed of eight segments." It may be noticed also that the eyes in some Amphipoda can scarcely be called lateral, and in others are apparently altogether wanting; nor is it quite accurate to say (p. 450) that "the two eyes are always sessile, compound," since in Amelesina they are simple.

At p. 451 the suborder Amphipoda are thus defined: — "Arthrostraca with laterally compressed body, with gills on the thoracic feet and an elongated abdomen, of which the three anterior segments bear the swimming feet, while the three posterior bear posteriorly directed feet adapted for springing."

The plates forming the brood-pouch are here called oostegites. "The eggs pass into the brood-pouch and there develop. The yolk sometimes (G. lucta and other marine species) undergoes a complete segmentation. Sometimes (G. pulicis), after a superficial segmentation, a peripheral cell-layer is separated, which develop into a delicate blastoderm beneath the egg membrane. A ventral primitive streak is then formed, and on the dorsal side, beneath a differentiation which has been erroneously taken for a mieropyle, a peculiar globular organ makes its appearance; this is the first rudiment of the cervical gland (dorsal organ), which is confined to embryonic life. The appendages are developed from before backwards on the ventrally flexed body of the embryo. The young animals usually possess at hatching all their appendages and in all essential points have the structure of the adult animal, but the number of joints of the antennae and the special form of the legs still present differences. In the Hyperina alone the just hatched young may be without abdominal feet, and differ so much in their form from the adult that they may be said to undergo a metamorphosis."

The following classification is made: —

"Tribe 1.—Lesmodipoda. Amphipoda with cervically placed anterior legs and rudimentary apodal abdomen." "The abdomen is small and reduced to a short protuberance destitute of appendages." This statement requires modification. Caprella linearis, L., and Cyamus ceti, L., are given as examples.

"Tribe 2.—Crevettina. Amphipoda with small head, small eyes, and multiarticulate pediform maxillipeds." "The coxal joints of the thoracic legs have the form of broad and large epimeral plates. The abdomen has always the full number of segments. The three posterior pairs of abdominal feet (uropoda) are well developed and often much elongated. The epimeral plates, however, are not always large, nor are all the uropoda always well developed. Three families are assigned to the Crevettina: the Corophiidae, in which "the coxal joints of the legs are frequently very small"; the Orchestidae, and the Gammaride.

"Tribe 3.—Hyperina. Amphipoda with large swollen head and large eyes, usually divided into frontal and lateral eyes. They have a pair of rudimentary maxillipeds functioning as underlip.

"The antennae are sometimes short and rudimentary, sometimes of considerable size, and in the male are elongated into a multiarticulate flagellum (Hyperidae). The posterior antennae may in the female be reduced to the basal joint enclosing the glandular tube (Phronimida); in the male, on the contrary, they are folded in a zigzag, after the manner of a carpenter's rule (Platysceliditae). A paired auditory vesicle may be present above the brain (Oxycephalus, Rhabdosauma)." Three families are assigned to this group, the Hyperide, the Phronimide and Platyscelide. In the description of the family Phronimide, the statement "Head large, with projecting rostrum and large divided eye" should rather be "Head large, with projecting snout or muzzle and large pair of divided eyes.

("Zool. Chall. Exp.—Part LXVII.—1887.)
The parenthetic statement, on p. 453, that "the presence of Arctic species [of Amphipoda] in the Swedish and Norwegian seas is very interesting," loses its point by the introduction of the word "seas" through an oversight instead of "lakes."
The Isopoda are divided into two tribes, Anisopoda and Enisopoda. The Anisopoda are thus defined:—"Body more or less resembling that of an Amphipod. The abdomen with biramous swimming feet (Tanais), which do not function as gills, or with fin-like feet (Anceus)."

In the "General Part" of the volume, valuable information is to be found under various headings, in regard to organs of vision, nerves, &c.

1884. D'Urban, W. S. M.
The capture of half a dozen species of Amphipods, not new ones, is recorded.

1884. Faxon, Walter.
"It appears probable that the two forms of the crayfish are alternating periods in the life of the individual, the 'first form' being assumed during the pairing season, the 'second form' during the intervals between the pairing seasons." Mr. Faxon suggests that this curious discovery may explain the existence of two forms of the male in the genera Tanais and Orchestia pointed out by Fritz Müller (Für Darwin). It is obvious that, if the phenomenon in question should prove to be of frequent occurrence among the Crustacea, it may make necessary an extended revision of specific names.

1884. Hoek, P. P. C.
This paper, in Dutch and French, records from the locality mentioned in the title fifteen species of Amphipoda, none of them new. Among them was Atylus cellomensis, Ratz and Westwood; (also recorded from Guernsey, see Note on Kochler, 1885).

1884. Kingsley, John Sterling.
Crustacea are Class I. of the Arthropoda. The Ephiophthalmia are Subclass IV. of the Crustacea, and embrace two orders, Isopoda and Amphipoda. The Amphipoda, pages 72–77, include two suborders, Loxomopoda and Amphipoda genuina. The families assigned to the first suborder are the Caprellide and Cyamide, to the second, the Oxycophalidae, Phronimidae, Hyperidae, Cheluriidae, Corophidae, Gammaridae, Orchestidae.
Species are figured under the following names, but without names of the authors of the species; fig. 95. Caprella geometraca; fig. 97. Cyamus celt; fig. 98. Rhabdomonous batel; fig. 99.
REPORT ON THE AMPHIPODA.

555

*Thamnops pellucida*; fig. 100. *Hyperia*; fig. 101. *Cyatosoma nepitum*; fig. 102. *Cerapus rubricornis*; fig. 103. *Unciola irrorata*; fig. 104. *Gammarius ornatus*; fig. 105. *Orchestia australis*, beach-flea; fig. 106. *Amphithoe maculata.*

Among the miscellaneous remarks it is observed that "Unciola does not build a tube, but takes any that it may find vacant." According to S. I. Smith's account, in 1880, "the animal apparently does not construct tubes for itself, though often found in the tubes of other Amphipoda, and in the tubes of Annelida. In the Bay of Fundy," he says, "I have found it abundantly in small holes in sandy mud near low-water mark."

1884. Martens, Eduard von.

1884. Miers, E. J.

A brief review is given of earlier writings dealing with the Crustaceans of Australia. "In regard to the Amphipoda," Mr. Miers says, "the affinity of the Australian with the European fauna is very remarkable; and among the few species included in the present Report instances (Leucothoe spinicarpa, Caprella aquilina) occur where I have identified Australian examples with well-known European types, while in several other instances, the distinctions are so slight as to be scarcely of specific importance; hence I must qualify the opinion I formerly expressed as to the improbability of the species of such widely distant regions ever being actually identical."

In the determination of the Amphipoda, pages 311–321, 567–569, Mr. Miers has used Spence Bate's classification rather than Boeck's, presuming that Boeck's, being concerned with North Temperate and Arctic, would not without much modification suit the southern fauna. *Ephylliphiphora kroyeri,* White, which Boeck doubtfully referred to his genus *Socarpes,* is here upheld. "In the specimens from the 'Alert' collection the terminal segment is elongated, narrowing slightly to the distal extremity, with the sides straight, and is divided by a narrow median fissure." White's type specimens from Tasmania are unfortunately dry and broken, so that his species must apparently remain in some obscurity, but the imperfect terminal segments seen, Mr. Miers says, to show a structure like that of the "Alert" specimens, differing in this particular from *Lysianassa nitens,* Haswell. *Lysianassa australiensis,* Haswell, is said to come very near to *Ephylliphiphora kroyeri,* but to be probably distinguished from it by the telson, which Haswell leaves undescribed, as though similar to that of *Lysianassa nitens.* Mr. G. M. Thomson recorded the species from New Zealand, as "Lysianassa Kröyeri," but without describing the telson, so that Mr. Miers could not express an opinion on its identity. To judge by a specimen which Mr. Thomson has sent me, the New Zealand form must be quite distinct, since its telson is neither elongate, nor divided.

Mr. Haswell in 1886 explains that the telson in his *Lysianassa nitens* is not, as he at first thought, simple, but deeply cleft, and in *Lysianassa australiensis* also "the telson is cleft to the base." *Leucothoe commensalis,* Haswell, is regarded as at most a variety of *Leucothoe spinicarpa,* Abildgaard, and in this Mr. Haswell appears to acquiesce. Kossmann's *Leucothoe euciniana* from the Red Sea is thought to be another synonym of the same species. A new species, *Leucothoe brevidigitata,* pl. 34. fig. A., is figured and described, which, it is said, may be regarded as in some sense intermediate between *Leucothoe nora-
hollandica, Haswell, on the one hand, and, on the other, Lencosthoei communis with the closely allied species or varieties Lencosthoei diemenensis, Haswell, and Lencosthoei gracilis, Haswell. Melita australis, Haswell, is said to be very nearly allied to the Melita setipes, Dana, from Singapore. Additional particulars are given to supplement the original description by Haswell of Mora ramsayi, but that species is now recognised by Mr. Haswell as a synonym of Mora rubronasculata, Stimpson, which is also here described, but from imperfect specimens. A specimen, from which the head was wanting, is described under the provisional name of Mora crossimana. Another imperfect specimen is described, but not named. "In the form of the anterior legs and in the coloration it resembles Amphithoe setosa, Haswell, from Botany Bay, but differs in the form of the palm of the second leg, and, I suppose, of the posterior uropoda." Megamora swensii, Haswell, i is very fully described, and this description Mr. Haswell accepts as applying to the ordinary form of his species, so that Mr. Miers' alternative name, Megamora haswelli, is not needed. Megamora thomsoni, pl. 34. fig. B, is described and figured as a new species, though near to, and possibly only a variety of, Megamora semiseriata, Sp. Bate, or Megamora breviculata, Sp. Bate, which are British species. Its points of distinction from Megamora maderata, Haswell, are pointed out, but nevertheless Mr. Haswell in his latest revision considers it a synonym of that species. Podoecras australis, Haswell, is briefly discussed. Notes are given upon Caprella aequalis, Say, and a specimen, pl. 34. fig. C, is doubtfully referred to Caprella attenuata, Dana, of which Mr. Haswell has since observed, "the species figured by Miers is very different from the adult C. attenuata, but may be an immature form."

From the Seychelles a new species is described (p. 557) and figured under the name Mora diversimana, pl. 52. fig. D. It is compared with Mora truncatipes (Spinola) from the Mediterranean, and with Mora ramsayi, Haswell, already noticed, and it is suggested as possible that more specimens might offer transitional characters serving to unite the two forms.

1884. SCHNEIDER, J. SPARRE.

Undersøgelser af dyrelivet i de arktiske fjorde. II. Crustacea og Pycnogonida indsamlede i Kvennafjorden 1881. (Aftryk af Tromsø Museums aarshefter VII.) Tromsø. 1884. pp. 56-134. PL I-V.

A new species is figured (Tab. I. & II.) and described under the title Menigrates (Oreomone?) arcticus. Complaint is made, as has been done by several authors, of the minute and over subtle distinctions on which Boeck has founded some of his numerous genera in his subfamily Lysianassinse, the result often being, as in this instance, that the author of a new species cannot decide in which of the genera he ought to place it. Another new species, Metopa spilberyi (Tab. III. & IV.), here figured and described, is said to be akin to Metopa longicornis, A. Boeck. A species described and figured in 1883 as Monoculodes norvegicus is here separated from that species and recognised as a new one under the name Monoculodes tessellatus, Schneider, agreeing in part with Ædiceros affinis, Goës, the last-named author being supposed to have confused two species together, one of them being Monoculodes tessellatus, the other Monoculodes borealis, A. Boeck.

Besides the description of new species, many important observations are given in regard to species already known. Among others, Pardalisca cuspidata, Kroyer, is discussed. Schneider, comparing his own drawings with Boeck's, finds that the maxillipeds differ somewhat, and that the second maxillae assigned in Boeck's plate to Pardalisca in fact belong to Syrtribo crenulata. In some points he finds that his drawings correspond far better with Boeck's description of Pardalisca abyssi than with that of Pardalisca cuspidata. In the full
description which follows, however, Schneider describes the finger of the gnathopods as oval, which will not suit _Paralatia abyssi_, Boeck. He then speaks of the finger being two-jointed, inasmuch as it possesses a curved nail, which is obviously movable, thus making the number of joints to the limb in all seven. It may however be questioned whether this nail is anything more than a (possibly) movable spine. Were Buchholz and Schneider both right in their views as to the gnathopods of _Paralatia eupindata_, these limbs would have eight joints instead of the usual six.

A single damaged example of a _Melphilippa_ is referred provisionally to _Melphilippa borealis_, Boeck. Figures (Tab. V) and as full a description as circumstances would permit are given of it.

In the account of _Amphicera eschrichtii_, Kroyer, notice is taken of the spine-bearing incision in the side of the outer branch of the second uropods, and the author remarks that he has found this peculiarity also in several species of _Oenestus_, _Trygona_, _Scarcus_ and _Aonyx_. It occurs also in _Ichnopus_. The objection to Boeck's description of _Hippomedon hoffelli_, Kroyer, that it makes the hand of the first gnathopod longer than the wrist, instead of the reverse, does not apply to the Latin account, and the error is evidently due only to the accidental omission of a word in the printing.

1884. Smith, S. I.

He records the capture of _Eurytides gryllus_, Mandt, over 4½ inches long, in deep water off the middle Atlantic Coast of the United States, thus explaining the apparent anomaly of "its occurrence in the extreme arctic and antarctic seas" discussed by Lilljeborg.

_Andania pentonitis_, Sars, 1882, is described and figured (Taf. 7, figs. 1-12). Of the four characters by which Boeck distinguishes _Andania_ from _Stegecephalus_, Aurivillius observes that this species has only two. In regard to the two-jointed palp of the first maxille, and the undivided telson, it agrees with Boeck's description of _Andania_, but in regard to the mandibles and the palp of the second maxille it agrees with _Stegecephalus_. Unless a new genus were formed to receive it, Aurivillius inclines to leave it in the genus _Andania_, but its mandibles, in my opinion, decisively separate it from _Andania_, and assign it at any rate provisionally to _Stegecephalus_.

Variations are noticed in specimens of "_Aristias tumidus_ Kroyer," from different localities.

1885. Boavallius, Carl.

In this acute and ingenious paper Boavallius vindicates the genus _Lanerotta_, Say, 1818, as distinct from _Hyppria_, Latreille, and _Vibilia_, Milne-Edwards, and gives preliminary descriptions of the
THE VOYAGE OF H.M.S. CHALLENGER.

following new species, "Lanciola Lovisi," "Lanciola Sayana" (Fig. 1. 1a and 1b), Lanciola felina, Lanciola serrata, Lanciola curtipes, "Lanciola Clausii." He considers that the genus Dauro, Milne-Edwards, 1830, is either identical with or very near to Paraphronina, Claus, and that Dairinia, Dana, is quite distinct, synonymous with Thamyrus, Spence Bate, and belonging to Claus' family Lyceideae. Dairinia [or rather Dairilidæ] was substituted by Dana for Dauro, the latter being preoccupied. Bovallius describes the new species Paraphronina cloepeta (Fig. 2), Paraphronina californica, "Paraphronina Edwardsii," and, for the sake of comparison, Paraphronina gracilis, Claus, and Paraphronina crassipes, Claus. He argues that Tyro, Milne-Edwards, 1840, is the same as Clydonia, Dana, which the latter author placed among the Cerophidæ instead of the Hyperidæ. It may be noted that G. O. Sars had already, in 1882, transferred Clydonia to the Hyperidæ, but without recognising its identity with Tyro. Bovallius gives preliminary descriptions of the new species, "Tyro Clausii," Tyro atlantica, Tyro marginala, "Tyro Sarsi" (Fig. 3 and 3a), "Tyro Tullbergii." Lastly he upholds the genus Tauria, Dana, 1853, as distinct both from Hyperia, Latreille, and Metoecus, Kroyer; he gives figures copied from Dana of the type species, Tauria macrocephala, and concludes with the following observation:—

"The Tauria medusarum O. F. Fabr. [A. Boeck] is to be united with the genus Hyperia, because the development of the carpal process is gradual through the species and no generic character. But as the name H. medusarum has been already given by O. F. Müller to another Hyperia, I propose for it the name Hyperia Kroeyeri, the diagnosis being the same as that given by Boeck l. c. pag. 83. Tauria abyssorum, A. Boeck, must be named Hyperia abyssorum, A. Boeck." As already observed, if G. O. Sars is right in identifying Tauria abyssorum, Boeck, with Tauria medusarum, Boeck, then Hyperia abyssorum will take precedence of Bovallius's Hyperia Kroeyeri. The remark is scarcely accurate that Spence Bate "has been deceived into transferring Hyperids with totally opposite characters to Dana's genus," since Hyperia tauriformis, Latre and Westwood, the species referred to, is not transferred to Dana's genus at all, but I think that Bovallius is justified in dropping the specific name tauriformis on the ground of its misleading character, though otherwise (see Note on Norman, 1869, in Appendix) it would take precedence of the name Kroeyeri which Bovallius proposes, as well as of Boeck's abyssorum.

1885. BOVALLIUS, CARL.

Mimonectes, a remarkable genus of Amphipoda Hyperidea. With 3 Plates. (Presented to the Royal Society of Sciences of Upsala the 10th October 1885.) Upsala, 1885.

The name refers to the "mimicry" presented by these Amphipods; the creature offering "a striking resemblance to a little jelly-fish." A new family is constituted as follows:—

"Mimonectidae. Hyperids with the head and a part or the whole of the pereion developed into an enormous balloon-shaped globe. Ocelli not united but dispersed on each side of the head. The upper antennæ long, more or less straight. The lower small, four-jointed. The maxillipeds without pulp. The maxillipeds well developed."

The new genus Mimonectes is thus defined:—"Caput magnum, Istum, valde inflatum, simul cum pereio spharam formans. Ocelli parvi, dispersi. Antennas superiores longae, rectae, flagello articulato. Antennas inferiores parvae. Pleon compressum non inflatum. Pedes ursi duos ramos gerentes." "The genus Mimonectes is easily distinguished from other Hyperids by its globular shape, with all the legs, branchial sacks, ovigerous lamellæ, and the urus hanging down, similar to the filaments of a Medusa. But it differs also by some anatomical and morphological characteristics from all or most of the other Hyperids.
As important points I mention the structure of the eyes and of the nervous system, and that the interior of the pereon forms a bladder containing a fluid. With the genus Lanceola, Say, it agrees in the strong development of the maxillipeds, with Cyneosoma, Guérin, and Tyro, Milne-Edwards, in the form of the upper antennae, with the true Hyperia in the shape of the urus and its appendages.

The type species, "Mimonectes Lovii," is very minutely described. The two other new species are called Mimonectes sphelicus and "Mimonectes Stenstrupii." They all three come from the Atlantic, and give the impression of being specifically very closely allied. The fact that the bell or globe in the first and largest is formed by five segments, in the second by six, and in the third and smallest by seven segments of the pereon, though producing a striking difference to the eye, may well be due to age or sex, and would naturally carry with it some differences in the proportions of other parts of the animal.

1885. Carrière, Just.

According to the Zool. Jahresbericht für 1885, this paper discusses among others the eyes of Gammarus, Hyperia, and Phronima.

1885. Carus, Julius Victor.

Pages 386 to 428 embrace the Amphipoda. These are classified as follows:—

It does not seem consistent, in the definition of the Lemodipoda to give "abdomen rudimentare asque appendicibus," and to follow this by a definition of Proto, including "abdomen triarticulatum, pedum paribus duoibus biarticularibus rudimentibus." The epithet triarticulatum is not in agreement with Mayer's account of Proto, "die Anhänge des eingliedrigen Abdomens sind in beiden Geschlechtern 2 Paare zwei- oder dreigliedriger Fussstummel."

Caprella granulimana, Mayer, is here made a synonym of "Caprella Dolomii," Heller. Cyamus erratius, Roussel de Vauzéme, is given as a synonym of Cyamus ceti, contrary to Lütken's view. The genus Cyamus is attributed to Lamarck, instead of Latreille, the actual author.

In the "Subfam. Corophinæ (Dana) Cls.," are given "Cratiphus pusillus Hell. (Colomastix pusilla Grube)," and Cratiphus crassicornis, Heller, but Colomastix, Grube, has priority over Cratiphus, Sp. Date. To Corophium acherusianum. A. Costa, is attached the synonym, "C. crassicornis Bruz. To Corophium crassicornis, Bruzelius, is attached the synonym "C. Bowellii Sp. B. et W.,?" In the "Subfam. Podocerina Cls.," to the genus Cerapus, Say, "Eridithionium et Cerapedina M.-Edw., Pyetilus Dana," are given as synonyms, but the definition does not
say whether the second uropods are biramous or uniramous. Ericthonius bidens, A. Costa, is named Cerapus bidens, V. Crs. (nee Czern.). Of Pyctilus macroactylus, Dana, and Pyctilus paganax, Dana, referred to Cerapus by Czerniavski, Carus remarks, "The species due maris orientalis (insula Selo) a Czerniavski in Ponto Euxino repertus forsan etiam in Mediteranneo occurrent." Elasmopus rupax, A. Costa, is here named Podocerus rupax, V. Crs. Grabia, Czern., is placed between Podocerus and Amphithoe. "Amphithoe Saleskii," V. Crs., is thus described:"Caput rotundatum, sine rostro; antennae I. inferioribus duplo longeris, stipite biarticulato et flagello 16-articulato, antennae II. stipite triarticulato, flagello 5–6-articulato; dorsum leviter rotundatum, absque spinis; ocelli ferc orbiculares; pedes I. secundis multo robustiores, ungue magno terminati; pedes VII. omnium longissimi; pedum caudalium pars anterioria multo longiora; telson trigonale. Hab.: Napoli (Salensky)." By the biarticulate stipes of the upper antennae it is presumably meant that the third joint of the peduncle is indistinguishable in size from the succeeding joints of the flagellum. The first gnathopods stouter than the second, and the elongate fifth pereopods seem to point in the direction rather of Micropleontus than of Amphithoe, but nothing is said of a secondary flagellum.

In the family Orchestidae, Dana. Allorchestes, Dana, is given, with Hyale, Rathke, for a synonym, and thus defined, "Antennae I. acque longae ac stipites inferiores articulis basalis superiort cuncta equales, spina effectoria ramificata; mandibula palpo carinata; maxillipedia uncino terminali acuminato; pedes I. et II. subcheliformes." The tenth species assigned to this genus is Allorchestes punctatus, Sp. B. (Eunoe punctata, Risso). Risso's definition of his genus is quoted. The name should be Eunoe, not Eunoe. This is followed by "Nicca Nicolet (Hyale Rathyke, Amphithoe M. Edw. p., Allorchestes Dana p.). Antennae I. et II. subquadratae, vix capito longiores; telson profunde divixum (aut duplex); pedes pars I. et II. subchelati; relicus notu uti in Allorchestes." Thirteen species are assigned to Nicca, ending with "N. pontica Costa (Hyale pontica Rathyke)."

In the family Gammaridae (M. Edw.), Sp. B., "subfam. Atylinea Cla.," to Pherusa, Leach, is given the synonymy, "Amphithoe M. Edw., Titanellina Schiödtte, Paramphithoe Bruz. p." Titanellina, Schiödtte, however, is the name of an Isopod, given in place of Pherusa, Koch, preoccupied. Probolomus, A. Costa, is retained, with five species, but as the definition given of it includes "mandibula sine palpo," this suffices to show that the species in question, polygonum, Costa, marina, Sp. Bate, longimanus, Sp. Bate, megacheles, Heller, tergestina, Nebeski, belong to Stenothoë, Dana, if in each case the character of the mandibles has been ascertained. The third of these three species is entered as "Pr. longimanum V. Crs. (Montagu longimanus Sp. B.)." Amphithoeus, Costa, is given, with Tritypia, Boeck, for a synonym. Among the species is included "A. Bobretzkii Costa. Nondum descripta. (Corpus omnino inernae.) Hab.: Malmk, Caluque de Podesta (Catta)."

In the second subfam. Ampheliscinae, Lilljeb. (Sp. B.), "A. Gaimardi Kr.," has the synonymy, "Tetromatus typicus Sp. B., Araneops diadema Costa, Elphias Gaimardi Boeck." "A. brevicornis Marion," has the synonymy "Araneops brevicornis A. Costa, A. Belliana Sp. B., A. lavaigata Lilljeb." In the third subfam. Lencothoeina, Dana, under Lencothoe, Leach, is given as the second species, "L. Richardili Lesson. A L. furina differt parieti pedum spuriarum projicientem uti in L. furina, sed in chelam bidigitalem terminato. Thorax, antennae et par pedum chelatum rubra, abdomen maculis rubris. Hab.: Genova, sinus (Lessona)." It is not said whether the peculiarity has been observed in more than one individual, and the description is the more puzzling, as the words "projicientem uti in L. furina" seem to contradict what is said in the account given of that species, "par ultimum pedum caudalium extremitatem precedentem non supennis." The account given of "Seba A. Costa" and of its species, "S. inomnimata A. Costa," agrees exactly with that given in the Brit. Mus.
REPORT ON THE AMPHIPODA.

561

Catal. by Spence Bate, except that to the generic account is added the fact that the upper antennae are without accessory flagellum, and from the specific account is omitted the statement that the pereopods are subequal.

In the fourth subfam. Phoxinae, Sp. B., is given "Phoxus cryphrophthalmus" Catta. A. Ph. Holboëllii different ocasio perfecto in utroque latero. (Descripsum plenior nonulam existat.)

Habit.: Marseille, Montredon (Catta)"; to Pontocrates, Boeck, is attached the synonym "Krgeria Sp. B.," which should be "Krgera. Acanthomatus, Owen, is retained in preference to "Lysiana, Costa, which, however, rightly superseded "Arachnomatus, preoccupied long before Owen used it. Here also Carus places "Lillobrorites Sp. B," and Guerinia, Hope.

In the fifth subfam. Gammarinae (Dana), Cls., the habitat of "Macro Blanckardii Sp. B.," is given as "Capo S. Viti, Sicilia (Mifne-Edwards)," but the Brit. Mus., Catal., p. 190, gives for this species "Hab. Cape of Santo Viti, Sicily (M. Blanckard)," and ascribes to M. Blanchard "the description as well as the figure." To "Macro cryphrophthalmus," Heller, "Eurythlceus cryphrophthalmus Sp. B," is assigned as a synonym, although the latter species has the telson tubular, while Heller's species has "telson in partes duas triangulares, invicem imbriicas divisum." Ceralocus, A. Costa, is given as a synonym for "Melita, Leach, as well as for "Macro, Leach, Ceradocus, A. Costa, being assigned under the latter as a synonym to "Macro oristipes," Heller. "Melita oriscus, Catta, is thus described:"—"Stipitis antennarum I. articul. 1. in extremitate spina fortai arnatus; segmenta caudalia margine postero-inferiori fortier ducticato; stili caudales posteriores graciles breves. Habit: Marseille, Ratonneau, 10–13 org. prof. (Catta)." To "Protothelia, A. Kn., the synonym "Leptocheirus Zadd.," "Ptilochirus Stimpson," is assigned. Zaddach's genus "Leptocheirus" has, however, been shown by Boeck to be distinct from "Protothelis, A."

Some rearrangement therefore is necessary of the species assigned to this genus, viz. 1. "Protothelis hirciniana, Sp. B. 2. "Habit: Marseille (var. massiliensis)" Catta," which should be "Leptocheirus hircinianus;" 2. Pr. pilosa Sp. B. ("Leptocheirus pilosus Zadd.)," which should be "Leptocheirus pilosus, Zaddach;" 3. Pr. guttata Gr. 2,; "4. Pr. fasciata A. Costa." The name "Protothelis fasciata," was used by Krüyer for the briefly described type species of his genus. Stimpson's genus is not "Ptilochirus," but "Ptilocheirus.

In the sixth subfam. Lysianassinae, Dana, for the eighth species, "Lysianassa ciliata," Grube, the synonym "L. Achniinae ciliata, Sp. B," is suggested, but whereas in "Lysianassa ciliata, the central tail-piece is simple, squamiform, concave above, and rounded at the apex," which agrees with the definition of "Lysianassa here given (telson squamiformis)," "Lysianassa ciliata," Grube, on the contrary, has the telson "nasque ultra medium fissum." Egidia, A. Costa, has been identified by Boeck with "Urodus, Dana, 1852. Ichnotopus calceolatus, Heller, 1867, is identified by Boeck with his own "Ichnotopus spinicornis, 1860. Callisoma Bartholomewy Hope," entered as "non descripta," has been both described and figured. See Note on Costa, 1853.

In the third tribe Hyperina, M.-Edw., in the first fam. Vibillidae (Dana) Cls., to "Vibilia Jeangerardi Luc., are suggested as synonyms, "V. speciosa A. Costa, "V. mediterranea Cls." In the second fam. Hyperidae (M.-Edw.), Sp. B., for "Lestrigonous mediterranea, A. Costa, is substituted "Hyperia mediterranea, V. Cls." In the fourth fam. Platyceridae, Cls., and its first subfam. Typhilde, Cls., the name "Entypis, Cls., is adopted with the synonym "Typhis Risse, Thytopus Dana, Ditylurus Dana et Platycerus Sp. B. 2," of which, however, "Ditylurus, Dana, has the claim of priority over "Entypis. In the third subfam. Lacycidae, Cls., to "Lycera robusta, Cls., a synonym is suggested in "L. puler, Marion. In the fourth subfam. Oxycephalidae, Cls., "Oxycephalus, M.-Edw., has the synonym "Natalius A. Costa, "Oxycephalus De Nat.," and the species "Oxycephalus similis, Claus, is accompanied by the synonym, "Natalius candidissimus A. Costa." In

(zool. Chall. Exp.—part LXVII.—1887.)
this subfamily are also placed, with notes of interrogation, the genera Carcinornis, A.
Costa; Orio, Coeco; Chiropristis, Coeco; "Ornithorhampus," de Natale.
It would have added to the usefulness of this exceedingly useful work, had there been an
Index to this Part, in which the Latin descriptions of so large a number of genera and
species are brought together. In regard to the arrangement of the group here adopted, it is
not easy to see why some authors should place the Lernodipoda at the head or in the
fore-front of the Amphipoda, since their structure, however well adapted to their modes
of life, points very obviously to degradation, and seems as little as possible typical or
representative.

1885. Chilton, Charles.

On an Example of Polymorphism in the Amphipoda. The Annals and
pp. 368–376. Pl. X.

Mr. Chilton gives as the synonymy of Aora typica, Kröyer, the following names, Lataria
longitarsis, Niclet, Microdeuteropus mortoni, Haswell, Microdeuteropus tenules, Haswell,
Microdeuteropus maculatus, G. M. Thomson. He supports his view by minute details and
figures of various specimens, and while giving one description for the female, he describes
the other sex thus:—"Male. Three forms, all differing from the female in the character
of the first gnathopod, which in each has the meros produced into a long spine reaching
about to the end of the carpus.

"The forms may be distinguished as follows:—
1. (Aora typica, Kröyer)—Basos with a tooth projecting forwards on the anterior margin;
carpus longer than the propodos, but of about the same breadth.
2. (Microdeuteropus maculatus, Chilton.)—Carpus longer and broader than propodos;
meros with small tuft of setae on posterior margin.
3. (Microdeuteropus Mortoni, Haswell.)—Carpus longer and broader than the propodos;
meros hollowed anteriorly and with each lateral margin densely fringed with setae; dactylos
as long as propodos and with two or three tufts of setae on concave border."
He repeats an opinion previously expressed that the name Microdeuteropus will have to become
a synonym of Aora.

