VOYAGE OF H.M.S. CHALLENGER.

ZOOLOGY—VOL. XXIX.

TEXT—FIRST HALF.

Spec. Col.

R E P O R T
ON THE
SCIENTIFIC RESULTS
OF THE
VOYAGE OF H.M.S. CHALLENGER
DURING THE YEARS 1873-76

UNDER THE COMMAND OF
CAPTAIN GEORGE S. NARES, R.N., F.R.S.
AND THE LATE
CAPTAIN FRANK TOURLE THOMSON, R.N.

PREPARED UNDER THE SUPERINTENDENCE OF
THE LATE
Sir C. WYVILLE THOMSON, Knt., F.R.S., &c.
REGIUS PROFESSOR OF NATURAL HISTORY IN THE UNIVERSITY OF EDINBURGH
DIRECTOR OF THE CIVILIAN SCIENTIFIC STAFF ON BOARD
AND NOW OF
JOHN MURRAY, LL.D., Ph.D., &c.
ONE OF THE NATURALISTS OF THE EXPEDITION

ZOOLOGY—VOL. XXIX.

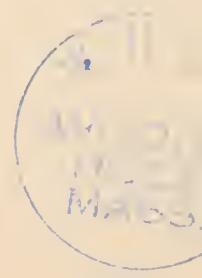

TEXT—FIRST HALF

Published by Order of Her Majesty's Government

PRINTED FOR HER MAJESTY'S STATIONERY OFFICE
AND SOLD BY
LONDON:—EYRE & SPOTTISWOODE, EAST HARDING STREET, FETTER LANE
EDINBURGH:—ADAM & CHARLES BLACK
DUBLIN:—HODGES, FIGGIS, & CO.

C O N T E N T S.

REPORT on the AMPHIPODA collected by H.M.S. CHALLENGER during the
years 1873-1876.

By Rev. THOMAS R. R. STEBBING, M.A.

FIRST HALF.

79101

EDITORIAL NOTE.

THE collections of AMPHIPODA procured in the trawls, dredges, and tow-nets during the voyage of H.M.S. Challenger were placed in the hands of the Rev. Thomas R. R. Stebbing for examination and description in the summer of 1882. From not long after that date up to the present time Mr. Stebbing has been almost exclusively occupied in the work connected with the preparation of this extensive and valuable Report, which will be welcomed by all students of the Crustacea.

There is the same uncertainty connected with the Amphipoda as with several other groups of animals taken in the trawls and tow-nets, as to the depths at which the specimens were captured. Some were undoubtedly taken at or near the bottom, while others were certainly taken in the surface and subsurface waters, but with others again there is a great deal of doubt. Although a record of the depths to which the nets were let down was attached to the specimens, the naturalists of the Expedition did not intend to convey the impression that the specimens necessarily came from the depths indicated.

This Report, which forms Part LXVII. and Volume XXIX. of the Zoological Series of Reports, consists of 1774 pages of letterpress, with 212 Plates and a Map. The whole is bound up in three separate portions, two of letterpress and one of Plates.

The first Instalment of the Manuscript was received by me on the 5th December 1885, and the last on the 30th November 1888.

JOHN MURRAY.

ZOOLOGY.

REPORT on the AMPHIPODA collected by H.M.S. Challenger during the Years
1873-76. By the Rev. THOMAS R. R. STEBBING, M.A.

P R E F A C E.

IT will easily be understood that the various portions of this Report have not been prepared without a considerable amount of laborious perseverance. Even points of slight importance, such as the derivations of generic names, have involved no little expenditure of time and toil, and (as with those names for which no derivation has been found) sometimes most trouble has been taken where the result is least satisfactory. Considering that the earlier pages were printed off before the work represented by the later pages had shed its light upon them, the Report is unlikely to be wholly free from deficiencies, inconsistencies, and other faults and mischances. In the completed volume it may well happen that many of these will be far easier to detect than they were to avoid. But, whatever the defects that may actually exist, either in the descriptive part of the Report or in that which deals with the literature of the subject, I venture to suppose that they might have been fewer had all the writings taken into account been always at hand to be referred to, compared, and pondered over whenever occasion required, while I am sure that they must have been far more numerous, had I not fortunately met with the different forms of assistance which I now desire most gratefully to acknowledge.

The ready and courteous liberality with which the Royal, the Linnean, and the Zoological Societies of London, the Royal Society of Edinburgh, and the Advocates' Library, place their rich stores of literature at the service of the student, has laid me,

no doubt in common with many others, under a deep obligation. My earnest thanks are also due to my personal friends, Mr. Spence Bate, the Rev. Canon Norman, and Dr. Murray, the Editor of the Challenger Reports, for the uncommon generosity with which they have allowed me to borrow from their libraries, and retain, not for weeks only, but in some instances for years together, rare and costly books and pamphlets. For the loan of valuable books or papers I am indebted likewise to Professor Alphonse Milne-Edwards, to Mr. W. E. Hoyle, of the Challenger Office, to Mr. Edward Saunders, of Lloyds, and to one or two other friends. Nor must I forget the friendly and unsparing zeal with which both Mr. Hoyle and Mr. James Chumley, of the Challenger Office, have assisted me in my book-borrowing career.

For favouring me with one or several or all of their contributions to the literature of the Amphipoda I have to thank a large number of gentlemen: in Great Britain, C. Spence Bate, G. Herbert Fowler, E. J. Miers, A. M. Norman, David Robertson, W. Baldwin Spencer, and A. O. Walker; on the Continent of Europe, Carl W. S. Aurivillius, Th. Barrois, Jules Bonnier, Carl Bovallius, Edouard Chevreux, A. Della Valle, Adrien Dollfus, Henri Gadeau de Kerville, Jules de Guerne, H. J. Hansen, R. Koehler, W. Lilljeborg, G. Pfeffer, G. O. Sars, J. Sparre Schneider, and August Wrześniowski; in the United States of America, Walter Faxon and S. I. Smith; in Australia, W. A. Haswell; in New Zealand, Charles Chilton, T. W. Kirke, and G. M. Thomson. To the kindness of Professor S. I. Smith and Mr. E. J. Miers I am under a special obligation, since, when the first sets which they had sent me of their valuable papers had been destroyed by an accident, they generously and to my great convenience repeated their gifts.

In obtaining the biographical dates, given where possible in connection with the notice of each author's earliest work on the Amphipoda, I have received much kind assistance from Professor G. O. Sars, Professor S. I. Smith, and Mr. W. E. Hoyle.

For various specimens of Amphipoda I wish cordially to thank Dr. Bruce, of the Military Hospital, Malta, Mr. Charles Chilton, of Dunedin, New Zealand, Mr. W. A. Haswell, of the University of Sydney, Australia, Canon Norman, of Burnmoor Rectory, Fence Houses, Mr. David Robertson, of Cumbrac, Scotland, Herr Conservator J. Sparre Schneider, of Tromsø, Norway, Professor S. I. Smith, of New Haven, Connecticut, U.S.A., Mr. G. M. Thomson, Rector of the High School, Dunedin, New Zealand, and Mr. A. O. Walker, of Chester. For purposes of comparison with the Challenger collection, as well as for throwing light upon frequent doubts which the literature of the subject suggested, many of these specimens were of great importance. Some proved in actual fact extremely useful, and almost all might have been of the highest service had not the pressure imposed by the limits of time forced me too much to neglect them.

INTRODUCTION.

Bibliography.—In literature the age of the Amphipoda scarcely reaches back beyond a century and a quarter. Linnæus knew almost nothing about them. At least, in one of his descriptions he is shrewdly suspected of having mistaken the head of the animal for its tail. Of particular species, it is true, earlier writers, such as Friderich Martens the ship's barber of Hamburg, had formed fairly accurate conceptions. In the middle of the sixteenth century Rondelet figured a specimen, but perhaps, like Linnæus two centuries later, without clearly knowing at which end of the creature to look for its head. Nearly two thousand years before Rondelet it is surmised that the keen glance of Aristotle had noted the existence of this tribe of diminutive shrimps, but his observation, though it throws a venerable prestige over their scientific record, did nothing to awaken any fruitful interest in their character and distribution. The institution of the genus *Gammarus* by J. C. Fabricius in 1775 presently brought the Amphipoda together as a group, although naturally it was due to earlier labours that any necessity for grouping was perceived. During the next forty years these Crustaceans no longer suffered from the neglect which had previously left them obscure. When Latreille, in 1816, gave them the name Amphipoda, an important stage was marked in the growing knowledge and interest about them. Since then they have received a very ample measure of attention, and at the present day they are studied in many parts of the world with great skill and evident enthusiasm. Of the literature of the subject numerous lists have been published, among which that by the late Axel Boeck in 1872 is the most important. He arranges in alphabetical order the names of one hundred and fifty authors, giving the titles of their contributions to the number in all of two hundred and seventy-three. This catalogue extends to the year 1871. A separate chronological review of the literature is carried down only to the year 1855. This part of Boeck's work is especially valuable for the comments which his large knowledge of the subject enabled him to supply. He intimates, however, that his comments are chiefly concerned with northern species. For dealing properly with the almost cosmopolitan Challenger collection it seemed indispensable to verify, and as far as possible to complete, the review which Boeck had so admirably begun. Neither the difficulty of the task nor the prodigious bulk of the material result was at first foreseen. From folio to pamphlet a vast mass of literature had to be consulted. How much borrowing of

books and buying of books, how many journeyings to and fro, how many researches ending in nothing, are necessarily involved in such consultation, those who have had a similar experience will well know, and those who have not had it can scarcely be made to understand. Without therefore expatiating on the difficulties which I suppose myself to have conquered or on the difficulties which conquered me, it may suffice to mention that, as the record proceeded, the plan of it was more than once changed, the earlier notices being rewritten and expanded, under the influence of a growing desire that as much of the task as possible should be done once for all and need no second doing. In the form actually adopted, the titles of works are given in chronological order, so far as the year of publication is concerned, but within that year they for the most part follow the alphabetical order of the authors' names.¹ Accuracy in the dates given has been anxiously aimed at, seeing that without this accuracy it is sometimes impossible to determine those questions of priority on which scientific nomenclature so much depends. But precision is very difficult to arrive at, when the only available copy of a work is an undated extract from a foreign magazine, or from the proceedings of a learned society, read in one year and published in the next or the next but one. It is greatly to be wished that "separate copies" should not only have the true paging, as Darwin² urges, but that they should also have that date of publication from which the new genera and species contained in them have a claim to reckon their priority.

The title of each work mentioned in the Bibliography is accompanied, it will be seen, as a rule by some notice of its contents. There are a few exceptions, where papers, of which the titles could be cited on adequate authority, have remained inaccessible, or where the titles themselves seemed sufficiently suggestive without further comment. Here and there, like a sign-post with the legend "No Road" upon it, the title of a book has been given for the sake of saying that it contains nothing about the Amphipoda. On the other hand some obscure works, perhaps really bearing on the subject, are omitted from the general list and only incidentally referred to as occasion offered. In the notices taken collectively two special objects have been aimed at :—

1. To quote the original definition of every genus of the Amphipoda.
2. To give under its proper date the name of every new species.

Two objects of a more general character have also been kept in view, namely, first, to give some idea of the character of the information which the various writings supply, and secondly, in so doing to produce a record, after the annalistic method, of the progress of knowledge in this branch of natural history.

It will be readily understood that a generic definition as at first framed is often little

¹ The following names are exceptions to the alphabetical order on the pages mentioned:—Seba, Linnaeus, p. 18; Linnaeus, p. 20; Ström, p. 28; Olafsen, p. 36; Ginnani, Hammier, p. 38; Fabricius, p. 40; Pallas, p. 41; Forskål, p. 43; de Quérone, p. 47; Linnaeus, p. 53; Roemer, p. 55; Pallas, p. 65; Latreille, p. 71; Rafinesque, p. 87; Leach, p. 89; Pollini, de Blainville, p. 93; Leach, p. 107; Costa, Krøyer, p. 177; Kraus, p. 205; Bate and Westwood, p. 340; Gerstaecker, p. 342; Cunningham, p. 404.

² The Life and Letters of Charles Darwin, edited by his son, Francis Darwin, vol. iii. p. 141.

suites for the purposes of later classifications, yet each remodelling requires to be tested by that earliest form which is here reproduced. While every definition has been given which claimed to refer to a new genus, references have also been made, wherever available, to authorities who have disputed the claim of novelty, or to other reasonable grounds for rejecting the defined name. When the type-species is well known, and specimens of it have been examined by more than one competent observer, the true position of a genus is comparatively easy to determine. But sometimes the solitary specimen on which a genus was founded has since been lost or destroyed or damaged past recognition. In some of these cases the genus remains either absolutely obscure or only the sport of ingenious guesses. It would be convenient if some limit of time could be established, so that after fifty or a hundred years the names which no one had been able to identify throughout such a period should lose their right of priority.

With species, as with genera, all that have ever been published as new ones are admitted to the record. So far the task is simple. But here too an attempt has been made, by references and suggestions, to guide the reader through the labyrinth of synonyms. This part of the work is full of perplexity and complication, and the labour here bestowed upon it can pretend to little more success than that of having drawn into one view a large number of problems still requiring solution. Conjectural determinations for or against the validity of a species, apart from observation of the actual specimens described, must be accepted with much reserve even from the most experienced writers ; for example, a consensus of important authorities had long referred Krøyer's *Stegocephalus inflatus* to Phipp's earlier *Cancer ampulla*, yet in 1887 Hansen decides that Krøyer's species is after all distinct. But the very fact that mistakes are so often made in the attempt to regulate synonymy should at least have the useful result of awakening attention to the extraordinary amount of trouble caused by vague and inadequate descriptions, especially when these are given without explanatory figures of the object described.

In the general treatment of the large mass of literature here brought under review I have desired as much as possible to save trouble to any naturalist who might in the future have to deal with a collection similar to that which is the subject of this Report. Hence brief notices of the Amphipoda and descriptions of single species embalmed in large works have been quoted in full, and occasionally for the same reason short separate treatises have received a longer notice than their intrinsic importance, apart from their rarity, would have demanded. On the other hand, some works, such as the British Sessile-Eyed Crustacea by Bate and Westwood, and Boeck's great work on the Arctic and Scandinavian Amphipoda, have been only briefly noticed, since they are already widely known and of necessity in general use, so that the enormous space required for an exhaustive discussion of their contents would have been to a great extent needlessly absorbed. Among the writings of the last century, attention should, I think,

be called to the superiority whieh Pallas displays in his descriptions of Amphipoda. In the present eentury Krøyer can have but few rivals for eombined fulness and accuracy of detail. In the whole multitude of contributions to the voluminous literature here considered, it is obvious that some writers have done more harm than good, or that, to speak in the most lenient terms, their productions are of no value whatever ; but while this can be fairly said only in rare cases, the examples are very numerous of fruitful industry and high scientific exellenee. Without, however, any attempt to appraise seriatim the merits and serviees of this host of writers, it may be convenient to mention a few works which the student will find, if not indispensable, at least of foremost value, for particular branches of the sujet. Thus, for the general structure of an Amphipod, he should certainly consult the *Histoire Naturelle des Crustacés d'eau douce de Norvège*, by G. O. Sars, 1867 ; for embryogeny, the *Mémoire sur la formation du Blastoderme chez les Amphipodes, les Lernéens et les Copépodes*, by E. van Beneden and E. Bessels, 1869, and Ulianin's *Essay*, 1881 ; for the circulation of the blood, the papers by Wrześniowski, 1879, and Delage, 1881 ; for the family of the Cyamidæ, the contributions of Lütken, 1873 and 1887 ; for the Caprellidæ, Mayer's *Die Caprelliden*, 1882, to whieh an Appendix is to be presently published ; for the Phronimidæ, Claus' *Essay*, 1879, and for the Platyselidæ, the same writer's work of 1887 ; and to this list the treatise by Bovallius on the Amphipoda Hyperina, and that by Wrześniowski on the subterranean Amphipods, when completed, will doubtless need to be added. For the study of the Amphipoda Gammarina the works of importanee are so numerous that it might be misleading to point out a few as more prominently essential than the rest, yet on the difficult subject of the *Œdiceridæ* the paper by J. Sparre Schneider in 1883 ought not to be overlooked.

Classification.—The division of the Amphipoda into three groups, the Gammarina, Caprellina, and Hyperina, has been long and widely accepted, and is followed in this Report as of practical utility and based on reasonable grounds. Geology is unfortunately almost silent about these Crustacea. To all intents and purposes there have been as yet no fossil Amphipods discovered.¹ If, nevertheless, we may assume the three groups to have been all derived from a common ancestral form, then the evidenee of the groups themselves may be taken to show that the Gammarina and Caprellina, by their similar mouth organs, are more nearly connected with one another than either with the Hyperina, and that the Hyperina, in respect of their mouth organs, are furthest removed from the primitive form, inasmuch as their maxillipeds have lost that resemblance to modified legs which is so striking in the other two groups. From both the Gammarina and the Hyperina the Caprellina are separated by the slight development of the pleon. This character can be readily explained as an acquired adaptation to their habits of life. If the suggestion be made that the ample pleon might as well have been developed from

¹ See pp. 111, 118, 276, 300, 353, 409, 471, 486.

the feebler form as the feeble have been degraded or reduced from the more ample, the answer is this, that the impoverished condition attributed to the pleon in the Caprellina is correlated to other appearances of degradation in the same group, that no Caprelline stage has ever been observed in the embryos of the other two groups, and that the strongly developed pleon would scarcely have been so general, not only among Amphipods, but also in the neighbouring orders of Crustacea, had the ancestral form been nearest to the rudimentary one. Hence it appears to be a natural arrangement to place the Caprellina after, though next to, the Gammarina, and to let the Hyperina come last.

To any one glancing over the great variety of forms presented by different species of Amphipoda, and comparing an *Orchestia* with a *Cystisoma*, a *Rhabdosoma* with an *Anonyx*, a *Pariambus* with a *Gammaracanthus*, it might seem extremely rash to assume that all the Amphipoda could possibly have a lineage in common. But after prolonged examination of homologous parts the observer would not be so much impressed with the difficulty of a common descent as with the intrinsic simplicity of the processes by which these wonderful differences of structure might have been produced. For if a son may be taller than his father, a daughter stouter than her mother, in the same family one child have straight hair and another curls, one brother be smooth and the other a hairy man, variations of a corresponding kind suffice to explain the most striking dissimilarities that the Amphipoda can furnish. Lengthen or contract a limb, make a joint tumid or flatten it out, multiply the spines or prickles, narrow or expand the body, or so treat one part of it at the expense of another, let it be cylindrical or depressed or laterally pinched, stiffly outstretched or coiled into a ball,—by such differences as these, in regard to which many species present the most minute transitions, it will be found that genera and families are separated, without the least necessity or reasonableness of attributing to them other than a common origin.

In the hinder part of the pleon the Hyperina show a general but very variable agreement with the Gammarina, but in the front part of the pleon, and especially in the appendages of that part, the agreement is great and very constant. These appendages, commonly called pleopods, are perhaps less subject to variation throughout the two groups than any other part of the organism. Each of the first three segments of the pleon has a pair of these swimming-feet, the three pairs usually differing only a little one from the other; each member of a pair consists of a stem or peduncle supporting two branches; the branches as a rule differ only slightly from one another, each being of tapering form, composed of several joints, of which the first is invariably the largest; of these joints every one has an apical pair of long feathered setæ, which on the small terminal joint are close together. No joint except the first is ever privileged to have more than one pair of these plumes, and no joint is ever normally without its pair.

On the peduncles of these swimming-feet, near the lower angle on the inner side, there

is the curious apparatus spoken of in this Report as the coupling-spines.¹ Among the Gammarina occasionally these spines are numerous; among the Hyperina there are rarely, normally perhaps never, more than two to each peduncle. In both groups they are clearly spines that have been modified to serve one and the same purpose, namely, to hold the peduncles together for the swimming-stroke. For this purpose the apex of each spine is blunted and has backward directed teeth, the edges also often having a retroverted serrature, so that the spines of each pair of peduncles can be interlocked. That both groups, notwithstanding their otherwise extremely divergent forms, should so universally possess these coupling-spines, is surely a note of common ancestry. It is also easy to see that two quite simple spines in this position might be of some service for the object in view by the effect of mere friction, while natural selection would be ready to avail itself of any variation in the direction of the roughening of the spine, until the strongly serrate edges and dentate apices had been at length evolved. In the branches of the pleopods we find another note of community of origin for the two groups above mentioned. Besides the obvious similarity which these branches display in almost all the genera and species, they have in common the less easily noticed feature of carrying one or more cleft spines² on the inner margin of the first joint of the inner branch. To this there are only rare exceptions, and those, perhaps, not difficult to explain. Throughout the Hyperina it appears that the joint in question never has more than one such spine, while in the Gammarina the number varies. The object served by these spines is no doubt similar to that of the coupling-spines. One arm of the cleft apex has a subterminal expansion, and the other arm is internally roughened or serrulate. By these contrivances a pair of the spines lying crosswise helps to keep together the branches of the pair of pleopods, and so to add force to the swimming-stroke. But these spines with cleft terminations have plumose shafts, and are evidently plumose setæ modified for a special purpose. Indeed, in some species, in which the pairs of cleft spines are numerous, some of them show a gradational form combining the flexibility of the seta with the cleft termination of the spine.

Another example of gradational forms is exhibited by the maxillipeds of the Gammarina. The outer plates of these organs are commonly fringed with an apparatus, parts of which may be distinguished as respectively, teeth, spines, and setæ, yet the teeth pass into spines, and the spines into setæ by gradations so minute, that the practical difficulty arises in description of determining how many of these little appendages ought to be grouped under one name, and how many under another, yet no one would dream of interchanging the names of the two extremes of the series, the tooth and the seta.

In classifying the families of the Amphipoda within the principal divisions, not a few difficulties are encountered. We may attempt to place side by side those which in the

¹ Described and figured by G. O. Sars in his account of "*Gammarus neglectus*, Lilljeborg," Hist. Nat. Crust. d'eau douce de Norv., p. 53, pl. v. fig. 8, "épines particulières," and indicated by S. I. Smith in his figure of *Cerapus tubularis*, Say, *Trans. Connect. Acad.*, vol. iv. pl. ii. a, fig. 5, but not, I think, alluded to by any other writers.

² "Soie particulière à bout bifurqué," Sars, *loc. cit.*, fig. 8.

present state of knowledge appear to have the largest number of important affinities. But what affinities should be considered important for classification it is by no means easy to determine. Animals genealogically very wide apart may have adopted similar modes of life, and in so doing have become modified on parallel lines, while on the other hand, in species nearly related by descent, great divergence of character may have resulted from difference of habits, such as the assumption of a parasitic life by one branch of a family, when the other branches have remained independent. In classifying the Gammarina authors have usually placed the Orchestidae first. In the order of evolution they might rather be placed last. Among these alone of the Amphipoda has a capacity for terrestrial existence been acquired; some of them are gradually adding the faculty of walking upon dry land to the ordinary movements of slithering and leaping; all of them have lost the mandibular palp. Delage, founding his view upon the circulatory apparatus,¹ suggests that the Corophidae are the ancestors in common of the other Gammarina and the Caprellidae. But *Corophium volutator* (Pallas), the subject of Delage's investigation, is far removed from a typical Amphipod. Though it has not the variety of movement found among the Orchestidae, yet, by having a body flattened instead of laterally compressed, it is perfectly capable of walking. It cannot perhaps, strictly speaking, be said to walk upon dry land, but it walks freely over moist mud in the open air. Of the three pairs of lateral orifices to the heart, so generally found among the Amphipoda, Delage has observed that the first two pairs are wanting in *Corophium volutator*, and that they are small and inactive in the Caprellidae. But it may safely be said that if the Gammarina and Caprellidae were descended in separate lines from the *Corophium*, the degraded and inert Caprellidae would never have acquired the two additional pairs of orifices for which they have, it seems, no urgent need, and which their supposed ancestor of a higher type and more active habits is able to dispense with. Thus, while the character of the heart makes it very improbable that *Corophium* should have been an ancestor of the Caprellidae, its shape and habits make it quite as unlikely that it should have been an ancestor of the Gammarina, so few of which have any activity out of water, and so many of which, the Orchestidae included, have the body laterally compressed.