1885. Filhol, H.

Observations relatives aux espèces du genre Paramithrax, vivant en Nouvelle

Contains notes on Allorchestes stewarti, n. s., and Allorchestes campbellica, n. s., p. 54. (G.
H. Fowler, Zool. Record for 1885.)

1885. Frenzel, Joh.

Über den Darmcanal der Crustaceen nebst Bemerkungen zur Epithelregeneration.

According to the Zool. Jahresbericht für 1885, Phronima is one of the animals investigated in
regard to the subject of this paper.
1885. GIESEBRECHT, W.

1885. GILES, G. M.

The careful description and figures of this new species “found in the surface-net about the Palmyras shoal and the mouth of the Dhamra river on the Orissa Coast,” show that it is not a Cyrtophium, but a Cerapiis. Templeton’s notes on Cerapus abditus will be recalled by the remark made upon this species, that “when alive and at ease, it would frequently turn itself inside its tube, and protrude its head from the opposite extremity.” Observations made on the structure of the tube are here recorded. In this paper the appendages of the thorax are reckoned as eight pairs, the first gnathopods being called the “2nd pair of appendages” as an alternative title, and the fifth peraeopods being spoken of only as the 8th pair of appendages.

1885. GILES, G. M.

Two specimens, a male and female, were available for the description of the new species, named Melita megacheles. They were “brought up by the hempen tangles from 12½ fathoms near the Mutla Light Ship.” The species is figured on pl. iii.

1885. GILSON, G.

La Cellule: Recueil de Cytologie et d’Histologie générale. Lierre, 1885.

“Spermatogénese chez les Arthropodes (188 pp., 8 pls.) by G. Gilson; Oniscus, Asellus, Gammarus, p. 140 et seq.” (G. H. Fowler, in Zool. Rec. for 1885.)

1885. GUERNE, JULES DE, born August 20, 1855 (J. de G.).

M. de Guerne, in discussing the fauna of the buoys, says (p. 327) that upon them “au milieu des hydrides grouille une innombrable quantité d’amphipodes (Podocerus pulchellus).”
THE VOYAGE OF H.M.S. CHALLENGER.

"Ces petits crustacés construisent des cellules où la vase entre pour une grande part." He combat the view expressed in the British Sessile-eyed Crustacea, i. 438, that in rough weather they withdraw to the depths, by the following arguments; neither the Podoceri nor their nests are ever dredged in the neighbourhood of the buoys, although other Amphipods of similar size and agility are so procured; the whole Podocerus family is found on the buoy, showing that multiplication takes place there, and implying a permanent residence; other creatures less well endowed than the Podoceri, as to means of adhesion and locomotion, pass their lives on the buoys and lay their eggs there.

1885. Haswell, W. A.

This paper is a commencement of the revision to which Mr. Haswell proposes to subject his earlier work, now that attention has been so much drawn to the Amphipod fauna of the south, as well by Mr. Haswell’s own writings, as by those of the zealous naturalists of New Zealand, Mr. G. M. Thomson, Mr. Charles Chilton, and Mr. T. W. Kirk. The paper describes and figures parts of two new species, Proto cylindrica and Proto spinosa. It gives additional figures and particulars relating to Protella australis, Haswell, and states that “it is a very well-marked species and quite distinct from Protella gracilis of Dana, to which Mayer is inclined to unite it, both in the form of the head and of the gnathopoda.” The description is quoted which Mayer gives of “Protella Haswelliana,” a species which has the two last segments of the pronotae coalesced. Cuprolina corniger, Haswell, = ? Proto corniger, Mayer, is transferred to a new genus, Hirscola, somewhat prematurely, on the supposition that the three anterior pairs of peraeopods are rudimentary. Mayer proposed the new genus if it should prove that the appendages mentioned are in the supposed condition, but Mr. Haswell does not say whether he has or has not had an opportunity of determining this point.

1885. Haswell, W. A.

To Talitrus syphaticus, Haswell, pl. x, fig. 1, Talitrus affinis, Haswell, is assigned as a synonym, affinis being evidently a mistake for affinitis.

Remarks are made on some of the Australian species of Allorchestes instituted by Dana and by Mr. Haswell respectively. Under Neobole algicola, pl. xi., figs. 4–6, it is suggested that the genus Neobole, Haswell, may be the same as Hyale, Rathke. Of Aspidophoreta, Haswell, it is said:—“This genus stands between Allorchestes and Nicea, differing from both in the large size of the anterior coxae, from Allorchestes also in the character of the telson, and from Nicea in the large size of both upper and lower antennae, and in having the lower pair much larger than the upper.

Additional details are given as to Stenopephalus latus, Haswell, pl. xi., figs. 7–12, and Ampelisca australis, Haswell, pl. xii., figs. 7–16, and pl. xiii., figs. 1–4.

Mr. Haswell here refers Lysianassa nitens, pl. xii., figs. 1, 2, to the genus Ancyz. He would keep Lysianassa australicenis and Lysianassa affinis as distinct species, but I still think that the distinctions he mentions are insufficient to keep them separate from Ancyz nitens. He mentions that the telson is deeply cleft in all, a character inconsistent with the received
definition of *Lysianassa*. To *Eusirus dubius*, Haswell, he adds the account of a variety, pl. xiv., fig. 1, and a new species, *Eusirus affinis*, pl. xiv., figs. 2-4. From the information given I am inclined to group all three forms with one described in this Report under the name *Liljeborgia haswellii*. It would not, I think, be reasonable to transfer the specific title *dubius*, which was applicable enough in connection with the generic name *Eusirus*, to the undoubted position of the new species in the genus *Liljeborgia*. In the British Museum Catalogue by some accident the telson in this genus is said to be entire, a mistake corrected in Bate and Westwood's subsequent work. Probably Mr. Haswell's attention was diverted from the genus *Liljeborgia*, when he found the telson in his own species went almost to the root. He accepts the view of Miers that *Lencellothrix commenalis* is a variety of *Lencellothrix spinicarpa*, and states that *Lencellothrix gracilis* and *Lencellothrix diemenensis* are to be regarded as marked varieties of the same. He describes a new species under the name *ATius hounchir*, pl. xiii., figs. 5-7, which will also be found described and figured among those brought home by the Challenger. "*Dexamine Miersii*," n. s., pl. xiii., figs. 8-12, is described. Figures, pl. xv., figs. 1-4, and description are given of "a species from Port Stephens which is very nearly related to *Meganora suensis*, and yet differs from it in several particulars." "This species bears a considerable general resemblance also to *Mina hemigera*, but the modification of the left posterior gnathopod in this latter species is so special as to distinguish it very clearly. *Meganora Miersii*, Miers, is identified with *Meganora mastersii*, Haswell. *Mina spinosa*, Haswell, *Mina ramaygi*, Haswell, and *Mina festiva*, Chilton, are identified with *Mina rubromaculata*, Stimpson. To this list of synonyms must no doubt be added *Meganora serrata*, Specker Bate. Mr. Haswell speaks of "the form figured by Stimpson," but without saying where the figure is to be found. Fresh figures are given of *Neoscheira fasciata*, Haswell, pl. xvi., figs. 1-3, with the remark that "in most of its characteristics this species shows evident relationships with *Micro- denteceraus*. In fact it is only the form and proportions of the gnathopods (figs. 1 and 2) that separate it from the normal members of that genus, with which it is connected through the European *M. versiculatus*, Specker Bate." Of *Haplocheira typica*, pl. xvi., figs. 4-8, Mr. Haswell writes that its relations are rather with the Podoceridae than with the Gammaridae, "the last pair of pleopods being short, with slightly hooked spines on the outer rami, and a very short inner rami with a simple pointed spine, and the telson (fig. 8), being a small undivided plate with a strong hook at each of its posterior-lateral angles." He says further, "the superior antenna have small two-jointed appendages—a feature which I overlooked in my first examination. The flagellum of the inferior antenna has three distinct joints. The anterior gnathopods (fig. 4) might be described as very imperfectly subcheliform—the propus having a small lobe at the base of the dactylus. The nearest ally of the genus seems to be *Corophium*, and C. Lendenfeldi of Chilton (Trans. N. Z. Inst. etc.) is probably this species." *Gammarus barbinanus*, Thomson, 1879, takes precedence as *Haplocheira barbinanus*. Of *Harmonia crassipes*, Haswell, pl. xvi., fig. 9, he writes, "The relations of this species were not correctly expressed by the position in which it was placed in the 'Catalogue of Australian Crustacea.' It is a member of the family *Corophidae*, distinguished from *Amphithoe*, *Sunaephyllus* and *Nenius*, among other points, by the presence of an appendage on the superior antenna, from *Cerapus* by the biramous character of the posterior pleopoda, and from *Podocerus* by the multi-articulate flagella of both pairs of antenna. The genus may be defined as follows:—Coxa not so deep as the corresponding segment; antenna both with multi-articulate flagella, the superior pair with an appendage. Mandibles paliporous. Maxillipeds unguiculate, sub-pediform, with a squamiform process on the basos only. Gnathopods sub-chelate, unequal, posterior pair very large. Posterior pleopods biramous, the outer rami with slightly hooked spines and straight hairs, the inner with straight hairs only. Telson single, long, pointed." From
this description it seems possible that *Harmonia* may be a synonym of *Grobia*, Czerniavski, 1868, but for that genus the mouth-organs have not been described.

*Cyrtophium dentatum*, Haswell, pl. xvii., figs. 8-12, is transferred to a new genus, *Dexiocerella*, described as differing from Dana’s genus *Cyrtophium* as defined by Spence Bate, by “the superior antennae having a short, multi-articulate flagellum and a well-developed secondary appendage.” This is obviously the same as Dana’s *Plataphium*. See Note on Dana, 1892. *Dexiocerella lobata*, pl. xviii., figs. 6-8, and *Dexiocerella larvae*, pl. xviii., figs. 10-12, are described and in part figured, as new species belonging to this genus. *Cyrtophium hystrix*, Haswell, is transferred to *Lxmatophilus*, Brazelius, since the superior antennae have no secondary appendage, and the second uropods are wanting. *Cyrtophium minutum*, pl. xviii., figs. 1-5 and fig. 9, remains as satisfying the requirements of Spence Bate’s definition of *Cyrtophium*, while *Cyrtophium parasilicicum*, pl. xvii., figs. 1-7, is stated to be a connecting link between the new genus *Dexiocerella* and the old *Cyrtophium*, since it “has the flagellum of the lower antennae well-developed and indistinctly multi-articulate, but has no appendage to the superior antennae.” The genus of Brazelius is given as *Lxmatophilus*, but there cannot be any doubt about the true spelling, as Brazelius derives it from λαύρια and φλόος. Some additional figures and particulars are given for *Proto nove-hollandiae*, pl. xviii., figs. 13-16.

1885. Koehler, René.

Extract from the Bulletin de la Société des Sciences de Nancy.

Among the 126 species of Crustacea which Dr. Koehler took in the Channel Islands, and principally in Jersey, were several Amphipods, which he enumerates. At Sark he took several specimens of *Aorla gracilis*, which, however, is not, as he supposes it, rare.

A species of *Gammarella*, closely allied to *Gammarella brevicornata*, he proposes to name *Gammarella longicormis*, from the length of the antennae, but this is too variable a character to be any criterion of a distinct species, and the specimens, as Dr. Koehler informs me, had accidentally been dried up, before he could submit them to detailed examination. He mentions, among other common Amphipods at Jersey, *Eurythoeus erythrophthalmus*, Sp. B., which is in all probability a slip of the pen for *Eurythoeus erythropthalmus*. Thirty-two species of Amphipoda were observed. From Guernsey Dr. Koehler has since sent me a specimen of *Atylus vellomensis*, Bate and Westwood.

1885. Martens, E. von.

Crustacea. The Zoological Record for 1884; being Volume the twenty-first of the Record of Zoological Literature. London, M.DCCC.LXXXV.

In the “Biological Observations,” the recorder mentions “Several new Gregarinides found in *Portheus*, Carcinus, Pelekypagaeus, Dromia, Nicella [? Nissa], Pharonida, and Caprella; J. Fraenkel, Arch. mikr. Anat. xxiv. pp. 545-579, pl. i. figs. 1-69.”

Under “Geographical Distribution,” he mentions, from papers which I have not seen, the occurrence in Limfjord, Jutland, of two Caprellidae, on the authority of “J. Collin, Limfjordens marine Fauna, pp. 21 & 22,” and in the Baltic of eleven Amphipods, including the fresh-water *Gammarsus pulex*, on the authority of “M. Braun, Arch. Nat. Liv. (2) x. pp. 98-102, 114, & 112.”
1885. Murdoch, J.

Acanthoeone pulpantha, n. s., Melita formosa, n. s., Melita leonis, n. s. (G. H. Fowler, in Zool. Record for 1885.)

1885. Packard, A. S.

The investigation appears to refer almost exclusively to Isopods, but in the section headed "Morphology of the Brain," Packard says, "the brain of the Isopods and Amphipods is a synencephalon, though far less complicated than in the Decapods. It will be remembered that Professor Lankester, in his memoir on Apus, designates the simple brain of that crustacean as an archencephalon, while the composite brain of 'all crustacea, excepting Apus, and possibly some other Phyllopods,' he denominates a synencephalon. "As seen in Fig. 1, the brain or suprarenaophaegal ganglion is a composite mass or group of four pairs of ganglia, i.e. (1) the brain proper or procerebral lobes, (2) the optic ganglia, (3) the first antennal, and (4) the second antennal lobes. These lobes are quite separate from each other in the Isopoda and Amphipoda as compared with the Decapoda."

On "the histological elements of the ganglia," he remarks that "there are in the Asellidae, as in insects and Decapods, three kinds of elements in the brain and other ganglia, viz.: (1) ganglion cells; (2) nerve fibers; and (3) Leydig's punktsubstanz (mark-substanz of Leydig and Rabel-Rückhard, and especially Dietl), which might be called the myeloid tissue or substance." "This is the central finely granular part of the brain, in which granules have short irregular fibers passing through them."

Pages 10 to 13 contain a "Bibliography of works on the nervous system of Crustacea."

1885. Sars, G. O.

Not only is the title-page of this fine work given in English as well as in Norwegian, but the two languages are employed throughout in parallel columns. The description of the Amphipoda extends from page 139 to page 233, with supplementary notes on page 270. They are figured on Plates 12 to 18, and Plate 20, Fig. 21, in this author's usual masterly manner. He reminds his readers on page 1 that the new forms to be discussed in the present work have already been briefly characterised in earlier papers, the Prodromus descriptionis of 1876, and the Crustacea et Pycnogonida of 1879. Hence, of the species here called new all belong in fact to one or other of those dates, with the exception of the very remarkable Hyperiopoda Viringii.

In Tribus I. Gammarina, the genera and species are distributed and numbered as follows:—
Fam. I. Lysianassidae. Gen. I. Scearce, Boeck, 1870, with the note, "I retain for the
present the generic subdivision proposed by Boeck, though, in my judgment, a closer revision of the family will show the need of slightly reducing the number of genera."  
31. Secernue bidenticulatus, Sp. Bate, with the synonymy, "Lysianassa bidenticulata, Sp. Bate, Ann. & Mag. Nat. Hist., Ser. 3, Vol. 1, p. 362. Lysianassa vulgar, Sp. Bate, Cat. Amphip. Brit. Mus. p. 65, Pl. x. fig. 3 (non Phipps). Lysianassa Vahl, Gen. Crust. Amphip. Spitsb. No. 2 (ex parte). Anonyx bidenticulatus, Miens, Spitsb. Crust. Ann. & Mag. Nat. Hist., 1877. p. 136," distinguished from the closely allied Anonyx vahlii, to which Goës has referred it, by the bidenticulate lateral plates of the third abdominal segment; Gen. 2. Hippomenes, Boeck, 1870. 32. Hippomenes holboelli (Krøyer), var., with the synonymy, "Hippomenes abyssi, G. O. Sars, Prodromus descriptionis Crust., etc., No. 94 (non Goës)," a variety without eyes. Gen. 3. Anonyx, Krøyer, 1883 [1838]. 33. Anonyx calcarius, "Anonyx (Hippomenes) calcarius, G. O. Sars, Crust. & Pycnogonida nova etc., No. 16." "Of the previously known Anonyx species, it unquestionably approximates closest A. paullus Lilljeborg, but is easily recognized by the much more produced posterior lateral corners on the 3rd abdominal segment, as also the peculiar spur-like projection on the basal joint of the last pair of legs, a character that suggested the specific designation. In the imperfect subcheliform structure of the 1st pair of legs, it differs from all other known species of the genus, agreeing in this respect rather with the genera Lysianassa and Secernue." 34. Anonyx typhlops, carinate on the fourth abdominal segment, totally devoid of eyes. Gen. 1. Otidinmus, Boeck, 1870, in the table of contents and index spelt Otidinmus. 35. Otidinmus turgiis, "Otidinmus torgiis, G. O. Sars, Crust. et Pycnogonida nova etc., No. 13," "approximates closest O. Eldwensii Krøyer, from which however it may at once be distinguished by the remarkably clumsy and inflated form of body, a character that gives the animal greater resemblance to O. planus Krøyer, which, in other respects, however, differs very decidedly." 36. Otidinmus brevis, "Otidinmus brevis, G. O. Sars, Crust. & Pycnogonida nova etc., No. 14," distinguished by "the imperfect development of the eyes and the shape of the telson," which is "very faintly emarginate at extremity." Gen. 3. Tryphosa, Boeck, 1870. 37. Tryphosa paullia, "Anonyx (Tryphosa) paullia, G. O. Sars, Crust. & Pycnogonida nova etc., No. 15." "The present species I refer here to Boeck's genus Tryphosa. In my judgment, however, both this genus and the genera Otidinmus and Oreohomone should, perhaps, more properly be eliminated and their species ranged under the genus Anonyx. From the other forms referred by Boeck to the genus Tryphosa, the present species may be recognised by the total absence of eyes, the remarkably slender secondary flagellum on the 1st pair of antennae, and the form of the head." Gen. 6. Acidostoma, Lilljeborg, 1865. 38. Acidostoma laticeps, "from the only hitherto known species of this genus, viz. A. obscura Sp. Bate, the present is easily distinguished by the total absence of eyes, the prodigiously developed 1st pair of antennae, and the remarkably robust 3 posterior pairs of legs. Moreover, in the rudimentary character of the last pair of caudal styles, as also the posteriorly non-incised telson, this species differs essentially from the typical form."  
Fam. 2. Phoxidae. Gen. 1. Phorus, Krøyer, 1842. 39. Phorus oculatus, distinguished by the well-developed, darkly pigmented eyes, and from Phorus holboelli, Krøyer, "by the more thickset form of body, the shorter and more obtuse frontal plate, as also by a somewhat different shape characterizing the basal joint of the last pair of legs." Gen. 2. Harpiniur, Boeck, 1870. 40. Harpiniur alatus, distinguished by its size, reaching 13 mm., peculiar form of basal joint of last pair of legs, "by the obtusely rounded lateral plates on the 3rd abdominal segment, and finally by the hunched projection formed above by the succeeding segment." 41. Harpiniur carinata, possibly males of preceding species, but differing in structure of antennae, and also in "the distinctly keeled posterior division of
the body, the form of the 2 posterior pairs of legs and of the telson.” 42. Harpina macronota, “distinguished by the strong, hook-shaped point formed posteriorly by the lateral plates of the 3rd abdominal segment, as also by the very peculiar form characterizing the basal joint of the last pair of legs.” 43. Harpina serrata, very near to Harpina plumosa, Kröyer, but distinguished by “the anterior abdominal segments being densely pubescent above,” and by the serrate basal joint of the last pair of legs. Gen. 3. Urothoe, Dana, 1852. 44. Urothoe abbreviata, length, 3 mm., “easily recognizable by its remarkably short and thickset body, the peculiar form distinguishing the first pair of antennae, the absence of eyes, and by the short last pair of caudal styles.”

Fam. 3. Epimeridae. Gen. 1. Epimeria, Costa, 1851. 45. Epimeria loricata, “Colour a gorgeous red. Length reaching 40 mm., distinguished from Epimeria coriacea, Fabr., by “size, remarkably firm integuments, and the deviating armature of the body. Gen. 2. Paramphithoe, Bruzelius, 1859. 46. Paramphithoe eucanatha, “Pleustes eucanatus [eucanith], G. O. Sars, Prodomus Crust. et Pycnog. etc., No. 110,” “approximates very closely P. pulchella Kröyer, but is easily recognized by the thoracic segments, including the 3 anterior ones, being all of them keeled and running out as dorsal projections, whereas in the former species this is the case with the posterior ones only. Moreover, the form of the 2 anterior pairs of legs differs somewhat. The genus Paramphithoe is referred by Boeck to the family Oedicerinae. In my judgment it should rather be classed among the Epimeridae. Furthermore, I have seen fit to retain Sp. Boeck’s genus Pleustes for P. panura, Kröyer, and the species nearest related to that form.” Sars is here referring to Boeck’s work of 1870, for in his posthumous volume, 1876, Paramphithoe, as limited by Boeck, is made a synonym of Pleustes, Sp. Boeck, included indeed among the Oedicerinae, but with the remark, “Genus Pleustes ad subfamiliam Oedicerinae vix referendum est.”

Fam. 4. Oediceridae. Gen. Oedicerus, Kröyer, 1842. 47. Oedicerus macrocheir, to be “recognized by the remarkably small and non-inspissated frontal projection, the absence of eyes, and the prodigious development characterizing the 2 anterior pairs of legs.”

Fam. 5. Atylidae. Gen. Halirynes, Boeck, 1870. 48. Halirynes quadridentatus, very near Halirynes fulcoivicatus, M. Sars, but distinguished by size, length 24 mm., “greater number of dorsal spines, and the deviating form and armature of the lateral plates of the 3rd abdominal segment.” Gen. 2. Cleippides, Boeck, 1870. 49. Cleippides quadriruncipes, Heller, total length of specimens reaching 52 mm., the antennae not included. Gen. 3. Amphithoeis, Boeck, 1860. 50. Amphithoeis pulchella, nearest Amphithoeis latipes, M. Sars, but “distinguished by a less thickset body, the absence of a dorsal keel, less robust ambulatory legs, as also by its colour. Moreover, the form of the 2 anterior pairs of legs is rather different.”

Fam. Gammaridae. Gen. 1. Maera, Leach, 1813. 51. Maera tenera, “Maera tenera, G. O. Sars, Prodomus descriptionis Crust. etc., No. 119 (non Stimpson),” distinguished by its remarkably slender body, the evenly rounded 1st pair of epimera, the total absence of eyes, and the linear form of the basal joint of the 3 posterior pairs of legs.” Gen. 2. Melita, Leach, 1813. 52. Melita pallida, “posterior margin of all abdominal segments, with exception of last, jutting out above as 2 flat, appressed spines, from between which rise two or three considerably smaller one. Lateral plates of 3rd segment produced posteriorly to a sharp point. No eyes.” Gen. 3. Amathillopes, Heller, 1875. 53. Amathillopes spiniger, Heller, “length of largest specimens reaching 50 mm.”

Fam. Syrphoidae. Gen. Brunzia, Boeck, 1870. 54. Brunzia serrata, distinguished from Brunzia typica, Boeck, “by the sharply-marked dorsal keel, with its high, compressed projections, as also by the posteriorly serrate lateral plates on the 3rd abdominal segment.”

14 mm,” very near to Metopa alderi, Sp. Bate, but “let alone the far greater size, it can
immediately be recognized by the very unequal development of the 2 pairs of antennae—
perfectly uniform in both sexes; whereas the antennae (in the female of M. Alderi at least)
are about equal in length; moreover, by the armature characterizing the hand of the 2nd
pair of legs; and finally, by the 3rd joint of the hindmost pair of legs being less dilated
posteriorly.” Sars notes that he has well-marked specimens from Hammerfest, “which are
indeed a good deal smaller.” 56. Metopa qyvicornis, “length 7½ mm,” distinguished from
Metopa spectabilis “by its inferior size, as also by the greatly elongated and equally
developed antennae. From M. longicornis, Boeck, which, in the appearance of the antennae,
approximates closest the present species, it differs by the greater elongation of the 2nd joint
of the 1st pair of antennae, as also by the different form and armature of the hand of the
2nd pair of legs.” Gen. 2. Danaia, Sp. Bate, 1882, with Cressa, Boeck, for a synonym.
57. Danaia abyssicola, differs from Danaia dubia, Sp. Bate, and Danaia minuta, Boeck,
“by the total want of eyes, the remarkably elongated first pair of antennae, and by the
form of the first pair of legs.” As the oral appendages could not be examined, it remains
uncertain whether this species agrees with Bate’s account of Danaia or Boeck’s of Cressa.
“by its want of distinctly developed eyes, by the presence of only one dorsal spine, by the
uniform development of the antennae, and finally by the peculiar structure of the first pair
of legs in the male.” The generic name is properly Liljeborgia. Gen. 2. Tritrops, Boeck,
1870. 59. Tritrops appendiculata, “the form treated of here exhibits in some respects a
rather striking deviation from the other species referred to the genus Tritrops, and may
possibly be found to constitute a separate genus.” See Note on G. O. Sars, 1880. No. 27.
24 mm.” distinguished “by its total want of eyes and the peculiar dentiform projection on
each of the three anterior pairs of epimera, a character that suggested the specific
designation,” “presenting in its outer habitus closest resemblance to A. spinipes, Boeck.”
61. Ampelisca minuta, “length 8 mm.” to be recognised “by the unusually small antennae, its want of eyes, as also the considerable size of the expansion distinguishing the
basal joint of the last pair of legs posteriorly.” Gen. 2. Byblis, Boeck, 1870. 62. Byblis
abyssi, “differs from the typical species, B. Gaimardi Kroyer, by the total want of eyes
and the much less elongate head,” and is distinguished from Byblis crassicornis, Metzger,
“by the somewhat different structure of the antennae and the caudal stylets,” which “are
all uniform in structure, with simple lanceolate and naked branches. They diminish
successively in length backwards, and reach therefore, when stretched back, to about the
same transverse line.”
from the other two Norwegian species by its total want of eyes, the greatly elongated basal
joint of the 1st pair of antennae, and the structure characterizing the 1st, and in part too,
the 3rd and 4th pairs of legs, as also by their far less dense armature of bristles.”
Fam. Podoceridae. Gen. 1. Podocerus, Leach, 1815. 64. Podocerus assimilis, nearest Podocerus
megacheir, Boeck, “but differs from that animal in having a somewhat robust form of
body, larger epimera, the rudimentary character distinguishing the secondary flagellum of its
1st pair of antennae, as also in the lateral plates of the 3rd abdominal segment not being
angular, but obtuse; rounded posteriorly.” 65. Podocerus brevicornis, somewhat resembles
Podocerus latipes, Kroeyer, but differs “in its want of eyes, the pointed lateral corners of the
head, the shorter and less abundantly bristle-covered antennae, as also in some way deviating
form distinguishing the 2 foremost pairs of legs.” 66. Podocerus tenuicornis, “Podocerus
longicornis, G. O. Sars. Crust. & Fycog. nova etc., No. 38 (non Heller),” “length 3 mm.,”
a species “distinguished from the 2 preceding ones by its remarkably elongate and slender
antennae, furnished posteriorly with long fascicles of bristles,—by the greatly produced lateral corners of the head, and also by the comparatively feeble structure characterising the foremost pair of legs." Gen. 2. *Erichthonius*, Edw., 1850. 67. *Erichthonius megaplos*, "Caprella megalops", G. O. Sars, Crust. & Pycnog. nov. etc., No. 39," distinguished "by its unusually large and dark-coloured eyes, greatly elongated antennae, and the form of the 2nd pair of legs in the male. The genus *Corynus*, Say, of which *C. tubularis* is the type, differs essentially, as shown by Sidney Smith, from the genus *Erichthonius* Edw., belonging, as it does, to the family *Corophiidae*. The only Northern species of this genus is *C. crassicornis* (Siphonocrates) Sp. Bate, also met with on the coasts of Norway."

Fam. Corophiidae. Gen. *Unciola*, Say, 1818. "Syn: Glaucome, Kröyer, 1845." 68. *Unciola petalocea*, "Glaucome petalocea", G. O. Sars. Crust. & Pycnog. nova etc., No. 40," "length 10 mm." "The present species bears closest resemblance to *U. planipes* Norman, but it is easily recognized by its greater size and the peculiar lamellar form of the 3rd and 4th joints of the 2nd pair of antennae in the male, as also by the structure of the 1st pair of legs. The 2nd pair of legs differs in the two sexes from those of *U. planipes*, the hand occurring vertically truncate at the extremity and with a well-defined palmar margin."" 69. *Unciola septentrionalis*, G. O. Sars. Crust. et Pycnog. nova etc., No. 41." 70. *Unciola triticornis*, distinguished from earlier species "by its remarkably clumsy form of body, comparatively robust and densely hisute antennae, and small whitish-yellow eyes." 71. *Unciola macera*, "distinguished by its slim form of body and greatly produced limbs, rudimentary eyes, as also the peculiar form characterising the 2nd pair of legs in the male." "

Tribe 3. Caprellina. Fam. Caprellidae. Gen. *Caprella*, Lamk. 1818 [1801]. 72. *Caprella microtuberculata*, "of the previously known species, this approximates closest *C. linearis* Lin., but admits at once of being distinguished by the much more produced 1st pair of antennae, the form of the 2nd pair of legs, and the different colouring." The last of those distinctions must be noted as of very doubtful specific value. 73. *Caprella spinosissima*, Norman, "Caprella spinosissima*, Wyville Thomson, The Depths of the Sea, p. 126. *Caprella horrida*, G. O. Sars, Prodromus descript. Crust. & Pycnog. etc., No. 137. "On a former occasion," Sars observes, "I recorded this characteristic species under a new name, viz., *horrida*, to prevent its being confounded with Stimpson's *Egina spinosissima*. Meanwhile, as the latter is identical with the form *Caprella spinifera*, described somewhat earlier by Bell, and must, therefore, bear the last-mentioned specific designation, I see no reason for suggesting any change in the name proposed by Norman for the species treated of here; wherefore it is now retained." As, however, the name *Caprella spinosissima* has been used by Spencer Bate for the species named *Egina spinosissima* by Stimpson in 1854 and *Caprella spinifera* by Bell in 1855, it becomes a synonym of the former, and cannot be used again for Norman's species, which will therefore revert to the name *Caprella horrida*, G. O. Sars. See also Note on C. Wyville Thomson, 1873. Gen. 2. *Egina*, Kröyer, 1843. 74. *Egina spinifera*, Bell, the synonymy given being *Caprella spinifera*, Bell, 1855, *Egina spinosissima*, Stimpson, 1857. *Egina spinosissima*, G. O. Sars, Prodromus descript. Crust. & Pycnog. No. 135. "Böeck's *Egina echinata* differs obviously alike in the armature of the body and the structure of the 2nd pair of legs." The species is therefore, as just observed, *Egina spinosissima*, Stimpson, 1854. Indeed, as to Stimpson's priority, I may here mention that a separate copy of Stimpson's Synopsis, which I have recently obtained, shows the following dates; on the cover, "Washington City: published by the Smithsonian Institution, January 1853."; on the title-page, "[accepted for publication January, 1853.]; the introduction signed "William Stimpson. Smithsonian Institution, February, 1853."; on the page containing "references to the figures," "published by the Smithsonian Institution, Washington, D.C. March, 1853."
Tribe 4. Hyperiina. Fam. Hyperiidae. Gen. Hyperiopsis, n. "Generic Character.—Body of the usual form in Hyperidians, tumid anteriorly, with back broad and small epinera. Head large, with upper part prominently arcuate. Eyes incompletely developed. First pair of antennae larger than 2nd, with peduncle short and a well-developed accessory flagellum. Mandibles furnished with distinctly developed palps. The 2 foremost pairs of legs feeble in structure, simple, non-subechelform; the 2 succeeding pairs with 3rd joint very large, compressed, lamelliform; the 3 posterior pairs slender, almost filiform, with basal joint but slightly expanded; last joint longest. Pleopods powerfully developed. The 2 foremost pairs of caudal stylets simple, two-jointed; last pair biramous. Telson rudimentary." "It is far from improbable that a closer examination will show the necessity of selecting it [Hyperiopsis Vöringii] as the type of a distinct group within the tribe Hyperiina. The most striking peculiarity in the present form is the distinct and rather large secondary flagellum on the 1st pair of antennae, a character quite alien to Hyperidians in general." 75. "Hyperiopsis Vöringii," n. sp. "The specimen examined would appear, judging from the structure of the antennae, to be a female," length 11 mm., taken off the Norwegian coast at a depth of 600 fathoms. [The fifth and sixth pleon-segments are not condesced.]

In the Oversigt af Norges Crustaceer, 1882, Sars divides the Amphipoda into Tribe 1. Hyperina, Tribe 2. Gammarina, Tribe 3. Caprellina. In the present work we find Tribe 3. Caprellina, but Tribe 1. Gammarina, and Tribe 4. Hyperina, without any Tribe 2. It may be presumed that the change of order was intentional, and that the numbers would have been consecutive but for an oversight.

The appendix, p. 376, mentions that Socarnes ovalis, Hoek, is a synonym of Socarnes bidenticulatus (Sp. Bate), and that in regard to the shallow-water specimen from north of Spitzbergen referred by Hoek to Onesimus leucoptis, G. O. Sars, the correctness of the determination is very questionable.

1885. Schneider, J. Sparre.

Pontocrates norvegicus, Boeck, is described and figured in much detail, distinguished from Pontocrates (Kroyera) arenarius, Sp. Bate, and identified with Kroyera altamarina, Bate and Westwood. The genus Pontocrates, as defined by Boeck, is considered to be scarcely if at all distinguishable from Monoculodes. A very striking relationship is pointed out between Monoculodes carinatus, Sp. Bate, and Pontocrates norvegicus. Since Monoculodes carinatus was originally instituted as the type-species of Kroyera, Sp. Bate, Schneider’s investigations seem to tend either to the restoration of the name Kroyera, with the species carinata, arenaria and norvegica, or to the merging of Kroyera and Pontocrates alike in Monoculodes. [The form Kroyera, instead of the earlier and more correct Kroyera, is uniformly used in the British Sessile-eyed Crustacea.]

Dexamine then, Boeck, is fully described and figured. On the first maxille Schneider observes, "A want of symmetry in the mouth-organs is found in most Amphipoda, especially in the mandibles, but so irregular a pair of first maxillae I have hitherto found only in Dexamine." It is apparently very like Dexamine kelbergi, Boeck. "In regard to the telson, Boeck speaks of it as split to the root; I remarked to be sure," Schneider says, "a suture along the whole telson, but even under strong pressure could only make the points dehiscent. The third segment of the pleon is, just as in many Lysianasside, drawn out into a pointed, somewhat upward curved, hook, whereas Boeck expressly affirms the contrary."
Schneider prefers to retain the Dexamines († Dexaminiidae), with the palpsless mandibles, peculiarly unsymmetrical first maxilla, and exudivate palpe of the maxillipeds, as a separate family for the genera Dexamines and Tritexa, in contradistinction to the Atylidae, with the genera Atylus, Halysages, Calliopius, Amphileptus and Loophos, "which in these respects are tolerably normal."

1885. SCHNEIDER, ROBERT.

Der unterirdische Gammarus von Clausthal. (G. pulex var. subterraneus.)

Dr. Schneider refers to an earlier essay on "subterrane Organismen" (Abhandlung zum Programm des Königl. Real-Gymnasiums zu Berlin. Ostern 1885), in which he had already mentioned this *Gammarus*. The summary of the present paper says that the subterranean *Gammarus* from Clausthal differs from the common form of *Gammarus pulex* and approaches the blind cavern-form in the following points:—"1. in der absoluten Bleichheit des Körpers; 2. in der beginnenden Verkürzung des Auges; 3. in der Form des fünften Gliedes des zweiten Greiffüusses; 4. event. in der Streckung der Vorder-Antennen." "Dazu kommen noch die Eigenthümlichkeiten der verstärkten Kalk- und Eisenaufnahme." It is not, he says, strictly a "Mittelform," but at any rate a "Vermittlungsf orm." The special interest of the form lies in its occurrence in the waters of mines of which the age can be more or less definitely ascertained. "Zwischen ihr und jenem Extrem, welches der völlig blinde *G. pulex* in seinen verschiedenen Variationen darstellt, liegt unbetrüchtliche ungleichere Kluft, als zwischen eben derselben und unseren einheimischen oberirdisch lebenden Formen. Noch für menschliche Begriffe unerreich langer Zeiträume müssen erforderlich sein und gewesen sein, um jene vollkommen subterrane modifizierte Form aus einer unserem Clausthaler Vorkommen entsprechenden Anpassungsstufe entstehen zu lassen, wenn wir bedenken, dass letztere von Normalzustande noch nicht allzu weit differirende immerhin ein bis zwei Jahrhunderte (und vielleicht darüber) bis zu ihrem jetzigen Standpunkte gebraucht haben wird."

1885. SIMON, EUGÈNE.

On page 6, besides a note on *Gammarus pulex*, there is given the following description of *Gammarus truncatus*, n. s.

"Long, 8 mm. *Gammarus pulex* valde affinis, differt tegumentis corporis parceis et minutissime punctatis, capite paulo longiore et antice paululum attenuato, oculis longius remotioribus supra basin antennarum paululum superantibus (in *G. pulex* brevius ovatis et supra basin antennarum non attingesistentibus), antennarum superiorum ramo flagelli longiore articulum flagelli 6° attingente sexarticulato, articulis 3, 4 et 5 reliquis paulo longioribus et inter se brevioris sequis (in *G. pulex* ramo semper triarticulato, articulo ultimo longiore setiformi, articulum flagelli 3° vix aequante), antennis inferioribus flagello breviore octoarticulato articulis

"Gammarus locusta valde affinis, oculis antennis et superioribus fere similibus, sed antennarum inferiorum flagello minus breviore articularibus et fere terciis differt (in G. locusta flagello robustiore paulum depresso 15–20-articulato, articularis saltem 2–5 latioribus quam longioribus)."

The views of earlier writers on these organs are stated. Mr. Spencer has investigated them specially in Talitrus locusta, in which the two tubes in question open at a considerable distance from the anus and run backwards instead of forwards, as in Gammarus, to end blindly in the last segment. Their openings into the gut are lateral, not dorsal as in Gammarus. In certain specimens these tubes were found to contain very definite concretions, of which Mr. Spencer says, "distilled water does not dissolve them, nor is there any uric acid present, but I have been able to clearly detect phosphoric acid, and hence they seem to differ from those found by Nebeski in Orchestia caximana, where he states that they consist of carbonate of lime." The general result agrees with Mayer's view of these organs, which Mr. Spencer gives as follows:—

"Mayer has also described them in the Caprellide, where he states that they are well developed in Caprella, and absent, or only very feebly developed, in Protella, Proto, and Pedalirius, but when present he has never found in them characteristic concretions, and is very decided in asserting that throughout the Amphipoda these diverticula, whatever may be their function and whether they contain excretory products or not, belong morphologically to the mid and not to the hind gut, and that hence they cannot be considered as analogous to the Malpighian tubes of insects. He states that there is always present a sharp break in the epithelium where the mid and hind gut meet, and that the chitin lining of the latter is not continued into the tubes whose epithelium resembles that of the mid, and not that of the hind gut."

1885. Stebbing, T. R. R.

Cyprodelia damnoniensis, n. sp. is here described and figured, and the correspondence pointed out between the genus Cyprodelia, Haswell, 1880, and the genus Stegoplos, G. O. Sars, 1882. Both may have been anticipated by Pellocera, Catta. See Note on Catta, 1875.

1885. Stebbing, T. R. R.

Figures are given of Andania gigantea and Acanthosoma tricarinata, the latter of which is now transferred to a new genus, Acanthocheilus. In this part of the Narrative also the figure by
1886. AURIVILLIUS, C. W. S.

At page 41 it is mentioned that Amphithopsis longinaudata, A. Boeck, is found, as well as Aristias tunichis, Kroyer, and Amblyoa pediculata, G. O. Sars, in the branchial sac of Ascidians. A specimen, 8 mm. long, the antennae not included, was found in Phallusia obliqua, Heller. On Megapora hoops many specimens of Cyana boaepi, Litken, were found, principally on the sides of the head, a few on the fins, and one further back on the whole's body. Curiously, out of 102 individuals only 12 were females. The largest of the male specimens was 12 mm. long, of the females 9 mm., antennae not included.

1886. BOVALLIUS, CARL.

Bovallius considers that Guérin's Cystisoma must be corrected into Cystosoma, and then remarks that "as the name Cystosoma or Cystisoma has been previously given to a genus of Coleoptera by Westwood, it must be rejected and consequently the name of WILLEMOES-SUHUM Thaumatops be substituted." But in fact Westwood's genus is Cystosoma, and Guérin's name ought neither to be corrected nor rejected. Thaumatops is itself a correction of Thaumops, a correction already suggested in the Zoological Record for 1873, but these corrections only multiply synonyms needlessly, and are in my opinion very unjust to the founders of genera. If the niceties of classical philology must be attended to in the invention of new names, it would be better for authors to beware of Greek and Latin altogether and adopt Leach's device of throwing letters together into chance names like Rocinella, at the composition of which no scholar will be able to carp.

The family called by Willemoes-Suhm Cystisomidae is renamed by Bovallius Thaumatopsidae. This, he says, "is to be ranged between the families Mimonectidae and Thronimidæ. It also shows some relations to the family formed by the genus Tyro, MILNE-EDWARDS." He has elsewhere shown that Tyro is the same as the later Clydonia, Dana. To Thaumatops he assigns four species; 1. Thaumatos neptunus, Guérin, 1842, under which he doubtfully includes Thaumatos pellucida (the male), Willemoes Suhm, 1874, "Phil. Trans. Roy. Soc. Lond. vol. 163, part 3, p. 637, (the male)."; 2. Thaumatos pellucida, Willemoes Suhm, 1874, "Phil. Trans. Roy. Soc. vol. 163, p. i. p. 629 (non p. 538), pl. 49–50, fig. 1–9a;" 3. "Thaumatos Lovinii," n. s., Fig. 1–14, in which "the two first pectoral segments are free, not coalesced," and "on the under-side of the head there is no shorter row of spines as in Th. Neptunus and Th. pellucida;" the single known specimen, in "length, 105 mm., was taken in the Indian Ocean; 4. Thaumatos longipes, n. s., Fig. 15–23, in which also "the two first pectoral segments are free, not coalesced;" the
single specimen, in "length, 57 mm., was taken off the west coast of Australia;" "through the long and coarsely denticulated legs this species," Bovallius says, "is easily distinguished from the others." Detailed descriptions are given of all the four species.

Of the species described by J. C. Fabricius in 1775, under the name *Oniscus spinosus*, mention is not made.

1886. Bovallius, Carl.

Amphipoda Synopidea. With 3 Plates. (Presented to the Royal Society of Sciences of Upsala the 10th May 1886.) Upsala, 1886.

Bovallius here divides the Amphipoda into five tribes, distinguished as I. Tanaidea; II. Gammaridea; III. Synopidea; IV. Hyperiidea; V. Caprellidea. In the diagnosis the distinction between the Amphipoda Gammaridea, and the Amphipoda Synopidea, is made to depend upon the eyes and the maxillipeds; in the former the eyes are described as "oculi mediocres, sessiles," in the latter as "oculi grandis, maximam partem capitis occupantes, sessiles;" but when we compare the size of the eyes in such a species as that which has been named *Calliopus grandoculis*, with the size of the eyes in the various species assigned to *Synopia*, this distinction seems untenable; the maxillipeds of the Gammaridea are said to be "non coaliti, palpum quattuor-articulatum gerentes," while those of the Synopidea are described as "plus minusve coaliti, palpum quattuor-articulatum gerentes," but surely in both tribes the maxillipeds are coalesced at the base, and in the Gammaridea the fourth joint of the palp is occasionally wanting, as in *Normania*, Böeck, and occasionally both the third and fourth joints are absent, as in *Lafyptius*, Kröyer. The further character assigned to the Gammaridea, "urus mediocre, triarticulatum," is not universally applicable, since in the family Dalichidae, Dana, the uropod-bearing portion (urus) of the pleon has only two joints; and lastly, the character "telson supissime fissum," seems out of place when in so many genera the telson is not cleft.

His tribe Synopidea Bovallius divides into three families; 1. Synopidea; 2. Trischizostominatide; 3. Hyperiopside. He admits that the Synopidea "resemble the true Gammarids in more points than those of the two following families do." In the diagnosis of this family, he says that "the eyes occupy the upper median part of the head, and are distinctly faceted." To the genus *Synopia*, Dana, he assigns six species, of which he gives descriptions, and, of all but the last, figures; all the species, he says, "are closely allied and seem rather to deserve the name of varieties than of species," but, "as their differences seem to be constant," he keeps them distinct under the following names; 1. *Synopia ultramarina*, Dana; 2. *Synopia carabidens*, n. s.; 3. *Synopia angulifrons*, Dana; 4. *Synopia Schollei*, n. s.; 5. *Synopia gracilis*, Dana; 6. *Synopia orientalis*, Kossmann. Of these *Synopia Schollei*, had long ago been figured for this Report, having been taken by the Challenger at the surface in the Pacific and elsewhere. One or two minute differences between the description by Bovallius and my own are noticed in the account of the species.

To the family Trischizostomatide, Sars, the genus *Trischizostoma*, Böeck, is assigned without companions, and with the single species *Trischizostoma raschi*, Böeck. New descriptions and figures are given of the adult female and young male. For my opinion on the proper name for this genus, see Note on A. Costa, 1853.

The third family Hyperiopside has the single genus *Hyperiopsis*, Sars, and the one species "Hyperiopsis Voertiauëi, Sars," the figures and details being borrowed from G. O. Sars' recent work on the Crustacea of the Norwegian North Atlantic Expedition 1870–1878.
REPORT ON THE AMPHIPODA.

1886. Forstrand, Carl.

Det arktiska hafsområdets djurgeografiska begränsning med ledning af skal-kräftornas (crustacea malacostraca) utbredning. Upsala, 1886. 55 pages and map.

It is mentioned in a note, p. 4, that L. K. Schumardt, in Die geographische Verbreitung der Thiere, Wien, 1853, calls the Arctic maritime region "Reich der Meersungeheire und Amphipoden." The circumpolar realm is thus divided, starting eastward from Behring Strait; 1. Americana iskaf, from Behring Strait to Smith Sound and Baffin Bay; 2. Vestgrönlandiska hafet, the tract of sea between the American Archipelago and mainland and Greenland; 3. Europeiska Nordhafet, between East Greenland, West Finnmarken and Spitzbergen; 4. Barentz haf, between East Spitzbergen, Franz Joseph Land, Nova Zembla, Northern Russia and East Finnmarken; 5. Karikiis hafet, from the east coast of Nova Zembla to Cape Chelyuskin; 6. Siberiens iskaf, from Cape Chelyuskin to Behring Strait; 7. Beaufort's haf, the sea immediately north of Behring Strait and south of it to the Aleutian Islands and Sea of Ochotok.

Referring to the Royal Society Manual of the Natural History, etc. of Greenland, London, 1873, containing the "Crustacea of Greenland by Chr. Lütken," he says that the West Greenland Sea has eighty species of Amphipoda, of which the following are not yet known from other seas, "Igina longicornis Kr., Cercops Holboelli Kr., Cephalopodes tricuspid (Kr.), Cyprinus monodon L. var. mystici L. var. odosus L., Cyprinocaris annus L., Monocathodes affinis (Braun) och Parathemisto compost (Goës)." At page 36 he remarks that many species, especially pelagic and surface-living animals, such as Themisto, Hyperia, and many Copepoda, may be subject to a passive distribution, due to marine currents. He finishes by giving a list of 304 Crustacea, of which those numbered 133 to 304 are Amphipoda, showing their distribution in the regions above-mentioned, of which he subdivides the third into "O. Grönland, Ishafsdjupet, Spetsbergen." He adds for comparison two other regions, Great Britain and the Baltic. To the list of species an addendum gives "Lanceola Chausi I. Bovall," from West Greenland. Hock's new species, 1882, are not included in the list.

1886. Fowler, George Herbert, born September 4, 1861 (G. H. F.).

Forty-five species of Amphipoda are enumerated, with here and there a synonym and occasional notes by Mr. Fowler and Mr. A. O. Walker. "Bathyporeia pelagica, var. roberstoni, Sp. Fals," is separated from Bathyporeia pilosa, Lindström, by an accidental misapprehension. On Dexamine spinosa, Leach, the remark is made that "two very small specimens lack the characteristic tooth on the first antenna, = D. leucocermis?; on Gammarus locusta, Linn., "a black form is common; the red spots on the abdominal segments are not always present;" on Gammarus marinus, Leach, "some specimens dredged from Welshman's Gut are apparently a variety between G. locusta and G. marinus, having the first two abdominal segments rounded off, but still not agreeing with G. campylurus in the form of the last pair (Zool. Chall. Exp.—Part LXVII.—1887.) \textsuperscript{XXX 73}
of feet." Podocerus falcatus, Montagn, Podocerus pelagicus, Leach, and Podocerus pulchellus, Leach, are given as three species, but with the statement that "the last two species may be varieties of P. falcatus. Figure 1 on Plate IV. is an outline of "Protella phasna, Dana (young)," of which Mr. Fowler observes that "none of the characteristic spines on the back are developed except that on the head; and the palm of the second cheliped is much simpler than that of the adult, exhibiting only one, not very strong, tooth."

1886. Fowler, G. Herbert.

The Zoological Record for 1885; being Volume the twenty-second of the Record of zoological literature. London, m.dccc.lxxxvi. Crustacea by G. Herbert Fowler, B.A., Ph.D. 29 pages.

1886. Gerstaecker, A.

In this part is finished the discussion of the variety of colouring found among the Amphipoda, and mention made of the correspondence in some species between the colour of the animal and its surroundings. A section, number 3, follows on habitat, in which the remark is made that hitherto only a single species, Orchestia cavimana, Holter, has been proved (by Graeffe's experiments) to have entirely given up the water and become an air-breather like the terrestrial Isopods. It is further said that of the Gammarid group hitherto only a single species, Pherusa fucicola, Leach, has been observed as an inhabitant of the wrack thrown up by the sea. But surely the common Gammaris, locusta and marinus, are much more frequently found in such circumstances than Pherusa fucicola, which along with many other species, haunts the woods between tide marks. Section 4 describes some of the contrivances by which Amphipoda provide themselves with dwellings, giving an account, among other matters, of the investigation by which P. Mayer discovered that Phronima sedentaria makes use of other animals for a residence besides Pygospio. In Section 5, on the means of boring, it is suggested that the large lower antennae of Chelura teredora may be of use in removing the gnawed-off particles of wood from the passages. Section 6 is on the period of appearance of some of the Amphipoda. Section 7, on motion, describes Gerstaecker's own observations on Gammarus pales. This, he says, swims never on its side except when the shallowness of the water compels it, but otherwise almost always with the back uppermost, only occasionally and for a short time back downwards. It always swims straight forward, with the last three pairs of pereopods turned upwards, the first two pairs by their movements assisting the pleopods, the gnathopods held perfectly quiet, the antennae for the most part kept in motion. In reference to "Talitrus saltator," Gerstaecker makes the suggestion that the second gnathopod may be employed in digging the hole in the sand for the creature to bury itself, though the small size and fineness of the integument of the hand of this limb are recognised as out of harmony with the suggestion. The first gnathopod would seem to be a more efficient instrument for the purpose in question. Gerstaecker suspects that the swimming movements of "Lepidactylis (Sculcator) arenaria" must be especially
peculiar. In fact they very much agree with those of the thin and delicate *Niphargus aquilon.* Both species are to all appearance unwilling swimmers, struggling often in a more or less upright position, then swimming back downwards, and soon sinking to the bottom. Section 8, on nourishment, gives reasons for the opinion that the Amphipoda principally if not exclusively feed on animal substances, whether dead or living. Section 9, on commensalism and parasitism, distinguishes the species which have been noticed as respectively inhabitants of Sponges, of Hydrozoa, of Echinoderms, of Tunicata, of Mollusca, of Crustacea, of Fishes, of Reptilia, of Cetacea; those on Reptilia probably belonging rather to the surface growth of sea-weeds than to the animals on which the sea-weed happens to grow. Section 10 discusses the good and harm which the Amphipoda are supposed to do, the good consisting in their constituting the food of various animals of more directly obvious importance, the harm inculpating only two species, *Chatura terebrans,* which bores into submarine timber, and *Gammarus locusta,* which is supposed to destroy fishing-nets. Section 11, on parasites, mentions as internal parasites *Echinorhynchus polycentrus,* Breus, *Echinorhynchus proteus,* Westr., *Distomum sp.,* *Gregaria longissima,* Sieb., *Zygopeltis putana,* Laehmann, *Gregaria clausi,* Frenzel, *Calyxthelamys phronia,* Frenzel, *Gregaria nicae,* Frenzel, *Gregaria caprella,* Frenzel, and as external parasites "Epistyli Steini,* Wress., and *Carchesium sp.,* on *Gammarus pulex; Podobrya cybotermus,* Clap., and *Dendrocomaetes paradoxus,* Stein, on *Gammarus pulex; Voginaea crystallina,* on *Gammarus marinus; Vorticella sp. on Darreina compressa* and on *Lepidactylis arenaria; Carchesium sp. and Podobrya crustascorum* on *Coprella equilis.*"

Chapter V. is on classification, and begins by describing successively the systems of Milne-Edwards, Dana, Spence Bate (1857 and 1862), Lillieberg, Boeck, Nebelski and (for the *Hyperina*) Clap., but without recognising the important service rendered by Axel Boeck in laying stress upon the mouth-organs in addition to other important parts of the structure. An interesting discussion follows bearing largely upon the Tanaides, which it seems to be a point of honour with Gerstaecker to include under the Amphipoda. The order Amphipoda itself, as distinguished from the Isopoda, he characterizes "als annähernd homonom segmentirte Malacostraca mit in der Regel selbstständigem, seltener (Laemolipoda, Tanaides) mit dem ersten Mittelleibring verschmolzenem Kopftheil, zwei über einander eingelenkten Fühlerpaaren, nicht facettirtem Augen-Integument, im Mittelteil gelegenen Herzenschlauch und lediglich der Ortsbewegung (nicht der Athmung) dienenden Hinterleibsbeinen."

He makes three suborders, thus defined:—

A conspectus follows, which is not completed in this part, giving definitions of the divisions, tribes, families and most of the genera which Gerstaecker accepts. Division I. *Hyperina,* is
subdivided into two tribes, of which the first “Hyperina anomala, M.-Edw. (Platycheiria Claus),” follows Claus’ arrangement of 1879, adding, however, Phoroco, M.-Edw., as a fourth genus in Fam. 3. Pronotidae, Claus, whereas Claus, who omitted it in 1879, places it, in 1887, in the family Lysidae. Tribus II. Hyperina normalis, M.-Edw., is divided into three families. Fam. 1. Phoronimidae, Dana, is divided into two groups, Phoroniina and Phorominina (see Note on Claus, 1879), with the suggestion that Tryphosa, Boeck, should be included in the family Phoronimidae, the fact escaping notice that this genus had been identified by Sars with Lycosa, Dana, a genus belonging to the preceding tribe. Fam. 2. Hyperididae, Dana, receives the following genera, 1. “Thermia Guér. (Parathermia Boeck),” 2. “Clytopus Dana,” 3. “Clytoma Guér. (Thaumops Willemoes),” 4. “Tyro M.-Edw.,” 5. “Hyperia, Lutr. (Hiella Straus, mas: Lestrigonus M.-Edw., fem: Metoecus Kroyer, Tourin Dana),” 6. “Daira M.-Edw. (Dairia Dana),” 7. “Mimonectes Boeck,” with the concluding remark “hierher ferner: Gatt. Lanceola Say.” Clytoma should be written Cystosoma, and Lestrigonus is commonly regarded as the male of Hyperia. Fam. 3. Vibiliae, Dana (Hyperina Guimarariae M.-Edw.), contains only the genus Vibilia, M.-Edw.

Division II. Gammarina, begins with “Tribus I. Corophiina (Marchena M.-Edw.).” This has five families, thus arranged:—

Fam. 1. Cheluridae, Ailm. Genus Chelura, Phil. (Nemertes, White, Linnorn, Hesse).

Fam. 5. Clydonine, Dana. Genus Clydonia, Dana.

Tribus II. Gammarina genuina (Sauter, M.-Edw.); begins with Fam. 6. Gammaridae. (The branchial vesicles in subfamilies 1–5 normally developed.)

The above classification suggests the following comments:

The definition of Fam. 2. Dulichidae, Dana, includes the statements, “Das vierte und fiente Hinterleibsegment mit einander verschmolzen; von den drei hinteren griffelförmigen Spaltbeimparen eines fehelen.” But in Phatophium, Dana, here given as a synonym of Coryphkins, Dana, the fourth and fifth pleon-segments are not coalesced, and there are third uropods, though small and without rami.

In Fam. 3. Corophiidae, Dana, Cerapus, Say, is identified with Erichthornites, M.-Edw., from which S. I. Smith has shown it to be an acid, and is included in the group which have pairs of rami on the first and second uropods, whereas the second uropods in Cerapus have single rami. Dercothoe, Dana, is probably the female of Erichthornites, certainly not the female of Cerapus, Say. Holoc, Bocck, being preoccupied, has been changed into Neohela.
In the second group of the Corophiidae, Elasmopus, Costa, is given as a synonym of Podocerus, Leach, but afterwards in the fifth subfamily of the Gammaridae as a synonym of Mero, Leach, to which it comes in fact much nearer. It is not easy to see why Microdendrops, Costa, and Autonoe, Braz., should become synonyms of Aera, Kroyer, while Stimpsonia, Sp. Bate, is retained as an independent genus. Gratippus, Sp. Bate, is of later date than Collonastix, Grube. The preoccupied name Anisopus, Templet., should rather be assigned as a synonym to Swanamphitoe, Sp. Bate, than to Amphitoe, Leach. The same may be said of Pleonexes, Sp. Bate, since its type species, Pleonexes gammaroides, is almost undoubtedly a Swanamphitoe. Leptocheirus, Zaddach, should not be made a synonym of Protomedeia, Kroyer; Boeck even put the two genera in different subfamilies.

In Fam. 4. Ilcinus, Dana, it should not be given as a generic character of Ilcina that the second uropods are longer than the third; they are not so represented by Dana in the type species. If Ilcina, Grube, is the same as Percionotus, Bate and Westwood, as most probably is the case, the latter name has priority. In the definition of the family, the expression "die beiden vorderen Reinsporen von den folgenden nicht formell abweichend" is inaccurate, since, at least in Ilcina, the gnathopods have the third joint under-riding the wrist.

In Fam. 5. Clydenina, Dana, Clydonia, Dana, has recently been identified by Bovallius with Tyg, M.-Edw.

In Fam. 6. Gammaridae, Subfam. 1. Lysianassina (et Stegocephalina), Dana, an attempt, with which most students will sympathise, is heroically made to reduce the number of genera, by grouping several that Boeck has established, under earlier names and comprehensive definitions. But it seems hardly just to set aside without argument results at which Boeck arrived by patient and laborious investigation. Moreover, rejected genera are very apt to make their reappearance, when fresh research and the discovery of new species makes the want of them felt, and then the earlier rejection has only the effect of complicating the synonymy. Many of Leach’s genera were at one time thought superfluous, but are now firmly established. On the other hand, comprehensive definitions such as that of Paramphitoe by Boeckius, are apt to introduce a confusion which it almost needs a General Council to disentangle. The preoccupied Opis, Kroyer, has been altered by Boeck into Opica; the definition here given does not suit Normania, Boeck, which is made synonymous with it. Eglia, Costa, here given among the Lysianassina, is no doubt synonymous with Urothoe, Dana, given later on among the Phoxina, Sp. Bate. Glyceria, Haswell, being preoccupied, has been altered to Glyceria.

In the second group of this subfamily, Andania, Boeck, is made a synonym of Stegocephalus, Kroyer, but I venture to think that a comparison of the mandibles shows such a combination to be impossible; on what grounds Priscilla and Arpesia, Boeck, are made synonyms of Pontoporeia, Kroyer, I can still less understand, since the type species of these three genera are strikingly different in outward form.

In Subfam. 2. Phoxina, Sp. Bate, the definition begins with the words, “Kopf niedrig, schnabelförmig ausgezogen, den Ursprung der oberen Fühler kappenförmig überlappend.” But the first genus assigned to the subfamily is Lepidactylis, in which there is no such hook-like prolongation of the head, the small acute rostrum being between the antennae. A similar remark will apply to Urothoe, of which indeed Gerstacker himself says, “Kopf nur kurz schnabelförmig ausgezogen,” as well as to Cheirocratus, Norman, which is here given as a synonym of Liljaborgia [rather Liljeborgia] Sp. Bate, although in fact it cannot in classification be placed even beside it, if any attention be paid to the mouth-organs. Acanthonotus, Owen, being preoccupied, has been altered by Boeck into Acanthonomatia.

In Subfam. 5. Gammarina, Cressa, Boeck, which is given as a synonym of genus 37, Stenothoe, Dana, has been identified by G. O. Sars with Danaita, Sp. Bate. Metopa, Boeck, a genus in which there is a mandibular palp, is also given as a synonym of Stenothoe, in which the
mandible has no palp. The genus Calliopeus, Stebbing, is a synonym of Amphilochus, Sp. Bate. Calliope, Leach, being preoccupied, must yield to Calliopeus, Liljeborg. Of the genera Mucronia and Polychara, Haswell, named as genera related to Isaac, M.-Edw., the former is a synonym of Weyllea (see Notes on Haswell, 1889), the latter is synonymous with Tribunca, Boeck. Cerothoe, Costa, in which the third uropods have both rami elongate, is here given as a synonym of Melitta, Leach, although in regard to the third uropods of that genus it is rightly said, "ihre Innemannelle stark verkürzt." Goplana, Wrzesien, is made a synonym of Gammarus, without notice of the curious coalescence of segments which distinguishes the former genus from the latter. Anathilla, Rathke, being preoccupied, must give place to Anathilla, Sp. Bate, and not vice versa.

1886. Giesbrecht, W.

In an "aperçu de la faune actuelle de l’estuaire," the Crustacea are said to number about sixty-five species, and "parmi les plus intéressantes" are included six species of Amphipods, none of them new. Two other species are named in the following observation, "deux espèces très affines, les Gammarus locusta, L. et Gam. pulcher, L. = Gam. fluviatilis, H. Milne-Edwards, sont très abondantes dans la Seine et à son embouchure. La première de ces deux espèces, le Gammarus locusta, se tient constamment dans l’eau salée, tandis que le Gammarus pulcher, très difficile à distinguer du précédent, vit à la fois, d’après mes observations, dans les eaux salées, saumâtres et douces."