On the supposition of a common origin of all the Amphipoda, it is obvious that families will have been gradually separated by the successive acquisition of distinctive characters. The supposition itself is based upon the fact that some characters are common to many families, since that fact is explained most simply on the principle of inheritance from a common ancestor. In the search, then, for ancestral characters, we must look away from what is rare and exceptional to what is commonplace and unattractive. When any single character is investigated in all the known species, some form will often be found of marked simplicity and completeness, round which the rest

¹ See p. 526.

will be grouped at greater or less distances. These two attributes, simplicity and completeness, are evidently appropriate to an ancestral form. To begin with, each part of an organism will, by inheritance, resemble the part from which it has budded out. Successive variations introduce distinctions between the parts of an organism, just as they introduce distinctions between one organism and another. At the same time the simplicity sought for must be limited by some standard of completeness, otherwise we should be looking for the origin of things in general, not the ancestry of a particular group. In the structure of an Amphipod we may recognize simplicity in the segments of the peræon, where, as a rule, each segment is to a certain extent free from its neighbour and closely resembles it, and we may recognize it also in the flagella of the antennæ and branches of the pleopods, in which, commonly, numerous joints exhibit one and the same pattern. The theoretical completeness of the appendages rests to some extent on a comparison with other groups of Crustacea, but the limits either of completeness or simplicity which are to be expected in the special group are soon arrived at. If, then, by comparing not only one but every available character in all the families, we at length make some approach to a complete set of ancestral characteristics, we shall be able to construct an ideal Amphipod, with no parts degraded and none exaggerated. And if further, by comparing this ideal with existing species, we find one among them bearing an exceptionally close resemblance to it, such a species will have some claim to stand, not perhaps at the head, but in the centre of our classification, as most directly representing the type or original from which the other Amphipoda have in various degrees more widely diverged. As a matter of fact, in the genus *Gammarus* the well known species *Gammarus pulex* and *Gammarus locusta* are very much of the commonplace facies desired. They are naturally chosen for explanatory purposes and as representative species. They have the requisite completeness; the secondary flagellum of the upper antennæ is not wanting as in *Amphithoë*, nor the mandibular palp as in *Dexamine* and the Orchestidae; the palp of the first maxillæ is not degraded as in *Orchestia*, nor the maxilliped palp curtailed as in *Lafystius*; no segments of the peræon are coalesced as in *Dulichia*, nor of the pleon as in *Atylus* and *Goplana*; the third uropods are not uniramous as in *Metopa*, nor the second as in *Cerapus*. They have also the requisite simplicity, as could easily be shown by a detailed comparison with other species. The distribution of these two species lends an additional probability to the view that they represent an ancestral form. Far more than any other Amphipod *Gammarus pulex* appears to have spread itself over the fresh-water streams of the world, and *Gammarus pulex* is connected by the very closest ties with *Gammarus locusta*. It is clear from the general distribution of the Gammarina that the chief nurseries whence they issue are the weeds of the coast. From these the rivers are accessible as well as the ocean, yet in the rivers the species of Amphipoda are few, while in the ocean they are multitudinous. This admits of a simple explanation, if we accept *Gammarus locusta* as representing the ancestral form which at one time occupied the

world without the competition of other species of Amphipods. In order to enable the family to extend its range over the fresh-waters of the world, no further change was needed than such as would enable some of the progeny to pass from salt-water to brackish, and from brackish to fresh. But the sections of this genus having once obtained command of the rivers, by the capacity of living vigorously in the river-water, would have an immense advantage over all rivals attempting in the future to make a lodgment in the streams, while their capacity for life therein was in its initial stages and only feebly developed.

In the arrangement around and near to *Gammarus* of such genera as *Niphargus* and *Gammaracanthus* and *Mæra*, there is in point of fact a very general agreement, so that we shall not be very rash in regarding the Gammaridæ as a natural family. If from the considerations already mentioned we may regard it also as the typical family of the Amphipoda, the next point of interest will be to determine whether the other families can only be grouped confusedly around it, or whether any lines of succession can be suggested. It is evident that if the *Gammarus*-form had at any time such possession of the ocean-world that it was able to stock the majority of the fresh-water streams with genera and species which can be traced back to it in a direct line, the more or less amphibious Orchestidæ ought to be traceable to the same source. Between *Gammarus* and *Talitrus* there are, it is true, important distinctions, but they are in part bridged over by the genera *Hyale* and *Hyalella*, and to a very considerable extent they show adaptation on the part of the Orchestidæ in general to altered conditions of life.

The next family which seems easily derivable from *Gammarus* is that represented by the genus *Amphithoë*. It will be noticed in the history of the subject, that, before the minute subdivision of genera, the discoverer of a new species, if he did not assign it to *Gammarus*, was very apt to call it an *Amphithoë*. *Amphithoë* indeed has before now been chosen for description as a typical genus of the Amphipoda. The genus, in its present acceptation, has an extremely extensive distribution, and by the simplicity of structure which it exhibits, and its general approximation to *Gammarus*, it is well fitted to be the link between that genus and the nest-forming Podoceridæ in general. Near to, yet not to be derived from, the Podoceridæ, and by their somewhat more erratic characters placed at a greater distance from *Gammarus*, come the Photidæ. Again, at various distances beyond the Podoceridæ, we may imagine positions for the Corophidæ, Cheluridæ, Dulichidæ, and Iciliidæ. The Dulichidæ seem to lead on by a very natural sequence to the Caprellidæ, with which Bate and Westwood have gone to the extreme length of actually classing them, in their group Aberrantia.

Returning to the family of the Gammaridæ, we find in close alliance with it two other families, the Atylidæ and Eusiridæ; nor are these remote from the Pleustidæ and Epimeridæ. The remainder are by no means easy to group in any plausible order of relationship to the ancestral form. The eyes of the Ampeliscidæ give them a position

apart from all the rest. The Lysianassidæ are set apart in another direction by the peculiarities of the upper antennæ, the second gnathopods, and especially that character of the mandibles, on account of which Schiødte has named them the Trochalognatha. As far, however, as the antennæ are concerned, they are united to Schiødte's other group, the Eleutherognatha, by the new family Valettidæ. The Stegocephalidæ, while agreeing with the Lysianassidæ in the upper antennæ, are less remote from *Gammarus* in the form of the second gnathopods. On the other hand, the character of the mandibles shows a further departure from the common type than is found anywhere else among the Gammarina. Hence a common ancestry may be supposed for these three families, branching off from *Gammarus* at a remote period.

In the Stenothoidæ the genus *Stenothoe* itself, being without the mandibular palp, may be regarded as a later form than the companion genus *Metopa*, in which that palp is retained. In the Leucothoidæ the genus *Leucothoë*, by the characters of its mandibles and maxillipeds, seems to lead up to the Stenothoidæ.

The Syrrhoidæ and Synopidæ on several accounts may plausibly be placed side by side. In one particular, the very short terminal joint of the mandibular palp, these families show an affinity to the Stenothoidæ; but apart from this one point their affinities are with the Pontoporeiidæ. Nearer than any of these to *Gammarus* stand the Ædieridæ.

The Iphimedidæ, Pardaliscidæ, and Amphiochidæ remain, with peculiarities that make every suggestion for their classification hazardous. At a venture the Pardaliscidæ may be grouped with the Syrrhoidæ, Synopidæ, and Pontoporeiidæ; the Iphimedidæ with the Pleustidæ and Epimeridæ; and lastly, the Amphiochidæ left, where they are usually placed, in a somewhat dubious proximity to the Stenothoidæ.

Between the Gammarina and Hyperina there is a wide gap, over which at one point no bridge has yet been found, for, while in the Gammarina the maxillipeds always have a palp, they never have one in the Hyperina. In the Gammarina the mandibular palp has, with the rarest exceptions, a short first joint, whereas in the Hyperina this joint is frequently of great length, but here there are all sorts of connecting links, the mandibular palp in *Cyllopus* being quite of the pattern common among the Gammarina. Milne-Edwards, in 1840, when establishing the Tribu des Hypérines Gammaroides, went so far as to say that the single genus, *Vibiliæ*, which he placed in it as a link between the Gammarina and the ordinary Hyperina, might almost as well stand in one division as the other. To this overstatement of the closeness of the tie between the two groups he was no doubt led by wrongly supposing that *Vibiliæ* had rudimentary palps to the maxillipeds.

Within the Hyperina, although marvellous diversity of form has been arrived at, there is comparatively little difficulty in tracing a family resemblance between the different sections. Naturally the Platyscelidæ or Hypérines anomales, with their strange zigzag

folding antennæ, may be regarded as the latest development, but the whole group of Hyperina must be supposed to be interconnected, not to be derived partly from one branch and partly from another branch of the existing Gammarina. It may be noticed, indeed, that though the Gammarina by their maxillipeds testify to an older type than is seen in the Hyperina, yet the latter in some genera retain in their turn a mark of antiquity which the Gammarina have lost, in the simplicity of the gnathopods, for these in *Dairella* and *Lycaopsis* are like ordinary peræopods. The general structure of the upper antennæ in the Hyperina calls to mind the family Lysianassidæ, but there is the marked distinction that in none of the Hyperina is there a secondary flagellum to these antennæ; yet here the recently discovered *Hyperiopsis vöringii*, Sars, may supply a link, since with the antennæ of the Lysianassidæ this curious species combines the eyes of a Hyperid. A connection between the Hyperina and the Lysianassidæ has already been indicated by Boeck, who placed the family Prostomatidæ at the head of the Gammarina, in immediate sequence to the Hyperina, because of the agreement which he considered to exist between that family and the Hyperidæ and Orchestidæ. The Prostomatidæ are in close relationship with the Lysianassidæ, and might, in my view, well be included in the older family. But if the Hyperina make any real approach to the Lysianassidæ, it must not be supposed that they are derived from them, for the mandibles of the Gammaroid Hyperina point more directly to the *Gammarus*-form than to that found in the Trochalognatha.

In offering these contributory suggestions towards a classification of the Amphipoda, my hope is that either by occasionally hitting the mark they may be of service, or that where they have missed it they may provoke a fruitful criticism, and either way that they may excite the ambition of the discerning and ingenious to throw light upon the many problems which are still obscure.

Nomenclature.—Most naturalists will sympathise with the lady who thought that, of all the discoveries astronomers had made about the stars, the finding out their names was the most wonderful. In zoology the new discoveries are generally far more troublesome to name than they would be if they were only stars or planets. A genus of sharks is bound to give way, if it turns out that a genus of animalcules has received the same appellation a month earlier, and the genus of animalcules, however laboriously and scientifically described, must give way in its turn, if it should prove that the same group of creatures has been obscured rather than explained fifty years before under a different name. But apart from these casualties, there is the enormous and increasing difficulty which arises from the multitude of workers in every field of natural history, who, in the absence of any rule or convention to the contrary, publish new genera and species in any literary vehicle that is for the moment handiest. One isolated description may have to be sought for in a costly volume of travels, and another in the local journal of Timbuctoo. It is rather to be wished than expected that an international law in science should intervene, and allow validity and priority only to names adequately published in

definite periodicals, of which one or more might be assigned to each large division of the animal and vegetable kingdoms. Even under this utopian arrangement the requirements of adequate publication would be very much at the mercy of different contributors.

Looking only to the Amphipoda, one sees and feels the natural tendency in those who describe actual specimens to multiply genera and species, while in those who classify the results obtained by others, the tendency is to be impatient of minute distinctions, to rejoice at being able to unite two species into one, and to ignore one genus in favour of another which they regard as embracing it. Nothing but good is done by those who pare away the superfluities of nomenclature by discovering that the same genus or species has been described under more than one name, but it is a question whether much profit has resulted from attempts to discard small genera in favour of a large comprehensive genus. In the history of the subject we see that the names of the rejected genera almost invariably obtain eventual acceptance, so that the attempts at suppression only result in a confused synonymy. Few authors, for instance, would now dispense with *Melita* and *Mera* of Leach, which to Milne-Edwards appeared useless and even injurious subdivisions of *Gammarus*.¹ Those who take the lead in introducing minute subdivisions do, indeed, force the hand of their successors, since differences which might well have been regarded as specific under a moderately wide genus, have to be accounted generic when the already existing genera of a family are separated by very small distinctions. But premature interference rather increases than remedies the confusion, although, when knowledge of the subject has largely advanced, the time and opportunity for a general revision may arrive and be thoroughly welcome.

As far as the form of a name is concerned, it has seemed to me beyond all question best to adopt that which the author of the name himself gave to it. This was far from being my original opinion. It is, of course, a delightful effort of criticism, and a token of one's own intrinsic superiority, to be able to correct the spelling of some eminent man of science. But in actual practice each correction makes a new name, adding therefore to the synonymy, and often making necessary the citation of two authorities instead of one. Sometimes the corrected form of a name comes into collision with a genus established before or since in some other branch of zoology. Sometimes a name is inconveniently lengthened in the effort to make it conform to the laws of philology, and a syllable is inserted which the originator of the name perhaps intentionally left out. As Leach has shown, it is not necessary for a scientific name to have a derivation at all, so that in the last resort the names which do not satisfy the laws of classical formation may be defended on the ground that one congeries of letters is as good as another. At any rate, for the purposes of natural history, the fixity of a name is of far more importance than any indirect lesson in scholarship of which it may be made the text. I may as well, however, confess that in respect to the genus *Amphithoë* I have not had courage to

¹ Hist. Nat. des Crust., t. iii. p. 54.

revive Leach's original *Ampithoe*, and that in pedantically printing *Caprella equilibra*, Say, instead of Spence Bate's *Caprella aequilibra*, my object has been much more to emphasize the general view here advocated than to make converts to the use of that particular illustration of it. The custom of changing the gender of specific names, when species are transferred from genus to genus, seems to me inconvenient and unnatural. In every species of the Amphipoda there are males and females, and since the ungallant Romans imagined the masculine to be the worthier gender, it would tend to simplicity if that gender were preferred in the formation of all specific names. Changing the masculine ending into a feminine, to match the nominal sex of the genus, is much like saying that a man must be a woman if his parents have happened to christen him Maria.

The pronunciation of the names used in natural history is of comparatively little importance, since they are so much more frequently read by the eye than pronounced by the tongue. Nevertheless, it would be an advantageous custom if authors, when introducing a new name, would supply their readers with some means of determining the quantity of a doubtful syllable. In pronouncing long-established names, such as Gammarina, Caprellina, Hyperina, where the derivation will not help us, we must be guided either by usage which may fluctuate, or by euphony in respect of which tastes may differ, or by the genius of our own language which is pretty sure to prevail in the end. In the three examples cited, my own opinion is, that the penultimate syllable ought to be pronounced short, the accent being in each case laid upon the ante-penultimate. Although the Greek word *ὑπέρινος*, so accented and having a short penultimate syllable, has nothing to do with our Hyperina, yet the mere existence of such a word proves that there is nothing monstrous in the pronunciation now recommended.

Distribution.—How very extensive is the range of the Amphipoda may partly be seen by a glance at the map accompanying this Report. Northward, Amphipoda have been taken within 400 miles of the pole; in the opposite direction as far down as lat. 68° S. Of the great depths from which some of the Challenger Amphipoda are reported I do not like to speak with too much certainty, but there is no special reason for doubting that *Lanceola pacifica*, for instance, came actually from the depth assigned it of 2300 fathoms. It does not seem unnatural that some of the group should have been able to penetrate even to so great a depth as 13,800 feet beneath the surface of the sea, since on the continent of South America Mr. Whymper has found them at 13,300 feet above it. All the waters of the world, arctic and tropical, salt, brackish and fresh, oceans, lakes, rivers and wells, are tenanted by Amphipoda. From the rocks and sands and muddy fringes of coast and shore they are pushing out advanced guards in a sort of tentative manner on to the land, where, for ought we know, they may yet have a great future before them. That they have thriven so well hitherto may be attributed to various advantages, chiefly perhaps to their ready adaptability to so many varying circumstances. Diminutive size and mimetic colouring will often have helped to protect

them. An appetite, voracious, indeed, but not over fastidious, will seldom have allowed them, like more serupulous feeders, to starve in the midst of plenty, while the prodigious swarms they bring forth have enabled them to offer a wholesome banquet to the monsters of the deep without any injurious diminution of their own numbers. The following list exhibits the species which have a more or less doubtful claim to have come from a depth greater than 300 fathoms. It is interesting to notice, that in the thirty-one specimens of Gammarina reported from these vast depths, twenty-five genera are represented, of which ten are new, and twenty-eight species, of which twenty-six are new.

<i>Lanecola suhmi</i> , n. sp., .	1250	<i>Cystisoma</i> sp.,	500
<i>Lanccola australis</i> , n. sp., .	1800	<i>Phronima novæ-zealandiæ</i> (?), ¹ Powell.	
<i>Cystisoma spinosum</i> (Fabricius), .	1500	<i>Platyseclus ovoides</i> (Risso?). Deep tow-net. ²	

¹ 1800 fathoms was the depth at the station at which this species of *Phronima* was taken, but in all probability the *Phronima* was taken at the surface.

² The depth at Station 243 at which this species was taken is 2800 fathoms.

Almost all the Hyperina, except in the genera *Lanceola*, *Cystisoma*, and *Phronima*, were expressly labelled as having been taken at or near the surface. In regard to the specimens of *Phronima*, it was probably considered that their capture at the surface would be taken for granted, their floating habitations having been frequently obtained.

How incomplete is our present knowledge of the whole group may be inferred, as well from the numerous additions which almost every voyage of scientific exploration makes to it, as in especial from those additions which the Challenger made by a few weeks stay in the Southern Ocean at Kerguelen Island and Heard Island. For, by the exertions of the Challenger Naturalists, from this small region, previously supposed to be very barren in Amphipods, the following list of species was obtained :—

Among the Gammarina :—

- Anonyx cicadoides*, n. sp., K.¹
- Tryphosa antennipotens*, n. sp., H.
- Tryphosa barbatipes*, n. sp., K.
- Hippomedon kergueleni* (Miers), K.
- Hippomedon trigonicus*, n. sp., K.
- Cheirimedon crenatipalmatus*, n. sp., K.
- Sophrosync murrayi*, n. sp., K.
- Orchomene cavimanus*, n. sp., K.
- Lepidepeircum foraminiferum*, n. sp., K.
- Socarnoides kergueleni*, n. sp., K.
- Ambasia integriceauda*, n. sp., K.
- Aeontiostoma pepinii*, n. sp., K.
- Aeontiostoma kergueleni*, n. sp., K.
- Kerguelenia compacta*, n. sp., K.
- Metopa nasutigenes*, n. sp., K.
- Cardenio paurodactylus*, n. sp., K.
- Phoxocephalus kergueleni*, n. sp., K.
- Harpinia obtusifrons*, n. sp., K.
- Urothoë lachneëssa*, n. sp., K.
- Halimedon schneideri*, n. sp., K.
- Edieeroides rostrata*, n. sp., K. and H.
- Zaramilla kergueleni*, n. sp., K.

Among the Caprellina :—

- Dodecas elongata*, n. sp., K.

Among the Hyperina :—

- Vibilia* sp., between K. and H.

- Primno* sp., K.

¹ K. stand for Kerguelen, H. for Heard Island.

- Acanthechinus tricarinatus*, n. sp., H.
- Iphimedia pacifica*, n. sp., K.
- Iphimedia pulchridentata*, n. sp., H.
- Atyloides australis* (Miers), K.
- Harpinoides drepanocheir*, n. sp., K.
- Tritæta kergueleni*, n. sp., K.
- Rhachotropis kergueleni*, n. sp., K.
- Eusirus longipes*, Boeck, K. and H.
- Eusiroides pompeii*, n. sp., H.
- Liljeborgia consanguinea*, n. sp., K. and H.
- Photis macrocarpus*, n. sp., K.
- Aora kergueleni*, n. sp., K.
- Aora trichobostrychus*, n. sp., K.
- Autonoe kergueleni*, n. sp., K.
- Gammaropsis exsertipes*, n. sp., K.
- Amphithoë kergueleni*, n. sp., K.
- Podocerus falcatus* (Montagu), K.
- Cerapus sismithi*, n. sp., K.
- Haplocheira plumosa*, n. sp., K.
- Platophium danæ*, n. sp., K.
- Neohela serrata*, n. sp., K.

- Protelopsis kergueleni*, n. sp., K.

- Euthemisto gaudichaudii* (Guérin), K.

Of the forty-eight species here enumerated, all but about half a dozen have been brought to light by the Challenger researches, and of the genera over which these species are distributed thirteen out of forty-three are new.

It may be convenient here to group together the names of the thirty-one new genera established in this Report :—

<i>Cheirimedon.</i>	<i>Atylopsis.</i>
<i>Platamon.</i>	<i>Harpinioides.</i>
<i>Onesimoides.</i>	<i>Stenopleura.</i>
<i>Sophrosyne.</i>	<i>Cleonardo</i>
<i>Cyelocaris.</i>	<i>Eusiroides.</i>
<i>Socarnoides.</i>	<i>Synopioides.</i>
<i>Aeontiostoma.</i>	<i>Parelasmopus.</i>
<i>Kerguelenia.</i>	<i>Dryopoides.</i>
<i>Valettia.</i>	<i>Paradryope.</i>
<i>Cardenio.</i>	<i>Camacho.</i>
<i>Platyischnopus.</i>	<i>Chosroës.</i>
<i>Œdieeroides.</i>	<i>Dodeeas.¹</i>
<i>Zaramilla.</i>	<i>Caprellinoides.</i>
<i>Acantheehinus.</i>	<i>Protellopsis.</i>
<i>Atyloides.</i>	<i>Sympnomoë.</i>

Streetsia.

The new generic names proposed in the Report in exchange for older but preoccupied names of valid genera are as follows :—*Caprellinopsis* for *Caprellina*, G. M. Thomson ; *Euseeliotes* for *Euseelus*, Claus ; *Lysianax* for *Lysianassa*, Milne-Edwards ; *Pariambus* for *Podalirius*, Kröyer ; *Phoreorrhaphis* for *Phorcus*, Milne-Edwards ; *Phoxocephalus* for *Phoxus*, Kröyer ; *Priscillina* for *Priseilla*, Bock. *Haustorius*, Müller, is reinstated in place of *Lepidaetlylis*, Say, *Phtisica*, Slabber, in place of *Proto*, Leach, and *Seinà*, Prestandres, in place of *Tyro*, Milne-Edwards, and *Clydonia*, Dana. *Æginella*, Boeck, is taken to include the preoccupied *Ægina*, Kröyer. For *Constantia*, Dybowsky, *Costantia*, a form accidentally occurring in Dybowsky's own work, is adopted. For *Eurytenes*, Lilljeborg, *Eurythenes* is accepted from the pen of Professor S. I. Smith. For *Dryope*, Sp. Bate, although preoccupied, no alternative name is for the present offered, its relationship to the new genus *Dryopoides* requiring further consideration.

Of the hundred and eighty species which the Report describes as new, it is possible that a few come too near to older species to deserve specific distinction. Especially in the genera *Hippomedon*, *Leueothoë*, and *Aora* my suspicions are aroused that I may have introduced some unnecessary names ; but such errors of judgment, if found to exist, will also, I hope, be found to be few.

¹ This genus was first published in a preliminary notice in 1883.

BIBLIOGRAPHY.

B.C. ARISTOTELES, born about 385, died 322 B.C.
Cent. IV.

De Animalibus Historiæ. Libri x. (Jo. Gottlob Schneider, Lipsiæ, 1811). These *iστορίαι περὶ τὰ ζῶα* were probably published within the last thirteen years of their author's life. After his writings had met with sundry changes and chances, there is reason to believe "that about 50 years b.c. Andronieus produced the first edition of the collective works of Aristotle." See The Ethies of Aristotle, by Sir Alexander Grant, 1874, p. 9.