1886. Koehler, R.

This is practically the same paper as that already noticed in the Note on Koehler, 1885, p. 566. For "Erystheus ebrighthalanus Sp. B.," "Erystheus erythropthalmus Sp. B." is here read, so that Erystheus erythropthalmus is clearly intended. Some other obvious corrections of nomenclature are requisite in the lists given.

1886. Koelbel, Carl.

Out of thirty-four species of Crustacea in the collection, seventeen were Amphipods, among which the following were conspicuous for the very large number of specimens met with:—
THE VOYAGE OF H.M.S. CHALLENGER.

"Amphithulla Sabineii" the largest example measured, without the antenna, 37 mm. "The
young, 6 mm. long, show considerable differences from the adult, especially in regard to
the antenna, telson and uropods. The antennae are still short and comparatively thick;
the flagellum of the upper antennae with only 6 or 7 joints, of the lower with 8 or 9; the
accessory flagellum with 2. The telson is shorter than the preceding segment; the two
rami of the last uropods are strikingly unequal, the inner scarcely more than a third the
length of the outer. On the other hand, there is already a clear indication of the dentate
dorsal carina; and on the first three pleon-segments the edges could be already perceived
running obliquely downwards to the hinder angle. In the two latter points, therefore,
compared with the young form described and figured by Buchholz [1874], notwithstanding the
nearly equal size of the specimens examined, there was here an advance in development."

On "Acanthone cuspidata" (Lepechin), Koelbel says, "For this curious species with its rows
and rows of spines, Hoek's criticism on the figure published by Buchholz (Die zweite
deutsche Nordpolfahrt, 1874, 2, B, Taf. XL), as well in regard to the equipment of the
first joint of the peduncle of the upper antennae as also in regard to the form of the first
joint in the three hinder pereopods and to the origin of the first medio-dorsal spine, are
confirmed by two very large and well-preserved specimens, which were taken at a depth
of 140 Metres. The first median dorsal spine arises from the front rim of the first
pereon-segment, and, running almost parallel with the longitudinal axis of the body, lies
with a gently undulating curve over the head, extending beyond it with the second half of
its length. Also I see the hinder end of the telson with a very shallow emargination, by
no means with an acute-angled slit, as figured by Buchholz." The possibility, however,
should be borne in mind, that Buchholz may have had another species or a variety under
examination.

1886. Norman, A. M.

Museum Normanianum, or a Catalogue of the Invertebrata of Europe, and the
Arctic and North Atlantic Oceans, which are contained in the collection of the

Four tables give the numbers of Crustacea under the following heads: "I. Total Crustacea
described from the World in Milne-Edwards' Histoire des Crustacés," including Amphipoda
130, "II. Species in Milne-Edwards from the Area of this Catalogue," Amphipoda 95,
"III. Species now described from the Area of this Catalogue," Amphipoda 663, "IV.
Species in the collection of A. M. N.," Amphipoda 272. A preliminary remark is made
that "while, on the one hand, it is certain that very many of the forms in Column III.
will hereafter prove spurious or synonymous with others; on the other hand, we know
little of the Amphipoda of the Western Atlantic, and nothing of the Ostracoda free living
Copepoda and other smaller Crustacea of that district, and very little of those of some
other parts of the area." The total number of species in Column III. is 3209, and Mr.
Norman remarks that "the Crustacea is the class which undoubtedly embraces more forms
than any other outside the Insecta." The species of Amphipoda referred to in Table IV.
are named on pages 13–18, and numbered from 528 to 799; though this is only a list of names, with synonyms occasionally given, it has its value for the student as showing the names preferred by an accomplished carcinologist.

1886. PERRIER, EDMOND.

On pages 194, 195, a brief popular account is given of the Amphipoda. In "Fig. 103.—Caprella,—Grossie deux fois," the two antennae are represented of equal length. It is stated that "l'Eurytenea magnellanica, proche parent de la Crevette des ruisseaux, atteint sur les côtes de la Terre de Feu plus de quatre centimètres de long." But Milne-Edwards, see Note, 1848, p. 223, gives this Amphipod a length of nine centimetres by a depth of three.

On pages 288, 289, in illustration of "formes antiques [arctiques] d'Amphipodes dans les grands fonds," the figures of "Encaus cepidatus, Kroyer," and "Caprella spinosissima, Norman," from Wyville-Thomson's Depths of the Sea are reproduced. The rarity of deep-sea Amphipods is discussed, and in connection with the "Talisman" expedition, the remark is made that "une seule fois, sur les côtes du Soudan, le chalut est revenu de 655 mètres avec un filet presque entièrement couvert de Caprelles."

The contents of the concluding chapter embrace the following headings:—"La population de la mer s'appauvrit à mesure que la profondeur augmente.—Distinction entre la zone paléozoïque et la zone abyssale.—Hypothèse de Louis Agassiz.—Prétendue origine polaire de la faune des grands fonds.—Théorie de Fuchs: la faune de la lumière et la faune de l'obscurité.—Arguments en faveur de l'origine litorale de la faune profonde.—Tous les rivages ont pris part à sa formation."

1886. POUCHET, G., et GUERNE, J. de.

In the stomach of Thalassochelys caretta, Linné, were found among other animals "plusieurs Crustacés amphipodes (Hyperia medusarum), absorbés sans doute avec la Méduse dont ils étaient parasites."

1886. ROBERTSON, DAVID, born 1806 (D. R.).

Experiments made with Talitrus locustus appear to show that with this species "a few hours close confinement in fresh water is destructive to life." In sea-water they lived for days, and when kept for many days without food they never attacked one another. Eighteen enclosed in a thin muslin bag made no attempt to perforate. Mr. Robertson therefore questions the statements of Mr. Swain quoted by Bate and Westwood, i. p. 21, as to the Talitri lying piled together in cartloads, yet hopping and leaping about, devouring each other as if for very wantonness, and reducing a lady's handkerchief to a piece of open-work, apparently before it could be rescued from them.

Preliminary descriptions are given of *Bathyrella balliheraeus*, n. s., from Singapore, and of *Talitrus tumida*, n. s., and *Pharion carvalus*, n. s., the two latter so named by Mr. G. M. Thomson, who discovered them in New Zealand. The suggestion that Mr. Thomson’s "Pharion?" should be referred to the genus *Amphithoe*, Bosc, is withdrawn in the full report on the species, 1887.

1886. Thomson and Chilton.

To *Tribe I. Lémomolopoda*, four species are assigned, of which the fourth is given as:

"Hab. Parasitic on whales (Virgula breviceps), C. C. It appears to be common on various whales (and sharks). I have it from several localities in the New Zealand seas, G. M. T. On small hump-backed whale, Napier, A. Hamilton."

*Tribe II. Crebiterina*. has sixty-five species divided between three families:—

**Fam. I. Corophiidae**, begins with species 5–17, beginning with *Corophium contractum*, Stimpson, and ending with *Iphigenia typica*, Thomson. A note on "Corophium crus(ecocaerum, Bruzelius," says, "This species is taken along with *C. contractum*, and it is probable that they are only male and female of the same species. C. Rouselli (Milne-Edwards) is probably the same as *C. contractum*.—C. C."

**Fam. II. Orchestidiidae**, begins with species 18, *Nicca neozelanicus*, and ends with species 32, *Teilurus breviceps*, M.-Edw. "Following Professor von Martens' suggestion," the authors say, "the specific name *nicca neozelanicus* has been adopted in place of all the various forms of the word meaning 'of' or 'from New Zealand.'" Accordingly they change *Allorchestes neozelanicus*, Dana, into *Allochrestes neozelanicus*, and *Nicca neozelanicus*, Thomson, into *Nicca neozelanicus*. But these changes in my opinion are neither lawful nor expedient.

"61–63. *Lysianassa sp.*

"The above identification is extremely doubtful; the species referred to it has been found at Dunedin Harbour and Stewart Island, G. M. T. I have at least three species of the genus from Lyttelton and elsewhere, none of them referable to *L. krügeri* without considerable doubt, C. C. [Descriptions of these are not published pending the publication of the *Challenger* report on the Amphipoda.]"
REPORT ON THE AMPHIPODA.

"[In the 'Zool. Coll. of H.M.S. Alert,' p. 312, Mr. Miers refers to this genus and species as Ephippiphora krygeri (White), the original designation. Meanwhile the limits of the genus and the characters of the species require complete revision]." Compare Note on Miers, 1884. To Tribe III. Hyperiina, two families are assigned, embracing between them five species.

**Fam. I. Phronimidae.** Contains *Phronima nova-zealandica*, altered from *Phronima nova-zealandia*, Powell, and *Thomisio antarctica*, Dana, for which see Note on Thomson, 1879.

**Fam. II. Platyscelidae.** Contains the species *Platyscelus intermedius*, Thomson, *Oxycephalus olivaris*, Thomson, and *Phreatoicus typicus*, Chilton, with the following remarks upon the last:—"The systematic position of this singular crustacean is doubtful. In general appearance, I was inclined to place it among the Amphipoda, but from the fact of the first five pairs of pleopoda acting as branchial organs, and from the absence of any such organs attached to the pericranial, Mr. Chilton places it among the Isopoda.—G.M.T." The list continues with "Suborder II.—Isopoda. Tribe I. Anisopoda. Fam. I. Tanaidae," and probably the affinities of *Phreatoicus* will eventually prove to be rather with the Tanaidae than with the Hyperiina. I do not know what are the special reasons for classing it among the Platyscelidae.

Note sur quelques points de la morphologie des Orchesties suivie d'une liste succincte des amphipodes du Bouloinais. Lille, 1887. 20 pages, with plate.

The various forms assumed by the second gnathopods of *Orchestia deshayesi*, Andouin, are described and figured. The lower antennae in this species have calcareous, whereas in "Orchestia littorea Montagu," Blanc's observation that they are not to be found is confirmed. *Orchestia brevipedata*, Late and Westwood, is shown to be in all probability only a young, though somewhat abnormal, form of *Orchestia littorea*. The list of species includes three Orchestidae, eleven Gammaridae, nine Corophiidae, two Hyperidae, four "Lamodi-podes," but it is recognised that several of the names given are probably synonyms.

1887. Bovallius, C.

For the group Bovallius gives the following diagnosis:—

"Head free, not coalesced with the first pericranial segment.

"Eyes mostly large, often occupying the whole surface of the head.

"First pair of antennae without secondary flagellum.

"Maxillipeds coalesced into a kind of operculum, without palps.

"Uropoda more or less laminar, forming natatory organs.

"Telson undivided."

The expression "more or less laminar" applied to the uropoda will only be accurate if understood to include some forms that are narrowly elongate and some that are prismatic. The group is divided into sixteen families, thus:—

**Fam. I. Tyronidae.**

Fam. 2. Lanceolide.

Fam. 3. Vibilide, Claus, 1872.

Fam. 4. Cyllopiide.
Gen. 1. *Cyllops*, Dana, 1852, with six species, of which the first is *Cyllops magellanicus*, Dana, 1852, the second "Cyllops Batei," a new name for the *Cyllops magellanicus*, so called by Spence-Bate. *Cyllops armatus*, n. s., and *Cyllops levis*, n. s., are described. The genus *Cyllops* is followed by "1. Gen. 2. Cyllops, n. g. Type: Hyperia tricuspidata, Streets," thus defined:—

"Head large, irregularly quadrangular from a lateral view. Flagellum of first pair of antennae ovate, acute at the apex. Carpus of first pair of pereiopods dilated, twice as broad as metacarps. Carpus of second pair narrow, not produced into a process; metacarps slightly produced into a pointed process on either side of the dactylius. Dactylus of seventh pair!"

The single species is "C. tricuspidata, H. Streets, 1877."

Fam. 5. Paraphrinide.

"Fam. 6. Thaumatoide, C. Bovallius, 1886."

Fam. 7. Mimonectide, C. Bovallius, 1885.

Fam. 8. Hyperide, Dana, 1852.

Gen. 2. *Idolopis*, n. g., is thus defined:—

Gen. 3. *Hyperocche*, n. g., is thus defined:—

Gen. 5. *Hyperella*, n. g., is thus defined:—

Gen. 8. *Themistella*, n. g., is thus defined:—

“Body smooth. Head medio, deeper than long. First three joints of flagellum of first pair of antennae provided with olfactory processes. The second pair like that in *Hyperia.* First two pairs of pereiopods subcheliform, with narrow, gauge-shaped carpal processes. Carpi of third and fourth pairs not dilated. Fifth pair are the longest, the following decreasing in length. Metacarpi of last three pairs somewhat elongated. Epimerals not distinct. Uropods long and narrow. Telson medio.” This genus receives the single species, “*Th. Steenstrupi*, n. sp.”

Fam. 9. *Phorominidae*, Dana, 1852, is divided into two subfamilies.

“Subfamily 1. *Dairellinae*. *Diacius*. Head almost round. All the pereiopods are simple, walking legs. Epimerals marked but not articulated.”

“Gen. 1. *Dairella*, n. g.,” is thus defined:—

“Subfamily 2. *Phoromininae*. *Diacius*. Head conical. Fifth pair of pereiopods are transformed into a strong prehensile organ. Epimerals coalesced with the pereiopods segments.”

Family 10. *Anchyliomeridae*.

Fam. 11. “*Phoromina*, Spence Bate, 1860 [1862].”

Chaus, 1879, receives the species "1. L. themistoides, Claus, 1879;" "2. L. Lindbergi, n. sp."

Fam. 12. "Tryphanidae, A. Boeck, 1870."

"Gen. 1. Tryphon, A. Boeck, 1870," receives the species "1. T. Malai, A. Boeck, 1870;" "2. T. Nordestriobi, n. sp." It will be noticed that Boeck's family Tryphanidae and genus Tryphon are here altered in spelling evidently on philological grounds, an improvement which in my opinion is both malaflow and inconvenient, as multiplying synonyms and making the authority for the names uncertain. Sars' identification of Boeck's Tryphon with Lycxa, Dana, is tacitly rejected. Gen. 2. "Thamysis, Spence Bate, 1860," receives six species, "1. Th. tapaz, Claus, 1879;" "2. Th. globiceps, Claus, 1879;" "3. Th. cruciulum, Spence Bate, 1860;" "4. Th. antipodes, Spence Bate, 1860;" "5. Th. insquipes, Dana, 1852;" "6. Th. elegans, n. sp." But the position of Dana's Dairilia insquipes in this genus seems to warrant the transfer of all the six species to Dairilia, Dana, 1852, with the species insquipes for the type. In Dana's work, under Daira, M.-Edw., for which Dana further substituted Dairilia, the first species given is Daira insquipes, the second is Daira depressa, the third Daira insquipes. As apparently none of these belong to Milne-Edwards' genus, it is reasonable to take the species unmarked by a note of interrogation as the type of Dana's own genus.

"Gen. 3. Thamnus, n. g., is thus defined:—

"Head small, depressed. Body broad, depressed. First two pairs of pereiopoda similar to those in Thamysis. Femora of fifth and sixth pair small. Seventh pair perfectly developed, with claw-formed dactylus. Telson distinctly articulating with last urosomal segment." This has the species "1. Th. rostratus, n. sp.;" "2. Th. delibis, Dana, 1852," the reference being to Daira insquipes, Dana. Of Dana's Daira insquipes, Bovallius does not seem to take account. Gen. 4. Lycxa, Dana, 1852, has the following seven species, "1. L. ochracea, Dana, 1852;" "2. L. pulex, Marion, 1875;" "3. L. similis, Claus, 1879;" "4. L. robusta, Claus, 1879;" "5. L. nasuta, Claus, 1879;" "6. L. serrata, Claus, 1879;" "7. L. Stebbingi, n. sp." It is not explained why the Lycxa pulex of Marion and the Lycxa robusta of Claus are upheld as distinct species. Gen. 5. Paralycsea, Claus, 1879, has the species "1. P. gracilis, Claus, 1879;" "2. P. Neveoliana, n. sp.," definitions being given of both. Gen. 6. [5]. Porolycsea, Claus, 1879, has one species, "P. pachyopoda, Claus, 1879." Gen. 7. Simorhynchus, Claus, 1871, has the species, "1. S. antennaria, Claus, 1871;" "2. S. Lilljeborgi, n. sp."

Fam. 13. Oxycepheulidae, Spence Bate, 1862.

Gen. 1. Glossoccpheus, n. g., is thus defined:—"Head anteriorly produced into a thick, rounded, tongue-shaped rostrum. Tibia, carpus, and metacarpus of fifth pair of pereiopoda very dilated, not tumid. Uropoda short and broad." This receives the species, "1. G. Milne-Edwardsi, n. sp.;" "2. G. spiniger, n. sp."

Gen. 3. Leptocelis, Streets, 1877, has the species, "1. L. Lindströmi, n. sp.;" "2. L. tetramerostris, Claus, 1871."

Gen. 4. Talibera, n. g., is thus defined:—"Head anteriorly produced into a short, sharp, wedge-shaped rostrum. Body thick and broad. First two pairs of pereiopoda strongly chelate. Femora of fifth and sixth pairs broadly dilated. Seventh pair rudimentary. Urna and uropoda short; interior rami not coalesced with the peduncle." This has one species, "T. euspidata, n. sp."
REPORT ON THE AMPHIPODA.

591

Gen. 5. Calamorhynchus, H. Streets, 1878, has the one species, "C. pellucidus, II. Streets, 1878."

"Gen. 6. Rhabdoleutes, n.," a name substituted for Rhabdosoma, preoccupied, is thus defined:—

"Body very elongated, rod-like. Head elongated, with a distinct neck, and a very long, needle-shaped rostrum. Tibiae and carpi are linear, but periodically intumesced in the female. Seventh pair rudimentary. Ovitectrices wanting. Peduncles of uropoda very elongated and narrow. Telson very long, needle-shaped."

The species assigned are "1. Rh. armatus, II. Milne-Edwards, 1840;" "2. Rh. Whitei, Spence Bate, 1862," the definitions given being inconsistent with Claus' view that the latter species is not distinct, but the male of the former. The name Macerocephalus, given to this genus by Spence Bate in 1858, had been used several times before, and therefore, like Rhabdosoma, must yield to Rhabdoleutes.

Fam. 15. Parascelida, Claus, 1879.

Gen. 1. Thyropus, Dana, 1852, is tacitly substituted for the genus Tanyscehis of Claus, and receives three species, "1. Th. diaphanus, Dana, 1852;" "2. Th. sphaeroma, Claus, 1879," [this being Claus' Tanyscehis sphaeroma (Thyropus diaphanus, Dana)]; 3. "Th. atlanticus, n. sp."

Gen. 4. Euryseclida, Claus, 1879, has one species, "E. robustus, Claus, 1879."

Fam. 16. Eutyphida, Dana, 1852."

"Gen. 2. Diathyris, Dana, 1852," which Claus makes a synonym of Eutypus, is here re-established as a separate genus, tacitly superseding Henetyphs, Claus, of which it is made to Include both the species; it receives in all four species, "1. D. fula, Dana, 1852;" "2. D. tenuminus, Claus, 1879;" "3. D. crustatum, Claus, 1879;" "4. D. stellatus, n. sp."

"Gen. 3. Paratyphus, Claus, 1879," has the spelling altered from Paratyphis, Claus. It receives the species "1. P. maculatus, Claus, 1879;" "2. P. Thiri, n. sp."

Gen. 4. Tetrahyphus, Claus, 1879, has three species, "1. T. forcellatus, Claus, 1879;" "2. T. rectangularis, n. sp.;" "3. T. inerte, n. sp."

Gen. 5. Amphithyphus, Claus, 1879; receives four species, the fourth being "A. inermis, n. sp."

The new genera here constituted are nine in number, independently of those re-established or named anew. Short descriptions are given of forty-five new species. The work contains diagnoses of the several families, which it will be more convenient to notice in the descriptive part of this Report.
1887. Bovallius, C.

Arctic and Antarctic Hyperids. With eight Plates. [Ur "Vega-expeditionens vetenskapliga inkttagelser," Bd. IV., Stockholm, 1887.] pp. 545-582.

In the introductory part Bovallius says, "In my opinion the limits of the zoogeographical regions must be taken more generally with regard to truly pelagic animals than regarding the inhabitants of the depths and the shores. Therefore I shall fix the southern limit of the Arctic region at Lat. 60° N., and the northern limit of the Antarctic region at Lat. 50° S. Certainly a part of the Gulf Stream will thus be included within the limits of the Arctic region, but this seems to do but little harm, as is shown by the diagram of the geographical distribution of the species given below." Then tracing the history of the discovery of Arctic and Antarctic Hyperids, he says, "after reducing the various synonyms to the names, which in my opinion are the true ones, we find in the above cited literature altogether 15 species mentioned from the arctic region, viz., Tyro borealis G. O. Sars, Lanceola Lovaci C. Bovallius, Lanceola Clausi C. Bovallius, Hyperia mehshvarum O. F. Müller, Hyperia Latrellii H. Milne-Edwards. Hyperia galba Montagu. Hyperoche Kroeyeri C. Bovallius, Hyperoche abyssorum A. Boeck, Parathemisto oblicta Kroeyer. Parathemisto compressa A. Gies. Parathemisto abyssorum A. Boeck. Euthemisto libellula Mandt. Euthemisto bipinnata A. Boeck. Euthemisto Nordenskiöldi C. Bovallius. Tryphura Malus A. Boeck. From the antarctic region 10 species, viz., Cylopsus magellanicus Dana. Cylopsus Lucasii Spence Bate. Cylopsus Danae, Spence Bate. Thamnora maevocephala Dana. Parathemisto trigona, Dana. Euthemisto Gaudichaucli Guérin. Euthemisto antarctica, Guérin [Dana]. Anchlygemma abbreviata Spence Bate. Anchlygemma antipodes Spence Bate. Thaumastops antipodes Spence Bate." In this paper the number of the Arctic species is raised to twenty-two, and the Antarctic to thirteen.

In the descriptive part, Cylopsus borealis, Sars, 1882, becomes Tyro borealis. Brief descriptions are given of "Tyro Clausi," Pl. 40, figs. 1-3, "Syn. 1885. Tyro Clausi, C. Bovallius;" "Tyro Tullbergii," Pl. 40, figs. 4-10, "Syn. 1885. Tyro Tullbergii, C. Bovallius;" "Lanceola Clausi," Pl. 41, figs. 11-14, "Syn. 1885. Lanceola Clausi, C. Bovallius;" "Lanceola Lovaci, C. Bovallius," 1885; "Lanceola serrata, C. Bovallius, 1885;" "Fibulla Kroeyeri, C. Bovallius," 1887; "Cylopsus magellanicus, Dana. Cylopsus Lucasii, Spence Bate. Cylopsus Danae, Spence Bate, 1862. "Syn. 1862. Cylopsus Lucasci, Spence Bate;" "Cylopsus Danae, Spence Bate, 1862;" "Cylopsus armatus, C. Bovallius, 1887. Pl. 41, fig. 15-25;" "Thaumastops longipes, C. Bovallius, 1886;" on which Bovallius remarks, "One specimen taken just at the southern limit of the Arctic region, at Lat. 59° 38' N.; Long. 5° 24' W. The other known specimen is taken off the westerne shore of the Australian mainland. Indeed a wide distribution for the species," "Minomnetes steenstrupii, Pl. 47, figs. 111-115. "Syn. 1855. Minonnetes steenstrupii, C. Bovallius;" "Hyperia mehshvarum, O. F. Müller, 1776. Pl. 42, fig. 26-33;" "Hyperia Latrellii, H. Milne-Edwards, 1830. Pl. 42, fig. 34-39; Pl. 43, fig. 40-46; Hyperia galba, Montagu, 1813. Pl. 43, fig. 47-54;" "Hyperoche Kroeyeri, C. Bovallius, 1885," which would rather seem to be entitled to the name Hyperia mehshvarum, since Bovallius gives as its earliest synonym "Minonnetes steenstrupii, Kroeyer, 1838; "Hyperoche abyssorum, A. Boeck, 1870. Pl. 44, fig. 55-62," the opinion of Sars, 1882, that this is the same species as the preceding, not being noticed; "Hyperoche Latrellii, C. Bovallius, 1887. Pl. 44, fig. 63-71;" "Hyperiella antarctica, C. Bovallius, 1887. Pl. 45, fig. 72-80;" "Parathemisto abyssorum, A. Boeck, 1870. Pl. 45, fig. 81-89;" "Parathemisto compressa, A. Gies, 1865," transferred from Themisto by Boeck in 1870; "Parathemisto oblicta, Kroeyer, 1838," transferred from Hyperia by Bovallius in 1887; "Parathemisto trigona, Dana, 1852," in like manner transferred by

As far as Bovallius has himself observed, the Arctic and Antarctic Hyperids do not include species of the Paraphronimidae, Phoronimidae, Phoronidae, Oxychelidae, Proneida, Seacladidae, or Typhlidae. From his whole review he draws the conclusions, that:—

"1:o) the genus Euthemiostus (and possibly also Hyperia) is common to both the arctic and the Antarctic regions; as it has only few representatives in the Northern and Southern temperate regions and none in the tropical, its centre of development are most likely to be searched for in both the frigid zones;

"2:o) the genus Lanceola is a true arctic form with only a few emigrants in the Northern temperate region;

"3:o) the genera Hyperia and Paraltemiostus are cosmopolites, probably to be found in all the seas;

"4:o) the genus Cylopus is a true antarctic form with its centre in the American Antarctic Ocean;

"5:o) the genus Hyperiella is a connecting link between Hyperia and Euthemiostus, with same centre as Cylopus;

"6:o) the genus Hyperoche is an arctic form with its centre in the European Arctic Ocean;

"7:o) the genera Vibilia, Thaenatopis, Minomectes and Tryphana are occasional immigrants into the arctic region from the tropical and temperate regions, probably to be found occasionally also in the antarctic region (except Minomectes);

"8:o) the genera Anchyllomera and Thamyrus are occasional immigrants into the antarctic region, not likely to be found in the arctic realm."

The Challenger collection, I may observe, shows the genus Lanceola to have an immensely wider range than that given above. One specimen was obtained, along with a specimen of Phoronias, in lat. 50° 1'S.; another specimen was taken in lat. 8° 37'S. Bovallius himself records Lanceola curticeps from Cape Verde Islands and Lanceola felina from Tristan da Cunha. The genus Hyperiella is represented at the Cape of Good Hope.

For Hyperia mediocrum, O. F. Müller, the following synonymy is given:—Pulex cancriformis antennis brevissimis, H. Ström, 1762; Cancer mediocrum, O. F. Müller, 1776; Gammarus mediocrum [O. F. Müller], J. C. Fabricius, 1779; Pharonia, Latreille, 1818; Talitrus cyanus, Sabine, 1824; "Hyperia Lestricth, Latreille," in Desmaur, 1825, and in Milne-Edwards, 1849; Hyperia spinipes, A. Boeck, 1861 [1860] and 1872; Hyperia crevatus, var., A. Goës, 1866 [1863].

To Hyperia Latreille, M.-Edw., 1830, the synonyms assigned are Lestrigonous crevatus, Kroyer.

To Hyperia galba, Montagu, 1813, the synonyms given are "Hyperia galba, Montagu," 1813, (which should rather be Cancer Gammarus galba); "Lestrigonous crevatus, Kroyer, Spence Bate," 1862; "Hyperia mediocrum [O. Fabricius] Spence Bate," 1862; "Lestrigonous

(Zool. Chall. Exp.—Part LXVII.—1887.)
exulans, [Kroyer], Spence Bate and Westwood,” 1868 [1863]; “Hyperia galba. Montagu. Spence Bate and Westwood,” 1868 [1863].

To “Hyperoche Kroyeri, C. Bovallius,” the synonyms are *Metocerus medusarum* Kroyer, 1838; *Hyperia medusarum* (O. Fabr.). Spence Bate, 1862; *Metocerus medusarum* (O. Fabr.), A. Boeck, 1870; *Tania medusarum* (O. Fabr.), A. Boeck, 1872; “Hyperia Kroyeri, C. Bovallius,” 1885. Thus Bate’s *Hyperia medusarum* is cited for two genera.

1887. Chevreux, Édouard.

Sur les Crustacés amphipodes de la côte ouest de Bretagne. 3 Janvier 1887. Paris. (“Communication faite à l’Academie de Paris, le 3 Janvier 1887.”)

A short account is given of Amphipods obtained on the coast or by dredging “entre la pointe de Penmarch et l’embouchure de la Loire,” an extent of about 100 marine miles. “La baie du Croisic” was specially examined, a locality prolific in forms in proportion to the varied nature of the ground which its waters cover. *Elaeomorpus latipes*, Boeck, was found by M. Chevreux to be a commensal of *Maia equinula*, together with *Ilex montagni*, M.-Edwards. Twenty other species, he says, are found more or less often on this crab. The total number of known species obtained in the region examined amounted to 115, to which are to be added three new forms, briefly described under the names *Ptilocheirus tricristatus*, *Microprotopus longimanus*, *Microdentopus armatus*. The last of these appears to come very near to *Stimpsonia splifera*, Sp. Bate; see Ann. and Mag. Nat. Hist., ser. 5, vol. i. pl. v, 1878.

Incidentally “*Stenotheus monoculus* Mont., *Atylus Steammerdami* Milne-Edwards, *Achnathella Sabini* Leach” are recorded from the coast of Algeria.

Notes sur les Amphipodes des Côtes de France. (Extrait des Procès-verbaux des séances de la Société Zoologique de France, t. XI. séance du 28 décembre 1886.)

Fuller descriptions are here given by M. Chevreux of *Ptilocheirus tricristatus*, n. s., *Microprotopus longimanus*, n. s., and *Microdentopus armatus*, n. s., from the south-west of Brittany. M. de Guerne gives a list of thirty species of Amphipods from the north of France, but he notes that the *Podocerus fulcatus*, Montagu, and the *Jannasa rariogata*, Leach, which he includes in the number mentioned, are regarded by Nebeski as the male and female of a single species. In my opinion the *Amphilithoe podoceroides*, Rathke, and *Amphilithoe rubricata*, Montagu, are also a single species, though some specimens are green and others red. Probably also the species named in the list *Podocrasps rimapalmata*, Sp. Bate, and *Podoceras ps decurata*, Sp. Bate, are identical.

1887. Chevreux, E.

Among the weeds and Hydrozoan zoophytes which commonly grow on the carapace of *Maia equinula*, M. Chevreux has been able to discover no less than twenty-three species of
Amphipods, the list beginning with "Isca Montagni Edw." and "Laphystias sturiorum Kröy.," and ending with "Postalirius typhicus Kröy." Altogether the Catalogue enumerates 123 species, with notes principally on synonymy and locality. Bathyporea robertsoni, Spence Bate, is upheld as a distinct species, with the remark that "chez ce dernier type, et quelle que soit sa taille, les articles du fouet des antennes inférieures sont assez allongés, et garnis de volumineuses baguettes olfactives, tandis que chez les B. pelagica de toutes tailles, ils sont extrêmement courts et ne présentent pas de baguettes olfactives bien apparentes." This distinction between specimens, however interesting in itself, is not, I think, of specific importance apart from other distinguishing characters. On Urothoe marina, Sp. Bate, M. Chevreux observes, "c’est certainement à tort que Meinert considère U. marina comme le mâle d’U. brevicornis Sp. Bate; chez toutes les Urothoe, les mâles se distinguent des femelles par leurs longues antennes inférieures. M. le Professeur Giard a signalé, il y a longtemps déjà, ce caractère sexuel. J’ai trouvé du reste un certain nombre d’U. marina portant des œufs." Of Urothoe elegans, Sp. Bate, he says, "c’est très probablement la forme mâle d’U. marina."

Of Monocyathodes longimanus, Bate and Westwood, the antennæ are described and figured, Pl. V. figs. 1, 2, and the suggestion is made that this species ought perhaps to be placed in a new genus.

"Guernica, nov. gen." in place of Helleria, Norman, preoccupied, is thus defined:—"Antennæ superiores filamento appendiculato instructæ. Pedes 1° et 2° parvis maxim subcheliformi. Pedes 3° parvis setis longis plumosis instructi. Segmentum abdominis 5° et 6° conoida. Pedes saltatorii ultimi parvis 2 vamosi. Appendice caudalis laminiformis, profunde fusa." Of the type species, "Guernica rothii Norman," figures are given in the text on page 5, though referring to the description of the female on page 16.

Of Eusimops latipes, Boeck, found on Maia spinulosa, it is remarked, page 21, that the male differs from the female (which Boeck describes) in the hand of the second gnathopods, which is much larger, and carries two or three large obtuse teeth on the lower margin, while in the female it is smooth. The hand of the male is represented, fig. 3, on page 6.

Protomocera pectinata, Norman, and Protomocera hirsutimanus, Spence Bate, are here referred to the genus Pitolechirus, S impson.

Pitolechirus tricoloratus, n. s., is described at some length, parts of it being represented on page 6, fig. 4, and on Pl. V. figs. 3, 4.

Microprotopus longimanus, n. s., is likewise described, with illustrative figures on Pl. V. figs. 5–10, and fig. 5 on page 8 of the text.

Of Microrchestes armatus, n. s., the two sexes are described, and illustrated by fig. 6 and fig. 7 on page 9 of the text, and Pl. V. figs. 6, 7.

Boeck's Jawaes variegata, Leach, is here regarded as an independent species, with "? Podocerus capillatus Sp. Bate and Westwood," for a synonym.

But from Templeton's description of the tube and habits of his species, it is probable that he had in view a true species of Cerapus. On the other hand I believe that the forms named respectively Cerapus ablitis, Cerapus difforsus, and Dercothoe (Cerapus ?) punctatus, in the British Sessile-eyed Crustaceae, are all synonyms of Erichthonius difforsus, Milne-Edwards. I have found them all at Ilfracombe nesting together on tufts of Chondrus crispus in the same small rock-pool. There can be little doubt that the so-called Cerapus ablitis of this family group is the most fully developed male; Dercothoe punctatus is
certainly the female, and Ceropus diformis is probably the male in a less advanced stage, or possibly a form assumed between the pairing seasons. The account given by Gosse of the tubes of his "Ceropus Whitei" taken at Ilfracombe (see Notes on Gosse, 1853 and 1855, and Brit. Sess. Crust., i. p. 468) induces me to suppose that his species ought not to be referred to Siphonocrates but to be made an additional synonym of Erichthonius diformis.

Dryope irregularis, Sp. Bate, and Dryope renotipectus, Sp. Bate, are entered as separate species, but recognised as "deux formes très voisines." The fact that they were dredged together tends to confirm my opinion that they are forms of a single species.

In the Second Part, M. Chevreux gives, he says, "un résumé de tous les documents que j'ai pu réunir sur la répartition géographique des Amphipodes de nos côtes." In the notes he observes that Sp. Bate has not described any species of the name Meganaxa substricta, as in Grube's list from Saint-Vaast-la-Hougue, 1859. Grube no doubt intended the species Meganaxa semipectus, Sp. Bate. Of the existence of the true Microdontopus anomalous on the French coasts M. Chevreux is not certain; but in regard to the females of the genera Microdontopus, Aora, and Stimpsonia, he promises soon to publish differentiating characters, based on the examination of living specimens at the moment of reproduction.

In "la liste des Amphipodes recueillis sur le littoral des Alpes-Maritimes par M. Adrien Dollfus," two new species are included:—"Stenothoe Dollfus n. sp.," thus described:—"Antennae protractae, subterminalis; antiarum flagellum elongatum generis. Pedes 26 pars manus elongata, plus quam duplo longiore quam latum, palma valde excava, in parte anteriori dentibus duobus instructa (fig. 8)," on page 10 of the text.

"Guernia laxis n. sp," thus described:—"G. coalite valde aphanis, sol carina segmentorum adorinatis duorum posteriorum non denticulara differt." If there be no other distinction between the species than that here mentioned, I should be inclined to regard Guernia laxis as a synonym of Guernia coaliita.

The "relevé général de nos espèces de la Méditerranée" includes the names of 75 species, beginning with "Vibilia Jeangerardi Lucas" and ending with "Cyamus ceti."

The "Distribution géographique et bathyétrique" is given in a tabular form, the "liste des espèces marines signalées sur les côtes de France" in this table numbering 174. As to the bathyetric distribution M. Chevreux says, "Enfin, le fait le plus frappant est la capture par l'Expedition Norvégienne 1876-1878, de l'Hippomedon Holbo, dragué par 1215 brasses (2284 m.) de profondeur. Cette forme ne diffère de celle qui habite les fonds de 5 à 10 m. de la baie du Croisic que par l'absence des organes de vision." He remarks in a note that adult specimens of Podocerus fulcatus, Amphithoe rubricata, and Proto ventricosa coming from depths of 80 to 100 m. are much smaller than shore-specimens; but this observation cannot, I think, have any very general application.

The "Index bibliographique" contains sixty-six entries, beginning with Risso, 1816, and ending with J. de Guerne, 1887.

1887. Claus, C.

Die Platysceliden. Mit 26 lithographirten Tafeln. Wien, 1887.

The preface notices that hitherto sufficient attention has not been paid to sexual dimorphism and metamorphosis occurring in the Hyperina, and that accurate details in regard to the mouth-organs and inner structure of the Platysclidae have been entirely wanting.

The description of families, genera and species, pages 30 to 75, corresponds closely with that already published by Claus in 1879; see Note on Claus under that date. But the value of that description is here enormously increased by the addition of the beautifully executed and highly instructive plates.
The introduction, pages 3 to 29, comprises eight sections, as follows:—

1. Allgemeine Charaktere. Among these are noted the very striking differences presented by the antennae in the two sexes, the absence of palp-appendages from the maxillae as well as the maxillipeds, and the limitation of the triarticulate mandibular palp to the male sex.

2. Äussere Erscheinung und Körperform. Claus knows of no instance in this group in which the epimera or side-plates are absorbed in the segment as in the Phronima-group. The fifth and sixth pleon-segments are always coalesced, and sometimes the telson is united to them without suture.

3. Gliedmassen. The upper or front antennae never have an accessory flagellum; observers have been misled by the produced peduncle in Phorcos to regard the principal flagellum as accessory. The second or hinder antennae have the peduncle and flagellum not sharply defined the one from the other. In almost all cases the first or coxal joint is absorbed into the integument of the head. Claus notices that there are fine setae along all the joints except the first of the folding antennae of the male, but of their function he is not quite certain. The left mandible has a tooth-like process of considerable size, which is either absent or as a rule very weakly indicated on the right mandible. The first joint of the mandibular palp, which is generally small in the Gammarina, is generally large, and sometimes enormous, in the Platyscelida. For the terminal part of the gnathopods various expressions are used, Griffhand (Zange) for a subchelate, Scheere (fingers) for a chelate, hand and fingers, doppelse Scheere when the chelate hand and fingers are applied against an immovable process of the wrist, and zusammengesiefte Scheere when the chela is formed by a simple hand and finger applied against the process of the wrist. The marsupial plates of the female are generally lancolate, yet widening at the free end, and occasionally so much so as to be like a stalked leaf.

4. Integument und Hautdärse.

7. Herz, Gefass-system und Atemung. In the Platyscelidae the heart has only two pairs of venous ostia, the slits being wanting in the second person-segment; besides the two aortae it has three pairs of lateral arteries, occurring respectively in the third, fourth and fifth segments. Of the branchial vesicles Claus says, "mit Ausnahme der männlichen Rhabdocamens, welche nur zwei Paare von Kiemen am fünften und sechsten Beinpaares der Brust tragen, finde ich die Fünfzahl der Kiemenpaare überall eingehalten." Lycopsis, as Claus himself subsequently shows, is another exception, but whether that genus should hold a position among the Platyscelidae he is doubtful. Bovallius places it in the family Phorideae.

8. Geschlechtsorgane. Entwicklungen. Claus mentions by the way that he is unable to corroborate the statement of Fr. Müller that the young of Hyperia leave the egg-sheath without abdominal feet. From a comparison of young with adult forms he draws the conclusion that the Hyperidae have developed from the Gammarinae, and that from the Hyperidae have sprung the Platyscelidae as an aberrant offshoot.

1887. Hansen, H. J., and Holm, Th.

The account of the Amphipoda extends from page 210 to page 234, and is illustrated on Plates XXI. and XXII., of which the explicatio is given on pages 282, 283. Spence Bate's view is adopted that the so-called epimera are the first joints of the thoracic legs, the joints of which are accordingly in the descriptions numbered from one to seven, not, as many authors prefer, from one to six. Forty one species are mentioned. Onisimus caricos, n. s. (Tab. xxi, Fig. 6–6), is said to be very near to Onisimus edwardsi, Kroyer (Tab. xxi, Fig. 8, 8a), but distinguished from it by its superior size, and among other things especially by the second gnathopods, thus described, "in utroque sexu articulo sexto quan articulo quinto vix duplo breviore, sub triangulo, ad apicem versus nonnihil dilatato, dimidio longiore quam latior, marginie anteriore quam posteriori nonnulli longiore, apicem emarginato; unguis (e articulo septimo et ungue vero formato) sat robusto, valde curvato, ut intervalum inter unguem et articulum sextum praestet." Besides the differences of the antennae in the male, female, and young of the Lysianassidae, Dr. Hansen says that much difference may be found between the second gnathopod of the male and that of the female. This he illustrates by Onisimus brevirostratus, n. s. (Tab. xxi, Fig. 7–7c), in which the female has the second gnathopod nearly as in the closely allied Onisimus caricos, while in this limp of the male "articulus sextus allo modo formatus est, non triangulus, marginibus ad apicem versus subparallelis, apicem oblique truncato, ut margo anterior brevier quam margo posteriori evallat, 'ungue' brevior et gracilior in medio marginie apiculi sito." Onisimus afinity, n. s. (Tab. xxi, Fig. 9, 9c), is said to be very near to Onisimus edwardsi, the distinctions being apparently only drawn from measurements of.
REPORT ON THE AMPHIPODA.

the second gnathopods and telson. "Eunysis Holmiit, n. s. (Tab. xxii, Fig. 1–15), is said to be very like Eunysis cuspidatus in respect to the carina and dentation of the back and in the form of the hands, while it much resembles Eunysis longipes by the length of its legs, which, however, are considerably longer than in the last-named species, but it is said to differ from both the species mentioned by its specially long upper antennae, by the size and form of the three first pairs of epimera, and in several other respects. The length of an adult female was 53 mm. Microcentopus arcticus, n. s. (Tab. xxii, Fig. 3), is also remarkable for its size, attaining a length of 29 mm. Dr. Hansen was under the impression moreover that none of his specimens were full grown.

A description and figures are given (Tab. xxii, Fig. 5–5e) of the maxille and maxillipeds of Stegocephalus bidenteculatus (Sp. Bate). Of "Stegocephalus ampulla" (Phipps) (Tab. xxii, Fig. 10–10c)" the mandibles and maxille are described and figured. In a footnote, however, Dr. Hansen says that, judging by the length in comparison with the depth of the fourth side-plate, and by the form of the widened second [first free] joint of the fifth pereopod in Phipps's figure, as well as by the size of the animal, Phipps's species must be the same as Stegocephalus koesleri, Stuxberg. His own specimens ought therefore, he says, to have been named Stegocephalus inflatus, Krøyer. Dr. Hansen also states that Stegocephalus koesleri, Stuxberg, is pretty certainly the same as Stegocephalus ampulla, forma altera, Goös.

Of "Arctostethuscheia Malagrenii" (Goös) (Tab. xxii, Fig. 11, 11a.)," the maxille are described and figured.

"? Ooelicerus micros G. O. Sars (Tab. xxii, Fig. 12.)" is thought to be possibly an intermediate form between Ooelicerus micros, Sars, and Ooelicerus macrorchis, Sars.

Boeck's Arcahionotomona is altered into Arcahionotomona for the three species, cristatum (Owen), serratum (O. Fabr.), and inflatum (Krøyer). Of the last species Hansen’s largest specimen was "18,5 mm" in length, and the postero-lateral angles of the first two pleon-segments were acute, making it doubtful whether Boeck's Arcahionotomona inflatum, 6,5 mm long, and with these angles rounded, is really the same as Krøyer's species.

To Arcahionone cuspoidata (Lepechin) the synonyms assigned are "Ooelius cuspoidatus Lepechin," "Amphiloe Hyparix Krøyer," "Arcahionone cuspoidata Boeck," and the species is said to be easily distinguishable from all other Amphipods, without notice of the doubt thrown upon this point by E. J. Miers. See Note on Lepechin, 1789.

Of "Gammarus Locusta" (Lin.) (Tab. xxii, Fig. 2–2e.)" the maxille and maxillipeds are figured, with a view more particularly to show the basal joints.

Melita dentata (Kr.) is recorded, and "Gammarus dentatus forma altera Goös" is described as a new species "Melita Goësi n. s. (Tab. xxii, Fig. 13.)" It is a little singular, if the two forms are really distinct, that a single specimen of each should have been obtained at the same spot, the two specimens also closely agreeing in size; but the differences are said to be numerous.

"Melphilippa spinosa" (Goös) is identified with "Gammarus spinosus Goës," but doubtfully with Boeck's Melphilippa spinosa.

A female Podocerus is named "(f) Podocerus brevicornis G. O. Sars." Nine specimens of "Ejina epinosissima" Stimpson were obtained, and Dr. Hansen observes that the species from the "Vega" expedition named Ejina echinata is obviously this species.

Of "Caprella spinosissima" Norman (Tab. xxii, Fig. 4, 4a.)" the maxille are described and figured, and the statement made that on the second pair and three hindmost pairs of legs there is a short but well chitinized and movable first joint. This species should rather be called Caprella torrida, Sars. See p. 571, in Note on Sars, 1885.

The other species here recorded are named "Parathemisto abysorum A. Boeck;" "Searnes Vahlie (Kr.);" "Anonyx lapaza Kr.;" "Anonyx gulosus Kr.;" "Orchomenespectinus G. O. Sars;" "Harpinia plumosa" (Krøyer); "Halicreion latipes G. O. Sars;" "Aceros
The resume, pp. 508-511, mentions three other species, "Orechone minuta (Kr.);" "Aristias linius (Kr., non Boeck);" "Amphipnops glacialis n. sp.," to be described in a work on the Malacostraca of West Greenland. In discussing the second maxilla of the Malacostraca, Dr. Hansen says, "in the Amphipodæ, the elements of the maxilla are a few reduced: the fourth article is the only one which can be confused with the third one, which is prolonged into a large lobe." Of the first maxilla he says, "the first article, in the types that we have seen, is a prominent lobe, and the part basal of this lobe is inconstant, in the Boreophausia, Mysis, and Diastylis, in which the article is always small and elongated, directed from within to the face of the maxilla. The second article is always small and the third lobe is elongated and projects in a large lobe. The maxilla has a few more articles in the Isopodæ and the Mysis; in the Diastylis and the Boreophausia, there is a third article which is directed from within, and the Amphi t e p i d è not Amphipodes present a fourth and fifth article as a single bilaterally, directed in advance."

M. Th. Holm, who accompanied the expedition, gives at pp. 495, 496 interesting notes on the colours of the living Amphipodes. "Socarines bicentricatus" is "blancâtre with a coloration rouge foncé on the midrib and descending upon the backs of the corps." "Socarines injecting" is "the most often a deep bronze red, with a tinge of white on the membranes and on the epipods." "Acanthosoma injecting" is "attracts the attention at the base of the colour carmin, with a, or without, the colour transverse, more obvious. "Ganitomas longis" is "white, with green tumescent, "Acanthosoma cupulata" "se distingue . . . par . . . sa couleur bigarrée, blanchâtre with the colour transverse of a deep fonce, and the other white, yeux d'un rouge chair." "Acanthosoma serratum" is "white, with bands transverse of a rouge jaunâtre, "Halirages falcicinctus," of a blonde of snow with a large centre transverse of a rouge vif on the midrib of the thorax." "Acanthostegaria Malmgreni, gris." "Eusirus Holmi," d'un rose pale, presque diaphane. Their abundance in the region explored (about lat. 71° N., long. 62° E.) may be estimated from the fact which he mentions that, "quand on descendait, jusqu'au fond, des chiens morts et qu'on les remontait au bout de vingt-quatre heures, non seulement ces derniers, mais encore le grand sac de toile à voiles où ils étaient placés, étaient garnis de Socarines bicentricatus and de deux ou trois espèces d'Onisimus si bien qu'on ne pouvait, littéralement parlant, distinguer ni chien, ni sac."

[A few papers which have not been described in their proper places will be found recorded in the Appendix.]
DESCRIPTION OF GENERA AND SPECIES.

Class CRUSTACEA.

Subclass MALACOSTRACA.

Thoracipoda, H. Woodward.

Order EDRIOPHTHALMA, Leach, 1815.

Tetradecapodes, de Blainville, 1816.

Arthrostraca, Burmeister, 1837.

Choristopoda, Dana, 1846.

Suborder AMPHIPODA, Latreille, 1816.

Tribe I. AMPHIPODA GAMMARINA.

Head not coalesced with the first segment of the person.

Person of seven distinct segments, very rarely reduced to six (Dulichia) by the coalescence of the last two.

Pleon of six distinct segments bearing appendages, and the telson; rarely with two (Atylus), or with three (Gopland), of the segments coalesced, or with only five distinct segments and five pairs of appendages (Dulichidae); the telson (probably) never absent.¹

Eyes generally two, sometimes four (Ampelisca) or none (Byblis abyssi, Sars, &c.), seldom very large or projecting much above the surface of the head; generally with many component ocelli, sometimes simple (Ampeliscidae).

Antennæ, two pairs; the proportions not constant; the upper often having a secondary flagellum, well-developed or rudimentary, but very rarely (Gammarus sarmatus, Dybowski) of great length.

Maxillipeds generally with two pairs of plates, neither pair coalesced, and a four-jointed palp; the palp rarely with only three joints (Normania), or only two (Lafystius).

¹ For definitions, see Glossary, and Notes on Latreille, 1816 (p. 95), 1817 (p. 95), 1829 (p. 137); Burmeister, 1837 (p. 170); Milne-Edwards, 1840 (p. 184); Dana, 1852 (p. 256); Claus, 1880 (p. 508); Gerstaecker, 1886 (p. 570).

² But see, in Bibliography, Notes on Isidium, Grube, 1864 (p. 345), Ichthyomyzocus, Hesse, 1875 (p. 417, and in Appendix), the Orchestidea, Zaddach, 1878 (p. 489).

(zool. chall. exp.—part lxvii.—1887.)
The side-plates of the person varying greatly in size, but those of the sixth and seventh segments never very large.

Pleopods generally having the inner angle of the peduncle armed with two or more small coupling spines, and the first joint of the inner ramus furnished with some apically-cleft spine-like setae.

Family Orchestidae, Leach, 1814.

The following is the definition of the family by Boeck, 1872:

"Upper Lip strong, rounded at the apex.
"Mandibles very strong, curved, much dentate at the apex, carrying a row of plumose spines; inner appendage strongly dentate; molar tubercle very prominent; palp wanting.
"First Maxillae armed with strong pectinate teeth; inner plate elongate, narrow, with two plumose setae at the apex; palp small or wanting.
"Second Maxillae with broad plates.
"Maxillipeds with the outer plate small, broad, ovate, having on the margin slender spines or setae; the inner plate elongate, broad, apically truncate, armed with three strong teeth; palp strong and broad, the last joint sometimes wanting.
"Body compressed; back rounded; side plates well developed.
"Upper Antennae more or less shorter than the lower, without accessory flagellum.
"Lower Antennae with the two anterior joints very short but pretty broad.
"Uropods short and strong; the first and second biramous, the last pair one-branched.
"Telson short and thick."

Genus Orchestia, Leach, 1813.

Leach, in 1813, in the first division of his family Gammarini, defines Talitrus as having "Anterior pair of feet larger than the second pair; no hands," and Orchestia as having "Two anterior pair furnished with a movable thumb, which is capable of being bent on the edge of the hand; second pair largest, having a compressed hand." For further definitions, see Notes on Leach, 1815 (p. 90), Friedrich Müller, 1848 (p. 226), J. F. Brandt, 1851 (p. 244), Dana, 1852 (p. 257). Boeck's definition, 1872, includes "Maxillae Imi paris palpo destitutae," but some species of Orchestia, if not all, have a rudimentary palp on the first maxillae; it also includes "pedes maxillares palpis per-brevibus latis; articulo palpi 2do sursum dilatato, 4to absenti," in which statement it would probably be more accurate to substitute rudimentari or tuberculiformi in the place of the word absenti.
Orchestia selkirkii, n. sp. (Pls. I., II.).

The Head is somewhat longer than the first segment of the pleon; rostrum rudimentary. Peraeon moderately dilated; beyond its fourth segment the body tapers rather rapidly to the telson. Segments not greatly differing in length; first of the pleon the longest. The first three pleon-segments are posterolaterally squared, the angles very slightly outdrawn, and the margins above them serrate upwards.

Eyes roundish to oval, conspicuously black in the spirit specimens; distance between the two equal to the smaller diameter of one.

Upper Antennæ.—Three joints of peduncle small, successively decreasing much in thickness. Flagellum shorter than peduncle. In the male specimen figured the flagellum on one side had nine joints, that on the other only eight. In the female the flagellum had only six joints.

Lower Antennæ.—Last two joints of peduncle long and stout, the last thinner than the preceding. The tapering flagellum consists of about twenty-eight joints, all except the last one or two distally widened.

Upper Lip with rounded distal border minutely furred, the hairs on either side inclining towards the centre of the margin.

Mandibles.—The cutting edge of each mandible ends in a strong double tooth, preceded in the left-hand mandible by four, in the right-hand by three or four smaller teeth; the secondary plate, on the left mandible, resembles the cutting edge, except that it ends in a single tooth and is less powerful; on the right mandible it has a bidentate termination, the ridges of the double tooth being minutely denticulate, and preceded by three inconspicuous teeth. The spine-row consists of four sinuous plumose bristles, two stout and two thinner ones. The prominent molar tubercle has the oval face set with numerous rows of denticles. There is a long plumose bristle at one corner, and a sort of hairy tuft at the opposite corner. I can find no trace of any rudimentary articulated palp, such as is figured by Saviugy for Orchestia montagui and Guérin for "Orchestia gammarella." There is a prominent lobe rising just above the base of the molar tubercle, obviously connected with the articulation and movement of the mandible, which has perhaps in other species suggested the presence of a palp.

Lower Lip.—The principal lobes very slightly dehiscent; the mandibular processes broadly rounded, not projecting far.

First Maxillæ.—The inner plate narrow, tipped with two plumose bristles, its inner edge nearly straight, the other edge sinuous; the broad outer plate is distally edged with nine denticulate teeth in a double row. Just below the broadest part of the plate, within the outer rim, springs a minute palp consisting of one slender joint, at the tip of which a little pimple may be the rudiment of a second joint or of a spine.

1 See Note on Schisde, 1873 (p. 449).
Second Maxille.—Outer plate longer and slightly broader than the inner one, distally fringed with a mass of slender curved spines, the outer ones the longer; the inner plate has the distal fringe of short spines passing in an even curve some way down the inner margin to a plumose bristle much longer and stouter than the spines; below this there are some hairs, as there are also on the other margins of both plates.

Maxillipeds.—Inner plates rather long, with plumose bristles passing up the inner margin, within the distal, and down part of the outer margin; three short, strong teeth on the distal margin, and one having its insertion just below the inner angle of the plate. Outer plates short, not reaching beyond first joint of palp, short spines within distal margin and upper part of inner margin; other spines, of various sizes, but none large, singly or in groups, on the outer side of this and the preceding joint. First joint of palp with outer border much longer than the inner; second joint distally lobed on the inner side; inner margin of this and the next joint fringed with short spines; all three joints with small rows of spines on the outer sides; the fourth joint rudimentary, a tubercle, tipped with spines.

In the so-called triturating organ at the anterior end of the stomach a row of twenty-eight spines is found, becoming longer and thinner at both ends of the row.

First Gnathopod.—The side-plate almost concealed by that of the second segment; spines on its lower border, and on the inner side, and on an inner lobe where the first free joint articulates. In the male, first joint broad except at its origin; fourth joint postero-distally lobed, much longer than fifth; hand with a conspicuous postero-distal lobe; finger short, closing over the slightly concave palm so as to reach the inside of this lobe; distributed over all the joints on margins and surfaces are spines with subterminal accessory threads; a row of minute straight hairs on the palm; and a stronger spine where the tip of the finger closes down; some fine spines on the finger at the origin of the nail, where also the inner margin of the finger slightly projects. In the female, the first joint almost parallel-sided, the fourth joint a long narrow triangle, with hinder (especially the distal) spines prominent; hand widening a little distally, the finger projecting beyond the slightly convex palm.

Second Gnathopods.—The side-plate fringed below with spinules; the hinder margin in this and the next two pairs of side-plates having a projecting process for purposes of articulation; branchial vesicle much broader than long, upper border very sinuous; in the male first joint shorter than hand, broadest near its origin, lower edge slightly lobed; second joint antero-distally lobed on the outside and medio-distally on the inside; third joint squared; wrist a small cup, almost lost in the outswelling of the hand beyond it; the immensely powerful hand broadest near its origin; palm sinuous, bordered with spines of various sizes, and forming a groove on the inner side into which the point of the finger closes down; the finger itself strong, inner margin fringed with spinules, and forming a double concavity, that near the tip leaving an open space between finger
and hand, even when the two are tightly closed together. The spines on this limb, except on the palm of the hand, are few and small. In the female, the first joint is more narrowed distally than in the male, the second joint is lobed on the front margin; the third and fourth joints much resemble in form the corresponding joints in the first gnathopod of the male, but the hinder margin of the fourth joint is here thin and without spines; the hand, narrow at its origin, swells out to a postero-distal lobe beyond the palm, without spines on the thin, curved hinder, or nearly straight front, margin; a row of spines along each side, a group close to the hinge of the feeble finger, spinules along the palm, over which the finger closes tightly; fur on the thin lobe which projects beyond the palm. Wrist rather longer than hand and shorter than first joint.

First Peraeopods longer than second; spines on both edges of all joints but the second; third joint longer than any but the first, fourth not much, sometimes not at all, longer than fifth, both spinous; finger short, with curved nail; branchial vesicle with a large basal, and a narrow terminal, lobe.

Second Peraeopods very similar to first, but dimensions smaller in regard to length, the side-plate somewhat broader, the fourth and fifth joints equal in length; the finger in both sexes differing from that of the first peraeopod in having its hinder margin sinuous. There is a corresponding irregularity of outline in this margin in the second peraeopods of Talitrus locusta, of Orchestia gammarellus, and in an exaggerated form in Talorchestia tumida, G. M. Thomson; but not, so far as I know, in Hyale or Hyalella.

Third Peraeopods very much shorter than the two following, though more than half the length of the fifth peraeopod; front lobe of the side-plate nearly as deep as that of the fourth segment; branchial vesicle with a small basal, and a large oval terminal, lobe; first joint oval, with spines on front, and spinules on hinder, margin; third, fourth, and fifth joints spined on both edges, not differing greatly in length, decreasing successively in breadth; finger small, with curved nail.

Fourth Peraeopods.—Hinder lobe of side-plate larger than the front one; branchial vesicle with a short narrow basal and a long narrow terminal lobe, the latter curving first backwards and then downwards; first joint a long oval, third and fourth joints subequal, fifth rather longer and considerably thinner; finger slender, longer than that in the third peraeopods.

Fifth Peraeopods.—Side-plate not bilobed, deeper behind than in front; first joint broader than that of the fourth peraeopods, which in most respects these closely resemble, but with the third, fourth, and fifth joints longer.

Pleopods.—Peduncles long and slender, longer than the rami, wide apart at the base, curving in towards one another, armed with a few small spines; the joints of the rami numbering from seven to eleven; the setae very finely plumose; I cannot perceive any cleft spines on the long first joint of the inner ramus, such as are commonly found in other families, nor even a single short one, such as occurs in Talitrus locusta; the
coupling-spines at the distal end on the inner side of each peduncle are two in number, and something like those of *Talitrus locusta*; the shafts are a little bent and exceedingly short, while the heads by comparison are very broad, showing a retroverted tooth on either side.

**Uropods.**—The first have the peduncle longer than the subequal rami; both peduncle and rami spined on the edges, a group of spines at the tip of each ramus, one of predominant size. In one of the specimens examined the rami on one side were much shorter than those on the other. The second uropods similar to the first in armature, but shorter, the peduncle subequal in length to the rami. The third uropods with short peduncle and short ramus spined on the outer edges; the peduncle tapering distally, broad below, from above looking as if cylindrically folded over.

**Telson.**—Broad at origin, tapering to two small distal lobes, these and the lateral margins runs along with spines; a median suture runs from the base some way towards the meeting point of the distal lobes. The sixth segment of the pleon scarcely visible from above folds beneath the whole length of the telson.

**Length** about half an inch, sometimes reaching seven-tenths, without counting the antennae.

**Locality.**—Fifty-two specimens were taken on the shore at Juan Fernandez. The species is named after Alexander Selkirk, whose romantic story is connected with that island.

**Remarks.**—*Orchestia serrulata*, Dana, from New Zealand, seems to be its nearest ally, but the two species are separated by numerous differences in detail, among which may be noticed the first gnathopods in the female, the palm of the second gnathopods in the male, the relative lengths of the pereopods.

**Family Lysianassidae,** G. O. Sars, 1882.

For the original definition of the subfamily Lysianassinae, Dana, see Note on Dana, 1849 (p. 229). The subfamily Lysianassinae, Boeck, 1870, is changed by Sars into the family Lysianassidae, without further definition. Boeck’s definition of it in 1872 is as follows:

"*Upper Lip* and *Epistome* more or less prominent.

*Mandibles* elongate; cutting edge broad, not dentate or only furnished with very few teeth on the inner margin; an inner plate on the left mandible; molar tubercle small, more or less prominent; spine-row furnished with few blunt and often very small teeth; palp elongate, triradiate.

"*Lower Lip* elongate; inner plates little, near the apex [1 generally absent].

"*First Maxillae* with two-jointed palp; rarely without palp.

"*Second Maxillae* more or less elongate.

1 For Schiodte's *Trochalegnathia,* see Note on Schiodte, 1875 (p. 440).
"Maxillipeds robust; plates more or less elongate; last joint of the palp unguiform, rarely tubercle-shaped or obsolete.

"Body deep; back thick, generally rounded; very rarely carinate.

"Side-plates deep, narrow.

"Upper Antennae with the peduncle very short, thick; the second and third joints very small; flagellum more or less elongate; first joint more or less elongate, always longer than the following joints, and on the inner side furnished with two brush-like rows of setae.

"Lower Antennae with the flagellum elongate in the male, shorter in the female.

"First Gnathopods more or less elongate, generally with a small subchelate hand; rarely with the hand large or not subchelate.

"Second Gnathopods elongate, filiform, with a small hand; rarely without a nail.

"Pereopods of the last three pairs successively longer; the first joint posteriorly laminar, dilated."