The passages in Aristotle which probably refer to the Amphipoda are the following:—Book iv. eh. 2, Τῶν δὲ μαλακοστράκων ἐν μέν ἔστι τὸ γένος τὸ τῶν καράβων καὶ τούτῳ παραπλήσιον ἔτερον τὸ τῶν καλουμένων ἀστακῶν. Οὗτοι δὲ διαφέρουσι τῶν καράβων τῷ μὴ ἔχειν χηλὰς καὶ ἄλλας τυὰς διαφορὰς οὐ πολλάς. Ἐν δὲ τὸ τῶν καρίδων, καὶ ἄλλο τὸ τῶν καρκίνων. Γένη δὲ πλείω τῶν καρίδων ἔστι καὶ τῶν καρκίνων τῶν μὲν γὰρ καρίδων αἵ τε κυφαὶ καὶ αἱ κραγγώνες καὶ τὸ μικρὸν γένος· αὗται γὰρ οὐ γίγνονται μεῖζους. Of the Malaeostraea one genus is that of the carabi, and near to this a second of those called astaei. These differ from the earabi in not having chelæ, and in a few other points. One genus is that of the carides, and another that of the careimi. There are several genera of the carides and of the careini; for to the carides belong the gibbae and the crangons, and the *little genus*; *for these grow no bigger*. Book iv. eh. 10, a passage, unfortunately incomplete, relating to the sleep of fishes and other water animals that have no eyelids: 'Αλίσκονται γὰρ οἱ ἰχθύες, εἰ μὴ διὰ τοὺς φθεῖρας καὶ τοὺς καλουμένους ψύλλους . . . [οὗτως ἀτρεμίζοντες,] ὥστε κἀν τῇ χειρὶ λαμβάνειν ῥαδίως· νῦν δᾶν χρονίσωσι οὖτοι τῆς νυκτὸς, κατεσθίουσι προσπίπτοντες πολλοὶ τὸ πλήθος ὄντες. Γίγνονται δ' ἐν τῷ βινθῷ τῆς θαλάττης καὶ τοσοῦτοι τὸ πλήθος, ὥστε καὶ τὸ δέλεαρ ὅ τι ἀν ἰχθύος ἦ, ἐὰν χρονίσῃ ἐπὶ τῆς γῆς, κατεσθίουσι· καὶ ἀνέλκουσι πολλάκις οἱ ἀλιεῖς περὶ τὸ δέλεαρ ὥσπερ σφαῖραν συνεχομένων αὐτῶν. For fish, unless [they are disturbed] by the liee and *so-called fleas*, are surprised in so tranquil a condition as to be easily taken even in the hand. But now if these are left [in the nets] during the night, they (the fleas) being many in number fall upon and devour them. In the deep of the sea they grow in such multitudes that any piece of fish for bait, if left long on the ground, they devour. And often the fishermen draw up round the bait as it were a globe of them clinging to it.

Gerstaecker thinks that the *little genus* of the first passage may well refer to such an Amphipod as *Gammarus locusta*. Boeck considers that the ψύλλοι of the second passage, which eat the fish in the nets, are also likely to be Amphipods, since in the northern seas these act exactly in the way described. The statements of Klein and Holboell confirm this. As Aristotle apparently speaks of the bait on land, "ἐπὶ τῆς γῆς," being eaten by these creatures, it is likely enough that he alludes to more than one species; unless, as Bellon evidently supposed, the land intended be not dry land or shore, but the ground at the bottom of the sea.

A.D. CAIUS PLINIUS SECUNDUS, born A.D. 23, died A.D. 79.
Cent. I.

Historia naturalis. Libri xxxvii. (Gabriel Brotier, Tomus ii., Parisiis, 1779).

In book xi. sect. lxii., Pliny speaks of Crustata among marine animals. No earlier use of the word in this application seems to be known. In book ix. sect. xxi. he says, "Animal est parvum, scorpionis effigie, araeui magnitudine. Hoc se, et thynno, et ei qui gladius vocatur, crebro delphini magnitudinem excedenti, sub pinnâ adfigit aculeo : tantoque infestat dolore, ut in naves sãepenumero exsiliant." This passage is only worth noting in comparison with Risso's statement that a species of *Cyamus* sometimes so irritates the thunnies in the Mediterranean that they jump out of water. Lütken supposes that Risso has assigned to *Cyamus* an effect produced really by *Brachiella thynni*. In book ix. sect. lxxi., Pliny appears to confuse, in a rather ludicrous passage, the *φθεῖρες* and *ψύλλοι* mentioned in book iv. ch. 10, of Aristotle's History of Animals. In book ix. sect. li. he gives "Cancrorum genera, carabi, astaci, maiæ, paguri, heracleotici, leones, et alia ignobiliora," among which the ignobiliora may be supposed to correspond to the *μικρὸν γένος* of Aristotle, and to include some at least of the Amphipoda.

1553. BELLON (or BELON), PIERRE, born about 1517, died 1564 (Encycl. Brit., 9th Ed.).

Petri Bellonii Cenomani De aquatilibus, Libri duo Cum iconibus ad viuam ipforum effigiem, quoad ejus fieri potuit, expressis. Parisiis, M.D.LIII.

The second book, pages 318-348, is de aquatilibus exanguibus. Of these "quæ Græcis ἔναιμα, nobis exanguia dicuntur," he says, "alia dura quidē testa operiuntur, quæ illi ὁστρακόδερμα, alia verò molli: quæ etiam μαλακόστρακα vocāt, atque alia rursus iusecta, sub quibus magna marinorum ac fluvialium phalanx contiuetur. Exanguin igitur molles à nobis describentur ac depingētur primum locustæ, cancri et id genus cæteri. . . . Ultimo loco dejectamenta mariua, nominibus etiam insignibus prædicta explicabuntur, quibus nonnquam etiam vesci solemus."

Among the Crustata he considers that the *Squilla fluviatilis* parva, the *Gambarella* of the Romaus, is intended by Aristotle's "parvæ quæ majores nunquā effici possunt." In this Bellon is evidently not thinking of auy Amphipod. The ouly allusion that he makes to Amphipods is to be found, if anywhere, in his cap. xii. p. 436, "De deiectamentis marinis," in the section headed "Asilus sive Estrum." This Isopod he figures with eight thoracic feet on each side, and coucludes his account of it as follows:—"Aristotles octauo de historia animalium: Thunni (inquit) et Gladii agitantur oestro, canis exortu. habent enim vtrique per id tempus sub pinna ceu vermiculum quem Asilum vocant. Idem author videtur oestrum seu Asilum diuersuu à pediculo et pulice constituere, quum eis etiam nomina propria φθεῖρα θαλάσσιον, id est, pediculum marinum, et ψύλλαν θαλάττιον, id est pulicem marinum, imponat. Vocat et in mari pediculos (inquit Plinius) eosque tritos iustillari ex aceto auribus jubent. Pisces vel manu caperentur, dum dormiuunt (inquit Aristoteles) nisi pediculis et pulicibus solicitarentur. Gignuntur iu profundo maris tanta fecunditate, vt escam de pisce emollitam, si diu iu imo manserit, totam corrodat atque absument. Et quidem sãepenumero piscator escam demissam, glomeratis vudique his bestiolis, perinde vt pilam attollit." Aristotle's "ἐπὶ τῆς γῆς," is here represented by "in imo," meaning "at the bottom of the sea," which is perhaps an attempt to correct the unmeaning words "in uno" in Gaza's translation, for which Aubert and Wimmer (1868) suggest "in humo."

1554. RONDELET, GUILLAUME, born 1507, died 1566 (Biographie Universelle).

Libri de piscibus marinis in quibus veræ piscium effigies expressæ sunt.
Lugduni, M.D.LIII. pp. 534–577.

Liber xviii., De Piscibus, quæ dicantur Crustacea, contains chapters on Stalk-eyed and Sessile-eyed Crustacea and on Echinoderms. Chapter xxvii., De Pulice marino, begins: “Cum Maris purgamentis aliquoties reperi bestiolam tenui crusta intactam, quam hic depinximus, quæ facie homunciones ridiculè pictos vel simiam repræsentat aliis partibus locustæ similis est, in cauda appendiculas habet locustæ et squillæ modo, tam exigua est ut particulæ corporis nisi ab oculato discerni possint, ob parvitatem negligitur. Hanc puto esse ψύλλον θαλάττιον, id est, pulicem marinum, de quo Aristoteles, quum de piscium sonno agit.” He then proceeds with a translation of the passage from Aristotle, lib. iv. ch. 10. Boeck thinks he means some species of *Gammarus*. The accompanying woodcut will give a fair idea of Rondelet's drawing, which has the special interest of being, I believe, the earliest known figure of an Amphipod, whether the original were a *Gammarus*, or, as seems equally possible, an *Orchestia*. In saying that its *facies* “represents a human being caricatured or a monkey,” Rondelet has probably mistaken the tail for the head.

In ch. xxviii., De Pediculo Marino, he gives the figure of an Isopod, but explains that the *φθεῖρ θαλάττιος* of Aristotle applies not only to this, but also to a species, “qui in mari, quod est à Cyrena ad Ægyptum circa delphinum est, qui omnium pinguissimus fit pabuli copia, quæ delphini opera suppeditatur.” The *οἰστρος* of Aristotle, from the fins of the thunny, like a scorpion, and of the size of a spider, is not to be confused, he says, with these *φθεῖρες*.

Fig. 1.

1558. GESNER, CONRAD (or GESSNER, KONRAD), born 1516, died 1565 (Encycl. Brit., 9th Ed.)

Conr. Gesner, medici Tigurini: Historiæ animalium Liber IV, qui est de piscium et aquatilium animalium natura cum iconibus singulorum ad vivum expressis fere omnib. DCCVI. Continentur in hoc volumine Gulielmi Rondeletii quoque medicinæ professoris Regii in Schola Montpeliensi & Petri Bellonii Cenomani, medici hoc tempore Lutetiæ eximii, de aquatilium singulis scripta. Tiguri, MDLVIII.

Boeck, De Skand. og Arkt. Amph., p. 19, gives the date of this work as 1548, and he says, p. 32, that it repeats on p. 994 Rondelet's text without any addition of importance, under the heading *De pulici marino Rondeletico*. Since the date 1548 was inconsistent with the reference to Rondelet, and the first edition of Gesner's work was not to be met with in England, I sought information from Copenhagen, and Mr. G. E. C. Gad has had the kindness to send me the full title and the date as above given of the first edition in question, from the Royal Library in Copenhagen. The first volume, he tells me, is dated 1551, the fourth volume 1558, and in this latter the heading “De publice [pulice] marino Rondeletius” occurs not on page 994, but on page 894. In the 2nd Edition, 1620, the notice occurs on pp. 759–760. To Rondelet's account is added “Gignuntur et in stagnis marinis similes,” and a “Corollarium” about the uses of the *psyllus marinus* which leaps about on the shore. The reference in the Index to the account of the *Pediculus marinus* of Rondelet is given wrongly as p. 649 instead of 694.

1560. GESNER, CONRAD.

Nomenclator aquatilium animantium. Icones animalium aquatilium in mari et dulcibus aquis degentium, plus quam DCC. cum nomenclaturis singulorum Latinis, Graecis, Italicis, Hispanicis, Gallicis, Germanicis, Anglicis, aliisq; interdum, per certos ordines digestæ. Tiguri, Anno M.D.LX.

In Tomus I. he includes seventeen orders of marine animals, the Crustata forming the fourteenth.

The fifteenth embraces the Testacea, a large portion of which in the body of the work is headed De Crustatis, apparently by a printer's error. The sixteenth order is formed of the Insecta Marina, "ut sunt, Hippocampus, Eruca, Pediculus, Pulex, Asilus, Hirudo mar. Vermes et Lumbrici quidam, Scolopendræ." On p. 267 he remarks, "Pulicem et Pediculum marinos, quanuis tenui crusta integantur, Insectis potius. quam ut Rondeletius Crustaceis, adiunximus, quod forma eorum tota à Crustatis pluriūm differre uideatur, magisq; ad Insecta accedere."

On p. 268 he says, "Pulex marinus Rondeletij. Ψύλλος θαλάττιος: sic dictus est nimis non tam à formæ, quam saliendi similitudine, et similiter pisces in mari infestandi natura, ut Pulices in terra molesti sunt animalibus." He then borrows from Rondelet, and concludes, "Niphus Scolopendras mar. uulgò Puliccs marinos dici scribit, quod pisces eodem modo infestent. nos Scolopendras mar. longe alias dabimus inferiū. Germ. F. Ein Meerflohe."

Among the fresh water animals of Tomus II. he gives *Astacus fluviatilis* and *Cancer fluviatilis* but no Amphipoda. His brief remarks on *Pulex marinus* are perhaps generalised from what he has read, heard, or seen of animals belonging to the Orchestidæ, Gammaridæ, and Cyamidæ.

1565. MATTHIOLUS (MATTIOLI), PETRUS ANDREAS, born 1500, died 1577 (Biographie Universelle).

Commentarii in vi libros Pedacii Dioscoridis Anazarbei de Medica materia, ab ipso autore recogniti, et locis plus mille aucti, MDLXXXIII. Venetiis. (Epistola nuncupatoria, dated MDLXV.)

Pages 278–284 discuss various Crustacea or Crustata, including *Cancer*, *Astacus*, *Gammarus*, *Squilla*, *Maia*, *Pugurus*, *Cancelli*; none of them Amphipods. He refers to Aristotle's book iv. ch. 2, producing the often quoted words "Squillarum enim genere continentur gibbæ, crangones, et parvæ, quæ majores nunquam effici possunt," with the remark, "Quibus liquidò constat, vulgares gammarulos Aristoteli parvas facile esse Squillas, cum ii majores nunquam evadant, quam qui semper parvi in piscariis habentur venales."

1606. ALDROVANDI, ULISS, born 1522, died 1605 (Biographie Universelle). (The date 1607, given in the Encycl. Brit., 9th Ed., is inconsistent with the title page here quoted).

Vlyssis Aldrovandi Philosophi, et Medici Bononiensis. De Reliquis Animalibus exanguibus libri quatuor, post mortem ejus editi: Nempe De Mollibus, Crustaceis, Testaccis, et Zoophytis. Bononiæ, 1606.

The second book is De Crustatis, and contains the wisdom of the ancients concerning these animals. In regard to the name he says, "Quæ Græci et præsertim Aristoteles μαλακόστρακα, Latui hoc tempore Crustacea vocant: Pluvius Crustata, cum inquit, In marinis

Crustata et Cartilaginea priores dentes habent." Nothing certain about Amphipods can be derived from Aldrovandus, though some of his allusions to the small kinds of Crustacea may have them in view. The remark attributed to Pliny is not that which he actually makes. On the contrary, as to these *dentes* he seems to express a doubt by the words, "At in marinis crustata et cartilaginea primores [sc. dentes] habere, item echinis quinos esse, unde intelligi potuerit, miror." Aldrovandi's misquotation reappears in Faccioli's great Latium Dictionary, except that "primores" is there correctly given instead of "priorcs."

1634. MOUFET, THOMAS, born about 1550, died 1604 (thirty years before his work was published).

Insectorum sive Minimorum Animalium Theatrum : *Olim ab Edoardo Wottono, Conrado Gesnero, Thomaque Pennio inchoatum* : Tandem Tho. Moufeti Londinatis operâ sumptibusq'; maximis coneinnatum, auctum, perfectum : Et ad vivum expressis Leonibus suprà quingentis illustratum. Londini, 1634.

On page 321 he says, "Pediculus marinus Insectum est Balneis [Balenis?] cetorumque generi infestum, quos mordendo titillandoque ita in furorem agit, ut se in arenas projicere aridumque petere cogantur." The figure at the side is not a *Cyamus* but one of the Cymothoidæ. On page 322 he says, *Pulex* sive *Asellus marinus* squillam molliorem refert, nisi quod quatuor tantum pedibus (pace Gesneri dixerim) donatur, et frequentibus longisque saltibus se liberat, à numero pedum. *Asellus* dicitur a saltu, Aristotelis *pulex* : à dorso gibboso, Serofula nuncupatur; color illi lividus cum nigredine. Longitudo fluviatilium, digitum transversum; latitudo, sémidigitum non superat; marinorum major dimensio, qui littore refluente, et in aquis dulcibus sæpe conspicitur. Venatoribus item spectatoribusque mirum agilitatis præbet exemplum." There is a figure given, without name or reference, on the last plate but one, which is probably a generalised representation of this description. It is rather a satire on the expression "ad vivum expressis Icouibus" in the title. The animals referred to may include the sand-hoppers and shore-hoppers, *Talitrus*, *Orchestia*, *Hyale*, as well as the fresh-water *Gammarus pulex* and the salt-water *Gammarus locusta*, *Gammarus marinus*, et hoc genus omne.

1665. SACHS, PHILIPP JACOB, born 1627, died 1672 (Hagen).

Γαμμαρολογια sive Gammarorum, vulgo Canerorum eonsideratio physieo-philologieo-historico-medieo-chymiea, *in qua*, Præter Gammarorum singularem Naturam, Indolem et multivarium usum non minus reliquorum Crustatorum instituitur tractatio Ad Normam Collegii Naturæ Curiosorum, Plurimis Inventis Seeretioribus Naturæ Artisq' Loeupletata à Philippo Jacobo Sachs à Lewenheim, Siles. Ph. & Med. D. et Colleg. Nat. Curios. Collega. Franeofurti & Lipsiæ, Sumptibus Esaiæ Feligbelii Bibliop. Wratislav. M.DCLXV.

The title of this curious and amusing book very fairly indicates its contents, only unfortunately at that time the Crustacea now known as Gammarids had excited little or no attention. On page 92 he mentions that the Squillæ are divided into *marinæ* and *fluviatiles*. He then continues: "Marinæ rursus secundum Arist. IV. II. 2, in Latas, κράγγονες, crangones, in Gibbas κύφας et in parvas quæ nunquam majores sunt" dividuntur. The *Squillæ gibbae*, he says, are divided by Schoenfeld into two species. With the smaller, which does not turn red when cooked, at the mouth of the Elbe and the Oder they feed pigs and ducks,

so numerous are these shrimps. This may refer to the common eatable shrimp, but what follows appears to include species of *Orchestide* or other Amphipods, for he says: "In Holsatia vocantur Purren / Dithmarsis Kront / Belgis Garnelen / Garners / Garnaten / Gallis Sauterde, Cheorette, Guernette, ein Seegityle / Meergeis Gesn. f. 127. Springfrehse. In Sanctonum littore maxima earum copia est, et alibi quoque in littoribus Germaniae et Belgii. Haec parvae Squillae gibbae avide expetuntur ab Harengis." He goes on to say that many eminent naturalists had stated that the herring fed on nothing but sea-water, an opinion which Behm had satisfactorily refuted by finding in a herring's stomach forty *Squillae gibbae* (Garnel), and Neueranzius by finding more than sixty, though smaller ones. (These may have been *Hyperina*, see note on Thomas Edward, 1868.) On pages 96-97, under the heading *Squilla minima*, he gives the following, § ix.: "Ex *Squillis parvis* et nomine fere carent. Germ. ein Zwergfrehlein / ein kleiner Gernier quibusdam ἐγλάροι [read ἐγχλωροι] a colore subfulvo, coctæ tamen rubescunt, χλωρὸς namque viridem, modo luteum colorem Graecis significat. Ob exiguitatem Vascones Civude quasi Avenam vocant, quas e Garuma copiose extrahunt, et pugillatim devorant, sicut avenam veteriuæ. Coci quidam vocant Brava, quæ vox itidem Avenam significat, dividitur in illam, 1, quæ Romæ Gambaretta dicitur.

- " 2. Quæ Gambaruccio, estque adeo exigua ut in ille vix unam libram æquent. *Squillis affine Animalculum* memorat Schoenfeld, p. LXXIII. piscatoribus infestum, quod ad mare Balthicum vulgus nominat Scheffie seu Sprackworm / squillis minimis figura respondens, crustaque instar illarum coniectum, vix transversum digitum longum retibus et tendiculis, quibus hamis affiguntur, mire noxiun, quæ magno piscatorum detimento arrodit."

It may be noted that at this date the Crustacea are not included among the Insecta. For *Animal* being divided into *Perfectum*, ἔναιμον sanguine præditum, and *Imperfectum*, ἔναιμον exsanguue, quod non habet sanguinem proprie sic dictum, sed humorem aliud proportione sanguini respondentem, the subdivision of *Imperfectum Animal* seu *exsanguue* is made as follows:— 1. In *Insectum ἔντομον*, quod corpus incisuris distinctum habeat: 2. In *molle*, quod molli cute coniectum μαλακόδερμα. 3. In *crustaceum*, quod tenui crusta obtectum μαλακόστρακον: 4. In *testaceum*, dura testa obtectum, δοτρακόδερμα" (pages 76-78).

1675. MARTENS, FRIDERICH.

Friderich Martens vom Hamburg Spitzbergische oder Groenländische Reise Beschreibung gethan im Jahr 1671. Aus eigner Erfahrung beschrieben / die dazu erforderete Figuren nach dem Leben selbst abgerissen / (so hierbey in Kupffer zu sehen) und jetzo durch den Druck mitgetheilet. Hamburg. Im Jahr 1675.

The fifth chapter, p. 83, is headed "Von etlichen Schild geschlechtern / so auff Grönlandischen / oder Spitsbergischen Reisen gefangen werden." Among these he distinguishes *Krabben* and *Sternfische*. Of the *Krabben* he had met with four kinds, first, the *Meerspinne* as the French call it, next, *rothe Krabben oder Garnellen*, thirdly, *kleine graue Krabben oder Granat*, and fourthly, *die so genandte Wallfischs Lauss*. In describing the two last of these, Martens has the distinction of having been, so far as is known, the first to give anything like a definite description of an Amphipod. For this reason the accounts of his third and fourth species seem worth giving in full, as also for other reasons the account of number two. They read as follows:—

2. *Garnell*. Unter den Garnellen die man hier sieht und die man in Spitzbergen findet ist kein Unterschied. Spitsbergische aber seynd von Farben auch ungekocht roth / rother wie die von Lübeck gekocht zu uns gebracht werden. Der Kopf ist souderlich / bestehet von

etlichen Stücken und hat vier Hörner / der ganze Kopf ist breit an zu sehen / wie eine Kornschauffel ohne Stiel. Am Ende des Kopfs sitzen ihm seine Augen erhoben aus dem Kopfe wie Krebs Augen. Er sieht nicht unterwerts / sondern forn aus und von der Seite. Das Schild auf dem Rücken ist Eines Harnischen Rüektheile am gleichsten ist auch hinter dem Kopfe als in seinen Nacken ein wenig eingebogen / und gar wenig pücklich / dahinten sitzt ein Stachel. Darnach folgen sechs Schilde wie die Sehilde an den Harnischen an den Armen und Beinen / nmb die Ecken desselben sitzen kleine schwarze Pflecklein / als wenn es Nägel an Harnischen seynd. Die Schilde liegen recht rundlich auf einander / wie die Striche und erhabene Theile an den Köpfen der Regenwürmer. Wann er den Schwanz nnter sieb zichtet / so ersebeinen die Sehilde hinten zu etwas eingekerbt mit noch einen erhobenen Theil dahinten. Der Schwanz ist von auch fünf Theilen / wann er den aussbreitet ist er wie ein Vogel Schwanz. Hat fornen zwei Scheren / davon der foderste Theil einer Zahnbreeher Zangen am ähnlichen sitzet / haben Zacken gleich daran. Hat 18. Beine / davon die nechsten an den Scheren die kürzten und dünnesten. Die fodersten 8. Beine haben vier gleich / davon das höchste das längste / und das unterste das kürzte ist / seynd gantz nicht haricht oder raueh. Die zehn hintersten Beine davon die fodersten die längsten / und das oberste gleich viel dicker und kürzer als die untersten langen seynd / haben zwey gleich / davon die Füsse etwas untenwerts gebogen und harig sind. An dem hintersten fodersten gleiche stossen herauss zwey Sebosse / unten an dem andern nur ein. Er schiest gar schnelle fort im Wasser. Er war so gross / wie ich ihm naeh dem heben abgerissen. Sie seynd der Vogel Speise / wie oben bey den Vogeln beschrieben ist. Denn ich hier vorstelle ; bekam ich von nngefahr / da eine Lumbe über nnser Schiff flog / und einen auff des Schiffs Deek oder Boden fallen liess / wie droben bey den Lumben beschrieben ist.

- “3. Kleiner Garnell. Ich habe auch gemercket auff der Spitsbergischen Reise / ein geschlecht von Krabben so den Würmern gleich ist. Der Kopf ist einen Fliegenkopf am ähnlichen. Hat fornen nnten am Kopf zwey Hörner ausstehen. Hat Schilde wie die breiten Maurwürmer. Ist rund auff den Rücken / unterwerts breit. Hat in allem 12 Beine. An jeder seite der fodersten Schilde hat er drey Beine. Vier Schilde vorbey sitzen an jeder seite noch drey beine. Seynd nicht grösser als ich sie abgerissen. Die Vogel fressen sie als ihr angenebmste Speise / welehes ich daher schliesse / weil sie sich häufig funden an den Orten da diese Würmer sich hatten. In dem Dänischen Hafen fand ich sie häufig / zwischen und nnter den Steinen im Wasser wenn man die Steine auffhebete. Hernach den 8. July bekam ich sie in dem Muschel Hafen / darnach dieser nach dem lebend abgerissen. Ich habe sie auch in des Wallfisches Samen der auff dem Wasser trieb vermenget gefunden. Tab. P. gezeichnet mit C.
- “4. Die so genandt Walfisches Lauss. Die so genandte Wallfisebes Lauss hat mit der Lauss ausserhalb des Kopfs kein gemeinsehaft / gehört mehr zu den Krebs geschlechten. Seynd hart von Schilden wie Krabben. Haben einen Kopf fast wie eine Lauss / mit vier hörner / seynd beyde von ansehend als ein doppelter A. Die zwey kürzten hörner von fornen ausstehen / haben zwey knöpff fornen als Paucken stöcke / und die zwey andern krummen hörner seynd fornen spits. Der Kopf hat meist die gestalt einer Eicheln / ist hinten tieff abgeschnitten. Hat zwcy augen, Ein Nasen loch. Der Halss ist nicht steiff vom Schilde / sondern von Hant als die Haut zwischen Krebsseilden. Hat sechs Schilde auff den Rücken. Das foderste Schild siehet aus wie die Spuhle (Seehetpsule genand) damit die Leinweber den Fadem werffen. Die andern drey als das Weissbrod / so wir Pümmelcken nennen. Die zwey hintersten seynd am aller ehnlichsten einem Schilde. Den Schwanz konte man wohl einen Schilde vergleichen / ist aber gar kurtz. An den fodersten Schilde hat er die Füsse / von Gestalt wie eine krumme Meyer Sense / seind vornen rund gebogen

Fig. 2.

wie ein viertel von Mond / inwerts aber auf die Helffte mit Zacken wie eine Zäge / und vornen ein spitziger krummer Klaue. An des andern und dritten Schildes jeder Seite stehen heraus vier Keulen als seine Ruders / haben unten ein kurtz Glid / darinnen seine

Fig. 3.

Ruder beweget werden / die Keulen legen sie kreutzweise über den Rücken wan sie vom Walfische fressen / oder sie legen sie also an einander in die höhe / wie die springer wann sie über Degen springen. Die sechs hintersten Beine / seynd von gleichen als Krebsbeine / haben an jedem Bein drey gleiche / davon die fordersten gekrümmet wie ein viertel Moud / fornen aber seind sie gantz spitz wie eine Nadel / so dass sie feste so wol Menschen als in des Wallfisches haut fassen können (wie die Filtzläusse / daher ihnen auch der Nahme Lauss gegeben) dass man sie in stücken zerschneiden muss / ehe man sie von der Haut reisse mag. Oder wer sie lebendig begeluret / muss sie mit der Walfisches haut heraus schneiden. Sie sitzen den Wallfischen an gewisse Orter des Leibes (als zwischen den Flossfedern oder Füßen / an der Scham und

Lefftzen / da er sich nicht wol reiben mag / und beißen ihm stücke aus der haut / als wann die Vogel von ihm gefressen hätten. Etliche Wallfische habeu sehr viel Läusse / etliche haben nicht eine / je wärmer ist je mehr läuse bekomen sie. wie ich von auderu vernommeu. Deu ich hier vorstelle habe ich abgerissen in den Muschel hafen den 7. Julii. Tab. Q. gezeichnet mit d."

On page 58, in describing the "Lumbe," he says, "In ihren Magen habe ich gefunden kleine Fische und rothe Garnellen / und etliche Sandsteine. Wie ich dann solche vollenkomlich erkant / nachdem eine Lumbe im fliegen eine grosse rothe Krabbe auff das Schiff fallen liess / welche ich auch an gemeldten Orthe abgerissen."

The woodcuts are copied from the figures given by Martens in his Plates P. and Q.

It seems quite obvious that the *Garnell*, number 2, with the eyes raised out of the head like *Krebs Augen*, and with eighteen legs, and capable of being described as a great red *Krabbe*, cannot have anything to do with a *Caprella*. On the other hand these rather curious circumstances are to be noticed: first, that while the description of "*Garnell*" refers to a life-size figure which is not to be found, the figure *i* on Plate P. is left without any description; secondly, that a copy of this figure, with the word "*Garnell*" attached to it in a peculiar manner, as if to avoid all possibility of mistake, is given by Adelung in 1768 to

accompany his modernised version of Martens, and is definitely referred to the description of "*Der Garnell*," while, lastly, Herbst, Nat. der Krabben and Krebse, II. 142–144, under "*Caucer (Gammarellus) linearis*," refers to "*Martin Spizberg, tab. B. fig. I. p. 115, Granat*," and winds up his account of this species with the words, "Die Vögel fressen diese Thiere als ihre liebste Speise, und halten sie häufig an denen Orten auf, wo man die findet. Man trifft sie aber vornehmlich in den Häfen zwischen und unten den Steinen im Wasser, und auch in des Wallfisches Saamen an, der auf dem Wasser treibt," thus adding to the perplexity by combining a reference to figure *i* with words obviously borrowed from the account that applies to figure *c*. Boeck is of opinion that the figure *i* represents *Caprella septentrionalis*, Kröyer, on the ground that no other *Caprella* is found at Spitzbergen. Mayer, Caprelliden, p. 2, does not accept Boeck's argument, and considers that, as the species represented is undescribed, it would be undeserving of further notice, but for the reference to it in Linnaeus.

The *Kleiner Garnell*, number 3, being found among and under stones, may in Boeck's opinion be *Gammarus locusta*, that being found in such situations at Spitzbergen.

Since the Wallfish of Martens is known to be the Greenland Whale, *Balaena mysticetus*, Lütken

Fig. 4.

infers that its parasite must be that which he has named *Cyamus mysticeti*, rejecting the name *Cyamus ceti*, as having been applied confusedly to several species. Though Martens drawing of this species, Plate Q, fig. *d*, is a very odd one, the description is vouched for by Lütken as being in many points correct, and in any case such as should have prevented later writers from confusing the species with the Pyenogonidae.

1705. RAY, JOHN, born 1628, died 1704 (1705 or 1707). "His proper name is Wray,"
H. A. Hagen, Bibl. Entom.

Methodus Insectorum seu Insecta in *Methodum aliqualem digesta*: a Joanne Raio. Londini, c*16*ccv.

"Insecta," he says, "sunt vel ἀμεταμόρφωτα, hoc est, quae nullam subeunt formæ mutationem; vel μεταμορφώμενα, hoc est, quae formam mutant."

"Insecta ἀμεταμόρφωτα sunt vel "Απόδα seu *Pedibus destituta*, vel *Pedata*. Ex his nonnulla pellem aliquoties mutant."

Under "Insecta ἀμεταμόρφωτα Pedata," he says:—

"Haec pro numero pedum dividi possunt in 1. Hexapoda, 2. Octapoda, 3. Τεσσαρεσκαιδεκάποδα, 4. Πολύποδα."

The third group he thus describes:—

"3. Τεσσαρεσκαιδεκάποδα, seu 14 pedibus donata, *Aselli*, quorum tres species novimus,
1. *Maritimus* est, in rupibus degens, reliquis major et longior. 2. *Lividus*, qui in globulum se convolvit, Angl. *Wood-lice* and *Sowls* and *Chess-Bugs*. 3. *Asininus*, caudâ bifurcâ, minus gibbus quam *Lividus*, nec in globum se colligens. His addenda, 1. *Asellus marinus* figuræ brevioris, in globulum se convolvens. 2. *Asellus aquarum dulcium*, binas habens in cauda setas, crura longiora. 3. *Pulex aquaticus*, squillæ nonnihil similis, saltatrix, tum in aquis salsis, tum in dulcibus degens. 4. *Pediculus aquaticus*, piscibus infestus, quibus adhaerescit. Hujus datur species caudata, duabus sc. in cauda productioribus setis."

The Πολύποδα contain Terrestria, *Julus* and *Scolopendra*; Aquatica, the Cornish Bugs, with 38 feet, *Scolopendra marina*, and *Animalculum bicorpor* seu *bicaudatum*.

The account of the ἀμεταμόρφωτα he concludes with the words, "Hanc Methodum Insectorum intransmutabilium D. Francisco Willughby debemus." This explains the initials F. W. in the following notice.

1710. RAY, JOHN.

Historia Insectorum. Opus posthumum, jussu Regiae Societatis Londinensis editum. Londini, M.DCC.X.

On pages 43, 44, the following notices are given:—

"*Pulex marinus cornutus*. F. W. Ad *Asellos* referendus. Numerus annulorum ex quibus corpus componitur 12. Pedum utrinque 7, ex quibus ultimi cæteris longiores, ante caput duo longa ingentia cornua. Corpus $\frac{1}{4}$ tam unciae æquat. Ad radicem cornuum majorum duo alia minora sunt. Pinnulas natatorias habet. Coloris est subalbidi, figuræ tenuis et angustæ.

"*Pulex marinus Bellonii de Avibus, Moufeti et Gesneri, an Squillæ minimæ fluviatiles?* F. W.
Asellis similis est, sed gracilior et rotundior, pedesque multò longiores habet. Color in dorso spadiceus. Oculi nigri: Antennæ articulatæ, ab eodem puncto prodeuntes, quos

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

Xxx 2

directè antrorum extendit; ad quarum radiccs aliae due, multò breviores. Corpus ferè pellucidum, celerrimè movetur saltaudo ut Pulex, sed præcipuè extra aquam. Pedum secundum par chelarum instar latum. Inter pedes et caudam alia sunt sive Appendices, sive pedes, graciles et breves quibus ova adhærcere probabile est ut in Locustis. Cauda cirrorum fasciculo constat. In litoribus sub lapidibus innumeræ inveniuntur.

"*Pulex fluviatilis*, q. An à marino differat. F. W. Pedum quinque paria posteriora longa et gracilia sunt, duo capiti proxima breviora, non chelis sed (ni fallor) hamulis donata, ut in Squillis. Juniores matribus adhaerent, quæ in circulum ferè se contorquent, et pullos amplectuntur. A capite duo procedunt Antennarum paria. Quæ in nostris rivulis sunt, non saltant ut marinæ, sed incurvant se et natant podicem exerendo satis celeriter. Haæ in aquis calidis in specu *Custozae* prope *Vincentiam* in *Italia* inveniuntur, ubi nulla animalia vivunt."

Of these three notices the first probably refers, as pointed out by Pallas himself, to *Oniscus volutator*, Pallas, 1766; the second, to judge by the short upper antennæ, the large-handed second feet, and the saltatory motion, especially out of water, no doubt principally refers to *Oniscus gammarellus*, Pallas, though the attendant query implies that species of *Gammarus* were also in view; the third notice evidently includes two species, that from the warm springs of Custoza in Italy being, Boeck says, *Gammarus pungens*, while the other is obviously the common fresh-water *Gammarus pulex*.

1728. FRISCH, JOHANN LEONHARD, born 1666, died 1743 (Hagen).

Beschreibung von allerley Inseeten in Teutschland, Nebst nützlichen Anmerkungen Und nöthigen Abbildungen Von diesem kriechenden und fliegenden Inländischen Gewürme, zur Bestätigung und Fortsetzung der Gründlichen Entdeckung, So einige von der Natur dieser Creaturen herausgegeben, und zur Ergänzung und Verbesserung der andern. Siebender Theil. Samt einer Vorrede, darinnen von Ulyssis Aldrovandi Buch von den Inseeten ausführliche Meldung geschieht. Berlin, 1728.

In part vii., section xviii., page 26, is headed "Vom Krebs-formigen Wasser-Wurm." Of this he says, "Der grösste wird etwan Zoll-lang die Übereinkunft mit Krebsen, der Gestalt nach, leidet gar wohl, dass man ihm davon einen Nahmen giebt, weiler noch keinen hat." With the longer upper antennæ he thinks it feels what is in front of and beside it, with the smaller lower ones it feels what underneath might do it harm or supply it with food. He concludes that it cannot be one of the insects which undergo further transformation. Its fresh-water habitat, and the figures which Frisch gives, justify Bocck's opinion that *Gammarus pulex* is here in question. It is

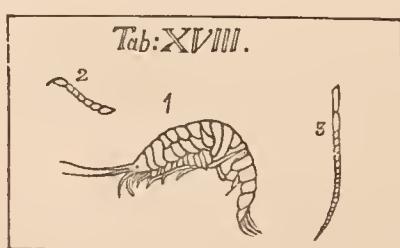

Fig. 5.

depicted on pl. xviii. figs. 1, 2, 3.
accompanying woodcut.

The whole plate is reproduced in the accom-

1734. SEBA, ALBERT, born 1665, died 1736 (*Biographie Universelle*).

Locupletissimi rerum naturalium Thesauri accurata descriptio, et iconibus artificiosissimis expressio, per universam physices historiam. Opus cui, in hoc rerum genere, nullum par exstitit. Ex toto terrarum orbe collegit, digessit, descripsit, et depingendum curavit Albertus Seba. Tomus i. Amstelædami, MDCCXXXIV.

On page 142 he gives *Pediculi ceti*, Poux de Baleine, with a sailor's story that they slip into the ears of the whales and pierce them with their bite. Lütken says that the figures, pl. xc. fig. 5, E, F, G, H, may with tolerable certainty be referred to *Cyamus mysticeti*, i.e., to the *Cyamus* which infests the Nordhval (a whalebone Whale, known in English as the Right-whale, the Greenland Whale, or the Common Whale), *Balaena mysticetus*, and that E, F represent a male, G a female, and H a young male. The "quatre pieds au milieu longs et menuis" are drawn as if articulated.

1735. LINNÉ, CARL (also Carolus Linnæus, Carl von Linné, and, in Trapp's translation of Stoever's Life, Sir Charles Linnæus), born 1707, died 1778.

Systema Naturæ, systematice proposita per Classes, Ordines, Genera, et Species. Lugduni Batavorum, MDCCXXXV.

In the Regnum Animale, the fifth of the six classes is devoted to the Insecta, "Corpus crista ossea cutis loco tectum. Caput antennis instructum." This class includes the Coleoptera, Angioptera, Hemiptera, and Aptera ("alæ nullæ"). The Aptera contain the divisions or genera, "Pediculus, Pulex, Monoculus, Acarus, Araneus, Cancer ("Pedes 12, priores cheliformes"), Oniscus ("Pedes 14"), Scolopendria." CANCER contains the species "Cancer, Pagurus, Maja, Gammarus, Astacus, Squilla, Eremita." ONISCUS contains "Ascellus Officin. Asellus aquat."

1738. LINNÆUS.

Animalia per Sveciam observata.

In this work the pages are headed Scient. Svec. A. MDCCXXXVI. Among the Aptera under *Cancer* are given, besides *Cancer marinus*, *Maja*, *Astacus*, *Gammarus*, four short descriptions of species of *Cancer*, and the name "Cancellus, Matth. Diosc., 230," corresponding probably to what he elsewhere calls *Eremita*, *Cancellus* being Swammerdam's name for Bernard l'Hermite, in 1681.

1740. LINNÆUS.

Systema Naturæ. Editio secunda, auctior. Stockholmiae, 1740.

The Regnum Animale has six classes: Insecta the fifth, "Corpus ossibus cutis loco tectum, Caput antennis instructum." The Insecta include four orders, the Aptera, "alæ nullæ," being the fourth. These comprise the genera, "Pediculus, Pulex, Podura, Monoculus, Kermes, Acarus, Aranea, Scorpio, Cancer, Oniscus, Scolopendra." CANCER ("Pedes X.; primores

*cheliformes. Oculi duo. Cauda foliosa") includes "Cancer, Pagurus, Majas, Gamarus Astacus, Squilla, Eremita." ONISCUS (*Pedes XIV.*) includes "Millepes, Asellus aqu." With the above agrees Editio quarta ab Auctore emendata et aucta. Parisiis MDCCXLIV.*

In a German edition, Halle, 1740, with a preface by Johann Joachim Langen, *Cancer* is defined "*Pedes* 12, priores cheliformes. Mit 12 Füssen, da die vordersten Scheren sind." The German explanation of *Gammarus* is "Der kleinste Krebs mit langen Schwanz (Spring-Krebs), as though *Gammarus* were an Amphipod, which in the intention of Linnæus it clearly was not. According to Herbst, Krabben und Krebse, ii. pp. 42, 43, "Cancer (Astacus) *gammarus*" is the great common lobster, which from the Greek κάρπαρος, through the Latin *Gammarus*, derived its name in Danish *Hammer*, in German *Hummer*, in French *Homar* (later *homard*).

1741. EGEDE, HANS, born 1686, died 1758 (Biographie Universelle).

Det gamle Grønlands nye Perlustration, eller Naturel-Historie, og Beskrivelse over det gamle Grønlands Situation, Luft, Temperament og Beskaffenhed, &c., &c. Kjbenhavn, 1741.

Cap. vi. p. 36, is headed "Hvad Slags Diur Fiske og Fugle den Grønlandske, Søe giver af sig etc." The accompanying plate contains a figure of a Hvalfisk, with a minute reproduction having the words "pag. 39, 1: 24" above it, and below it "Hvalf: luus" and a figure of

that creature, which is obviously borrowed from Martens. On page 39, where the smallness of the creatures which form the food of the whale is contrasted with the size of the whale itself, the author says, "Nu skulde mand tenke at saa stor en Krop maa nødvendig behøve mange andre Fiske og Søe-Dyr til sin Føde; men hans spise er intet uden noget som kaldes Hvalfiske Aas, af Skikkelse og Størrelse som i Figuren sees, det er brun af Farve haver 2. smaa Flosser hvormed det beveeger sig i Vandet, dog saa langsomt, at man kand øsse dem op af Vandet med Haanden, som med et

Øsse-Kar. Dette Slags Aas er veigt, Saa naar man rivet det imellem Fingrene, er det som Fet eller Thran." From which it may be supposed that Egede has confused the *Cyamus* which feeds on the whale with the Gammarids or other small fry on which the whale feeds.

1743. KLEIN, JACOB THEODOR, born 1685, died 1759 (Biographie Universelle), died February 27, 1760 (Hagen).

Summa dubiorum eirea classes Quadrupedum et Amphibiorum in eelebris domini Caroli Linnæi systemate naturæ: sive naturalis Quadrupedum Historiæ promovendæ Prodromus eum Praeludio de Crustatis. Lipsiæ. Gedani, 1743.

In the "Praeludium de Crustatis in specie de Squillis et Insectis Malacostracis Maris Balthici ubi et de Oniscis," he says, p. 32, "Primi generis malacostraca sunt; Caneri. Gamari. Squillæ. Secundi: Eutoma sive Insecta Crustata." On p. 34, the Squillæ, which he identifies with καρίσα and καριδία of Aristotle, are thus defined:—"Squillæ sunt malacostraca, corpore prælongato, quadantenus gibbo; quatuor calcaribus cheliformibus, d/cruribus octo, in exitu aculeatis, cauda tabellata.

"d/ Allucinati sunt autores, qvi Sqvillarum brachia forcepibus sive chelis parentia scripserunt; conferantur figuræ, quas ad vivum fieri fecimus. Error inde enatus, quod locutas, ursa

dictam, et locustam cælatam squillis adnumerarunt, cum sqvillæ habeant pedes una cum brachiis duodecim, ursa vero et locusta cælata decem."

On p. 35 he tells us, "Squillarum maris balthici non nisi duas, ad summum, si saltatricem connumeraverimus, tres habemus species." The first two, *Squilla fusca* and *Squilla cinerea* ("An, sqvilla parva Rondeletii ?") are Podophthalma; the third is thus described, p. 36, "*Sqvilla saltatrix*; Sqvilla parva, quæ major nunquam effici potest, *Wottonus* fol. 207. ex cinereo flavicans; minima; retibus et hamatili piscatiu fatalis. Uberrima hujus seges est in littoribus, qvam, tanqvam pestem, qvodammodo mitigantes gallinulæ aquaticæ, scolopaces, similesque aves vermivoræ avide sectantur; Pulex marinus, *Rondeletii*, quem Ψύλλον Θαλάττιον *Aristotelis* s. pulicem marinum esse autumat; *Hclensibus*: *Sandspringer*. Huic similis videtur D. *Frischii* de insectis Parte vii. num. xviii, frēbṣfōrmiger Wässerwurm aquæ dulcis et uliginosæ. Pulices marinos vel saltatrices sqvillas ad vivum delineandos præterita æstate neglexi, interim tamen Niedenthalii icones ab Excell. Breynio communicas trado: fig. δ. ε. ζ." He hesitates, as he well might, to guarantee the exact accuracy of the figures. The short upper antennæ make it clear that we have to do with Orchestidæ. Fig. ε rather points to a *Talitrus*. No dilated hands are shown in any of the figures.

1745. LINNÆUS.

Ölandska och Gothlandska resa på riksens Höglöflige Ständers befallning förrättad år 1741 med Anmerkninger uti Öconomien, Natural-Historien, Antiquiteter. Stockholm och Upsala, 1745.

He describes *Cancer pulex fluvialis*, p. 96, which he found on the strand at Oeland. From the mention of oblong red blotches on the sides of the segments, Boeck conjectures that this may be *Gammarus marinus*. Bate and Westwood, it may be noticed, regard the red spots on the sides as a distinguishing mark of *Gammarus locusta*, Brit. Sess. Crust., vol. i. p. 380. The *Cancer macrourus coeruleus thorace articulato*, p. 260, which Linnæus found on the shore in Gotland, may in Boeck's opinion be *Gammarus locusta*. Hans Ström, in 1765, expresses the opinion that Linnæus has here given two descriptions for one species. Bate and Westwood and Boeck alike refer to the *coeruleus* species of p. 260 as a synonym of *Gammarus locusta*, while the species of p. 96, with the red blotches, is not given as a synonym of any species either by Boeck or the other authors. The observation of Bruzelius, that *Gammarus locusta* is the only species of *Gammarus* which occurs in Gotland, is a negative argument on which but little stress can be laid.

1746. LINNÆUS.

Fauna Suecica sistens Animalia Sveciæ Regni, &c. Lugduni Batavorum, 1746.

The two last species of the genus *Cancer* are thus given:—

"1253. *Cancer macrourus rufescens*; thorace articulato. Raj. ins. 44. *Pulex fluvialis*. Frisch. germ. 7. p. 26. t. 18. *Vermis aquaticus canceriformis*. It. ocl. 42, 96. *Cancer Pulex fluvialis dietus*. Habitat ad littora maris vulgatissimus.