In the new genus *Sophrosyne* the maxillipeds are rather to be described as slender than robust; the epithet "narrow" is by no means universally applicable to the side-plates in this family, the fourth pair generally, and sometimes others, being of considerable breadth; occasionally the fourth pereopods are longer than the fifth. *Amaryllis*, Haswell, is an aberrant genus in regard to the upper antennae.

Genus *Anonyx*, Kroyer, 1838.

For the original definition see Note on Kroyer, 1838 (p. 178). Bocck in 1872 defines the genus as follows:—

"Epistome helmet-shaped.

"Mandibles with the palp fixed nearer the apex than the very prominent molar tubercle.

"First Maxillae with the inner plate ovate, small, furnished with two plumose setæ on the apex.

"Second Maxillae with the plates broad and short; the inner plate much shorter than the outer.

"Maxillipeds with the outer plate small, not reaching the distal end of the second joint of the palp, nodulous on the inner margin; palp robust; last joint unguiform.

"First Gnathopods more or less elongate, robust; hand quadrangular, obliquely truncate at the apex.

"Telson longer than the peduncle of the last uropods.

"Third Uropods with the branches longer than the peduncles, setose.

"Body not deep. Side-plates not deep; fourth not much excavate, not deeper than broad. Postero-lateral angle of the third pleon-segment produced, upturned, acute."
Aponyx ampulloides, Spence Bate (Stimpson, MS.) (Pl. III.).

Rostrum rudimentary; lateral lobes of the head rounded; the head as long as the first pereon-segment; first pereon-segment longer than the second. Peraeon dorsally rounded. First four segments of pleon dorsally acute, the third segment deeply excavate above the much upturned, slightly produced postero-lateral angles, the lower margin being as it were bent up so as to form a piece of the hinder margin. The fourth segment with a dorsal depression, the sixth laterally ridged above on each side of the telson.

Eyes reuniform, occupying a great part of the surface of the head, and nearly meeting at the top of it, therefore very large. The component ocelli short and small, numbering certainly more than three hundred.

Of the somewhat projecting connate epistome and upper lip a lateral view is given in the Plate.

Upper Antennae.—First joint large and tumid, second and third very small; flagellum incomplete, eleven joints remaining, of which the first, bearing a brush, equals in length some six or seven together of those which follow; the secondary flagellum, of seven or eight joints, has the first of equal length with the first of the primary and partially sheathed in a fold of that joint; its terminal joints are narrow.

Lower Antennae.—Gland-cone seemingly very obtuse; third joint narrow proximally, widened distally, with spines on the upper distal margin; fourth joint longer and much stouter than the fifth, furled on the upper margin, carrying a row of feathered cilia on the lower, and on its prominent apex a group of long setae; the fifth joint furled on its upper margin. Of the flagellum there remained only ten joints, the first of these being equal in length to the two following combined.

Mandibles.—The cutting edge smoothly convex, with a denticle at the top; the lower rim in front is cut into four spine-shaped teeth, the margin of the mandible behind these being straight and smooth; the secondary plate on the left mandible high up on the primary, ligulate or spiniform, very small; the spine-row consists of four spines followed by nine branching spiniform setae; the molar tubercle long, produced backwards, strongly furled with cilia, but not dentate; the palp set far forward, level with the front of the molar tubercle, the second joint considerably longer than the third, on its outer side a long row of spines or setae curving round the upper half of inner margin to the outer apex, three on the upper part of the outer margin; third joint widening for rather more than a quarter of its length, and from that point carrying a row of eighteen spines along the inner margin to the apex; this joint has also five setae in three sets on the inner side near the outer margin.

Lower Lip.—Strongly ciliated on the inner and apical borders; the distal portion of
the front lobes narrow, strongly dehiscent, suddenly widening and therefore coming nearer together about half-way down the long eleft that separates them.

First Maxillae.—Inner plate small, oval, with two plumose setae on the apex, the outer larger; outer plate with the very oblique apical margin densely ciliated, especially on the lower part; its eleven spines strikingly different from one another in their dentation; of the two which stand apart from the rest at the lower end one is slender with many small teeth, the other stout with three large ones; of those set round the upper end some are peculiar by their distal widenings. The large second joint of the palp widens distally, the distal border being cut into six teeth, the tip of each except the minute inner one having a small spine-tooth inserted in it; between the outermost marginal tooth and the next is an additional small prominenence, and again between the second and third teeth is a small cilium.

Second Maxillae.—The plates are similar to one another in general shape, the convex margins meeting in a pointed apex, the outer plate considerably longer than the inner. From the apex down half the inner margin the inner plate has plumose setse ending in one larger than the rest, and along the same part it has spines shorter than the sete, the spines being armed midway with straight spine-like cilia. The spines which in like manner arm the outer plate have these cilia, seemingly limited to four in number, except on the lowest spines, which become more seta-like.

Maxillipeds.—Inner plates small, not reaching nearly so far as the distal end of the first joint of the palp, apical margin with three tiny teeth inserted on little prominences, the plumose sete of the inner margin very long, passing over to quite small ones at the outer angle of the apex; the outer plates large and long, still not reaching the apex of the second joint of the palp, the inner border showing some six and twenty minute prominences as if for teeth, but with no appearance of teeth upon or within them, the same description applying to two on the rounded apical border; the second joint of the palp more slender and somewhat longer than the first; the third joint widening from a narrow neck, with sete on both borders, distally furred; finger long, with adpressed cilia on the surface, a dorsal cilium nearer to the aente point than to the base.

First Gnathopods.—Side-plates a little excavate in front, much wider below than above, with the usual little cilium-bearing indent at the lower end of the hinder margin. First joint broad, about as long as the third, fourth, and fifth together, with setae on both margins; third joint with no free front margin, its hinder margin furred, apically carrying geniculate spines and setae; wrist equal in length to the hand, dilated below, furred on the free part of the hinder margin, with spines round the distal part both before and behind; hand less wide than the wrist, widest at the base, but preserving most of its width all along to the by no means sublute palm, which is bordered with minute cilia, and defined by two spines, between which the finger closes down, the nail overlapping the palm. There are various spines and setae, singly, in rows, and in groups. 

(Zool. chall. exp.—part lvii.—1887.)
on the two borders and the sides of the hand. The finger has a denticle on the inner margin.

Second Gnathopods.—Side-plates widened below, the front, hind, and lower margins almost straight; the first joint fringed with setae behind, parallel-sided, distally bending backwards; second joint as long as the wrist, third with the anterior margin short, the posterior much rounded, furred, with several long setae near the rounded apex; the wrist a good deal longer than the hand, the front margin distally furred, and carrying long setae near and at the apex; the hinder margin furred nearer to the third joint, and carrying eleven groups of setae increasing in length successively to the apex; the hand much longer than broad, much furred, armed with the usual spines, narrowing a little distally, the finger comparatively long, occupying almost all the apical margin, its terminal portion not much crooked.

First Peraeopods.—Side-plates similar to those of the preceding segment, but larger. First joint strong, carrying setae on the hind margin; third joint large, nearly as long as the first joint, having groups of setae, short mixed with long, on the hinder border; fourth joint somewhat shorter, much narrower, armed with spines and setae, narrowing distally; fifth joint as long as fourth, slender, a little curved, on the hind margin carrying short spines and long ones, and close to the hinge of the finger a minute one with a hook at the tip, bent toward the comparatively short finger.

Second Peraeopods.—Side-plates with front and lower margins straight, hinder lunatey excavate; a small smooth ovigerous plate. The rest of the limb missing.

Third Peraeopods.—First joint much contracted below, at the upper part almost as broad as the side-plate, though not appearing so in the full figure on the Plate, because the side-plate is seen full, while the first joint is not quite full-face to the spectator; its hind margin is nearly straight, shallowly serrated, slightly concave below, while the front margin is convex and spined all round; third joint dilated, a little produced behind, with spines on hinder rim; both second and third joints have spines and setae on the front rim; fourth joint as long as the two preceding united, broader above than below, the front margin with five pairs of short spines, each of the upper four pairs with a long seta between the two spines, the fifth pair without a seta, a sixth apical pair with a long spine intervening; the fifth joint thinner than the fourth, equal in length, straight, with five pairs of spines on the front margin; finger rather short.

Fourth Peraeopods.—First joint oval, contracted below, closely spined on more than half the front margin which is smooth above, the lower margin behind forming a narrow lobe instead of a broad one as in the third pereopods; setae and spines on the front rim of the short second joint; the remaining joints similar to those of the preceding pair, but each longer than the corresponding one in that pair; the finger missing.

Fifth Peraeopods.—First joint of uniform breadth all along, front margin slightly concave, spines increasing in size towards the lower end, and the serrations of the hind margin
doing the same; the third joint not dilated, armed in front with four or five pairs of spines, behind with one at the apex, and another a little way from the apex. The rest of the limb missing on one side, on the other side represented by a somewhat tapering stump as long as the third joint and destitute of armature.

Pleopods.—In the third pair the two blunt-headed coupling spines on the peduncle were observed to have two or more retroverted teeth, and the rami to consist of twenty-one joints, the large first joint of the outer ramus having a fringe of thirteen plumose setae.

Uropods.—Peduncles of the first pair considerably longer than the rami, carrying numerous spines on both the upper edges, those on the outer edge being smaller than those on the inner; the outer ramus slightly longer than the inner; on its upper edge the outer has eight spines, the three approaching the tip being much stouter than the earlier five; on the inner edge is a row of three very fine spines; the inner ramus also has spines on both edges, and proximally has a little pocket on the under side into which the projecting edge of the other ramus can insert itself. Peduncles of the second pair equal in length to the rami, spined on both the upper edges, the outer edge having twenty-seven nearly uniform spines, the smallest not far from the base, the largest close to the apex, the intermediate not regularly graduated; the outer ramus is bordered with nine spines increasing gradually towards the apex, but stopping far short of it; the last is inserted in a sort of little pocket, as is the ease with the last three on the outer ramus of the first uropods. The inner branch is subequal in length to the outer; it has six or seven small spines on the border, followed by a long one inserted in the curved margin which abruptly terminates the broadest part of the branch, the remainder forming a finger-like termination without spines and apparently without any cilium in the angle. The lower border of this branch is much bent. The peduncles of the third pair are shorter than the rami; the rami are subequal, lanceolate, with spines on both borders. That which I take to be the outer ramus is represented in the lateral view of the pleon (fig. Pl. L.), without its companion; it terminates in a nail; the other ramus has on its margin a row of setae. In the other member of the pair, as the figure shows, the ramus with a nail seemed to be the inner one.

Telson.—Its upper lateral margins much overlapped by the folds of the sixth pleon-segment; the sides straight, only in a very slight degree convergent; eft for three-quarters of its length, the plates becoming gradually disheesent by the curving away of the inner sides towards the distal end; each outer apical corner a little produced, with a small spine between the angle and the adjoining inner curve.

Length from the front of the head to the back of the second pleon-segment, in the bent position represented, about nine-twentieths of an inch.

Locality.—Station 236, off Japan, June 3, 1875; lat. 34° 58’ N., long. 139° 29’ E.; depth, 775 fathoms; bottom, green mud; bottom temperature, 37°-6. One specimen, female. Trowled.
Remarks.—This species bears a close resemblance to that which Kroyer described as *Anonyx lagena*, *Anonyx appendiculosa* and *Anonyx ampulla*, and which Phipps had already described as *Cancer mugax*. Kroyer gave the name *ampulla* under the erroneous impression that his species was identical with Phipps’ *Cancer ampulla*, and described it with exact detail in his Naturhistorisk Tidsskrift, 2. R. i. 578–599. Though the name *ampulla* is untenable for Kroyer’s species, attention is well called to his admirable description of it by the name given to the present kindred species. *Anonyx ampulloides* differs from *Anonyx mugax* in that the eyes are not lageniform, flask-shaped; the apical border of the palp in the first maxille is peculiarly divided; the inner ramus of the second uropods is not stiliform, but bent on one side and abruptly narrowed on the other; and in other small details.

In the British Museum Catalogue of Amphipodous Crustacea, it is represented on pl. xii. fig. 8, and the following account is given:—

"Anonyx ampulloides, Stimpson, MS.

"In general aspect this species resembles *Anonyx lagena*; but close examination shows the following distinctions:—

"The inferior antennæ are much longer than the superior. The first pair of gnathopoda have the palm fringed with fine hairs, but not a comb-like margin. The second pair of gnathopoda have the carpus slight, and much longer than the propodos; the dactylos quite rudimentary. Telson deeply divided, becoming almost a double appendage.

"Length half an inch.

"I am indebted for this specimen to the kindness of the author, who brought it from Japan."

As I had myself chosen the name *ampulloides* for this Japanese species, before observing its resemblance to the figures, in Mr. Spence Bate’s Catalogue, of the species so called by Stimpson, the identification seems fairly to be depended upon.

*Anonyx cicadoides*, n. sp. (Pls. IV., V.).

*Rostral Margin* forming an obtuse but definite angle; the lobe of the head between the upper and lower antennæ rounded above and straight below. The three hinder pereon-segments longer than those which precede, but much shorter than the three segments of the pleon which follow them; the fourth segment of the pleon with a dorsal depression near its origin; the fifth and sixth segments very small, the sixth with a dorsal ridge or fold along either side of the back; the infero-posterior angle of the third pleon-segment much produced upwards.

*Eyes* not made out; in one of the specimens appearances suggest that they have been present, of a long oval shape, near the front of the head.
Upper Antennæ.—First joint stout, cylindrical, longer than the combined length of the two following joints, which are very short, and the long first joint of the flagellum. Flagellum tapering, in the female consisting of twenty joints, of which the first is longer than the four following united; besides the usual brush it has two large, slightly curved, distal spines; the second joint has two similar spines, and the fourth joint a similar but much smaller spine; the secondary flagellum is of nine joints, the first very long, the last minute. In the male the primary flagellum has calceoli on most of the joints.

Lower Antennæ.—First joint broad; the gland-cone with a conspicuous orifice, not spiniform; third joint with lower and distal margins lobed, fourth and fifth joints furred above, and with various groups of setæ below, one group in the fourth joint being on a little prominence near the base; the fifth joint somewhat longer than the fourth; flagellum in the female of about thirty joints, of which the first is much longer than the second. In the male the flagellum has about fifty joints, and is furnished with calceoli.

Mandibles with the palp far forward, just over the narrow interval between the molar tubercle and the spine-row; cutting edge smoothly convex, but with a small projection at the top, and an emargination in the return of the curve below. The secondary plate in the left mandible is short and narrowly ligulate. The spine-row consists of three curved spines. The molar tubercle is large and prominent, the crown of it minutely dentate and ciliate, pointing away from the cutting edge, the articular condyle pointing towards that edge. The first joint of the palp very short, the second very long, with a row of pectinate spines on the distal part of its margin. The third joint, about half the length of the first and second united, has two long spines near the outer angle of its base, and along almost the whole of its inner margin a row of pectinate spines, of which those at a little distance from the apex are the shortest, those at and close to the apex the longest.

Lower Lip deeply cleft, much ciliated round the margins of the forward lobes, which are rather abruptly contracted near their extremities, thus making the inner margins very sinuous; the ovate mandibular processes almost smooth.

First Maxillæ.—Inner plate small, oval, ciliated along the inner edge, and with two unequal plumose bristles at the apex; outer plate much ciliated on the surface and distal part of inner margin; at its apex five long spines, this row continued inwards on the outer side by two more, while a row of four, rather smaller, descend the sinuous inner margin; all are dentate on their edges some way short of the curved tip, the end one on the outer side having but one tooth, the end one on the inner side having several denticles. The two-jointed palp overtops the spines of the inner plate. The second joint is very much expanded distally, the curve of the outer margin ending in two microscopic teeth at the point of greatest expansion, the margin then running obliquely to meet the great distal curve set with nine teeth and a spine, the spine being outermost, with a short, spiny seta not far off.
Second Maxilla.—Inner plate much shorter and narrower than outer, fringed from the apex half-way down the inner margin with spines decreasing in size as they recede from the apex, and with plumose seta the longest of which are beyond the shortest of the spines; outer plate fringed with rows of long and short spines from the apex far down the inner margin, the longer spines curved at the tips. Both plates have their inner edges comparatively straight, the outer much curved, their surfaces and inner edges much ciliated; the outer plate has also a row of small spines from the apex down a small portion of the outer margin.

Maxillipeds narrow. The inner plates not reaching the distal end of the first joint of the palp, widening distally, apical border much excavated and forming a projection at the inner corner, which is set with three broad scarcely prominent teeth, just below which on the outer side of the inner margin are two small spines; long plumose setae occupy the inner margins, passing over into shorter ones on the distal margins. The outer plates are long, reaching just to the distal end of the second joint of the palp; the lower part of the joint to which they belong is fringed with spines on the inner margin, but this margin of the plate itself is clear of spines, being indented and in each indent carrying an almost rounded tooth, which scarcely projects beyond the margin; some way within the border are small spines, rather less numerous than the teeth. It would not be unnatural to suppose that the marginal teeth had been rounded by wear; but those of the new joint, not yet exposed to wear and tear, exhibit the same shape and position. On the apical portion of the rounded outer margin there is a row of five small spines, almost adpressed to the margin. The second joint of the palp is considerably the longest; like the first and third it is at the outer apex and along the inner edge fringed with long spines or setae, which, except for the terminal accessory thread, seem to be quite smooth. The fourth joint or finger is not of any unusual length.

First Gnathopods.—Side-plates dilated below and curving forwards, broader though less deep than those of the following segment. First joint not reaching beyond the side-plate, fringed in front and on the lower hinder angle; second joint subequal in length to third, with some fine setae on the hinder margin; third joint produced to a sharp point below, furled behind, carrying groups of setae on both sides near the apex; wrist furled behind, scarcely broader distally than the hand at its base, setae in groups at both the lower angles, and a small group near the middle of the front margin; hand narrowing distally, so as at the extreme apex to be scarcely broader than the finger, furled on upper part of hinder margin, with groups of setae along both sides of the front, and along the hinder margin and palm; that which may be considered the palm is slightly sinuous, minutely pectinate, a region shorter than the finger, determined by a short blunt spine; finger curved, with inner edge smooth, but for a tooth near the base of the nail; a spiniform ciliation arises in the neighbourhood of this tooth.

Second Gnathopods.—First joint long, a little dilated below, much more lightly
fringed than the corresponding joint of the first gnathopods; second joint longer than third, fringed in front and at the lower hinder angle; third joint rather densely furred behind, clasping the next joint closely with its dilated distal part, the hinder angle of which carries numerous long setiform spines, distally pectinate; the wrist elongate, much longer than the hand, densely furred on both sides, carrying spines similar to those of the preceding joint at the front apical angle and along the distal part of the hinder margin; the hand narrow, densely furred, surrounded on both margins with pectinate spines of various lengths, many both long and short at the point where the minute finger hinges.

Second Periopods.—Side-plates a little deeper than the preceding, as those of the third segment are, compared with those of the second. The branchial vesicles are not pleated. The marsupial plates are long and narrow, with a row of small cilia on one border, the usual long smooth setae on the other and round the apex. First joint tolerably stout and long, with a bunch of setae at each apical angle, and very little other furniture; second joint short, with some setae on the hinder margin, chiefly the group at the lower hinder angle; third joint longer and very much stouter than the following, a little produced downwards in front, fringed behind with several small groups of setae; fourth and fifth joints narrow, the latter the longer, narrowing a little distally, both bordered behind with numerous setae, the fourth joint showing also two spines near the base, the fifth joint having twelve or thirteen in a series extending along its whole margin; the finger short and much curved.

Third Periopods.—Side-plates rather broader below than above, and front margin slightly more convex than the hinder. First joint subequal in extent of surface to the side-plate, narrower below than above, front margin fringed with spines, hind margin serrate, the rounded distal portion overlapping the short second joint; two or three short spines and one long one on the front margin of the second joint; the same number on the hind margin of the third joint, which is short, dilated, slightly produced downwards behind, and has a row of spines and fine setae on its front margin; fourth joint somewhat dilated, narrower and longer than third; fifth joint much narrower and rather longer than fourth, both with spines on front margin. Finger small, curved.

Fourth Periopods.—First joint longer and more oval than that of preceding pair, rather narrower below than above; third joint much longer than in preceding pair, broader and shorter than the fourth joint, which in its turn is a little broader and shorter than the narrow fifth joint; armature of the various joints, and the finger, as in the preceding pair.

Fifth Periopods like the fourth pair, not longer.

Uropods.—Peduncles of the first pair longer than the rami, which are narrow, curving at the tips; the outer a little longer than the inner, with a row of seven spines on the inner margin, ceasing some distance from the apex; the inner with a similar row of ten spines. Peduncles of the second pair (Pl. V. uv. 2.) shorter than those of the first pair, subequal in length to the longer ramus; outer ramus considerably longer than inner, a
little curved at the tip, bordered within with eleven spines; inner ramus rather like a
tadpole, attached by a narrow neck to the peduncle, a broad oval portion following with
a row of six spines on the inner margin, a narrow rather sinuous piece forming the
termination, a minute cillum occurring where the ovate portion meets the linear. This
peculiar form of ramus has been noticed in *Ichnopus*, Costa, and some other genera.
Peduncles of the third pair much shorter than the lanceolate sharply pointed rami, which
stretch further back than either of the other pairs; outer ramus having a nail at the tip,
spines along the borders, some of them in groups on the outer margin, and plumose setae
on the inner margin; inner ramus shorter than the outer, with spines and plumose setae
on both margins, terminal nail minute.

*Telson* reaching further back than the peduncles of the third pair of uropods, narrowing
a little towards the apex, outer edges straight, cleft for three-fourths of its length, the
laminae not deliscent except where each curves away from the other to form the apical
margin, the outer end of which is produced into a little tooth. At this tooth commences
a row of three spines, diminishing in size from the tooth inwards, and followed by two
minute cilia. Along the outer edges there is a row of three spines on each side, the
largest a little lower down than the top of the cleft, the middle one the smallest.

*Length.*—The pair of specimens, male and female, to which the above description and the
figures of Pl. V. refer, measured each three-quarters of an inch, exclusive of the antennæ.

*Locality.*—Station 149d, Royal Sound, Kerguelen Island, January 20, 1874; depth,
28 fathoms; bottom, volcanic mud. Three specimens, which were especially noticeable
as being of a deep brown colour in spirits. Dredged.

Station 149, Accessible Bay, Kerguelen Island, January 9, 1874; depth, 20 fathoms;
bottom, volcanic mud. Several specimens. Dredged.

Station 149h, off Cumberland Bay, Kerguelen Island, January 29, 1874; depth,
127 fathoms; bottom, volcanic mud.

*Remarks.*—The specimens from Stations 149 and 149h were of various sizes, one
reaching as much as nine-tenths of an inch; they showed the light creamy colour so common
in spirit-specimens, and this difference in colouring, combined with other variations,
made me long hesitate as to whether the species of Pl. IV. was the same as that of Pl. V.
There were differences in the relative proportions of the joints of the antennæ, in the
shapes of the spines on the outer plate of the first maxillæ, in the proportions of the
second gnathopods, in the armature of the uropods, and especially the inner ramus of
the second pair of uropods, though exhibiting the sudden contraction above described,
was otherwise more regularly stiliform. I have, however, convinced myself that none of
these differences are of specific value. Among the light-coloured specimens the relative
proportions of the antennary joints are not constant; for example, in the upper antennæ
the first joint varies much in the peduncle, the primary flagellum and the secondary
flagellum; in the lower antennae the fifth joint of the peduncle may be a little longer or a little shorter than the fourth; the spines of the first maxillae vary much in general appearance, in this as in other species, according as they are fresh or worn with long use. To the ramus of the second uropods I should have attached more importance had I not found in a small light-coloured specimen the ramus shaped just as in the large dark-coloured specimens.

This species, in respect of the antenna, mouth-organs, second gnathopods, percepods, and general structure of the pleon, closely resembles Anonyx gudosus, Kroyer, the Anonyx cicada (O. Fabricius) of this Report (see pp. 46, 47). It differs from it in respect of the first gnathopods and the second uropods, in these two respects agreeing with Ichnopus, Costa, as defined by Boeck, but from that genus it differs in regard to the maxillipeds and the branchial vesicles, which are pointed below, but without the pectinate folds considered characteristic in Ichnopus. Since, by the omission of the epithet "quadrangular," as applied to the hand of the first gnathopod, in Boeck's definition of Anonyx, that definition will include the present species, it seems advisable by that expedient to save the creation of a new genus. To point to its agreement with the older species, I have therefore named the new one Anonyx cicadoides. Anonyx puninus, Lillieborg, is retained by Boeck himself in the genus Anonyx, although the hand of the first gnathopods is not quadrangular.

Genus Tryphosa, Boeck, 1870.

For the original definition, see Note on Boeck, 1870 (p. 399). The genus is so near to Anonyx, Kroyer, as defined by Boeck himself, that they ought perhaps to be reunited, as suggested both by G. O. Sars and Gerstaecker.

Tryphosa antennipotens, n. sp. (Pl. VI.).

Rostrum obsolete, lateral angles of the head acutely produced; back well-rounded, most dilated at the fifth segment of the pereon; postero-lateral angles of the third pleon-segment not acute or upturned; fourth pleon-segment with a dorsal depression, distally carinate, tip-tilted, the lateral margin continuous with the curve of the lower margin of the third segment; the sixth segment ridged on each side of the telson.

Eyes indistinct, but apparently large, set back from the front margin, reniform, meeting at the top of the head.

Upper Antennae.—First joint long and tumid, second and third joints short, narrowing distally, the distal borders sinuous; first joint of the flagellum short, equal to the four following, calceoli large and crowded, there being one on each of the fifty-two joints of the flagellum, with the exception of the first and two or three at the end. The
flagellum is long and thick, and seemingly little flexible. The secondary flagellum of four joints together is shorter than the first of the primary.

**Lower Antennæ.**—Gland-cone very prominent, third joint short, fourth and fifth subequal in length, with some cilia on the upper and setæ on the lower margins; flagellum of fifty-three joints, rather thinner and longer than that of the upper antennæ, the calceoli equally numerous, placed on the upper margin confronting those of the upper antennæ, but in both pairs so placed that, while the calceoli of alternate joints are seen full face, those of the other alternate joints will be seen in profile.

**Epistome** a little prominent.

**Mandibles.**—Cutting edge evenly convex, with a tooth at the top, the lower apex scarcely indented; secondary plate of the left mandible small, curved; spine-row of three small spines, behind these a long tract of fur leads to and partially lines the molar tubercle, the crown of which is minutely denticulate, strongly directed backwards, and carrying a furry tuft above; the palp is set forward, over the front of the molar tubercle, its first joint short, the second rather stout, with some five small spines on the inner margin near the apex, and three or four along the upper half of the outer margin; the third joint much curved, a short piece of its inner margin clear, the remainder fringed with eight and twenty spines, the first twenty-one pectinate on the upper border, the other seven longer, near and at the apex, pectinate below; a single long spine or setæ near the outer margin close to the base.

**Lower Lip.**—Apical margins of the forward lobes broad, somewhat squared, much ciliated, little dehiscent.

**First Maxilla.**—Inner plate small, with two unequal plumose setæ on the apex; outer plate with very oblique apical margin; of the eleven spines that which stands inmost has seven marginal teeth, the next above it four; these are somewhat isolated; of the rest the outer are the stoutest, with one, two, or three marginal teeth; one about central has seven; the second joint of the palp has six or seven small teeth on the apex and one spine or short setæ; below the palp the shaft has on its outer border some groups of long setæ.

**Second Maxilla.**—Outer plate decidedly longer than the inner; the long curved spines on its apical border are followed by a row of small ones continued some little way down the outer border; on the inner plate the spines and setæ of the very oblique apical border are terminated by a long plumose setæ.

**Maxillipeds.**—Inner prismatic\(^1\) plates broad, reaching nearly to the apex of the first joint of the palp, the plumose setæ in the usual position, the apical border almost squared, with three close-set teeth, followed by four curved spines decreasing in size as

---

\(^1\) The epithet **prismatic** was applied to these plates first, I believe, by Kroyer; it refers to that which an unshaded diagrammatic drawing cannot show, namely, that to a spectator looking upon the inner surface of the maxillipeds the inner edges of these plates are almost invariably nearer, sometimes much nearer, to the eye than their outer edges.
they pass round to the outer margin, on which lower down there is a fifth; below the
corner tooth on the outer side of the plate are two strong spines; the broad outer
plates, reaching nearly to the apex of the second joint of the palp, have on the inner
margin a score of small teeth set close together, followed by a separate single tooth on
the apical margin, which in turn is followed by eight spines passing round the apical
and some way down the outer margin; the second joint of the palp is a little longer
than the first and much longer than the third; the finger is not very long.

First Gnathopods.—Side-plates very broad, broader above than below; first joint
extending beyond the side-plate, broad, with setae extending down about two-thirds
of the front margin; the third joint with a short front margin and a long hinder one, which
is furred, and near the produced pointed apex carries a row of spines; the wrist rather
shorter than the hand, has the long front margin clear, except for the row of long spines
about the apex; the hinder margin is furred and also has spines about the apex; there
is a ridge or pocket on the inner side parallel with the furred part of the margin; the
hand is broad and long, at the base nearly as broad as the wrist distally, furred on the
hinder margin near the base, and here having on the side a ridge or fold of the skin
parallel with the margin; there are various groups of spines or setae on the hind
margin and surface of the hand and at the front apex; the finger closes down between
the two spines, which define the sloping apical palm.

Second Gnathopods.—Side-plates widening downwards, at the top much less wide
than those of the first pair. Branchial vesicles expanding greatly from a narrow neck,
narrowed below; marsupial plates moderately broad. First joint extending much
beyond the side-plate, equal in length to the third, fourth and fifth joints together, with
a few setae on the front margin; second joint as long as the wrist; third joint shorter,
front margin free for some distance, hind margin furred below, and with a large group
of long, thin spines on the rounded apex; wrist very lightly furred anteriorly, but
strongly behind, also towards the distal end carrying numerous groups of slender spines
of various lengths; one such group at the apex in front; the hand shorter than the
wrist, but elongate, the sides but little curved, much furred all along, while the centre
of the surface on both sides of the hand is naked or nearly so; in addition to the
furring, both edges and adjacent parts of the hand are crowded with groups of spines,
those in front when they reach the apex standing out far beyond the finger; they are
pectinate, very slightly curved; the finger is very small, closing down on a palm, the
outer part of which is nearly straight, at right angles to the hinder margin of the hand.

First Peraepods.—Side-plates with the hind margin straight; marsupial plates
expanded a little below till near the apex, having on the lower half and apex numerous very
long setae in front and a few short ones behind. First joint of the limb not reaching the
lower rim of the side-plate; third joint longer and stouter than either the fourth or fifth,
slightly decurrent in front, with groups of long, slender spines or setae on the hinder margin,
and the apex in front; the fourth joint similarly armed, stouter than the fifth, in length subequal to it; the fifth with numerous short as well as long setiform spines on the hinder margin; two very short ones at the junction with the slightly curved finger.

Second Peraxopods.—Side-plates excavate far down, the lower margin curving up to the excavation so as to form a rounded point. Branchial vesicles broad except at the neck. Joints of the limb similar to those of the preceding pair.

Third Peraxopods.—Side-plates rather wider than deep, front margin very convex, hind margin nearly straight. First joint a round oval, broader above than below, the rounded lower margin behind reaching as far down as the second joint, front margin with numerous spines fringing it entirely, hind margin serrate; third joint much longer than broad, somewhat decurrent behind, with spines at the back, spines and setae in front, and apical groups of spines; fourth joint scarcely so long as third, similarly armed; fifth joint much narrower but longer than fourth, with eight sets of spines on the front margins, some spinules on the back border; finger about half the length of the fifth joint, slightly curved.