"1254. *Cancer inacrourus cœruleus*; thorace articulato. It. gotl 260. Habitantem vidi ad montem *Thorsburg* in mari juxta Gotlandiam. Obs. Præcedenti major: totus cœruleus, rostrum nullum prominens, corpus 14 articulis. caulu trifolia; intermedio subulato."

Both of these, in Boeck's opinion, refer to *Gammarus locusta*, the references to Ray's and

Frisch's fresh-water forms being out of place. But, since under 1253 the reference to the Iter Oel. and the word "rufescens" imply that the shrimp with the red blotches, of the Ölandska resa, p. 96, is in question, Boeck can hardly be right in calling it in one place *marinus* and in the other *locusta*.

1747. LINNÆUS.

Systema Naturæ. Recusum et societatis, quæ impensas contvlit, vsvi accommodatum curante Mich. Gottl. Agnethlero Saxone Transilvano. Editio altera auctior et emendatior. Halæ Magdebvrgicæ. c1o Io ccxxxxvii.

For *Cancer* this fully agrees with the edition of 1740, and, as in the German edition of that date, against "Gamarus" is placed "kleinste Krebs mit langem Schwanz (Springkrebs)."

1748. LINNÆUS.

Systema Naturæ. Editio sexta, emendata et aucta. Stockholmiae, 1748.

In this, as in previous editions, the Animale Regnum has six classes, the Insecta being the fifth, which is divided into seven orders, of which the Aptera, "alæ nullæ," are the last. This contains eleven genera, *Pediculus*, *Pulex*, *Podura*, *Monoculus*, *Acarus*, *Aranea*, *Scorpio*, *Cancer*, *Oniscus*, *Scolopendra*, *Julus*. "Cancer" contains eight species, *Cancer*, *Pagurus*, *Majas*, *Gammarus*, *Astacus*, *Squilla*, *Eremita*, *Pulex aquaticus*. "Oniscus" has three, *Entomon pyramidale*, *Millepes*, *Asellus aquaticus*.

Cancer is defined as having "Pedes X: primores cheliformes. Oculi II. Cauda foliosa."

A copy of this edition was published Lipsiæ, 1748.

1749. KLEIN, J. T.

Jacobi Theodori Klein Historiae Piscium Naturalis promovendæ Missus quintus et ultimus de Piscibus per branchias apertas spirantibus. Gedani, 1749.

In the Fasciculus Septimus, on Callarias (*Gadus*, *Morrhua*, the Cod), he says, page 9, "Delectantur Callariae *squillis* cinereis (*prælud. de crustatis*, p. 36) & *pulicibus marinis*; Horum meliores figuræ superaddimus *Tab. IV. f. A. naturalis magnitudinis*. C sub vitro auctus sed pedibus mutilus, B vero exakte animaleulum repræsentat." He then proceeds, with a reference to "*Kilianus Stobæus* (Act Suec. 1733. p. 79)," to retract the opinion expressed in his earlier *Praeludium*, "quod nullum insectum crustaceum, nendum καρκίνον Aristot. exuvias suas deponat, neque *cancri* neque *astaci marini*." His figures evidently refer to *Gammarus locusta*, although, as Boeck notices, the secondary flagellum is not given, nor the eye correctly drawn.

1751. LINNÆUS.

Skånska resa, på höga Ofverhetens befallning förrättad år 1749. Stockholm, 1751.

The *Pulex fluvialis* which Linnaeus found skipping about on the strand like a grasshopper, is clearly, Boeck says, *Orchestia littorea*. It must therefore be distinguished from the *Cancer*

pulex fluvialis of the Ölandska resa, but there is always the possibility that Linnaeus may have given the name *fluvialis* from having observed a true *Gammarus pulex*, may have described the red blotches from a *Gammarus locusta*, and in the statement, Faun. Sv. 1253, "Habitat ad littora maris vulgatissimus," as well as in this work, may have been referring to the Orchestidae.

1751-3. STELLER, GEORG WILHELM, born 1709, died 1745 (Biographie Universelle),
died 1746 (Hagen).

Novi Commentarii Petropolitani, t. ii. pp. 298, 324, and 330. 1751.

Georg Wilhelm Stellers ausführliche Beschreibung von sonderbaren Meerthieren, mit Erläuterungen und nöthigen Kupfern versehen. Halle, 1753.

The passages from the Latin account, 1751, are quoted by J. F. Brandt, 1849. They fully agree with the German rendering, 1753, except that where the German says, "der Brustring stehet eine halbe Linie vor," the Latin says that this (which probably means the second pereou-) segment "dimidiam lentem refert."

At page 106 of the Beschreibung, Steller says, "Die Meerkuh wird von einem besondern Ungeziefer, welches gleichsam eine Laus ist, geplaget. Dasselbe hält sich in den runtzlichen Füssen, in den Brüsten, in der Wartze au heimlichen Orten, im Hintern, und in chagrin—ähnlichen Hölen der Oberhaut in grosser Menge auf. Indem sie auch die Oberhaut und Unterhaut durehlöehern, so entstehen von der auslauffenden wässerigen Feuchtigkeit Wartze, die hin und wieder zu sehen sind. Allein diesen Insecten stellen hinwieder die Meermöven (*Lari*) naeh," which kindly pick them off the creature's baek.

"Dieses Ungeziefer ist mehrentheils einen halben Zoll lang, voll Ringe und sechsfüssig, weiss oder gelblich und durehseheiend. Der Kopf ist länglich und spitzig, grösser als der Saamen von Hirsen. Vor den Stirn sind zwey kurtze knotige Fühlhörner, welche eine halbe Linie lang hervor gehen. Anstatt des Unterkinnbaekens hat es zwey dünne Aermgen, jedes mit zwey Gelencken, wie ein Meerkrebs, am Ende sehr spitzig und wie Nägel; das Uebrige bestehet nach Anzahl der Füsse in sechs Ringen, die querüber gehen, auf dem Rüeken gewölbt, und eine drittheil Linie breit sind. Der Ring oder Pantzer auf der Brust ist zweymal breiter, und die Ringe werden immer enger, ie näher es nach dem Schwanz geht. Der Brustring stehet eine halbe Linie vor; an diesen haften zur Seiten ein paar dicke Scheren mit zwey Gelenken. Eine jede Scheere ist mit einem biegsamen Stachel versehen, womit es in die Oberhaut des *Manati* sehr feste fasset. Die übrigen Füsse sind schlancker; alle endigen sich mit Stacheln, und werden allmälig kürzter. Die zwey letzten, welche die kürzesten sind, laufen aus dem Ringe des Schwanzes; sie sind das Ende vom Körper, und das Thier schiebet sieh darauf fort." There are other references at pages 54 and 97 to this parasite upon the (now extinet) Sea-Cow, *Rhytina borealis*. Steller's desription, though for the time carefully detailed, is so perplexing that J. F. Braudt proposed to place the creature in a new genus as *Sirenocystamus rhytinæ*. Lütkeu, 1873, gives a Danish translation of the passage above quoted. He provisionally accepts the species as *Cyamus rhytinæ*, J. F. Brandt, while agreeing with Brandt's suggestions that it may be some *Proto*-like form, or a link between the Cyamidæ and Caprellidæ, and that there may still be a chance of finding some species of *Sirenocystamus* on the still living Sea-Cows, the Dugongs and Manatees.

1754. LINNÆUS.

Museum Regis Adolphi Suecorum, &c., in quo animalia rariora, imprimis exotica, quadrupedia, aves, amphibia, pisces, insecta, vermes describuntur et determinantur. Stockholm, 1754.

The *Oniscus ceti* may be, Lütken thinks, the *Cyamus* which lives on *Balaena mysticetus*. He quotes the description from p. 89, "Oniscus ovalis, segmentis excepto secundo in medio interruptis ('med afbrutna leder'). Caput parvum." "Antennæ 2, singulæ articulis 4; corpus ovale, magnitudine Ricini, sectum segmentis 7, interruptis in medio, excepto solo secundo. Pedes paribus 7, quorum 1 minutum sub capite, 2 crassius ovatum, 3 & 4 mutica, 5, 6, 7 ovata, uncinata." Seba's figure is referred to. The statement that the segments, except the second, are interrupted in the middle, Lütken considers rather obscure. It seems to allude to their being articulated to one another only by the central portion, while between the first (cephalothoracic) segment and the second segment there are no such lateral interspaces.

1755. RÖSEL VON ROSENHOF, AUGUST JOHANN, born 1705, died 1759 (Biographie Universelle).

Der monathlich-herausgegebenen Insecten-Belustigung Dritter Theil worinnen ausser verschiedenen, zu den in den beeden ersten Theilen enthaltenen Classen, gehörigen Insecten, auch mancherley Arten von acht neuen Classen nach ihrem Ursprung, Verwandlung und andern wunderbaren Eigenschafften, aus eigener Erfahrung beschrieben, und in sauber illuminirten Kupfern, nach dem Leben abgebildet vorgestellet werden von August Johann Rösel von Rosenhof. Nürnberg, 1755.

He accepts Linnaeus's classification of the Crustacea with the Apterous Insects, for the additional reasons that, like insects, they have no bones, that their mouths open and shut not from above and below but from side to side, that they cannot shut their eyes, and that their breathing is not through mouth or nose but through lateral openings in the body (p. 306, mis-paginatio for p. 308). Pages 351–357 describe "Die kleine Garneele unserer Flüsse. Tab. LXII." From its agreement with the marine Garneele, Rösel thinks that the little river shrimp would fitly be called die kleine Flusgarneele, and as the Garneele is called *Squilla* in Latin, he explains that the inscription *Astacus fluvialis* on his plates Ixii. and lxiii. ought to read *Squilla fluvialis* for pl. Ixii., and *Squilla marina* for pl. lxiii. He carefully observed the habits and structure of his specimens of the former, which cannot be confused with *Gammarus pulex*, if any trust is placed in Rösel's statement, "Vom Leib ist solche ziemlich schmal, und diesen bedecken vierzehn Schuppen, von welchen die sieben hintersten oder letzteren, mitten auf dem Rücken mit rothen scharfen Spitzen verschen sind, welche, wenn sich die Garneele krümmt in die Höhe gehen und hervorragen." Burgersdijk, who discusses the synonymy and characteristics of *Gammarus pulex* with great fulness, retains the name *Gammarus roeselii*, first given to Rösel's species by Gervais in 1835, but there seems no adequate reason for rejecting the specific name *fluvialis* given by Rösel himself.

1756. BRISSON, MATHURIN-JACQUES, born 1723, died 1806 (Biographic Universelle).

Regnum Animale in Classes IX distributum, etc. Parisiis, M.DCC.LVI.

These nine classes are Quadrupeda, Cetacea, Aves, Reptilia, Pisces *cartilaginei*, Pisces *proprie dicti*, Crustacea, Insecta, Vermes. As to Classis VII., he says, "Horum character est Caput antennis instructum : et pedes octo et ultra."

1756. LINNÆUS.

Systema Naturæ. Editio multo auctior et emendatior. Lugduni Batavorum. MDCCCLVI.

The Aptera are the seventh order with the same genera as heretofore. *Cancer* is thus defined "Pedes X. vel XX., quorum duo priores semper cheliferi. Oculi duo stiliformes. Cauda foliosa, quandoque longa, interdum brevis." The species are as given in 1748.

1758. LINNÆUS.

Systema Naturæ. Stoekholm, vol. i. 1758. (The eleventh, reckoned by Linnaeus the tenth, edition.)

On p. 636 *Oniscus ceti* is described as in 1754, but besides the reference to Mus. Ad. Frid. and to Seba, one is given to Martens. (Lütken.)

1758. VANELLI, DOMENICO, born about 1732, died a little before the end of the century (Biographie Universelle).

De Aponi Thermis. Patav., 1758.

See Note on Olivi, Zoologia Adriatica, 1792.

1759. BASTER, JOB, born 1711, died 1775 (Biographie Universelle).

Opuseula subseeiva, observationes miseillaneas de animalculis et plantis quibusdam marinis, eorumque ovariis et seminibus continentia. II. Tom. Harlemi, 1759-65.

Natuurkundige Uitspanningen, behelzende eenige Waarnemingen, over sommige Zee-Planten en Zee-Inseeten, behelvend derzelver Zaadhuisjes en Eijernesten. Haarlem.

The original Dutch and Latin editions do not seem to differ from my own copy, which is a "new Dutch edition," published at Utrecht without date, and of which R. T. Maitland, in 1876, observes that it is "volkommen denzelfden druk als de oorspronkelijke uitgave van 1762 alleen met gewijzigden titel." In the first section of the first volume, pp. 37, 50, pl. iv. fig. 2, a, b, c., Baster describes and figures "a curious little animal found on *Zee-mos*," "mirum animaleulum in corallinis," which Boeck thinks is without doubt the male of Linnaeus's *Caprella linearis*. Mayer does not feel so sure of this, for Linnaeus himself, Syst.

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

Xxx 3

Nat., ed. xii., 1767, gives not *linearis* but *atomos* as Baster's species, defined as "Macrourus linearis articularis, manibus adactylis, pedibus undecim." Mayer remarks that Baster has given to the hand of the second gnathopod an armature of five teeth. In my copy there are only four. He also observes that Baster figures as the tailpiece a protruding portion of

TAB. IV.

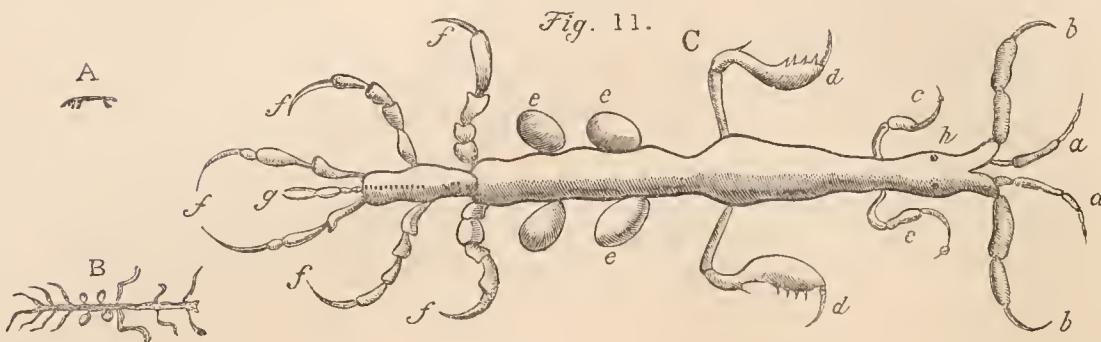

Fig. 7.

the intestinal canal. Probably the eleventh (!) leg in Linnæus' account is due to this supposed tail. The figures from Plate IV., which "I. Rhodius ad vivum piuxit," are reproduced in the accompanying woodcuts. Figures A, B, are the natural size; C, the enlargement of B; "a, Deszelfs Antennæ. b, Eerste paar pooten;" "g, Zyn Staartje en Anus."

1758—SEBA, ALBERT.

1760. *Loeupletissimi rerum naturalium Thesauri, &c.* Tomus iii. Amstelædami.
MDCCLVIII. (On the back of the index MDCCLX.)

On p. 55, *Squilla mantis, Amboinensis*, is thus described, "Hæc species, ex Amboina missa, plerumque ad squillas refertur, et hic locorum quoque inter illas reperitur; licet multo minor sit. Dorsum ejus minime scutatum est; sed testa superior è duodenis constat articulis, carnem coutientibus. Barba, itidem geniculata, binos protendit pilos acuminatos binosque alios quasi pennarum æmulos, tandemque duos adhuc breviores. Cæterum et antici pedes gemini magnis instructi sunt forceipibus spinosis; dum pedes reliqui in unguis desinuunt, exceptis posticis, ntpote qui longis admodum uncis terminantur. Pinnatæ locum caudæ molliculi quidam aculei supplent." This is figured on pl. xxi. fig. 11, and has since been called *Seba innominata*. Boeck supposes that fig. 12 on the same plate is taken from a defective Amphipod, but the description is conclusive against this, as it says among other things, "longiusculi duo tubuli, subcurvi, oculos in fine suo sustinent." The stalked eyes are also figured. The animal in question, which Seba names *Squilla mantis, Amboinensis maxima*, is, he says, called *Kambaretto* by the Italians.

1760. LINNÆUS.

In an edition of the *Systema Naturæ*, dated Halæ Magdeburgicæ, MDCCLX. (ad editionem decimam reformatam Holmiensem), *Cancer* is the tenth among fourteen genera of the Aptera. It is here defined "Pedes utrinque VIII.; præter Manus 2 chelatas. Oculi II. distantes, pedunculati, elongati, mobilis. Palpi II magni, cheliferi. Cauda articulata, inermis." The

last division, headed "Macronri manibus adactylis, testa thoracis brevissima, nec thoracem totam tegente," contains the following numbered species, 54 *Mantis*, 55 *Scyllarus*, 56 *Pulex*, 57 *Locusta*, 58 *Salinus*, and 59 *Stagnalis*, with the note, "Species 54-59 ob thoracem Lorica destitutum et singularem structuram corporis adeo a reliquis Canceris recedunt, ut facile genus distinctum constituerent." For *Oniscus ceti*, see the note on the edition dated 1758, of which the edition 1760 is a copy.

1760. GRONOV, LORENZ THEODOR, born 1730, died 1778 (Biographie Universelle).

Acta Helvetica, Physico-mathematico-anatomico-botanico-medica figuris aenca illustrata, et in usus publicos exarata. Volumen iv. Basileæ, MDCCCLX.

Pages 31-40 contain "Observationes de animalculis aliquot marinæ aquæ innatantibus atque in littoribus belgicis obviis" by Laur. Theod. Gronovius. Among other things he found, he says, some very minute Crustaceans, seen by the microscope to come near to the creatures which go by the name of *Pediculi Marini*, which Linnaeus mixed up with the *Cancri*, though they differ from them toto cœlo. He therefore determines the name and generic marks as for a new genus, thus:—"SQUILLA. *Corpus* filiforme, articulatum, longum, teres, in dorso reclinatum natans. *Antennæ* subulatae, articulatae, quatuor. *Pedes* prælongi graciles quatuordecim utrinque scilicet VII, binis anterioribus paribus cheliferis. *Oculi* duo, ad latera capitis, non stiliiformes, simplices utrinque uniciens. *SQUILLA* acaudata pedibus quatuordecim. *Fig. 8, 9.* *Caput* rotundum antice depresso-sculpnum superne planum. *Oculi* duo, sphærici, simplicissimi, hand styliformes quemadmodum in astacis cancerisque, utrinque in lateribus unicus. *Antennæ* quatuor, articulatae, subulatae, simplices, in antico capite sitae, per paria dispositæ. *Corpus* prælongum, teres, articulorum sex, excepto capite. Articulis secundo & tertio in gravidis intra pedes adhaeret prætenuis atque utrinque convexa membrana ova includens; qualem exhibui *fig. 10. a. b.* qui articuli respondent *fig. 9. litteris a. b.* *Pedes* graciles, longi, in universum quatuordecim, utrinque scilicet septem, horum bina priora paria chelis sunt instructa; reliqui vero pedes sunt subulati natatorii. Singulum par est adnexum articulo. *Chelæ* anticornum pedum sunt monodactylæ, prioris paris non dentatae, secundi vero dentatae & aculeatae. Canda nulla. Ultimum pedum par corpus terminat. Dum *natat* dorso incumbit atque velocissime ope posticornum pedum per aquas transiens. Color cinereus; Calida tempestate in obscuro lucet dum vivit. Frequentissimum animal in nostro mari." A very good figure, much more accurate than the later one by Slabber of his *Physisca marina*, accompanies this description, which evidently applies to *Proto ventricosa*, O. F. M.

1760. GODEHEU DE RIVILLE.

Mémoire sur la mer lumineuse. Mémoires de Mathématique et de Physique présentés à l'Académie Royale des Sciences par divers savants. Tom. iii., Paris, 1760, pp. 269-276.

He gives a figure, pl. x. fig. 6, of a *Caprella* from Ceylon, which in Boeck's opinion may be *Caprella ultima*, Sp. Bate. Mayer, however, finds nothing to justify a more definite determination than that it is the male of some species of *Caprella*. *Caprella ultima*, Sp. Bate, may itself, he thinks, be a synonym of *Caprella aequilibra*, Say. De Riville's figure has what for a *Caprella* would be a long tail, "G. sa queue armée aussi d'un crochet," but it probably only represents one of the hind legs.

1761. PODA, NICOLAUS, born 1723, died 1798 (Hagen, Bibl. Entom., calls him Poda von Neuhaus).

Insecta Musei Græcensis, quæ in ordines, genera et species Juxta Systema naturæ Caroli Linnaei digessit Nicolaus Poda. Græcii. Anno, M.DCC.LXI.

On page 121 this author, who lived at Grasse, in the south of France, gives the following description of an animal which he places among the Aptera in the genus *Podura*:
 “*Maritima. 2. P. oblonga, nitens, ferruginea. *Habitat sub saxis post maris refluxum Tergesti. Cl. SCOPOLI in epis.*” This is referred to by Scopoli under *Cancer locusta*. In the opinion of Pallas, 1772, it is his *Oniscus gammarellus*.

1761. LINNÆUS.

Fauna Svecica Sistens Animalia Sveciae Regni: Mammalia, Aves, Amphibia, Pisces, Insecta, Vermes, distributa per Classes et Ordines, Genera et Species, Cum Differentiis Specierum, Synonymis Auctorum, Nominibus Incolarum, Locis Natalium, Descriptionibus Insectorum. Editio Altera, Auctior. Stockholmiae, 1761.

The entries relating to the Amphipoda are on pages 496, 497, 499–501. Among the Insecta Aptera in the genus *Cancer* are given:—

“2041. CANCER *Pulex* macrourus articularis, rostro acuto manibus adactylis, cauda attenuata spinis bifidis.

“Cancer macrourus rufescens, thorace articulato. Fn. 1253. It. oel. 42, 96. It. scan. 125.

“*Raj ins.* 44. *Pulex* fluviatilis.

“*Frisch. germ.* 7. p. 26. t. 18. *Vermis aquaticus* cancriformis.

“It. oel. 42, 96. Cancer *Pulex* fluviatilis dictus.

“*Suecic* Márta. *Scanic* Sandhare.

“*Habitat* ad littora maris vulgatissimus, frequens, rodens retia, conficiens sceleta piscium; natat in dorso.

“DESCR. *Pedes* 7 parium, quorum 4 paria anterius versum; horum paria antica chelifera dito mobili absque pollice. Pedum 3 paria posterius retrorsum versum.

“2042. CANCER *Locusta* macrourus articularis, rostro obtuso, manibus adactylis, cauda attenuata spinis bifidis.

“Cancer macrourus cæruleus, thorace articulato. It. gotl. 260. Fn. 1254.

“Habitantur vidi ad montem Thorsburg in mari juxta Gotlandiam.

“Obs. Praecedenti major: totus cæruleus. Rostrum nullum prominens, Corpus 14 articulis. Cauda trifolia; intermedio subulata.”

In the genus *Oniscus* there are given:—

“2056. ONISCUS *Ceti* ovalis segmentis distinctis, pedibus tertii quartique paris linearibus muticis.

“*Martens, spitzb.* t. Q. f. D. Pediculus *Ceti*.

“*Habitat* in *Cetis* Oceani.

“DESCR. Corpus ovale, 7 articulis distinctis. Caput, quod primus articulus, minimum. Pedes 1, 2, 5, 6, 7 chelis crassis ungue mobili acuto terminati. Pedes vero 3, 4 paris filiformes muticis; primum par sub corpore situm est. Corporis articuli magis remoti et distincti, quam in reliquis speciebus.”

“2062. ONISCUS *bicaudatus* semicylindricus, caudis duabus longitudine corporis.

“*Habitat* ad littora maris Norvegici. Martin.

“DESCR. Corpus semicylindricum, fuscum, 12 articulis. Pedes utriusque 7, albi, quorum solitarii

postici reflexi. *Caudæ* 2, protentæ, longitudine corporis, 5 articulis; quorum tertius major, longior et crassior; primus et secundus brevis; quartus et quintus angustiores. Inter has caudas, caudæ 2 aliae, breves, subulatae."

Boeck, under the obviously misprinted date 1771, remarks that as number 2041 of this work is identified with number 1253 of the earlier edition, the synonyms from Ray and Frisch, and Linnaeus's own Skänska Resa, ought not to have been cited. Lütken calls attention to the improved definition of *Oniscus ceti*. The *Oniscus bicaudatus* must no doubt be identified with the species which Linnaeus afterwards called *Cancer grossipes*, the antennæ having been mistaken in the present instance for the tail, as O. F. Müller remarked in 1776. By Willughby and Ray, in 1710, this species was well-named *cornutus*, a name unfortunately excluded as pœ-Linnean. The *Astacus muticus* of Gronov, 1762, is only accidentally binominal. The *Oniscus bicaudatus* of Linnaeus, 1761, and his *Cancer grossipes*, 1767, must be given up as names founded on egregious mistakes. We are thus led to the *Oniscus volutator* of Pallas, 1766 and 1772, as rightfully determining the specific name. Though the *Corophium longicorne* of Latreille and numerous authors was highly appropriate, the name *Corophium volutator* is sufficiently suitable to an animal which may commonly be seen twisting and turning about at the entrance of its gallery in the mud, and which, according to Pallas, makes similar gyrations when in the water.

1761. SULZER, JOHANN HEINRICH, born 1735, died 1813 (Hagen).

Die Kennzeichen der Insekten nach Anleitung des Königl. Schwed. Ritters und Leibarzts Karl Linnaeus, durch xxiv. Kpf. erläutert und mit derselben natürlichen Geschichte begleitet. Mit einer Vorrede des Herrn Johannes Gessners, Zürich, 1761.

Sulzer gives a figure of Rösel's *Astacus (Squilla) fluviatilis* on pl. xxiii. fig. 152, and a. 4. He describes it on p. 192. On p. 65 of the explanations of the plates he says, "Fig. 152. Krebs, lange Scheeren, gegliedert, Hände ohne Finger, dünn ausgehender Schwanz mit zweienfachen Dörnen. Linn. Syst. Nat. Cancer, 57."

1762. BASTER, J.

Opuscula, Tom. II. Liber 1, Harlem, 1762.
Natuurkundige Uitspanningen, &c.

In the first section of the second volume, on pp. 34–36 and 49, pl. iii. figs. vii., viii., 1–6, he describes the hopper or sea-flea, in the vernacular "Een springertje of Zee-Vloo," with references to "Pulex marinus, Kleiu, Miss. v. Tab. iv. a, b, c.; Seba, Thes. iii. Tab. xxi., N. 11; Linn., Syst. Nat., N. 36. Cancer maerourus, articularis manibus adactylis, cauda attenuata, spinis bifidis; Rösel, Suppl. Tab. lxii. p. 351; Frisch, vii. Tab. xvii. 18, p. 26." This in Boeck's opinion is probably *Orchestia littorea*, but Baster's remark that it is found not only in sea and brackish water but also in freshwater rivers and even in ponds, but especially among and under the fronds of *Alga marina*, implies that he did not distinguish the actual creature described from other species such as *Gammarus pulex* and *Gammarus locusta*. His figure may refer to *Orchestia (littorea) gammarellus*, but if so he has fallen into some confusion in describing the lower antennæ, as well as in the synonymy.

1762. DESMARS.

Mélanges d'histoire naturelle. 1762.

From tome i pp. 217, &c., of this work, Latreille, in his *Histoire naturelle*, vol. vi. pp. 305–310 (1803), gives a long quotation, fully describing *Gammarus pulex* under the designation of *Cloporte aquatique*. A reference to some of Desmars' observations will be found also in the *Brit. Sess. Crust.*, vol. i. p. 396.

1762. GEOFFROY, ETIENNE LOUIS, born 1727 (1725), died 1810 (Hagen).

Histoire abrégée des Insectes, qui se trouvent aux environs de Paris ; Dans laquelle ces Animaux sont rangés suivant un ordre méthodique. A Paris, M.DCC.LXII. (This edition is anonymous. The work was published with the author's name in 1764.)

In the second volume, under "Cancer, Le Crabe," Geoffroy gives two species, the first being l'écrevisse (*Astacus fluviatilis*), well known in France as an article of food. The second he thus describes, pp. 667–668 :—

" 2. *CANCER macrourus rufescens, thorace articulato.* *Linn. faun. suec. n.* 1253. *Planch. 21,* fig. 6.

Pl. XXI

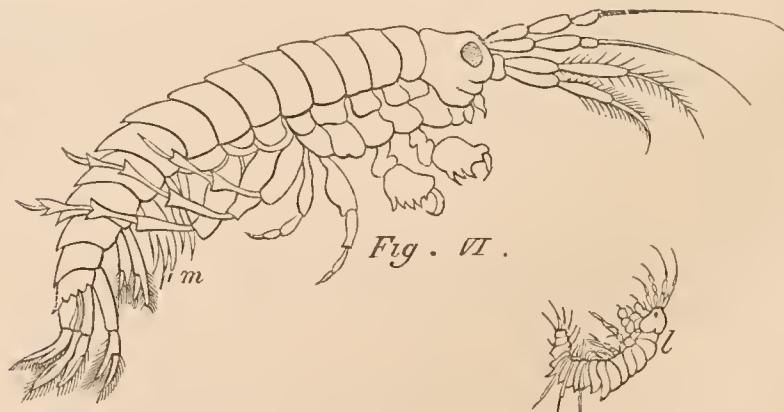

Fig. 8.

" *Linn. syst. nat. edit. 10, p. 631, n. 56.* *Cancer macrourus articularis, manibus adactylis, cauda attenuata spinis bifidis.*

" *Raj. ins., p. 44.* *Pulex fluviatilis.*

" *Frisch. germ. 7, p. 26, t. 18.* *Vermis aquaticus canceriformis.*

" *Iter Oeland. 42, 96.* *Cancer pulex fluviatilis dictus.*

" *Charlet. exercit. p. 57.* *Squilla.*

- " Merret. pin. p. 192. *Squilla fluviatilis*. *Squilla parva*.
 " Rosel. ins. vol. 3, suppl. tab. 62.
 " *La crevette des ruisseaux*. Longueur 7 lignes. Largeur 2 lignes.
 " Cette crevette est d'un janne couleur de ronille; ses yeux sont noirs; ses antennes sont fines et assez longues, à peu près de la longueur des deux tiers du corps. Elle a cinq pattes de chaque côté & plusiens appendices à la queue. Tout son corps est composé de douze anneaux sans la tête; quatre de ces anneaux composent le corcelet, qui dans l'écrevisse est d'une senle pièce. Cette crevette est aplatie par les côtés; aussi est elle toujours posée sur le côté, soit qu'elle se meuve, soit qu'elle reste en place, & lorsqu'elle marche, elle approche par des mouvemens viifs sa tête & sa queue l'une de l'autre.
 " Ou trouve communément cette crevette dans l'eau conrante des petits ruisseaux, elle est en grande quantité dans la riviere des Gobelins. Souvent les plus petites se retirent & se mettent à l'abri sous le ventre & entre les pattes des plus grosses."

The figures, life-size and enlarged, are here reproduced. It is obvious that Rösel's species *Astacus (Squilla) fluviatilis*, is represented, though Geoffroy is probably describing *Gammarus pulex*. Boeck rather singularly remarks, "Denne Afbildung er kopieret af Sulzer (253). Tab. xxiii, Fig. 152," the number 253 being a reference to the title of Sulzer's work in 1761, of which Boeck takes no further notice. The figure in question has fourteen segments, independently of head or telson, which is obviously one too many, although in agreement with Rösel's description. The last seven are strongly dentate medio-dorsally. The figure, being a striking one, was frequently repeated, without regard to its accuracy or its fitting the species, the description of which it was supposed to illustrate. Herbst in his large work, Bosc in his small one, alike use it, the former for *Cancer (Gammarellus) pulex*, the latter for *La Crevette des ruisseaux, Gammarus pulex*. An interesting discussion of the subject will be found in Bate and Westwood, Brit. Sess. Crust., vol. i. pp. 388-396.

Geoffroy shows in the figure a series of seven feet, but does not take the trouble to reconcile this with the definition which he gives of *Cancer*, including "Dix pattes, les denx premières en forme de pinces." On the contrary, he describes his species as having "cinq pattes de chaque côté." The statement that the body is composed of twelve annuli without the head, is an improvement upon Rösel's account, but all the same not in agreement with the figure.

1762. GRONOV, LORENZ THEODOR.

Acta Helvetica, Physico-mathematico-anatomico-botanico-medica figuris æneis illustrata, et in usus publicos exarata. Volumen V. Basileæ, MDCCCLXII.

Pages 353-382 contain "Animalium Belgicorum a Laur. Theod. Gronovio observatorum Centuria quinta." In this century of animals he describes, "455. *Astacus muticus*; pede ntriuqe antico subulato, edentulo, longissimo, crassissimo," of which he repeats the full account in his later work. (See Note on Gronov, 1764.) "456. *SQUILLA cauda nulla*" is his *Squilla acaudata* of 1760, to which he refers. "457. *SQUILLA canda nulla?* pedibus quatnordecim, tertio quartoque paribus vesicæformibus natatoriis" is referred to Baster's "Animal in coralliis." "458. *SQUILLA cauda subulata*, bifida: pedibus utrinque anticis binis cheliferis; quatuor subsequentibus natatoriis longissimis" is referred to *Cancer macrourus*, &c., Linn. *Syst. gen.* 239, n. 59, and to the "Krebsförmiger Wasser-Wurm. Frisch. Ins. Germ., part. 7. p. 26. § 18. Tab. 18. fig. 1." The full description is repeated in his larger work almost verbatim. "459. *SQUILLA cauda subulata integra*: pedibus utrinque anticis binis cheliferis: quatuor subsequentibus natatoriis longioribus" is referred to *Cancer macrourus*, &c., Linn. *Syst. gen.*, 239, n. 56?

and to "Pulex marinus, *Klein. Pisc. Miss. 5. p. 9. Tab. 4. fig. A. B. C.*" with the concluding remark, "Habitat in mari Septentrionali & staguis aquæ subsalsæ. Color cinerascens. Magnitudine et forma eonvenit cum præedenti." Number 991, the corresponding notice in his larger work, has, as will be seen, a very different concluding observation.

Of 457 a figure is given on Tab. V. The full description is as follows:—"Corpus oblongum teres, eompressiuseulum, dorso eurvato, earinato. Caput oblongum, obtusum. Antennæ 4 (b. c.) prælongæ, pediformes, antieo pari maximo, secundo piloso. Oculi duo minimi, in lateribus capitis, non cylindraei nt in Caueris, Astaeisque. Pedes quatuordeeim seu

457.

Fig. 9.

septem ntrinque. Horum *primum par* tenerimum, capiti insidens, ungulatum (d). *Secundum par* (e) omuium robustissimum cheliferum. *Chela* mouodaetyla, eompressa, ovata, margine iuteriore denticulato. *Digitus* ineurvatus, validus, deorsum versus earpum mobilis, subacutus, edentulus. *Tertium et Quartum Paria* (f. g.) vesieulas oviformes a Cl. *Bastero* dieta, sunt pedes natatorii, ovatae formæ, omnium minimi: inter hosee

pedes gravidæ. *Ova* gerunt: *Reliqua tria pedum paria* (h. i. k.) sunt subulata, longa, tenera, unguulata, ultimo pari longissimo. Hisce obvia arripit, ex illis dependet, et corpus quaquaversum movet. *Caudam* nullam detegere potui, licet ea a Cl. *Bastero* subulata depingatur. *Natans* dorso incumbit, capite præeunte. Maxima iu copia ad littora Ziriaeænsia inter eoralliuas. *Color* subrubescens. *Magnitudo* dimidio minor quam in ieoue."

1762. STRØM, HANS, born 1726, died 1797 (Hagen).

Physiske og Oeconomiske Beskrivelse over Fogderiet Søndmør, I. Deel, 1762.

He records a *Pulex cancriformis* or *Cancer macrourus rufescens*, which is found under stones on the beach or in the stomachs of fish. Further, he gives in plate i. figs. 12–13, a very recognisable drawing of *Hyperia medusarum* under the name of *Pulex cancriformis, antennis brevissimis, corpore latiore*, and states that it is found on large Medusæ (Boeck).

1763. SCOPOLI, JOHANN ANTON, born 1723, died 1788 (Biographie Universelle).

Entomologia Carniolica exhibens Insecta Carnioliae indigena et distributa in ordines, genera, species, varietates. Methodo Linnaeana. Vindobonæ, MDCCCLXIII.

Scopoli changes the Linnaean name *Aptera* into *Pedestria* for his seventh order. He defines *Cancer* thus: "Palpi (2) ehelati. Oeuli (2). Cauda inermis," and names the species numbered from 1123–1137, *Menax*, *Depurator*, *Pagurus*, *Maia*, *Gammarius*, *Astacus*, *Squilla*, *Bernhardus*, *Diogenes*, *Istrianus*, *Nutrix*, *Cruentatus*, *Mantis*, *Locusta*, *Pulex*. The last two are described as follows:—

" 1136. CANCER *Locusta*?

" LINN. Syst. Nat., p. 634.

" Faun. Svec. 2. 2042.

" *Diagn.* Corpus oblongum, gibbum, nitens, lateraliter compressum. Palpi antenpis triplo longiores: artieulis (20). Corpus sese ineurvando & explieando saltans, *Poduræ* adinstar.

" Habitat abunde, circa littora Maris, sub saxis, prope *Tergestum*.

" Statura fere *Poduræ Aquaticæ*. Habitus *Cancer pulicis*. Corpus pellueens, ferrugineum, suturis (11), & denuo septem aliis utrinque ad bases feueroru. Antennæ attenuatæ, artieulis

sex. Oculi fusi, minime petiolati. Pedes utrinque sex, hinc simul duodecim, quorum 1, 2, 3, 6 (a cauda antrorsum numerando) femora ovata, compressa gerunt. Tibiae vero primi paris pariter ovatae, compressae, & margine denticulatae. Par ultimum capiti proximum, seu brachia, manu falcata unguiformi, uno dente in medio armata. Cauda adscendens, conica, linea brevior, subjectas habet setas duas ad basim usque bifidas. Hæc *Podura Maritima* R. P. Poda, Mus. Græc., p. 121.

“ 1137. *CANCER Pulex*.

“ LINN. Syst. Nat., p. 633.

“ Faun. Svec. 2. 2041.

“ FRISCH. Ins. 7. Tab. 18. fig. 1.

“ *Diagn.* Facies prioris, sed duplo minor, & albidus. Antennæ palpis longiores, sed non crassiores. Pedes pilosi. Maculae croceæ laterales.

“ *Habitat* sub *Hypnis*, & saxis, ad scaturigines fontium.

“ Hic certe idem, qui a FRISCHIO pictus, sed semper habitans in aquis dulcibus, non vero circa Mare, hinc dubito cum priore a LINNÆO confundi, cum *Cancer Locusta* ab eo aliter describatur quam a nobis. Hic, quando exsiccatus, fulvus redditur, natat in latere, rarius in dorso; os fulvum gerit, nec corpus postice acuminatum. Interim certum adeo nobis cum priore a *Canceris* aliis diversum esse, ut novum Genus non immerito constitueret.”

The “*Cancer Locusta?*” Pallas considers to be his *Oniscus Gammarellus*, since known as *Orchestia gammarellus*. The “*Cancer Pulex*” is in all probability the *Gammarus pulex*, auctorum.

“ 1140. *ONISCUS Bicaudatus*,” with “cauda duplex; utraque biseta,” which “habitat copiosus Tergesti ad litus maris, inter saxa cursitans,” is said by Franz Leydig to be the same as *Ligia italica*, Fabr.

Yeats, Institutions of Entomology, 1773, says that Scopoli and Geoffroy call the shorter antennæ the palpi in the *Cancri macrouri*. It may therefore be noticed that Scopoli, in describing “*Cancer Locusta?*” says, “Palpi antennis triplo longiores: articulis (20),” meaning, apparently, that the lower antennæ are three times as long as the upper.

1764. BRÜNNICH, MARTIN THRANE, born 1737, died 1827 (Hagen).

M. Th. Brünnichii Entomologia, sistens Insectorum Tabulas Systematicas, cum Introductione et Iconibus. HAFNIÆ, CLOCCCLXIV. Insektaere, indeholdende Insekternes Systematiske Tavler, samt Indledning og Figurer. Kjøbenhavn, 1764.

After describing the different parts of an “insect,” and giving a list of the different writers on Entomology, Brünnich unfolds his own classification under the title “Tabulae Insectorum perfectorum.” There are two principal groups:—

“ A. Capite a thorace distincto,” containing,—“I. Hexapoda;” “II. Polypoda.” Of these the *Polypoda* include three subdivisions:—“Pedibus segmentis corporis utrinque paucioribus; XIV. et plures; Corpore ovali;

“(a) Antennis duabus, } ONISCUS.”

“(b) Antennis quatuor, } ”

In the second subdivision *Scolopendra* is placed, and *Julus* in the third.

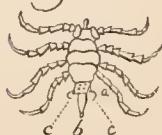

“ B. Capite cum thorace unito,” containing two sections, “I. Pedibus natatoris omnibus,” &c., for MONOCULUS; “II. Pedibus ambulatoriis,” for ACARUS, PYCNOGONUM, PHALANGIUM. ARANEA, SCORPIO, CANCER. Of these the first four are Pedibus Octo, the other two Pedibus “Decem, anticis cheliferis; Cauda elongata, articulata.” CANCER is defined “Oculis II, pedunculatis, distautibus; Cauda inermi;” with various (presumably specific) divisions,

grouped under the designations *Brachyurus* and *Macrourus*. The second section of the *Macrouri* is defined "Testa thoracem non tegente, brevissima: Manibus adactylis:" and may perhaps include the Amphipoda, notwithstanding the pedunculate eyes in the definition of *CANCER*.

In the preceding group, number 2 is the interesting new genus, which was soon after confounded with the Amphipod *Cyamus*. It is thus defined: "Oculis IV. Verticalibus; Corpore inciso tuberculato; Ore tubuloso producto: PYCNOGONUM (Fig. 7)." In the German rendering on the opposite page it is called "Strandspinde (Fig. 7)." The reference should obviously have been to Fig. 4.

In the "Explicatio tabulæ æneæ" the following account is given:—"Fig. IV. Novum genus, a R. D. Ström inter *phalangia* relatum, Söndm. Tom. 1. p. 209. t. 1 f. 17. Exemplar hujus

Fig: 4.

insecti, quod munificutia R. Autoris possideo, ita describo; Caput cum thorace unitum, tubo b. excavato cylindrico, antice angustiore, postice in thoracem recepto, prominens; Oculi IV. dorsales a. in gibbositate thoracis positi; c. Antennæ 2. tubo breviores moniliformes, subtus in segmento thoracis, cui oculi insident, radicatae; segmenta corporis, excepto tubo, IV. cum tuberculo e medio singuli segmenti prominulo. Pedes VIII. singuli ex articulis VII. brevissimis composi, ungue valido terminati. Ex descriptiunc patet insectum hoc a generibus antea notis omnino differre, ideoque novum genus, quod e crebris articulationibus *Pycnogonum* dico, constituit."

Brunnich's Fig. 4 is here reproduced.

1764. GRONOV, LORENZ THEODOR.

Zoophylacii Gronoviani Fasciculus secundus exhibens enumerationem Insectorum quae in Museo suo adservat, examini subjicit, systematice dispositus atque descripsit Laur. Theod. Gronovius. Additis rarissimorum Insectorum iconismis. Lugduni Batavorum, MDCCLXIV.

Among the Insecta Aptera he gives on p. 227 the following:—"ASTACUS, *Corpus* subcylindricum, oblongum, articulatum, deorsum inflexum. *Thorax* trunco multo brevior. *Antennæ* binæ, vel sex subulatæ, articulatæ, tenuissimæ. *Cauda* foliacca, horizontaliter expansilis. *Oculi* duo, pedunculati, in fronte siti. *Pedes* utrinque novem vel decem. *Posteriora* quatuor *quinqe* *paria* curta natatoria. *Anteriora* longissima, quorum nonnulla plerumque chelifera."

Under this genus several Podophthalma are included, till on p. 232 he gives the following:—

"989. ASTACUS muticus; pede utrinque antico subulato, edentulo, longissimo, crassissimo.

"Astacus (crassipes) cauda inflexa, pedibus secundi paris tenuibus muticis. *Pallas in litteris.*

"Inter medium animal inter Astacum descriptum N. 985, et subsequens genus Squillæ. Habitat in aquis substagnantibus prope Lugdunum Batavorum. *Thorax* compressus, laevis, brevis, latiusculus, postice truicatus ore subtus prominulo. *Antennæ* quatuor, quarum utrinque lateralis seu exterior corpore parum brevior, attenuata, articulo ultimo in setam abiente longissimo hispido: interius par brevissimum setaceo-articulatum. *Truncus* elongatus, compressus, incurvus, segmentorum deceni, quæ utriusque pone pedes (primo pari excepto) in triquetrum acumen abeunt. *Cauda* angusta, inflexa, expansilis, ejusdem structure, qua gaudent Astaci sub N. 985-988. descripti. *Pedes* in universum novem? *Prius* par toto corpore longius omniumque pedum maximum, et validissimum, corpori parallelum, autrorum [antrorum] protensum, crassum, corpori utrinque sub thorace adnexum: hujus paris arti-

culus primus et secundus rotundi et inermes, thorace jam majores; Articulus tertius oblongus, utrinque eompressus, margine inferiore versus articulum quartum cuspide valida aucto. Articulus quartus teres, reetus, oblongns, tertio parum brevior. Quintus subulatus, acutissimus, quarto dimidio brevior. Reliqui pedes brevissimi, exilitate aeiem oculorum fugientes. Tria posteriora paria deorsum et sursum versa. Color totius ex cinereo albido. Longitudo tota, extensis etiam prioribus pedibus, est quinque linearum." From this he passes at once to the genus *Squilla*, as follows:—

- "*SQUILLA*, *Corpus* teres, compressum, incurvatum. *Thorax* brevissimus. *Oculi* in lateribus duo, noui pedunculati. *Antennæ* quatuor, subulatae. *Pedes* longitudine inaequales utrinque septem, anticis paribus cheliferis.
- "990. *SQUILLA* eauda subulata, bifida: pede utrinque antico chelifero; tribusque utrinque ultimis natatoriis.
- "Caneer macrourus articularis, manibus adactylis, pedibus patentibus, eauda cylindrica bifida. *Linn. Syst. Nat. Ed. 10. gen. 239. n 59.* *Rosel. Ins. tom. tab. 62.*
- "Cancer macrourus rubescens, thorace artieulato. *Ins. Paris, vol. 2. p. 667. n. 2. tab. 21. fig. 6.*
- "Krebs-formigen Wasser-wurm. *Frisch. Ins. part. 7. p. 26. §. 28. tab. 18. fig. 1.*
- "Pulex marinus. *Baster, Opusec. subsec. tom. 2. lib. 1. p. 31. tab. 3. fig. 8.*
- "*Corpus* teres, oblongum, latius quam in congenere a me deseripta in *Actis Helveticis* vol. 4. p. 39, et a CL Bastero in *Opusc. subsec. tom. 1. lib. 1. tab. 4. fig. 2.* Dorsum curvatum, rotundatum. *Cuput* breve, obtusum. *Oculi* in lateribus, atri, minimi, non pedunculati. *Antennæ* quatuor incurvatae. *Incisuræ* duodecim aequales, laevissimæ, splendidæ. *Pedum* septem paria, quorum *primum par* articulo secundo tertioque trunei subnexum, breve, cheliferum, aequale, monodactylum: *Tria* subsequentia paria omnium longissima, subulata, subaequalia, admodum teretia, articulis quinto, sexto, septimo et octavo trunci subnexa. *Reliqui pedes* antrorum flexi teretes, articulis ultimis pilosis subulatis. *Cauda* laevis, subulata, bifida, haud longa. *Habitat* in stagnis aquæ dulcis atque salsæ. Dorso incumbens æque natat ac prone.
- "991. *Squilla* eauda subulata integra: pedibus utrinque anticis binis cheliferis; quatuor subsequentibus natatoriis reflexis.