Fourth Peraxopods.—First joint a long oval, narrower below than above, spines on the front margin few and small on the upper part, numerous and longer below, hind margin serrate; third joint as in the preceding pair, but somewhat longer; fourth joint longer than third, with nine groups of spines on the front border; fifth joint scarcely shorter than the fourth, with ten groups of spines on the front border; small spines on the hind margins of third, fourth and fifth joints; finger not nearly half as long as the fifth joint.

Fifth Peraxopods.—Branchial vesicles a broad oval, with the hind margin drawn out into somewhat pointed processes. First joint broadly oblong with rounded corners, the front margin as in the preceding pair, the hind margin serrate, rather deeply at the lower part; the third joint shorter and narrower than in the two preceding pairs, with four groups of spines in front, and four behind; fourth joint longer than third, with eight groups of spines in front, three behind; fifth joint longer than fourth, with nine groups of spines in front, five behind, these latter being all very small, except the apical; finger not half the length of the fifth joint.

Uropods.—Peduncles of the first pair longer than the rami, rami subequal, stiform, spines numerous on the peduncles and also on the rami. Peduncles of the second pair a little longer than the rami; the rami stout, the outer somewhat longer than the inner; marginal spines numerous. Peduncles of the third pair shorter than the rami, the rami broadly lanceolate, almost equal, extending much further back than the second pair; spines on both edges; plumose setae also on one.

Telson long, extending far beyond the peduncles of the third uropods, cleft for more than four-fifths of its length, narrowing distally, a series of five spines along each side; in each apical cleft two spines, of which the outer is the larger.
Length.—The specimen, in the position figured, measured, without the antennæ, three-quarters of an inch; with the outstretched antennæ, an inch.

Locality.—Station 150, off Heard Island, February 2, 1874; lat. 52° 4' S., long. 71° 22' E.; depth, 150 fathoms; bottom, coarse gravel; bottom temperature, 35°2. One specimen, female. Dredged.

Remarks.—The specific name refers to the singularly stout and stiff antennæ.

This species agrees well with Boeck’s definition of his genus Tryphosa, except that the outer plate of the maxillipeds does not reach beyond the second joint of the palp, in which respect it agrees better with his definition of the genus Anonyx; on the apex the plate in question is armed with the requisite two spines, but it has more than two. In Anonyx the inner plate of the second maxillæ is much shorter than the outer plate, which is not the case in Tryphosa, but beyond this it is not easy to find any character on which absolute reliance can be placed for distinguishing the two genera. Boeck, in his account of Tryphosa, compares it only with Orchomene, but when discussing the genus Anonyx, he says,¹ “the mouth-organs in this genus show a certain agreement with those in some of the following genera, especially in Orchomene, Tryphana [? Onesimus], and Tryphosa; the upper lip in them all is helmet-shaped and covers the tips of the mandibles with its thickened end. These genera differ, however, from one another in the form of the other mouth-organs, the antennæ, the two pairs of gnathopods, and the telson. Thus, the mandibles in Anonyx are very strong but not especially elongate, with a long but narrow molar tubercle, and the palp is fixed nearer the end than the molar tubercle. The first maxillæ are also very broad, but the inner plate is very short, only a little longer than broad, with two strong plumose setæ on the apex. The plates of the second maxillæ are also short but broad; the outer plates of the maxillipeds are very large, and have on the rims a close row of small nodules. The third joint of the lower antennæ is short, and the first gnathopods are more or less elongate. The telson is also elongate, longer than the peduncle of the last uropods, and deeply cleft. The body is also on the whole tolerably elongate, and the fifth side-plate accordingly longer than deep.”

Tryphosa barbatipes, n. sp. (Pl. VII).

The lateral lobes of the head much produced and sharply angled.

Postero-lateral angles of the third pleon-segment not acute and yet scarcely rounded. Fourth pleon-segment with a dorsal depression.

Eyes not discerned.

Upper Antennæ.—First joint tumid, second and third short, the third, as is often the case in the Lysianassidæ, excavate below; flagellum of eight joints, the first large, slightly

¹ De Skand. og Arkt. Amph., p. 151.
tapering, considerably longer than the other seven together, having the cylindrical hairs of the brush not very long, and carrying two spines at, and one spine near, the apex; the other joints diminishing successively in breadth, and towards the end in length also; the secondary flagellum of four joints together equal in length to the first of the primary.

Lower Antennæ.—Gland-cone prominent, third joint somewhat inflated, in length equal to the composite first and second joints, fourth and fifth subequal, both with small cilia above and setæ below; the flagellum tapering, probably consisting of seven or eight joints; in the specimen (female) examined there were five left on one member of the pair and six on the other.

Mandibles.—The cutting edge smoothly convex, bounded by a very small tooth above, pointed downwards, and an equally small one below pointing forwards; above this in the left mandible is a minute tubercle breaking the evenness of the convex edge, but this is probably only an individual peculiarity; the top border over the upper tooth is minutely serrate; the secondary plate of the left mandible is short and small, dilated forwards and apically cut into five or six minute denticles; the spine-row consists of three slender spines; the molar tubercle is prominent, the dentate crown pointing backwards, oval, with three central teeth apart from the lines of denticles; the region between the spine-row and the crown furred with cilia, a long group of these also above the crown; the palp not far back, over the molar tubercle’s front part, the first joint short, the second with nine spines near the apex; the third joint with the first subequal in length to the second; more than the first third of its inner margin smooth, the remainder fringed with fifteen spines; one spine near the base on the outer side. Behind the palp and molar tubercle the shaft of the mandible is broad.

First Maxillæ.—Inner plate short and narrow, with two unequal plumose setæ on the apex; outer plate long, two of the spines a little below the apical margin, the inner of the two with fifteen rather elongate teeth, the other spines much crowded together, nine in number, strong, the outer less dentate than the inner, the longest of all in company with a short one standing nearest to the two first mentioned; the second joint of the palp narrower proximally and distally than in the middle, its apical border set with seven spine-teeth serrate on the outer border, a single seta near the outer apex.

Second Maxillæ.—Outer plate longer and broader than the inner, apical margin oblique, with pectinate spines increasing in length to the apex on the outer side, a few shorter ones following down the outer border; apical border of the inner plate likewise oblique, armed with spines, a plumose seta on the inner margin just below the spine-row longer than any of the spines.

Maxillipeds.—Inner plates not reaching the apex of the first joint of the palp, with plumose setæ planted in the ordinary manner on the inner margin and passing across to the outer corner of the apical; apical border with three strong teeth, the innermost the most prominent, beyond these a plumose spine or seta distinct from the series just mentioned;
outer plates reaching as far as the second joint of the palp or a little beyond, with ten strong teeth on the inner margin set close together, an eleventh on the apical margin separated by a short interval from the rest, and beyond this two spiniform teeth; second joint of the palp not longer than the first, the third joint shorter; the finger short, with a rather long nail accompanied by three cilia, the usual dorsal cilium rather nearer the origin of the finger than that of the nail.

First Gnathopods.—Side-plates broader above than below, very convex behind, with a slight concavity in front. First joint extending much beyond the side-plate, fringed with long setæ in front; third joint with no free front margin, some groups of setæ on the hind margin; wrist subtriangular, much shorter than the hand, and scarcely broader distally than the base of the hand, very setose on the free hinder margin and the contiguous portion of the inner side; hand oblong, longer than the three preceding joints combined, a little broader at the base than at the palm, front margin continuous with that of the wrist, having few setæ except at the apex, while the hinder margin and contiguous inner side are densely setose with plumose setæ; palm a little concave, bounded by two stout spines with fine curved tips; along the palm are close-set straight cilia, and a row of longer cilia not close set; the finger just the length of the apical margin of the hand, with one tooth on its inner edge, and a dorsal cilium near the base.

Second Gnathopods.—Side-plates of very even width throughout. Branchial vesicles large and broad except at the neck. First joint a very little wider below than above, scarcely curved, the setæ on the front margin fewer and much shorter than in the preceding pair; the second joint nearly as long as the wrist; third much shorter, a little furred behind, with spines on the rounded apex; the wrist furred on the hinder margin, with little fan-shaped scales on the breast, and long pectinate spines near the apex; the hand furred but not densely, somewhat narrowed proximally and distally, the hinder margin a little outdrawn, the overarching spines of the front and apical margins and those of the hinder margin having their pectinations confronting in each set those of the other set; the palm sloping inwards, microscopically pectinate, the minute finger neatly fitting it with its inner edge also for the distal half microscopically pectinate, and carrying a dorsal cilium on the thick portion near the hinge. The tip of the finger closes down against spines at the outer end of the palm; it is probable that this is the case in all species of this family, but in regard to many the fact is not mentioned from the difficulty of observing such spines with certainty in the midst of the dense fur sometimes present.

First Peraeopods.—Side-plates long, slightly widening downwards. Branchial vesicles broad, seemingly without folds. Marsupial plates, in this specimen, narrow, with few setæ. First joint reaching about as far as the side-plate; third joint much longer than fourth or fifth; fourth scarcely so long as fifth; the third and fourth bordered behind with groups of setæ of various lengths; in the fifth the groups consist of a spine with a
long accessory thread and a seta, two short straight spines adjoining the hinge of the finger on the inner side; the finger short, little curved, with a small nail, the dorsal feathered cillum near the hinge.

Second Peropods.—Side-plates of considerable breadth below. The joints of the limb scarcely distinguishable from those of the preceding pair.

Third Peropods.—Side-plates a little outdrawn below in front, length and breadth subequal; first joint elongate but not narrow, broader above than below, the rounded lower margin behind descending below the second joint, front margin spinose, with a few setæ, the hinder margin not strongly serrate; the third joint expanded, hinder angle outdrawn downwards; fourth joint narrower, perhaps a little longer; fifth joint narrower and a little longer than the fourth; finger short, curved.

Fourth Peropods.—First joint similar to that of the preceding pair but larger, not drawn out below the second joint; the third joint much longer than in the preceding pair, and less expanded in proportion to its breadth; the fourth joint longer than the third or the fifth, which are subequal; finger short, but longer than that of the preceding pair; the whole limb considerably longer than the pair preceding or the pair following.

Fifth Peropods.—The first joint longer and much broader than in the preceding pairs, the third joint shorter and less expanded, the fourth equal in length to that in the third pair, but narrower; the fifth joint and the finger rather longer than those in the third pair. In these three pairs of limbs the armature is similar; on the hind borders of the third, fourth and fifth joints some small spines, with larger ones apically; setæ and spines on the front margins of all the earlier joints, spines only on the fifth; a rather large group of spines on the front apex of the fourth joint.

Pleopods.—The coupling spines on the peduncles exhibit a row of three marginal retroverted teeth; the joints of the rami number from fifteen to seventeen; the cleft spines form a series of four in the first pair and the second, of three in the third pair.

Uropods.—Peduncles of the first pair longer than the rami, rami stiliform, a little curved at the tips, with four or five marginal spines; peduncles of the second pair equal in length to the rami, the rami equal; the peduncles of the third pair subequal in length to the inner rami; the rami short, broadly lanceolate, the outer exceeding the length of the inner by nearly the length of its nail, the inner having no nail or only a rudiment.

Telson extending beyond the peduncles of the third uropods, cleft for more than two-thirds of its length, widening from the base to a level with the top of the cleft, then narrowing with convex outer margin to the apices, which are more outdrawn on the outer than the inner edges, between the two angles each containing a strong spine with accessory thread; on each side is a small spine nearly on a level with the top of the cleft, and lower down a larger one.

Length of the specimen, in the position figured, about seven-twentieths of an inch.
Locality.—Station 149H, off Cumberland Bay, Kerguelen, January 29, 1874; depth, 127 fathoms; bottom, volcanic mud. Dredged.

A minute specimen, not a tenth of an inch long, from the same locality, is probably the young of this species. Two other specimens were taken at Kerguelen, at a depth not mentioned.

Remarks.—The specific name alludes to the bearded appearance of the wrist and hand in the first gnathopods.

In the young specimen there are clear traces of eyes, the mandibles are well developed, but with few spines on the palp; on the palp of the first maxillae there are only four teeth; on the inner plate of the maxillipeds the three apical teeth are well developed, but the outer plate has on the inner margin but one tooth, which is that near the apex, and two on the apical margin; the branchial vesicles are narrow; the fingers of the peraeopods comparatively more developed than in the adult.

Genus Hippomedon, A. Boeck, 1870.

For Boeck's definition of this genus, see Note on Boeck, 1870 (p. 397). To embrace the new species here assigned to the genus, the first maxillae should be described as having two or more setae on the inner plate, and the epithet broad should be omitted from the account of the maxillipeds. The description of the lower antennae as having the fifth joint much longer than the fourth must be cancelled, being in fact contrary to the descriptions which Boeck himself gives of the only two species which he assigns to the genus.

Hippomedon kergueleni (Miers) (Pl. VIII).

1879. Anonyx kergueleni, Miers, Transit of Venus Exp., Zoology of Kerguelen Island, Crustacea, pp. 8, 9, pl. xi. fig. 4.

Lateral lobe of the head acute, produced some distance along the first joint of the upper antennae. Third segment of the pleon with the postero-lateral angles much prolonged and curved upwards as narrow pointed lobes. Fourth pleon-segment with a dorsal depression. There are some small scattered hairs upon the back.

Eyes not discerned.

Upper Antennae.—The first joint long, stout, cylindrical, with a row of minute cilia near the base, and some larger feathered ones on the opposite margin, distally, such being scattered also on the two following joints, which are very short, narrowing distally; flagellum of fourteen joints, the first as long as the four following combined, carrying the usual
brush of filamentary cylinders\(^1\) beneath; the other joints furnished with cilia, and some of them with cylinders; the accessory flagellum of five joints, of which the first is the longest.

**Lower Antennæ.**—Third joint as long as first and second united, and but little shorter than the fifth; fifth a little shorter and narrower than the fourth; gland-cone prominent, as can be seen when the antennæ are disengaged from the head; flagellum of sixteen articulations. Feathered cilia on the fourth and fifth joints of the peduncle, besides smooth setæ of various sizes.

**Mandibles.**—The palp set very far forward; the cutting edge evenly convex, with a small projection at the top; secondary plate of left mandible narrow, seemingly a little dentate at its slightly dilated apex; spine-row of three small spines or stiff curved setæ; molar tubercle with the dentate crown oval, not strongly outdrawn backwards as in *Anonyx cicadoideś*; palp with first joint very short, second joint very long, with slight bend or constriction below the centre, and a row of seven spines near the apex; the third much shorter joint has twelve short spines along the margin, followed by six more successively increasing in length to the apex; not far from the base, at and near the convex margin, there are two or three long setiform spines; the surface of this joint is as usual striated with closely adpressed cilia.

**Lower Lip** ciliated as usual on the forward apices; the outer margins and mandibular processes in the specimen figured quite smooth.

**First Maxillæ.**—Inner plate slender, ovate, apically furnished with two plumose setæ, the inner much the smaller; outer plate broad, carrying on the obliquely truncate apex six dentate spines, and others, probably five, in a second row below these; the second joint of the palp is laminar, much curved, overarched the outer plate, having its slightly narrowed apical margin fringed with twelve to thirteen teeth pectinate on the outer edge, and one cilium or small seta near the margin. In describing these maxille, Mr. E. J. Miers\(^2\) uses the following words, “the outer lobe strong, truncate, armed at the apex with three or four spines.” When the part in question is examined with a low power, this would be the natural way to describe it, but under a high power of the microscope it can be seen that the spines are much more numerous, those actually at the apex numbering six very much crowded together, and in the specimen here described very blunt at the tips. That this bluntness is only the effect of wear is clear from the sharply-pointed new spines which can be discerned within the plate.

**Second Maxillæ.**—The plates rather narrow, the outer a little longer than the inner, the apices with the usual fringes of pectinate spines, which pass rather further down the inner margin in the inner plate than in the outer; on the inner plate the row terminates with a plumose seta.

**The Maxillipeds** narrow, not broad at the base as might be inferred from the figure,

\(^1\) By the expression *filamentary cylinders or cylindrical setæ* I mean the organs now generally regarded as olfactory.

which represents the two halves much flattened out; inner plate reaching a little beyond the first joint of the palp, having three teeth on the apical margin, the plumose setae commencing near the middle of the inner margin, and passing round to the outer corner of the apical margin, but not continued down the outer edge; none of them large; the outer plate reaching much beyond the second joint of the palp, its inner border (beginning from the base) carrying a cilium, then a setiform spine, then a spine, then two microscopic teeth, then a close row of thirteen small teeth, those at the curve of the apex being the largest, beyond these the curved outer margin apparently quite naked; there is a row of five little spines on the side of the plate, a little removed from the inner margin; of the palp-joints the first is longer than the third, the second longer than the first, the fourth or finger provided with a sharp nail.

First Gnathopods.—Side-plates very little dilated below; first joint almost straight, sparingly setiferous in front; third joint with the emarginate front border much shorter than the hind border, which has a group of setae near the apex; the wrist rather longer than the hand, nearly half of its hinder margin coinciding with the distal margin of the preceding joint, the remainder parallel with the front margin, slightly furred and carrying two groups of setae; the hand almost parallel-sided, like the wrist having some groups of setae near the front border, and a conspicuous group at its apex, on the hinder border having four groups; the sloping, rather convex palm, microscopically pectinate, defined by a spine, bordered with spiniform cilia, in addition to two linear groups of setae, and close to the hinge of the finger two minute spines; the finger, besides the usual cilium on the back near the hinge, has one about the middle of its inner margin; this margin develops a small tooth near the origin of the nail, two cilia taking rise at this point.

Second Gnathopods.—Side-plates and the first joint of the leg a little longer and narrower than those of the preceding segment; branchial vesicle with a broadly rounded upper lobe rising above the neck, the central part of the vesicle having the twist of a screw, the lower part narrowing rather abruptly; 1 marsupial plate narrow; second joint as long as the wrist; third joint short, furred behind, apically somewhat rounded, and carrying a group of pectinate spines; wrist much longer than hand, densely furred behind, less so in front; pectinate spines near the lower end of the hinder margin; hand long-ovate, densely furred, numerous pectinate spines of very various sizes arrayed on both borders, especially in front apically, the pectination and curvature in both sets being directed towards the finger; the finger itself, as so commonly in this family of the Amphipoda, minute, almost lost in the surrounding forest of spines, broad at the base, then narrowing suddenly, the inner edge of the narrowed part microscopically pectinate and produced into a tooth, over which the nail bends, with cilia at its base; there is also a cilium on the back of the finger.

1 The figure, Pl. VIII. ga. 2., unfortunately does not show or even suggest the details above described, but only gives the shape of the vesicle flattened out and mounted on a slide for the microscope.
First Peropods.—Side-plates a little broader and longer than those of the preceding pair; branchial vesicle from a small neck swelling out into a broad sac with a narrow terminal lobe; first joint of the leg with the front margin straight; third joint stouter and much longer than the fourth, but little produced downwards; fourth joint stouter than fifth, subequal to it in length; fifth joint naked, like the two preceding, on the forward margin except at the apex; on the hinder margin all three have groups of spiniform setae, one long one at the apex of the fourth joint and some shorter ones on the border of the fifth seeming to be truly spines; the finger long, narrow, slightly curved, with edges bare except for the feathered ciliary on its back near the base.

Second Peropods.—Side-plates broad below, excavated above; the marsupial plates in this and in the preceding segment long and very narrow (in the specimen figured); the joints of the leg like those of the preceding pair.

Third Peropods.—The branchial vesicle broad and squared above, curling round in a narrow lobe below, with a long thin accessory vesicle starting from the base. First joint very broad, slightly broader above than below, lower margin behind with a deep rounded lobe overlapping the next joint, the lateral margins very little curved; the third joint short, broad, somewhat decurrent behind, with spines on the hinder margin, spines and fine setae on the front margin; fourth joint ovate, somewhat shorter and much narrower than the preceding, garnished in like manner; fifth joint slender, longer than the fourth, with few spines; finger long, thin, little curved, seemingly quite naked.

Fourth and Fifth Peropods similar in general structure to the third, but with the first joints longer and about the same breadth, the third joint in the fifth pair less dilated, the fifth joint longer in proportion to the finger. As the dorsal ciliary of the finger is here present, it may be only accidentally missing from the third pair. Branchial vesicle of the fourth pair was on one side of the specimen not unlike the accessory vesicle of the third, but curved instead of straight, and at the top broader, as also in the somewhat narrowed middle part, while the terminal part is thinner; on the other side the lower part of the branchia was expanded. The branchial vesicle of the fifth pair is quite small, irregularly shaped both as regards the neck lobe and the larger terminal one, which has the appearance of being attached to the other by one corner.

Pleopods.—In the coupling spines the apex is rounded, undilated; the lateral retroverted teeth are two in number; on the large basal joint of the inner ramus there are three cleft spines of the usual form, as described in the account of Cyphocaris micronyx (p. 660); the joints of the rami are from sixteen to twenty in number, the outer ramus apparently as a rule having one or two more joints than the inner.

Uropods.—The first pair have the peduncles somewhat longer than the rami; the outer ramus rather longer than the inner; both stiliform, slightly curved at the tips; in the second pair the peduncle is rather shorter than the rami; these are subequal, each, as
REPORT ON THE AMPHIPODA.

in the preceding pair, armed with three spines along the proximal part of the upper border; in the third pair the peduncle is short, the rami slenderly lanceolate, the outer and longer branch terminating with a nail, having five spines along one of its margins, on the other two spines and one or two setae near the nail; the inner branch with spines and setae along one margin, and some spines near to the other margin.

Telson.—Cleft nearly to the base, evenly narrowing to the apex, each half of which is emarginate, the inner part more produced than the outer, and carrying a spine and a feathered ciliation in the hollow; three spines are placed at intervals on the surface of the telson near each outer margin.

Length.—The specimen figured measured, without the antennae, about two-fifths of an inch.

Locality.—Station 149, Accessible Bay, Kerguelen Island, January 9, 1874; depth, 20 fathoms; bottom, volcanic mud. Dredged.

Station 149H, off Cumberland Bay, Kerguelen Island, January 29, 1874; depth, 127 fathoms; bottom, volcanic mud. Several specimens. Dredged.

Remarks.—Mr. Miers, in the Zoology of Kerguelen Island, p. 9, says:—

"In the form of the antero-lateral angles of the cephalon, and of the postero-lateral angles of the third segment of the pleon, this species to some extent resembles (1) Hippomedon holboelli, Kröyer, as described by Boeck, as well as (2) H. abyssi [abyssi], Goës, and (3) Anonyx pumilus, Lilljeborg,—all from the Northern Seas. But it differs from these species in having the inner lobes of the maxillipeds proportionately much longer; and in this respect it approaches more nearly to the type of structure exhibited in Orchomene, Boeck. The eyes also, which are well marked in the species just referred to, are not visible in any of the specimens of A. kergueleni.

"On account of the subcheliform character of the first pair of the gnathopods, and the divided telson, I refer this species to the genus Anonyx, as defined by Mr. C. Spence Bate, instead of retaining it in Lysianassa, where I placed it at first. I cannot refer it with certainty to any one of the numerous genera recently established by Boeck in his systematic arrangement of the Scandinavian and Arctic Amphipoda; I believe, indeed, that it will be found necessary to introduce important modifications of the systematic arrangement and generic characters proposed by this author into any general revision of this difficult order, which may hereafter be undertaken, based upon the comparison of species from foreign as well as the European and Arctic Seas."

A specimen, however, of Hippomedon abyssi (Goës), from the "Valorous" Expedition, lent me by Canon Norman, shows both the inner and outer lobes of the maxillipeds corresponding in their proportions with those of the present species, which I have therefore transferred to the genus Hippomedon, where Mr. Miers himself seems to have had some disposition to place it.
Hippomedon trigonius, n. sp. (Pl. IX.).

In many respects this species shows a very close resemblance to Hippomedon kergueleni (Miers), although there are peculiarities which have induced me, after some wavering, to keep it distinct. In the present form the postero-lateral angle of the third pleon-segment is but little, instead of greatly, curved upwards. Of the fourth pleon-segment the proximal portion is very convex, the depression being distal, so that the end of the segment forms a raised angular apex rising above, instead of forming a continuous curve with, the following segment.

It originally appeared to me that the dorsal depression in Hippomedon kergueleni was in a marked manner proximal, and in the form now under consideration conspicuously distal, but I find in this and many other species of Amphipods that the dorsal appearance of the fourth pleon-segment is very essentially altered according as the pleon happens to be more or less extended or flexed. In the state of extension the proximal portion of this segment often telescopes far into the third segment, sometimes completely hiding a dorsal depression, and at others making such a depression appear proximal, when in regard to the whole dorsal length of the segment it is in fact distal or central.

The other differences between the two forms may be judged of from the following account.

Upper Antennæ.—The peduncles comparatively slender, the first joint longer in proportion to its breadth than in the form already described; the flagellum consisting of eleven joints, the first equal in length to between two and three of those succeeding it; the secondary flagellum of three joints, of which the first is not quite so long as the first of the primary.

Lower Antennæ.—Gland-cone prominent, third joint equal in length to the fifth; fourth joint decidedly longer than either; flagellum nine-jointed.

The Mouth-Organs appear to be in close agreement with those previously described. In the specimen examined there were fewer teeth on the apex of the palp of the first maxilla.

First Gnathopods.—There seems to be no difference of importance except in the shape of the side-plates, which are here of less regular form, shorter and stouter, outdrawn in front below. At the beginning of the palm of the hand there are two spines.

Second Gnathopods.—In this species the wrist is a little plumper distally, hand and wrist both densely furred, but the distal spine-armature of the hand both at front and back less important than in the other species.

Second Peræopods.—What may be called the shank of the side-plate is here somewhat longer in proportion to the broad lower portion.

Third Peræopods.—First joint more contracted below, and with margins more curved, so as to have an oval rather than the square appearance presented in the other species; the third and fourth joints longer compared with their breadth.
**Fifth Peraeopods.**—The front margin of the first joint is here almost absolutely smooth for the upper two-thirds of its length, while in the other species it is spined almost through its whole length; on the other hand the cilia on the postero-distal curve are here more numerous. The fingers in this species are less slender than in the other.

**Pleopods.**—Two very small coupling spines, with a row of three back-turned teeth along the margin; the inner ramus with twelve, the outer with fourteen joints, the first of the outer fringed as in the companion species with numerous plumose setæ, the first of the inner with the eleft spines three in number.

**Uropods.**—In the first pair there are four spines on the margin of the outer ramus, and five on that of the inner, leaving a comparatively small terminal portion free from spines; in the second pair the outer branch has four, the inner three, spines; in the third pair the outer branch has three spines on one margin, and on the other one at the base of the nail; this branch is not longer than the peduncle, the other, which is much shorter, has but one spine.

**Telson.**—This, though similar in the details of its structure to that of *Hippomedon kergueleni*, is extremely different in its proportions, being in fact but little longer than its greatest breadth.

It is not very safe to establish new species upon small differences in the relative lengths of joints of the antennæ and limbs, or upon variations in the number of spines that form a marginal row, since these discrepancies and such as these may be due to age or sex or individuality, but in the present instance it must be noticed that in regard to the two forms named *Hippomedon kergueleni* and *Hippomedon trigonicus*, specimens of the same sex have been compared, and that the more striking form of the fourth pleon-segment, and the larger number of spines on the first and second uropods, belong to the smaller, not to the larger species.

**Length,** one-quarter of an inch without the antennæ.

**Locality.**—Kerguelen Island; depth not specified.

**Remark.**—The specific name *trigonicus*, triangular, refers to the shape of the hump on the fourth segment of the pleon.

*Hippomedon miersi*, n. sp. (Pl. X.).

Lateral lobe of the head produced into a rounded angle. Postero-lateral angle of the second segment of the pleon slightly acute, of the third segment rounded. The fourth segment with a dorsal depression, the sixth segment with dorsal ridges on either side of the telson.

There seemed to be a faint indication of eyes.
Upper Antennæ.—First joint short, tumid; second and third joints very short, the third a little outdrawn above; flagellum of eleven joints, the first subequal to the remainder united, and longer than the four-jointed secondary flagellum; on the first joint of the peduncle a spine-like feathered cilium on the central bulge below, longer feathered cilia on its distal border, and on the next joint; the usual brush on the first joint of the flagellum, this joint being distally drawn out into a little sharp tooth; calceoli on several of the small joints.

Lower Antennæ.—First three joints short, gland-cone twisted round towards the first joint; third joint shorter on the inner than the outer side; fourth and fifth joints furred above, fifth longer and thinner than the fourth; flagellum of some thirty-eight joints, with small calceoli seemingly only on every alternate joint.

Mandibles.—Cutting edge as usual convex, with a small projection above, the rounded part below perhaps a little indented behind; the secondary plate on the left mandible a little curved, bluntly pointed, too broad to be called spine-like, probably in a worn condition; spine-row seemingly of three small spines; molar tubercle prominent, the crown rather elongate; the palp long, set as far forward as the front of the molar tubercle, the second joint but little longer than the third, thirteen spines at the distal part of the second joint, in the third joint one spine at the back close to the base, on the opposite border nearly a third part free, the row of spines consisting of twelve decreasing, followed by six or seven increasing, in length successively towards the apex.

Lower Lip as in the next species, Hippomedon geelongi.

First Maxillæ.—Inner plate not very large, with two plumose setæ on the rather broad apex, the inner one much smaller than the outer; outer plate with eleven dentate spines crowded on and about the apical margin, the inner margin furred distally, the spines near to the inner margin slender, with numerous teeth, the outer more stout with few teeth; the palp over-arching the outer plate, with nine teeth round its apical margin, increasing successively towards the centre, pectinate on their concave outer edges; one seta projects near the outer apical angle.

Second Maxillæ.—The outer plate longer than the inner, the sloping apical margins of both fringed with rows of pectinate spines; on the inner plate there are stiff plumose setae as well as spines, and a little below the apex a larger and proportionately less stiff plumose seta on the inner margin.

Maxillipeds.—The inner plates reach about to the apex of the first joint of the palp, with three teeth followed by two curved eiliated spines on the apical margin, and one tooth on the inner margin just below the apex; the outer plates reach as far forward as the second joint of the palp or a little further, the ten teeth of the inner and apical margins increasing in size towards the apex, at which the ninth is the longest, though thinner than the eighth, while the tenth is both shorter and thinner than the ninth; the second joint of the palp is but little longer than the first; the third joint is much shorter
than either; the finger with its sharp curved nail is as long as the third joint; it has some cilia near the nail, and a dorsal cillum much nearer the nail than the base.

First Gnathopods.—Side-plates small, long-oval, narrowest at the lower end. First joint strong, projecting much beyond the side-plate; third joint very short in front, much longer behind; the wrist not so long as the hand, and scarcely broader, widened beyond the triangular portion which adjoins the third joint, and furred on the hind margin of the widened part; the hand long, nearly parallel-sided, with a slight curve, hinder border scarcely furred, some setae on both margins and on the side; palm sloping, a little convex, defined by two spines with stout accessory threads; between these spines the finger closes down neatly fitting the palm, and having a tooth on the inside just before the nail is reached.

Second Gnathopods.—Side-plates deeper than those of the preceding segment, much wider below than above; first joint long, widening a little and curving backwards as it approaches the long second joint; third joint shorter than second, furred about the middle of the hinder margin, which carries near the apex long slender spines or setae of geniculate appearance; the wrist but little longer than the second joint, furred both before and behind, and with long slender spines near the apex on both sides; the hand much shorter than the wrist, oval, densely furred, with the usual armature of spines; the finger very small, set pretty well clear of the anterior group of spines, lying close to the produced hinder portion of the hand which provides the palm.