"Caneer macrourus articularis, manibus adactylis, eauda attenuata, spinis bifidis. *Linn. Syst. Nat. Ed. 10. gen. 239. n. 56?*

"Pulex marinus. *Klein Pisc. Miss. v. p. 9. tab. 4. fig. A. B. C.*

"Habitat in Mari Septentrionali. *Balaenæ vexans mordendo.*"

The Ionographia sive Tabularum Explicatio, for pl. xvii. fig. 7, repeats the short definition of *Astacus muticus*, No. 989, of which the figure, though only life-size, is easily recognisable as *Oniscus volutator*, Pallas. The elaborate description of the first pair of feet obviously refers to the lower antennæ, and this, no doubt, together with the epithet *crassipes*, quoted by mistake from Pallas, led Linnaeus in 1767 to call the species *Cancer grossipes*. See Notes on Pallas, 1766, 1772. Possibly the description of the "lateral or exterior" antennæ may be derived from the second gnathopods. No. 990 cannot be determined from the inconsistent references or the indefinite description. The statement that "it lives in pools of fresh and salt water" would imply that *Gammarus pulcher* and *Gammarus locusta* are both in question. The description of the eyes as "minimi" suits neither. Herbst unites it with "Caneer gammarellus, Pallas," probably because Pallas does so. See Note on Pallas, 1772. No. 991, by the references, should be a *Gammarus*. The concluding observation points to a *Cyamus*. It is difficult to fit either to the description.

1765. STRØM, HANS.

Beskrivelse over Ti norske Insecter. Første Prøve. Skrifter som udi de Kiøbenhavnske Selskab af Laerdoms og Videnskabers Elskere ere fremlagte og oplæste i Aarene, 1761, 1762, 1763, og 1764. Niende Deel. Kiøbenhavn. Aar 1765. (Pl. VIII. figs. 1-5.)

On p. 588 he describes "Et Hummer-lignende Insect med runde haer paa Bag-føderne. *Cancer macrourus articularis*, manibus adactylis, femoribus posticis orbicularibus, spinis caudæ bifidis." One of its most remarkable peculiarities, he says, is that it can hop half an ell high from the ground (en halv Alen hoyt). He notices its likeness to the common *Maryflue*, or so-called *Pulex cancriformis*, but for the latter he gives seven good distinguishing characteristics, showing that he clearly understands the difference between his own species, which is *Orchestia gammarellus*, and the *Gammarus locusta*, which Linnæus describes as *Cancer macrourus rufescens thorace articulato*, Fn. Sv., § 1253. Of this *Pulex cancriformis* he observes, "Linnæus gives a second species, but nevertheless gives both one and the same name, as may be seen Syst. Nat. pag. 633 and 634; and though he gives a fresh description of each separately in his Ølandska Ress pag. 42 and 260, still it seems to me that both descriptions refer to one and the same. At any rate neither of them suits the insect here described." He notices that his own *Pulex cancriformis*, *antennis brevissimis*, *corpore latiore*, from Søndmor, is a third species, distinct from the hopper and from the Linnean species.

1765. BASTER, JOB.

Opuscula. Tom. II. Liber 3.

Natuurkundige Uitspanningen, &c.

On p. 155 (139) Baster remarks, that there is a creature which is called "Walvis-Luis," whale-louse, very different from the other fish lice, and which seems to him also to be a different creature from that described and figured under this name by Friderich Martens. Yet Linnæus, he says, Syst. Nat., p. 636, deems it the same, placing it among the *Onisci*, among which Baster thinks it cannot stand, since they have fourteen feet, while this animal, which Gronovius calls *Polygonopus*, has only eight. According to Lütken, 1873, Baster here described, and on pl. xii., figured *Pycnogonum littorale*, supposing it to be Martens' whale-louse, and so misled Linnaeus (see Note 1767); but Linnaeus in 1767 and Pallas in 1766 must have misunderstood Baster's accurate statements. Baster further points out that in Houttyn's Natural History, I. Deels 3. Stuk, p. 457, there is mention made of a Walvis-Luis which is in reality a *Balanus*.

1766. PALLAS, PETER SIMON, born 1741, died 1811 (Biographie Universelle).

Miscellanea zoologica. Quibus novæ imprimis atque obscuræ animalium species describuntur et observationibus iconibusque illustrantur. Hagæ Comitum, M.DCC.LXVI. pp. 190-194. Tab. XIV.

On page 189 he notices that his *Acarus marinus* seu *Polygonopus*, the *Pycnogonum* of Brünnich, is very different from the *Pediculus ceti* of Martens, which, he says, should properly be reckoned with the *Onisci*. "Non intelligo cur cel. Basterus Linnæum reprehendat, *Pediculum Ceti* Martensianum Oniscis adnumérantem."

- As *Oniscorum canceriformium* species, he enumerates and describes, “1. *Oniscus Pulex, compressus pedibus quatuor anticis cheliformibus*,” with references to Linnæus, Frisch and Roesel; “2. *Oniscus Locusta, compressus chelis nullis; pedibus secundi paris marcidis*,” with references to Linnæus, Scopoli, Ray, and Dodonæus, pempt. p. 476, and figure, Tab. XIV. fig. 15, this being the Amphipod since known as *Talitrus locusta*, Pallas; “3. *Oniscus Gammarellus, compressus pedibus secundi paris cheliformibus maximis*,” “apud auctores nusquam occurrit, meruitque ideo *Tab. XIV.* fig. 25. delineari,” this being since known variously as *Orchestia littorea* or *Orchestia gammarellus*, the latter name having priority beyond all contradiction. The next species is thus introduced: “Adfinis est *Onisci canceriformibus singularis* species, cui *Onisci volutatoris* nomen dedi, quia in aquæ superficie singulari modo capite cum autennis prævio volutatur.
- “4. *Oniscus volutator, subcompressus, antennis exterioribus maximis. Astacus muticus, pede utrinque antico subulato, edentulo, longissimo* GRONOV. *Zoophylac.* vol. II. p. 232. n. 989. *Oniscus bicaudatus* LIN. *Faun: svec. edit.* 2. n. 2062. *Pulex marinus cornutus* RAJ. hist. p. 43.
- “*Celeber.* GRONVIUS ad hanc speciem nomen meum citare dignatus est. Aliquot nempe Oniscorum descriptiones & icones in litteris olim communicaveram. Erant inter hos, quem supra descripsi, *O. Locusta*, & hic nunc describendus *O. volutator*. Priorem vocaveram (non *Astacum* crassipedem, sed *Oniscum* (crassicipitem) *cawla inflexa, pedibus secundi paris tenuibus muticis*). Hanc phrasin, nescio quo fato, ad *O. Volutatorem*, cui nullo modo convenit, excitavit Vir celeberrimus. Monendum hoc fuit, ne incuriae ipse accusarer a gnaris.
- “*Oniscum volutatorem* inveni olim iu fossis maritimis, prope Harvicum Essexiaæ. Cel. GRONVIUS in fossis stagnantibus prope Leydam legerat. *Tabulae nostræ XIV.* fig. 20. a latere visum exprimit.”

The descriptions of the above species are given more fully in the *Spicilegia Zoologica*, Fasc. ix. 1772.

1767. LINNÆUS.

Caroli a Linné *Systema Naturæ.* Tom. I. Pars II. Editio Duodecima Reformata. Holmiae, 1767.

The definition of *Cancer* now runs “*Pedes VIII. (10 s. 6 raro) insuper Mauus 2 chelatae. Oculi II, distantes, plerisque pedunculati; elongati, mobiles. Pupilli II, cheliferi. Cuuda articulata, inermis.*” The last division, with the same heading as in 1758–60, now contains twelve species. Among these, at pages 1055–1056, are the following Amphipods; No. 80, *Cancer grossipes*, thus defined, “*C. macrourus articularis, manibus adactylis longitudine corporis.* Gron. zooph. 989 *Astacus muticus, pede antico subulato edentulo longissimo crassissimo,*” the specific name *grossipes*, evidently based on the confusion made by Gronovius between the antennæ and gnathopods, being bound to yield to the earlier and more appropriate *volutator* of Pallas, as explained in the notes on that writer, under the dates 1766, 1772; No. 81. *Cancer pulex*, said to occur both in salt and fresh water, and to judge by the synonyms including, in Boeck’s opinion, *Gammarus pulex*, *Gammarus roeselii*, and *Gammarus locusta* of later authors; No. 82, *Cancer locusta*, probably including *Gammarus locusta* and *Orchestia gammarellus*, Linnæus’s remark about the uropods, “*Pediculi unius paris caudæ lateribus adstant, bidigitati,*” not being very intelligible or decisive; No. 83. *Cancer linearis*, which in Boeck’s view is without doubt the same as *Caprella lobata*, Müller, notwithstanding the reference to Martens’s *Caprella septentrionalis*; No. 84. *Cancer atomos* with “*pedibus undecim*” and a reference to Baster, and the observation “*habitat in Europæ aquis fluctuantibus dulcibus, nudis oculis vix visibilis, præcedenti*

affinis," which, together with No. 85, *Cancer filiformis*, Boeck considers to represent *Caprella lobata*. Mayer's opinion as to Nos. 83, 84, 85 is that the descriptions given by Linnaeus are practically worthless, that the reference to Martens is useless, since his species also is quite indefinite, so that, though he inclines to take Baster's *mirum animalculum in corallinis* as equivalent to the modern *Caprella linearis*, he only retains the latter name with the addition of "Bate" as an authority, because the so-named species has been commonly employed as type of the genus.

At page 1059 is given the definition of "ONISCUS. *Pedes XIV. Antennæ setaceæ. Corpus ovale.*"

On page 1060 the following Amphipods are referred to this genus:—

"Ceti. 6. O. ovalis; segmentis distinctis, pedibus tertii quartique paris linearibus ovaticis. *Mus.*

Ad. Fn. 1. p. 89. Fn. svec. 2056.

"*Habitat in Balaenis, distinguendus a Phalangio Balænarum, simili.*

"2 caudatus. 8. O. semicyliudriens, caudis duabus longitudine corporis, *Fn. svec. 2062.*

"*Habitat in O. Norvegico.*"

Thus *Oniscus ceti* appears with the same definition as in the Fauna Suecica, 1761, with the slight change of *ovaticis* for *muticis*, probably by a misprint, but Lütken points out that the reference to Martens is now omitted, while his whale-louse is now made a synonym of *Phalangium balænarum* (Brünnich's *Pycnogonum*), introducing a confusion that was not for a long time to be thoroughly dispersed. The *Oniscus bicaudatus* had been identified by Pallas in the previous year, 1766, with the *Astacus muticus* of Gronovius, which Linnaeus here calls *Cancer grossipes*, but the suggestion may have come too late to be available for the present edition of the *Systema Naturæ*.

1768. ADELUNG, JOHANN CHRISTOPH., born 1734, died about 1806 (Biographie Universelle).

Geschichte der Schiffahrten und Versuche welche zur Entdeckung des Nordöstlichen Weges nach Japan und China von verschiedenen Nationen unternommen worden. Zum Behufe der Erdbeschreibung und Naturgeschichte dieser Gegenden. Halle, 1768.

In a note to page 320, Adelung states that Fr. Martens made his journey to Spitzbergen "als Schiffsbarbier auf einem hamburgische Schiffe." The two first plates of Martens' work he does not consider worth reproducing, but all the rest of it, both figures and text, he gives in

11. *Walfischlaus*

Fig. 11.

5 *Garnell*

Fig. 12.

full, only polishing and modernising the language. To some of the figures also he seems to have thought it necessary to give a little extra finish. It has been already mentioned that he apportions Martens' fig. i. to *Der Garnell*, reproducing it as fig. 5 on Taf. xvii. in his own work, without any explanation of the inconsistency between the figure and the description. How highly Martens' book was valued may be inferred from Adelung's notice that "in the year 1685 a Dutch translation appeared at Amsterdam; an English one is to be found in

the Account of several late Voyages and Discoveries to the South and North by Sir John Narlorough [Narborough], Cap. Tasman, Cap. John Wood an Frederik Marten, London 1694 in 8., French one in the Recueil de Voyages au Nord Th. 2. S. 1."

1769. HOUTTUYN, F. (Publisher).

Natuurlyke Historie of uitvoerige Beschryving der Dieren, Planten en Mineralen, Volgens het Samenstel van der Heer Linnæus. Met naauwkeurige Afbeeldingen. Eerste Deels, dertiende Stuk. Vervolg en Besluit der Insekten. Te Amsterdam, By de Erven van F. Houttuyn, MDCCCLXIX.

In chapter 82, p. 295, of this voluminous work, the anonymous author begins the description "van 't Geslagt der Krabben en Kreeften." On page 436, among "de Kreeften," is given the following description:—"LXXX. Grossipes, Dikpoot, Pl. cvi. Fig. 1. (80) Krcftje, gebeel in Leiden verdeeld, met de Schaaren ongevingerd en zo lang als 't Lyf. De Heer Pallas, thans Hoogleeraar te Petersburg, hadt aan den Heer Gronovius de Kenmerken toegezonden van een Insekt, 'twelk zyn Ed in het Water der Vaarten by Leiden ontdekt hadt, en thans omstandig als een middelsoort tusehen de Garnaalen en Zee-Vlooijen, voorgesteld wordt. Die van onze Afbeelding, Plaat cvi. Fig. 1, schynen van de beide de volgende Soorten aanmerkelig

PLAAT CVI.

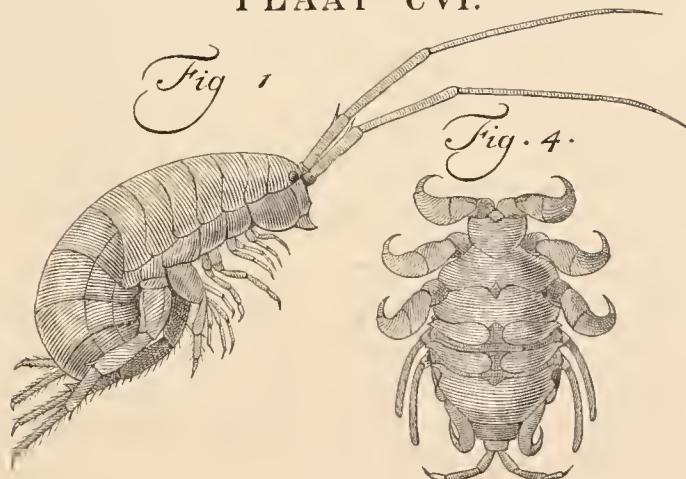

Fig. 13.

te verscheiden, en, indien men de Hoornjes op den Kop voor ongevingerde Schaaren neemt mogt, nader met de opgegevene Kenmerken overeen te komen; inzonderheid, dewyl de dikte der agterste Pooten gedagten Bynaam op dezelen toepasselykt maakt. Zodanige Springertjes komen hier, op natte zoute Gronden, zelfs in de Kelders der Huizen voor: zynde de Afbeelding in lange ongevaar drie of vier maal vergroot." A note says "(80) *Cancer macrourus* articularis, Manibus adactylis longitudine Corporis Syst. Nat. XII. *Astaeus muticus*, Pede antieo subulato, edentulo, longissimo, erassissimo, GRON. Zooph. 989." While therefore the reference is to *Cancer grossipes*, Linn., the figure is clearly one of the Orehestidae, probably *Talitrus locusta*. Under these circumstances, to account for the name *grossipes*, recourse is had to the thickness of the hindmost feet, "de dikte der agterste Pooten."

The following names are then attaelhed to species which the writer deseribes but does not figure, depending for his information on the authors, various and numerous, to whom he gives references :—81. “*Pulex*. Zee-Vloo.” 82. “*Locusta*, Springer,” and “*Rivier-Vloo*.” 83. “*Lineuris*, Smalle,” with a reference to “*MARTENS*, Spitsberg. 56. T. P. f. 1.” 84. “*Atomos*, Zeer kleine,” with references to Linnæus and Baster. 85. “*Filiformis*, Zeer dunne,” from Malacca, with a reference only to Godeheu de Riville, whose species from Ceylon the author considers to resemble this *filiformis*. 85. *Salinus*, and 87, *Stagnalis*, are not Amphipods.

Chapter 84, page 481, contains “*Beschrywing van 't Geslagt der Pissebedden ; het welke, behalve de gewone Land- en Water-Pissebedden, ook veelen, die men gemeenlyk Zee-Luizen noemt, en de eigentlyke Walvisch-Luizen bevat.*” On pp. 491–493 he gives an account of *Cyamus mysticeti*, Lütken, beginning as follows :—“*Ceti*. Groenlandse Walvisch-Luis. Pl. cvi. Fig. 4. 5. (6) Pissebed, die ovaal is met duidelyke verdeelingen; de Pooten van het derde en vierde Paar egaal van breedte, smal en stomp.

“De Insekten, op onze Plaat cvi. in Fig. 4 en 5, afgebeeld, zyn voor eigentlyke Walvischluizen uit Groenland gebragt, en komen overeen met de beschryving, welke Linnæus geeft van deeze Soort, zeggende, dat die het Lyf ovaal of eyrond heeft, bestaande uit zeven onderscheidelyke Ledjes, waar van de Kop het kleinste is: dat de Pooten van het eerste, tweede, vyfde, zesde en zevene Paar, dikke Sehaaren hebben, die uitloopen in een beweeglyke scherpe Klaauw; doch, dat die van het derde en vierde Paar Draadagtig en stomp zyn. Het eerste Paar is onder het Lyf geplaatst. De Verdeelingen zyn meer van elkander afgezonderd, dan in de overige Soorten.” Some observations upon earlier authors are then made. The desercription continues, “Die van onze Plaat zyn, in langte en breedte, ruim driemal zogroot als natuurlykt gemaakt, en geelagtig wit van Kleur, doch de smalle Pootjes zwart.” “Wy hebben 'er Fig. 5, van de onderzyde, bygevoed; om een groote Blaas te vertoonen, die sommigen van dese Insekten voor aan den Buik voeren, komende hier in met de Water-Pissebed van BAKER overeen. Mooglyk zullen zy, in dezelve, haare Eijertjes of jongen draagen. Dat die zwarte smalle Pootjes haar tot Riemen dienen, om eenigermaate te kunnen swemmen, is niet onwaarschynlyk. Zy zyn zeer duidelyk voorzien met Spieten of Hoornlijfjes en hebben voor, op den Kop, twee kleine gladde Oogjes.”

1769. SLABBER, MARTIN, born 1741, died 1835 (Bovallius).

Natuurkundige Verlustigingen, behelzende mieroseopise Waarneemingen van in- en uitlandse Water- en Land-Dieren. Door Martinus Slabber. Te Haarlem, 1769. (First title-page dated 1778.)

The “tiende Stukje,” pp. 79–83, deseribes a Zee-Seherminkel (*Phtisica marina*), which P. L. S. Müller renders *Seestengel*. The figure shows it pretty evidently to be *Proto ventricosa* O. F. M. The author says “each foot is on the under side at its base covered with a little elongate leaf as can be seen at e [in the figure] and at all the seven feet.” The legs and hands are all represented as filiform, the first pair shortest, the next four pairs equal to one another, the last two pairs much longer than those preceding.

The “elfde Stukje,” pp. 92–96, describes what he calls een Zand-Pissebed (*Oniscus arenarius*), *Oniscus Arenarius* in the preliminary List of Names. It is strikingly figured, pl. xi. figs. 3, 4. It has been made the type of several successive genera, different only in name, *Haustorius*, Müller, *Lepidactylis*, Say, *Pterygocera*, Latreille, *Bellia*, Sp. Bate, *Silcator*, Sp. Bate. See notes on P. L. S. Müller, 1775, Bovallius, 1878, and S. I. Smith, 1880.

It seems reasonable to accept the date 1769 for Slabber's book in preference to 1778, since the translation of it by P. L. S. Müller is dated 1775.

1770. PALLAS, P. S.

Dierkundig mengelwerk. 4° m. Pl. Utrecht, 1770.

This, I suppose, is the *Miseellanea zoologica*, of 1766, in Duteh. It is mentioned by R. T. Maitland, 1875, who refers to it under the species *Orchestia littorea*, Leach, and *Talitrus saltator*, Edw.

1770. STRÖM, HANS.

Beskrivelse over Norske Inseeter. Anden Prøve, pl. ii. figs. 1--8. Skrifter som udi det Kiøbenhavnske Selskab af Lærdoms og Videnskabers Elskere ere fremlagte og oplæste i Aarene 1765, 1766, 1767, 1768, og 1769. Tiende Decl. Kiøbenhavn. Aar 1770.

On p. 5 he describes "En Marflue, eller lidet Krabbe, med Kiøldannet og Sav-lignende Ryg. Cancer maerourus articularis, dorso earinato serrato, spinis eaudæ bifidis," and figures it Tab. ii. figs. 1--8. The mandibular palp in fig. 3 seems to show the outermost joint divided into three, a mistake perhaps owing to some folding of the palp accidentally in the course of dissection. Boeck identifies the creature described, no doubt correctly, with *Gammarus* (now *Amathilla*) *sabini*, Leach. The species appears to be the *Gammarus homari* of Fabrieus, and the *Amathilla sabini* of Bate and Westwood, in which case its name will properly stand as *Amathilla homari* Fabr.

1772. PALLAS, PETER SIMON.

Spicilegia zoologiae, quibus novæ imprimis et obseuræ animalium species iconibus, descriptionibus atque commentariis illustrantur cura P. S. Pallas. Faseiulus nonus. Berolini, MDCCCLXXII. pp. 50--80, Tab. iii. iv. (To the German version by E. G. Baldinger, Mayer, Caprelliden, p. 199, assigns the date 1769, probably referring only to the commencement, not to the ninth fasciculus, of the work.)

He here says "Cancris proximum est ONISCORUM genus, transitum indicantibus *Squillis*," and "Oniscorum squilliformium e phalange quatuor species mihi cognitæ sunt." Of these he proposes to leave out Roesel's already well-known species, and to describe the remaining three.

The first is a new species, peculiar to Siberia, as far as he knows, "abundat antem in Lena, fluvio ulterioris Sibiriae, & omnibus quæ in illam colliguntur fluentis, præcipue Angara & Laeu Baikal e quo profluit Angara." He has learnt some facts about it from Steller, "in eius sehedis de hæ specie (quam 'Squillam fluviatilem seu Phryganeum fluvii Angaræ' appellavit) quedam memoriam prodita inveni." Steller, he says, states that "individua dari quædam mueronibus dorsalibus destituta, quæ alterius sexus esse putat, nisi diverse potius speciei fuerint." E. Laxman, from whom Pallas received a specimen, called it "Cancerum baikalesem," but Pallas himself describes and figures it (Tab. III. Fig. 18) as *Oniscus cancellus*. This Dybowsky in 1874 is content to retain under the name *Gammarus cancellus*, Pallas, adding a variety *Gerstfeldtii* of his own discovering. By Spence Bate, however, in 1862, the species was made the type of a new genus *Pallasia*, which must not be corrected into *Pallasia*, and thereby confounded with the Dipterous genus *Pallasia* instituted by Robineau-Desvoidy in 1830.

Pallas next discusses the synonymy of "Oniscus Locusta," and thus decides,—"Præter RAJUM itaque, qui (*list. ins. p. 44*). Pulicem fluvatilem, a marino distinguit, et forte DODONÆUM (*pemptad. p. 476. icon.*) neminem ad Locustam citari posse arbitror; quam enim SCOPOLI (*Entom. carniol. p. 411*). Locustæ dedit descriptionem, sequenti potius speciei nostræ, *Onisco* nempe *Gammarello* convenient." In the description of *Oniscus locusta*, Tab. iv. fig. 7, he says "Pedes septem parium (non octo, ut in *Miscellaneis* fugitivo calamo scripseram); priores antrorsum versi, sex posticci retrorsum. Par primum crassiss reliquis; secundarii pedes exiles, velut atrophia absunti; mutici." This is now accepted as *Talitrus locusta*, Pallas.