First and Second Peraeopods.—Side-plates of the first similar to the preceding pair, but larger, side-plates of the second much wider below than above; first joint just reaching the lower rim of the side-plate; third joint nearly parallel-sided, scarcely produced downwards, considerably longer than the fourth joint, both fringed posteriorly with setae, which increase successively in length towards the distal end of the margin; the fifth joint as long as the third, but much thinner, gently curved, posteriorly armed with spines and setae, and carrying close to the hinge joint of the finger a pair of spines shorter than those above, blunter, and seemingly with fine backward serratures. Finger about half the length of the hand in the first peraeopod. In the second peraeopod the third joint and the hand are rather shorter than in the first.

Third Peraeopods.—Side-plates rather broader than deep. First joint as broad as side-plate, length and breadth about equal, narrowed below, the distal curve behind produced nearly to the end of the second joint, convex front border set with spines and setae; third joint dilated, not longer than the fourth, except for the produced infero-posterior angle; fourth joint more dilated above than below; fifth joint longer than fourth, much narrower, a little curved, with five pairs of spines on the anterior margin; finger rather long and slender.

Fourth Peraeopods.—First joint a long oval, most of the front border spined; the third joint shorter than either of the next; fourth a little wider but shorter than the
fifth, a row of four rather long spines on its front margin, each between two short ones; the fifth with five sets of spines on the front, each consisting of a long and a short spine, except the lowest set, in which the spines are equal. The finger is long and slender, curved near to the small nail.

Fifth Peraeopods.—First joint broader and longer than that of the preceding pair, widest above; third joint not dilated; rest of limb missing. The branchial vesicles were not in a good state for observation; they presented many irregular folds, and the usual gradations of size.

Pleopods.—So far as examined these correspond very nearly with those described for *Hippomedon geelongi*. Six cleft spines were observed on one of the rami.

Uropods.—Peduncles of the first pair longer than the rami, outer ramus rather longer than the inner, small spines on the upper margins, four on the outer ramus, three on the inner, a short bright nail at the tip; in the new rami in a state of preparation within the old this bright nail makes itself conspicuous, as though it were already a part of the outward armature (see fig. nr.2.). Peduncles of the second pair shorter than the rami, which are similar to those of the first pair, except that they are shorter without being less broad; peduncles and rami of the third pair shorter than those of the second pair, though not greatly so; outer ramus longer than inner, with some small spines along the side; each ramus ends in a small nail to which it rather abruptly narrows, and each has the border fringed with very long plumose setae.

Telson.—Much longer than broad, cleft about four-fifths of its length, distally narrowing a little, but so as to leave both divisions broad-ended. In a small emargination at the outer part of each apical border is a stout spine with a cilium close on each side of it. The inner part of the apical border is rounded. On each side nearly on a level with the top of the cleft is a feathered cilium, and two spines on the margin lower down.

Length.—The specimen, without the antennæ, was nearly half an inch long.

Locality.—Station 162, off East Monceur Island, April 2, 1874; lat. 39°10'30" S., long. 146°37'0" E.; depth, 38 fathoms; bottom, sand and shells. One specimen. Dredged.

Remarks.—There is much agreement between this species and *Hippomedon kergueleni*, Miers. To call attention to this, and at the same time to show respect to the clever naturalist who first described the species just mentioned, I have named the present species *Hippomedon miersi*. It possesses that character of the antennæ which Boeck makes generic, but which is perhaps peculiar to the male. It has many sufficiently distinct features, in the first joint of the flagellum of the upper antennæ, the long third joint of the mandible palp, the first side-plate of the pereon, the third pleon-segment, the tips of the uropods, the broad termination of the telson, and other details.
Hippomedon geelongi, n. sp. (Pl. XI.).

The head narrow, much longer than the very short first pereon-segment, produced into pointed lateral lobes between the upper and lower antennae. First segment of the pleon with the postero-lateral angles much, second with the same little, rounded; third with the same acute and bent upwards; the third segment the longest; the fourth segment with a dorsal depression.

No eyes were perceived.

Upper Antennæ.—First joint large and tumid, upper margin distally produced; the second joint almost embedded in the first; the second and third both short, narrowing as they approach the flagellum, of which the first joint is large and long, adorned with the usual brush; of the other joints only two remained, the second bearing a large calceolus, and a row of five cilia near it. The secondary flagellum consists of five joints, furnished with setae.

Lower Antennae.—Gland-cone rather prominent, third joint not long, still equalling in length the composite first and second; fourth joint thicker, but scarcely longer than fifth, both furred on the upper margin and carrying feathered cilia on the lower. Flagellum of thirty joints, each apparently except the last furnished with a calceolus and a row of cilia behind it. The calceoli seemed to be rather short-stalked and with the outer rims firmer than usual.

Mandibles.—The cutting edge not well observed, but probably in near agreement with that of Hippomedon kergueleni; the spine-row of three curved, rather short spines; the molar tuberacle with the dentate crown oval; the palp set just over the front part of the molar tuberacle, its second joint considerably longer than the third, slightly constricted below the middle, this being the place where the muscles in connection with the first joint end, and where those in connection with the third joint begin; nearer to the apex begins a row of fourteen spines, which increase successively in length as they approach the outer angle of the apex; the third joint is long, slightly curved, narrowing distally, with two long setae near the beginning of the outer border, and twenty-two pectinate spines along the concave edge; these slightly diminish in size as they approach the apex, till, close upon it, they rapidly increase.

Lower Lip.—The front lobes ciliated all round, apically as usual with more fulness; the mandibular processes narrow and not produced far back.

First Maxillæ.—The inner plate not very long, on the distal portion of its inner margin and the apex carrying a row of seven plumose setæ, graduated in size, the first of the row being very slight and the apical one very large; the proximal part of the margin is furred by the projection of the fine cilia on the surface of the plate; the outer plate carries distally eleven spines all strongly dentate, the six round the apical border very stout, the five below them on the surface of the plate more slender, not
in a parallel row; the second joint of the over-arching palp distally furnished with twelve teeth and a seta, in the maxilla examined.

Second Maxillae.—The inner plate with almost its whole inner margin fringed with plumose setiform spines; the outer plate over-topping the inner, its apical border fringed with pectinate spines; both plates furred with cilia.

Maxillipeds.—The inner plates scarcely reaching as far as the apex of the first joint of the palp, furnished with the usual setae on the inner margin passing round to the outer apical corner, and three teeth on the apical margin; the outer plates reaching some way beyond the second joint of the palp, carrying ten teeth on the inner margin, slightly increasing in length to the apex; a few small spines within the border; the curved outer and apical margin clean. The first two joints of the palp equal; the third joint shorter; the finger much shorter than the third joint, with some cilia on the inner side near the nail.

First Gnathopods.—These approach closely to the form described for Hippomedon hergueleni. The hand and wrist are equal in length; the hand widens a little distally, and the finger closes very exactly over the sloping convex palm, which the tip of the finger conspicuously overlaps, without any distinct tooth on its inner side; the palm being defined by some slender spines. There is no sign here of any furring of the hinder border of the third and fourth joints as in the species just mentioned, and in some other respects, as the figures show, they are somewhat differently furnished. The margins only must be compared in the figures, as of the present species it is the inside, not, as usually, the outside of the hand that has been represented.

Second Gnathopods.—In general appearance these are scarcely distinguishable from those of Hippomedon hergueleni; distally the wrist is a little fulled out, with short, bent spines or scales on the breast, that is, the postero-distal portion.

First and Second Percopods as in Hippomedon hergueleni, with the upper part of the side-plate of the second pair somewhat broader and less elongate.

Third Percopods.—Branchial vesicle much folded. First joint narrowed distally, much more prominently spined on the front border than in the species above mentioned; fourth joint widest proximally, not ovate; fifth joint much longer than fourth, both armed with rows of long and short spines. Finger long and slender, a little curved at the tip, naked except for the dorsal cilium near the base.

Fourth Percopods.—Branchial vesicle as usual much smaller than in the preceding pair, on one side of the specimen ending in a narrow sinuous sac, but on the other side more dilated. First joint a long oval, most of the upper half of the front margin free from spines; third joint but little dilated; rest of the limb missing.

Fifth Percopods.—First joint longer and broader than in the preceding pair, front margin rather sinuous, the concavity about the middle, upper half with only two
or three very small spines, hind margin very, but not evenly convex, rather deeply serrate; third joint not dilated; rest of the limb missing.

_Pleopods._—The round-headed coupling spines have from three to four retroverted teeth; the rami have each from nineteen to twenty joints carrying densely plumose setae; the first joints vary in the different pairs, being longer in the first pair than in the second, and in the second than in the third; the first joint has in the first pair thirteen or fourteen plumose setæ on one margin and four on the other, but fewer in the following pairs; the first joint of the inner ramus in the first pair has six eleft spines, in the second pair, I believe, only five, and in the third pair only three. The number of these spines, therefore, will not be of service as a specific character, unless all three pairs of pleopods are carefully scrutinized.

_Uropods._—The peduncle in the first pair longer than the slender rami, of which the outer is but slightly longer than the inner; peduncle in the second pair equal in length to the rami, which are equal to one another, shorter than those of the preceding pair; peduncle in the third pair much shorter than rami; outer ramus with a nail, spines on or near the outer border, plumose setæ on more than half the inner border as far as the nail; inner ramus slightly shorter than outer, with spines on both borders, and plumose setæ all along the inner border.

_Telson_ reaching beyond the peduncle of the third uropods; eleft for two-thirds or more of its length, the plates a little dehiscent distally, the apex of each rather more produced on the outer than the inner side of the terminal spine cavity; on each border two spines and between them a small feathered spiny seta.

_Len/th._—The specimen measured, without the antennæ, nearly half an inch.

_Locality._—Station 161, off Melbourne, April 1, 1874; depth, 33 fathoms; bottom, sand. One specimen. Trawled.

Remarks._—The specific name refers to Geelong, near the Station at which this species was captured.

I was tempted, chiefly on account of the mouth-organs, to refer this species to a new genus intermediate between _Callisoma_ and _Hippomedon_. The mandibular palp agrees with that of _Callisoma crenatum_, Spence Bate, in its shape, but in its position with that in the species of _Hippomedon_. The inner plates of the second pair of maxillae agree in their armature with _Callisoma_ and not with _Hippomedon_, those of the first pair also disagreeing with _Hippomedon_ as described by Boeck. The palps of the maxillipeds, the antennæ, the third uropods and telson nearly resemble the corresponding parts of _Callisoma crenatum_, while the gnathopods and other features are in closer agreement with _Hippomedon kergueleni_. However, on examining dissections of a specimen of _Hippomedon abyssi_ (Goës), kindly lent me by Canon Norman, I found that the inner plate of the first maxilla had, like the present species, more than two
setae, in agreement with the figure given by Goës himself. It seemed on the whole, therefore, better to widen Boeck's definition of *Hippomedon* than to add to genera already, as many authors think, too numerous.

Genus *Cheirimedon*, n. gen.

*Epistome* with an ascending lobe.

*Mandibles* with the palp set far forward, just over the molar tubercle, the third joint a little shorter than the second; molar tubercle prominent.

*First Maxillae* with the inner plate carrying two plumose setae; the palp not dilated, with several teeth on the apical border.

*Second Maxillae* with the outer plate rather longer than the inner, neither of the plates armed far down the inner margin.

*Maxillipeds* with the palp having none of its joints elongate, fourth joint unguiform; inner plate reaching as far as the apex of the first, outer as far as the apex of the second, joint of the palp; outer plate with well-developed teeth, two at the apex spiniform.

*Lower Antennae* with the peduncle elongate, fourth and fifth joints subequal.

*First Gnathopods* with the wrist very short, hand large, distally dilated, subcheliform.

*Body* with the postero-lateral angles of third pleon-segment sharply upturned.

*Telson* cleft.

The generic name *Cheirimedon*, χείρ, the hand, and μέδων, a lord, alludes to the importance in this genus of the hand of the first gnathopods. As usual, when a genus is founded for a single species, the characters should be regarded as preliminary and liable to modification, should other closely related species be subsequently found which could be included by small changes in the original definition of the genus.

*Cheirimedon erenatipalmatus*, n. sp. (Pl. XII.).

*Head* with a small rostrum and sharply produced lateral lobes; first two segments of the peraeon short, third pleon-segment longer than any other of the segments, its postero-lateral angles sharp, greatly upturned towards the downward bending dorsal margin, the hind margin thus forming a deep cavity; the fourth pleon-segment with a deep dorsal depression, the dorsal margin acutely prolonged backwards.

*Eyes* not perceived, yet not certainly altogether absent.

*Upper Antennæ.*—First joint long, cylindrical; second and third short, narrowing distally; flagellum of twelve joints, of which the first is very long, equalling seven or eight of the following joints combined, cylindrical, slightly tapering, with only one or two filamentary cylinders in our specimen, but an appearance as if a narrow brush of them
might have been present originally; the remaining joints short, successively diminishing in length and thickness, many of them carrying long filamentary cylinders; the secondary flagellum of three slender joints, two long and one very short, the three together not equal in length to the first of the primary.

Lower Antennæ.—The gland-cone prominent, the third joint not much shorter than the composite first and second, the fourth and fifth long, straight, parallel-sided, the fourth rather wider than the fifth, equal to it in length, and also equal in length to the first four joints of the seven-jointed flagellum.

Triturating Organ.—In the Lysianasside this organ differs much from the form presented in the Orchestide. In the present species the oval organ exhibits round one margin a row of some two dozen spines, of which the basal half is thick, the other half becoming abruptly thinner and curved; round the opposite margin is a still more closely set row of some twenty-eight longer spines, nearly straight, pretty evenly thick all along to the end, which is cut into a short fork; where the two rows meet at the outer extremity of the organ there are some ciliated spines.

Mandibles.—Cutting edge smoothly convex, with an upper tooth turned a little downwards and a lower one turned a little upwards; 1 secondary plate on the left mandible small, strap-shaped, its edge cut into four or five teeth; spine-row consisting of three slightly curved spines (only two present on the right mandible); molar tubercle prominent, its oval crown somewhat ciliated on the edges, carrying four or five teeth down the centre, the remainder divided into rows of very minute denticles; the palp set far forward just over the molar tubercle, the first joint short, the next rather long, with eight or nine spines near the apex; the third joint shorter than the second by about the length of the first. The pectinate spines on the inner margin of the third joint, beginning below the middle, increase in length to the apex; they numbered seventeen on the left, fourteen on the right mandible.

Lower Lip.—With the forward lobes broad, pretty strongly ciliated.

First Maxillæ.—Inner plate small, oval, with two plumose setæ at the apex, the inner being the smaller; outer plate large, the apical margin with six strong dentate spines, below which are five others, the outermost strong, little dentate, the others a little more slender, not much curved, each with four or five lateral teeth; the palp reaching beyond the outer plate, its second joint nearly parallel-sided, the apical margin carrying from nine (on the right maxilla) to twelve teeth (on the left maxilla), the outermost longest, and one pectinate seta on the surface not far from the outer tooth.

Second Maxillæ.—The outer plate broader than the inner and prolonged a little beyond it; on the apex and a short way down the inner margin of the inner plate

1 The true shape of this part of the mandibles was not clearly made out till after the figures, Pl. XII. m. m., had been lithographed.
are about a dozen spines, followed below by half-a-dozen plumose setae; the apical border of the outer plate set with spines curved at the tips, the longest at the outer apex, followed by two or three short ones down the outer margin.

Maxillipeds.—The inner plates reaching about as far as the apex of the first joint of the palp, with three teeth on the apical margin, of which the outer is much the smallest, and plumose setae on the inner margin passing over to the outer apex; outer plates reaching slightly beyond the second joint of the palp, the inner margin set with teeth numbering from nine to ten, followed by two longer ones on the apical margin; eight or nine small spines may be seen on the outer surface of the plate, at a little distance from the inner margin; the palp compact, the second joint but little longer than the first; the third joint not longer than the finger, which is robust, ending in a long, thin, sharp nail; it has two cilia on the inner margin near the nail, and the dorsal cillum not far from the base.

First Gnathopods.—Side-plates a little widened and much rounded below; first joint projecting a little beyond the side-plate, of even width, with setae on the front margin; second, third and fourth joints differing but little in length, together scarcely as long as the hand, the third oblong, the fourth triangular; the hand large, increasing in width distally, the palm a little sloping, defined by two spines, between which the finger-nail closes down, the palm-margin crenate, with cilia just within the border and setae a little deeper within it; the finger has a dorsal cillum near the hinge, and one at the base of the nail, which in our specimen was broken.

Second Gnathopods.—The side-plates narrow, slightly rounded below and scarcely at all dilated; the branchial vesicles broad except at the base, without folds. First joint a little dilated and bent below, nearly equal in length to the third, fourth and fifth united; the second joint nearly as long as the wrist; the third joint much shorter, equal in length to the hand, furred behind, with some small setae near the apex; the wrist lightly furred on the distal half of the front and the proximal half of the hind margin, below this on the dilated breast having tooth-like cilia or little incurved spinules, and, in addition, numerous scale-like ornaments, not, I believe, uncommon in this family, minute in size, fan-like in appearance; the hand is furred, a quadrangular oval, the lower part of the front and forepart of the apical margin occupied with the usual rows of pectinate spines, the small finger being set on beyond these, and antagonizing with the well-advanced point of the hinder margin of the hand, which is thickly set with pectinate, geniculate spines. The dorsal cillum of the finger fixed about centrally, projects over the tip of the finger.

First Peraopods.—Side-plates a little dilated below, scarcely rounded; first joint just reaching the lower rim of the side-plate; third joint much longer than fourth, rather broader, scarcely produced; fourth joint broader than fifth, but a little shorter; fifth joint with the hinder margin straight, with some spines; the hind margins of the
second, third, fourth and fifth joints all carrying setæ; the finger long and slender, almost straight.

Second Peraeopods.—The side-plates with the excavation of the hind border unusually shallow, the lower part of the border showing a serration of three or four teeth; the branchial vesicle contracted a little below, very broad centrally. The joints of the limb almost precisely as in the preceding pair, the fifth joint a little shorter.

Third Peraeopods.—Breadth and greatest depth of the side-plates about equal, the anterior lobe produced a little lower than the posterior; the first joint much longer than broad, its length surpassing that of the next four joints combined, broader above than below, spined along the front margin, the hinder serrate; the second joint has setæ on the front margin and some minute apical spines; the third joint dilated and out-drawn behind, has setæ and small spines on the front, spine-like setæ on the hind margin; the fourth joint scarcely equal in length to the third or the fifth joint and intermediate in thickness, has on its front margin long, single spines set between pairs of very small ones; the fifth joint narrows distally, its spine-groups, except the lowest, consisting of a long and a short spine side by side; the finger is much shorter than in the preceding pair.

Fourth Peraeopods.—First joint longer and broader than in the preceding pair, but not as long as the four next joints of the limb, very slightly narrowed below; front margin spined and ciliate, hind margin serrate; the third joint little expanded or produced, about equal in length to the fifth; the fourth a little shorter than the third; the fifth narrow, narrowest distally; small spines on the front margins of all these joints, long ones also on the fourth and fifth, and setæ on the second and third; the finger thin and short.

Fifth Peraeopods.—First joint longer and broader than in the preceding pair; hind border much more convex than in the two preceding pairs, but, as in them, deeply serrate, the upper part of the front border free from spines; the third joint shorter than the fourth, and the fourth than the fifth; the finger small; the armature of the joints similar in character to that of the preceding pair.

Pleopods.—The pair of coupling spines on each peduncle have two backward-directed hooks on each spine; the joints of the rami appear to vary in number from ten to twelve for the inner branch, and from twelve to thirteen for the outer; the cleft spines form a row of five on the first pair, of three on the second and third pairs.

Uropods.—The peduncles of the first pair are longer than the slender, almost straight rami; the outer ramus longer than the inner, the margin spines few, none of them near the sharp apex, which is formed by a minute nail with a cilia at its base on the lower margin; peduncles of the second pair subequal to the rami, which are more stoutly spined than those of the preceding pair, the outer ramus but little longer than the inner; peduncles of the third pair short, shorter than the outer, longer than the inner,
ramus; the outer ramus broadly lanceolate, with spines on one margin, and ending with a decided nail; the small branch ending acutely, without a nail, a slender spine on one margin near the apex, and some way above it a cilium; higher upon the other margin another cilium.

Telson projecting beyond the peduncles of the third uropods, cleft for more than three-quarters of its length, narrowing distally, where it becomes slightly delicient by the curving round of the margins of the cleft; the inner part of each apex a little more produced than the outer, and in the hollow a stout spine inserted with a cilium by its side. Near each outer margin, a little below the top of the cleft, the telson has a spine on the surface, and below this one or two feathered cilia, and here and there a simple cilium.

Length.—The specimen, in the position figured, measured three-tenths of an inch.

Locality.—Station 1498, off Cumberland Bay, Kerguelen, January 29, 1874; depth, 127 fathoms; bottom, volcanic mud. One specimen, female.

Remarks.—The specific name, crenatipalmatus, refers to the palm of the first gnathopods.

The only other species in this group which has a form of hand similar to that of our species is, so far as I know, Normania latimana, G. O. Sars, but that species has been only provisionally assigned to Boeck’s genus Normania, with which, as defined by its author, neither that species nor this agrees. The mouth-organs of Normania latimana have not yet been described, so that I cannot say whether it belongs or not to the genus now instituted.

Genus Platamon, n. gen.

Mandibles with the palp set forward over the dentate crown of the molar tubercle.

First Maxillae with the inner plate oval, carrying two plumose setae, the second joint of the palp greatly expanded, with numerous teeth on the apical border.

Second Maxillae with the inner plate broader than the outer, its inner border fringed as well as the apical.

Maxillipeds with the inner plates remarkably broad, the outer plates with numerous teeth on the inner border, and two closely adjacent to the rest on the apex.

Both pairs of Gnathopods long and slender, with the fingers well-developed, the hand in the first gnathopods shorter than the wrist, oval, subechelate.

Third Uropods with the rami as long as those of the second.

Telson divided beyond the centre, extending beyond the peduncles of the third uropods.

The generic name is derived from the Greek word πλασμα, a broad space, in allusion to the great breadth of the parts of the maxillae and maxillipeds above described.
Remarks.—There seem to be many points of affinity between this genus and the genus Glycerina of Haswell. Of the type species, Glycerina tenuicornis, Mr. Haswell very kindly sent me a specimen, but the bottle containing it being broken in transit, the specimen was dry when it came to hand, and therefore not well fitted for the observance of minute details. Mr. Haswell states that there is no accessory plate to the mandibles. On this I cannot pronounce any opinion from my own observation. I observed three strong spines in the spine-row, and on the long molar tubercles several (nine or ten) little bright spines of cylindrical appearance standing out, not closely set, surrounded by a fur of cilia; the spines of the first maxillae run some distance down below the apical margin; the teeth on the apex of the palp are only seven or eight in number; the outer plates of the maxillipeds are feebly toothed; nor are other differences wanting.

Platamon longimanus, n. sp. (Pl. XIII.).

A small rostrum; lateral lobes of the head produced to a point, forming an equilateral triangle, dorsal line of the head longer than that of the first peraeon-segment; posterolateral angles in the first segment of the pleon rounded, in the second rectangular, in the third acute and upturned; fourth segment with a dorsal depression, slightly carinate, pointed behind; the sixth segment with lateral ridges on the back, which converge towards the telson and diverge when they reach its base.

Eyes not observed.

Upper Antennæ.—First joint very broad, distally projecting over the two next joints, which are very short, the projection being (like the rest of the joint) dorsally sharp, apically rounded; the flagellum of seven joints, the first tapering, equalling in length the other six united, the cylindrical setæ short, in some thirty rows; a long spine is placed at the distal end of the first joint, a shorter one on the second; the secondary flagellum slender, of three joints, together nearly equal in length to the first of the primary flagellum, the first a little curved, longer than the other two combined.

Lower Antennæ.—First joint not greatly dilated, gland-cone of the second joint long and narrow, third joint short, fourth and fifth joints long, subequal, the fifth the narrower and rather the longer; flagellum (on one of the antennæ) of thirty-five joints.

Triturating Organs of the stomach present a double very sinuous row of short, somewhat curved spines on one edge, on the other a projecting row of seta-like spines, set as the ornamental pipes of an organ-front often are, with the longest in the middle, those on either side gradually decreasing in size.

Mandibles.—Cutting edge convex, bent out of shape in the specimen examined, but seemingly with the usual denticle-like prominence above, and the lower apex not divided; secondary plate of left mandible strap-shaped, rather long, ending acutely, with two teeth above the apex; spine-row not made out; dentate crown of molar tubercle very
prominent; palp long, set just over the molar tubercle, both being far forward, first joint of palp short, second with a row of eighteen spines on the upper part; the third joint widening a little from the base, then narrowing almost to a point, carrying a row of thirty spines on the inner border; none were present on the outer border.

Lower Lip with the distal part of the forward lobes strongly furred, the lobes seemingly dehiscent.

First Maxillæ.—Inner plate oval, rather broad, with two unequal plumose setæ on the rounded apex; outer plate broad, not greatly elongated beyond the inner, apical margin not confluent with the inner margin; all the spines and their denticles of stout structures, but especially the five or six of the upper row; the palp with its second joint remarkably dilated, both lateral margins convex but the outer much more than the inner, the very broad apical margin set with nineteen spine-teeth, of which the outer two are excavate on the outer side; they are followed by a straight pectinate spine at the outer corner, and a similar one is found at about the centre of the row of teeth but a little below it.

Second Maxillæ.—Inner plate shorter than outer, the lower part very broad, distally narrowing, its sinuous inner margin set with fifteen plumose setæ, the apical margin set with rows of spines of different sizes, the smaller seemingly smooth, the larger pectinate, the stoutest of these being at the inner angle near to the setæ; the outer plate less broad than inner, the outer margin so much folded over that it cannot be flattened out in mounting for the microscope without separating it from its shaft, the apex rather more oblique than that of the inner plate, set closely with rows of pectinate spines.

Maxillipeds.—The inner plates of very unusual breadth, projecting rather in advance of the first joint of the palp, the plumose setæ of the inner border being comparatively short, numbering fourteen actually on the margin, the row being continued by shorter ones passing over towards the outer apex; the apical margin carrying three pointed teeth followed by a row of several pectinate spines; the outer plates long, reaching beyond the second joint of the palp, the straight inner margin smooth for some distance from its base, then presenting a spine, at a short interval from which begins a close-set series of eighteen sharp teeth, succeeded at the apex by a nineteenth tooth and a curved spine; on the surface within the margin are eight small slender spines; the second joint of the palp is longer than the first; the finger is as long as the third joint; its inner margin is pectinate, the short sharp nail accompanied by some short cilia; the dorsal cillum much nearer to the base of the finger than to the nail. In position these maxillipeds are by no means broadly flattened out, as represented in the Plate for the sake of showing the details;¹ the two halves fold boatwise upwards, when in situ; in the

¹ In regard to all the Plates it will be understood that figures intended to give the minute details are drawn from dissections laid out as flat as possible with a view to examination under the microscope; in regard to the figures of this species that circumstance requires more than usually to be borne in mind.
figure it should be noticed that the inner plates are not flattened out to their full extent, the outer part being folded back against the outer plate; similarly it should be noticed that there is a folding over of the outer edges of the second and third joints of the palp. The dilated palp of the first maxillae, likewise, when in situ, was far from being in the same plane with the rest of the maxilla.

First Gnathopods.—Side-plates more than twice as long as broad, with a convex front margin projecting over the base of the lower antennae, hind margin nearly straight. First joint equal in length to the three following united, projecting considerably beyond the side-plate, a little expanded below, with some seven setae on the front margin; second joint shorter than third; third nearly equal in length to the hand; wrist longer than the hand, like the third joint having setae on the hind margin; hand long-oval, with setae in various parts, especially several groups on the hind margin, the lower half of which is marked off as a palm rather by its pair of spines than by any break in the convexity; the spines are of unequal length, the palm-margin is ornamented by being cut into a series of sharp straight denticles, below which are small cilia; the finger is curved to fit the palm; it has a dorsal cillum near the base, and the tip of the finger appears as if formed of two plates laid one upon the other, as though the finger itself ran out to a point, and had a small triangular process (the nail) laid within the point.

Second Gnathopods.—Side-plates similar to those of the preceding pair, the hind margin rather less, and the front rather more, convex; first joint as long as the three following united, a little expanded and bent below, numerous setae on the front margin; second joint much longer than third, smooth; third joint furred behind, with a few spines on the squared apex; the wrist longer than the second joint, very much furred behind and before, with spines on both the somewhat sloping sides of its apex; hand subequal in length to the third joint, narrow at base, but immediately expanding, widest at the palm, hind margin straight, front very convex, much furred on both sides, pectinate spines near the outer angle of the palm and round the hinge of the finger, the palm concave, not a thin edge but broad and set through most of its course with several rows of short sharp teeth, its sides also fringed with cilia and rows of pectinate spines, the pectinate spines having a short terminal piece abruptly narrower than the shaft, with a shorter accessory thread by its side; the finger is sickle-shaped, the much-curved inner margin being hairy, with cilia near the origin of the finger. The finger here is as strong as that in Euonyx chelatus, Norman.

First Periopods.—Side-plates larger than those of the preceding segment, hind margin straight, front but little curved. Marsupial plates long, slender, the setae extending along most of the front border. Branchial vesicles without folds, from a narrow neck expanding at once greatly for some distance, and then very much more to the long almost straight distal margin. The first joint of the limb broad, extending a little beyond the side-plate, with some setae on the front margin; second joint short,
third broad, rather longer than either of the next following, with setiform spines on the
front apex and the hind margin; fourth joint similarly armed, much broader than the
fifth joint, which is subequal in length to it and similarly armed, gently curved, attached
to the fourth joint at the anterior part of the distal margin; finger as long as the fifth
joint, slender, curved slightly, and unarmed except for a minute dorsal cillum near the
hinge, and a cap to the nail, the cap being a little broader than the nail and projecting
slightly beyond it. In the figures gu.1. and prp.1. the nail is not shown.

Second Peropods.—Side-plates not of any unusual breadth below, the greatest
breadth being where the excavation ends about the middle of the plate, giving the
appearance of an upturned point; the limb closely resembles that of the first
peropods.

Third Peropods.—Side-plates rather small, broader than deep, neither lobe produced
noticeably below the other. Branchial vesicles not reaching the dimensions of those of
the first peropods, broad above, narrow below, with a long and very narrow accessory
lobe and a short one. First joint ovoid, much broader above than below, front margin
with small spines, hinder with slight serrations, a lobe ascending at the top in front,
another descending behind; third joint broader but considerably shorter than fourth,
little decurrent, with spines on the front margin, and three on the hind margin, two
high up and one apical; fourth joint broader than fifth but scarcely so long, with five
groups of spines on the front margin, the apical group containing five spines of different
lengths; on the front margin of the fifth joint there are six or seven groups of spines;
the finger is long, very slender, shorter than the hand; the nail minute.

Fourth Peropods.—Side-plates not much smaller than the preceding pair. Branchial
vesicle with what appears to be an irregularly branched accessory lobe. First joint
narrower than in the preceding pair, scarcely wider above than below; all the joints
except the finger longer than in the preceding pair, but otherwise very similar.

Fifth Peropods.—First joint large and long, of even breadth for some way down,