For the next species he refers, as above, to Scopoli's "*Cancer Locusta*," and also to his friend Gronov's *Fasc. II. p. 232. num. 990*, where, however, he thinks that all the synonymy, except perhaps the reference to Baster, belongs to *Pulex*. That Boeck is right in assigning the name *Orchestia gammarellus*, Pallas, precedence over *Orchestia littorea*, Montagu, is clear from the following "Descriptio Onisci Gammarelli, Tab. IV. Fig. 8. Magnitudo Onisci Pulicis. Forma quasi media inter Pulicem & O. Locustam. Priore scil. brevior, posteriore gracilior est; capitibus tamen parvitate Pulici similior. Antennæ exteriore majora quam in utrolibet, secundus harum articulus præsertim notabilis, majusculus, linearis, quadrangularis, superiore latere scaber. Antennulæ intermediae minimæ, ut in O. Locusta; quum contra in O. Pulice exteriore ferme æquent. Pedes septem parium; primi paris parvuli, exiles; secundarii chela magna, ventricosa, adactyla terminati; quum in O. Pulice quatuor priores sint cheliferi, et subæquales. Pedes quarti paris (non quinti, ut habeat *Miscellanea*) omnium brevissimi, et cum sensim longioribus sex posticis retrorsum versi; vel saltem ambigui quarti; posticci vero, ut in affinibus planis, foliaceis, ovatis siugulares, qualia in O. *Cancello* supra observavimus. Styli caudales bifurci duorum parium, et mucro duplex terminales, pedunculique subcaudales, setacei, nt in affinibus. In spiritu vini albet hæc species, viva subcuerascens; at siccata rubescit, nt coctæ *Crangones*. Magnitudinem exprimit icon."

Boeck in his chronological review, p. 35, assigns the *locusta* and *gammarellus* of Pallas respectively to the female and male of *Orchestia littorea*, while in the body of his work, pp. 101, 104, he takes "*Oniscus gammarellus*, Pallas, (*Cancer gammarus littoreus*, Montagu)," as type of the genus *Orchestia*, Leach, but *Talitrus (Oniscus) locusta*, Pallas, as type of the genus *Talitrus*, Latreille. Meinert considers that the figures and descriptions by Pallas do not suffice to separate his *Oniscus gammarellus* from his *Oniscus locusta*, and that therefore Montagu's *Cancer (Gammarus) littoreus* should determine the specific name of *Orchestia littorea*, but surely the "chela magna, ventricosa" in *gammarellus* sufficiently proves that that species is an *Orchestia*, while Montagu himself identifies the *locusta* of Pallas with his own *saltator*, which is a *Talitrus*. It may be noted also that for "*Cancer gammarellus*, Pallas," Herbst gives Baster's figure, which pretty clearly refers to the *Orchestia* in question.

On *Oniscus volutator*, after repeating some of the observations already made in the *Miscellanea*, Pallas says, "Distinete satis Oniscum nostrum indigitat *Rufus* (*list. ins. p. 43*.) Pulicis marini cornuti nomine. Vix etiam dubium est Oniscum bicaudatum LINNÆI (*Faun. S. ed. II. n. 2062. Syst. Ed. XII. p. 1060 sp. 8.*) hunc ipsum nostrum esse, ubi LINNÆUS, e siccato forsitan specimine, antennas exteriore pro caudis nominavit. Amicus GRONOVIUS omnium novissime, ante edita *Miscellanea* mea, hanc speciem descriptis & Astacum vocavit, *Zoophylacii* *Fasc. II. p. 232. num. 989*, ubi quoque iconem a me communicatam, in *tab. 17. fig. 7.* adjecit. Ex GRONOVO iterum adoptavit speciem nostram LINNÆUS & vocavit *Cancerum grossipedem* (*Syst. nat. XII. p. 1055. sp. 80.*)" It is obvious therefore that the name *volutator* given by Pallas should take precedence, unless Linnæus alone of all men had a right to change suitable names already given for unsuitable ones of his own devising.

On *Oniscus ceti*, Pallas says, p. 76, "Oniscum Ceti primus, quantum video, et accurate quidem

descripsit FRID. MARTENS, (*itin. Spitzberg. ed. germ. p. 85. n. 4.*) adjecta etiam rudiori icone (*tab. 8. fig. d.*). MARTENSI locum LINNÆUS olim (*System. ed. X. p. 636. sp. 6.*) ad *Oniscum Ceti*, quem graphicō exprimit, recte citaverat. Verum eundem in editione novissima nessio quo permotus argumento, perperam de *Acaro polygonopo* nostro, quem inter Phalaugia collocat (*System. Ed. XII. p. 1028. p. 6. sp. 6.*), perperam interpretatus est; *Oniscum Ceti* autem absque synonymo ullo recensuit (pag. 1060. sp. 6.). Distinctissime tamen speciem delineat etiam SEBÈ *thes. Vol. I. tab. 90 fig. 5.* quæ icones LINNÆO ignotæ esse haud potuere." Of the young, he says, "Apprime miratus sum, quod eorundem forma gracilis, scolopendriformis exacte esset similis *speciei sequentis*, cuius minima, vulgaribus Poduris vix longiora specimina ita referunt, ut, nisi intra matris diversæ alvum pâne reperti, pro iisdem omnino haberentur." He gives a description of *Oniscus ceti*, Tab. iv. fig. 14, A. B. C., probably, in Lütken's opinion, referring to the species which Lütken calls *Cyamus mysticeti*.

This is followed by a discussion of *Oniscus scolopendroides*, in which he says, "Primam, ni fallor, hujus Insecti distinctam notitiam debemus CELEBERR. BASTERO. In honorem tamen Optimi STELLERI monendum est, accuratam descriptionem hujus insectuli marini, ad Kamtschatkam ab illo observati, in schedis ejus exstare.

"*Oniscus scolopendroides* qualem BASTERUS describit, quem LINNÆUS (*System. ed. XII. p. 1056. sp. 84.*) satis paradoxo nomine et genere *Cancrum atomon* vocat, forte ab EJUSDEM *Cancro linearis* atque *filiformi*, vel horum saltem priore, nonnisi æstate differt. Certe quod F. MARTENS (*itin. Spitzb.*, p. 85. n. 3. *Tab. P. fig. 1.*), nomine *Squillæ parvæ* describit & delineat insectum, vix aliud quam *Oniscus scolopendroides* noster videtur fuisse. Et adumbrationes, quas LINNÆUS dedit de *Canceris linearis* & *filiformis* suis, ambo in nostram speciem sat bene quadrant; ut summa saltem horum trium insectorum debeat esse affinitas.

"Quod vero hæc insecta ad *Canceros* malo omine reduxerit LINNÆUS, neque naturale eorum genus perspexerit, eo magis miror; quia *Oniscum Ceti* ad legitimum genus jamdudum judiciose retulit. Adeoque structuram prædictarum specierum cum *Onisco Ceti* contulisse non videtur; Nemo enim, qui oculis utitur, non videt eandem esse hujus *Onisci scolopendroidis* affiniumque compositionem, & structuram quoad omnes partes, truncum, antennas, pedes perfectos, & pedunculos. Imo tanta, ut jam monui horum est similitudo, ut minuta ab *Onisco Ceti* edita proles, quæ gracilis adhuc et macilenta est, vix ab *Onisco scolopendroide* discerni queat,

"*Onisco Ceti* etiam in eo convenit hæc species, quod *ovula* femiæ sub medio corpore membrauulis inclusa circum ferant; inter æstate adlatos, copiosissimas semper observavi feminas hoc more gravidas; quæ res a Diligentiss. BASTERO adnotata haud fuit; probatque corpusecula pedum mediorum vicaria minium esse ovula, quamvis sub ipsis illis globus ovulorum in fœtificantibus hæreat. Figura MAETENSI supra citata id boui habet, quod exprimat situm, quo *Oniscus scolopendroides* in aqua & spiritu vini convulsus mori constanter observatur."

The description which follows of *Oniscus scolopendroides*, and the figures, Tab. iv. fig. 15, A, b, c, do not suffice to establish its specific name. Lütken considers that Pallas presses rather too far the resemblance between the young of *Caprella* and those of *Cyamus*, though giving him due credit for having called attention to it, as well as for being the first to remark on the incubatory pouch of *Cyamus*, and on the difference between the young and adult forms, besides correcting Linnæus' reference of Martens' *Cyamus* to *Acarus polygonopus* (*Pycnogonum*).

1772. OLAFSEN, EGGERT, born 1726, died 1768 (Biographie Universelle).

Olafsen, Eggert, og Povelsen, Bjarne. Reise gjennem Island. Tom. i og ii. Sorø, 1772.

Olafsens und Povelsens Reise dureh Island, veranstaltet von der königlichen Societät der Wissenschaften in Kopenhagen und besehrieben von bemeldtem Eggert Olafsen. Aus dem Dänischen übersetzt. Kopenhagen und Leipzig, 1774.

§ 687, Von den Insecten, under VI., the Aptera, E. Cancri, &c., gives “d) Marflo ist Cancer pulex Linnaei Fn. Sv. 1253. Sie verdirbt das Netz, welches nach den Forellen und Rödmagen nahe an dem Ufer gestellt wird, und frisst die darinnen gefangene Fische. Macht man die untersten Maschen aus Pferdehaaren, soll sie selbige nicht zernagen.” This relates to the West-fjord. In § 746, Marfloen are also recorded from North Iceland. The destruction of nets by some species designated as *Cancer pulex* is confirmed by Ödmann's observations at this period, but that it attacks live fish he denies; the fish, on the contrary, he says, as any cook can tell you, devour the *Cancer pulex*.

1773. YEATS, THOMAS PATTINSON (born ?), died 1782 (Maunders).

Institutions of Entomology being a translation of Linnæus's Ordines et Genera Insectorum; or Systematic Arrangement of Insects. Collated with the different systems of Geoffroy, Schaeffer, and Scopoli; together with observations of the translator. London, MDCCCLXXIII.

He says that Schaeffer in his Elementa Entomologiæ, Ratisbon, 1766, has followed Geoffroy. His own work opens with a glossary of the terms used in entomology. In his account of Cancer, Genus X. in Order VII., the Aptera of Linnaeus, Syst. Nat., p. 1038, he gives as the second family the Macrouri or long-tailed crabs, with five subdivisions, of which the fifth may possibly refer to the Amphipoda. It is obscurely defined as “Those in which the shell of the thorax is shorter than that part, which it does not cover entirely.”

1774. PHIPPS, CONSTANTINE JOHN (afterwards Lord Mulgrave, born 1734, died 1794 (Biographie Universelle).

A Voyage towards the North Pole, undertaken by his Majesty's Command, 1773. London, MDCCCLXXIV.

In the Appendix, under the heading Insecta, pp. 189–193, pl. xii., Phipps gives two species which are not Amphipods; “*Cancer Squilla*, Linn. Syst. Nat., 1051, 66. The Prawn;” “*Cancer boreas*,” with a description and figure; and three Amphipods thus described:—

“*Cancer Ampulla*, macrourus, articularis, corpore ovali, pedibus quatuordecim simplicibus, laminis femorum postici paris ovato-subrotundis. Tab. xii. Fig. 3. This singular animal was also taken out of the stomach of the same seal in which the two former were found. Its place in the *Systema Naturæ* is next to *Cancer Pulex*. Description. Insectum ex ovali-oblongum, glabrum, punctulatum, articulis quatuordecim compositum, quorum primus capititis est, septem thoracem mentiuntur, et sex caudam tegunt. Capitis clypeus antice inter antennas in processum conicum, acutum descendit. Antennæ quatuor, subulatæ, articulatae, simplices, corpore decuplo breviores. Pedes quatuordecim, simplices, unguiculati; femora

postremi paris postice acuta, lamina dimidiato-subrotunda, integra, magna, quatuor lineas longa. *Cauda* foliata, folio uno brevi bifido: *Laciniæ* lanceolatae, acutæ. *Neusteri* duodecim, duplicati, subulati, pilis longis ciliati, posteriores retrorsum porrecti. *Obs.* Specimina magnitudine variant, uncialia et biuncialia erant." This is now the type of the genus *Stegocephalus*, Krøyer, 1842.

"*Cancer nugax*, macrourus, articularis, pedibus quatuordecim simplicibus, laminis femorum sex posteriorum dilatatis subrotundo-cordatis. Tab. xii. Fig. 2. This animal, which has not before been described, should be inserted in the *Systema Naturae* near *Cancer Pulex*; it was taken in the trawl near Maffen Island. Description. Insectum oblongum, compressum, dorso rotundatum, glabrum, sesquiunciale, articulis quatuordecim compositum, quorum primus capitinis est, septem thoracem mentiuntur, et sex caudam efficiunt. *Capitis clypeus* sinu obtuso antice pro antennis emarginatus. *Antennæ* quatuor, subulatae, multiarticulatae; *superiores* corpore sextuplo breviores, bifidae; articulo bascos communi, magno; *Ramulus* interior exterior duplo brevior. *Inferiores* simplices, superioribus duplo longiores. *Pedes* quatuordecim, simplices, unguiculati, unguibus parum incurvis. *Femora* sex posteriora postice aucta. *Lamina* foliacea, subrotundo-cordata, dimidiata, margine integra, magna, (tres lineas longa). *Caula* apice foliata. *Fololis* duobus, oblongis, obtusis, parvis. *Neusteri* duodecim, duplicati, lineari-lanceolati, posteriores retrorsum porrecti, ut facile pro appendicibus caudæ sumantur." Krøyer, Nat. Tidsskr. 2 R. i. p. 578 (1844), mixes up *Cancer ampulla*, Phipps, and "*Cancer nugax*, Phipps. ???" with his own *Anonyx lagena* and *Anonyx appendiculosus* under the title *Anonyx ampulla*, Phipps. *Cancer ampulla*, as already stated, belongs to *Stegocephalus*. *Cancer nugax*, Phipps, is almost beyond doubt the same as *Anonyx lagena*, Krøyer, and accordingly E. J. Miers, with good reason, gives precedence to the specific name *nugax*.

Of his third Amphipod species, Phipps only says: "Cancer *Pulex*, Linn. *Syst. Nat.* p. 1055. 81. Taken up in the trawl along with the former."

1774. STELLER, GEORG WILHELM, born 1709, died 1746.

Beschreibung von dem Lande Kamtschatka, dessen Einwohnern, deren Sitten, Nahmen, Lebensart und Verschiedenen Gewohnheiten herausgegeben von J. B. S. mit vielen Kupfern. Frankfurt und Leipzig, 1774.

Mayer, Caprelliden, p. 4, remarks, "Pallas, dessen Spicilegia zoologica ich nur aus der Uebersetzung von Baldinger kenne, fasst 1767 die ihm bekannter Amphipoden unter dem Namen *Oniscus* zusammen und beschreibt als *O. Scolopendroides* (Röhrpolypenlaus oder kleinsto Afterassel) einen halbdurchsigtigen, gelben, nach der Abbildung zur heutigen Gattung *Caprella* gehörigen Krebs, den Steller schon als *Pediculus marinus* in Kamtschatka beobachtet haben solle." He appends a note to explain that he has not himself had an opportunity of examining Steller's work on Kamtschatka. The only passage in it at all applicable, that I can find, is on page 199, where, in a note, Steller says, "An der See soll sich ein Insect befinden, wie eine Laus, welches durch die Poros der Haut in das Fleisch und immer weiter kriechet." This causes horrible pain, and can only be got rid of by cutting it out. Steller had not himself seen it, but promises to look out for a chance of doing so. His account of it so far is little suitable to *Caprella*. In the note on Pallas, 1772, it will be seen that he ascribes to Steller the credit of having accurately described *Oniscus scolopendroides* observed by him in Kamtschatka, but it is the description "hujus insectuli marinii," not of a *pediculus marinus*, that he has left in his papers. See also note on Tilesius, 1815.

1774. GINNANI, CO. FRANCESCO.

Storia civile e naturale della Pinetta Ractenati, 1774.

G. D. Nardo says that this author mentions, on p. 437, "il Pulce d'aequa dolee, *Gammarus*." I have not been able to meet with his work.

1775. HAMMER, CHRISTOPHER.

Forsøg til en Norsk Natur-Historie, 1. Deel. Kiøbenhavn, 1775.

In the Fauna Norvegia, with which the work begins, under "Krabbe, Cancer," there are given:—
"735 Marflue. *Cancer Pulex* 2041. Findes under Strand-stenene.

"736 Krebsformige Loppe, Krebsloppe, Marflue. *Pulex Cancriformis*. Hos Hr Strøm i Søndmørs Beskrivelse er den aftegnet. Tab. I. fig. 12 og 13. Olafsen, p. 609 d.

"738 Kiøldannet Marflue. *Cancer macrourus articularis*. Har sauglignende Ryg, er brun- og hvidplette; findes i Søen ved Strandbredden. Strøm i Aet, Hafn. 10 Tom. pag. 5, Tab. 2.

"739 Hæmmerlignende Insekt. *Cancer macrourus articularis*. Strøm i 9de Deel af Kiøbenhavnske Selskab-Skr. p. 588. Derom kan og eftersces Linnæi *Cancer Stagnalis*, 2043. S. N. 1 T. 12 Ed. p. 1056. N. 87."

On page 17, to his mention of "Sletbag, Grønlandsk Hval. *Balaena mysticetus*;" he appends a note: "Den næerer sig af smaa Orme, som af Hr Egede kaldes Hvalfiskaas."

The above Amphipoda are sufficiently explained by the references to Strøm and Egede.

1775. FORSKÅL, PEHR, born 1736, died 1763 (Encycl. Brit., 9th Ed.).

Descriptiones Animalium, Avium, Amphibiorum, Piscium, Insectorum, Vermium; quæ in itinere orientali observavit PETRUS FORSKÅL. Prof. Haun. Post mortem auctoris ed. Carsten Neibuhr. Adjuncta est materia medica Kahirina atque tabula maris rubri geographicæ. Hauniæ, 1775.

Among the Insecta, in the genus Cancer, division B. Maerouri, he describes, pages 95–96, what is now known as *Phronima sedentaria*, as follows:—"59. CANCER sedentarius; *macrourus*; *articularis*; *manibus adactylis*.

"Deser. Color vitreus, flavescens. *Caput* fere conicum, perpendicularare, ante paululum planatum, juxta verticem emarginatum. Ori utrinque sphærule oculiformis adjacet; supra quamque harum, cylinder perpendicularis erigitur, *oculum* referens; sint-ne ergo huic animali duo oculorum paria, affirmare non sntineo. *Antennæ* setaceæ longitndine cylindrorum, lateri eorum anteriori affixa. *Thorax* ovato-laneeolatus, septem-articulatus. *Cauda* linear-attennata, compressa, antice articulis 3. rotundatis, pone truneatis, utrinque nnispinosis. Articuli duo angustiores apieem eaudæ constitnnnt, eni insistunt spinæ sex, vel setæ lineares, apice bifidae, acute. *Pedes* ntrinque deem: paria enim septem, thoracis septem articulis adhærent; omnia adactyla, præter *quinti* ordinis par, cæteris mnlo erassius, longins, *femoribus* compressis, apiee uni-spinosis, carpis elavatis, chelis obovatis, ventricosis; digitis adeo curvatis, forficatis, introrsum dente instruetis. Priora 4. paria *plantis* gaudent setaceis, curvatis & longitndine snperantibus plantas posteriorum pednm thoraeicorum, qnorum paria retrorsum majora majoraque: & membrana subtus aeuta utrinque triplei, ovata, natatoria. Articulis Candæ tribns, totidem pedum paria, versns apieem eaudæ gradatim minora affiguntur, brevia, femoribns obovatis, membranaceis; tibiis recurvatis, concavis.

"In Mari mediterraneo. Mirum in suo genere Animal Oeulorum forma, et Pedum numero. Singularis arhitecturae inhabitat domum, eubieo-ventricosam, rugosam, gelatinosam, rigidam, utroque extremo patulam. Hic residet incurvum, saepe situm mutans: his cunis ova deponit pullosque exeludit."

On page xxi. it is briefly deseribed with the words "pedibus utrinque 10; domifex."

1775. MÜLLER, PHILIPP LUDWIG STATIUS, born 1725, died 1776 (Hagen).

Physiealische Belustigungen oder Microseopisehe Wahrnehmungen in- und ausländiseher Wasser- und Landthierchen dureh Martinus Slabber. Aus dem holländisehen übersetzt von P. L. St. Müller. Mit fein illuminirten Kupfertafeln. Nürnberg, 1775.

In this translation the account of *Phtisica marina*, i.e., *Proto ventricosa*, occurs on pages 41–43, tab. x. fig. 1, 2. The account of *Oniscus arenarius* or Sandasselwurm is on pages 48–52, tab. xi. fig. 3, 4. At page 52 the translator gives the following note on his own part, "I cannot find the relationship of this species to either of the genera above-mentioned [*Squilla* and *Oniscus*], since the remarkable structure of the feet must certainly be regarded as a characteristic. And I think the author might have regarded this little animal as forming a quite distinct genus, and under the name *Haustorius arenarius*, or Sandschöpfer, I would place it in a genus by itself between the Monoculi and Onisci. If it were not for the absence of a carapace (Schild), I should not hesitate to place it among the Monoculi; it is best therefore to place it in a genus by itself."

Bovallius, who adopts the name *Pterygocera arenaria* assigned to this Amphipod by Latreille, after praising the figures and description of it given by the Dutch naturalist, makes the following observations:—"Although appreeiating its numerous peculiarieties, Slabber nevertheless abstained from creating a new genus for its reception, and placed it in the genus *Oniscus* L., one of the three great Linnean genera, into which the whole of the Crustaeans, known at his time, were distributed, thereby also indicating his impression of its affinity to the Isopods of the present day. Statius Müller, his German translator, observed that the animal might be the type of a genus of its own, for which he proposed the name *Haustorius*, but this appellation, being an adjective, and consequently contrarious to the rules of Linnean nomenclature, has been justly forgotten." On the other hand, I venture to suggest that the reason mentioned is not sufficient to justify the rejection of *Haustorius* in favour of *Lepidactylis*.

The British Assoeiation Rules, 1878, include that against "Adjective generic names" only among "Recommendations for improving the Nomenclature *in future*." *Lepidactylis*, scale-fingered, is itself an adjective. *Anonyx*, *Euonyx*, *Eurytenes*, and many other approved names of genera, are adjectives. *Haustorius*, on the other hand, not being an actual Latin word at all, can scarcely be an adjective, while the termination *-ius* is kept in countenance by the comparatively recent change of *Calliope* into *Calliopius*. The excellent name *Sulcator* might well have been allowed to stand, but since that has been displaced, on grounds of priority, first by *Pterygocera* and then by *Lepidactylis*, it seems only just to go back a step further to Müller's *Haustorius*.

1775. FABRICIUS, JOHANN CHRISTIAN, born 1742, died 1807 (*Biographie Universelle*), born 1745, died 1808 (*Ene. Brit.*, 9th Ed.), or died 1810 (see Hagen).

Systema Entomologiæ, sistens Insectorum Classes, Ordines, Genera, Species, adjectis synonymis, loeis, descriptionibus, observationibus. Flensburgi et Lipsiæ, 1775.

In the Prolegomena, after commenting on the confusion which had prevailed in entomology before, and even since, the labours of "the immortal Linné," he says, "Novam ideo viam tentabo, characteres et classium et generum ex instrumentis cibariis desumens. Præbent sane sufficientes, præbent constantes et genera multo naturaliora." He proceeds to describe in general the labia upper and lower, the maxillæ upper and lower, the palpi, 2, 4, or 6, the lingua spiralis, the rostrum, proboscis, and haustellum. Specific differences he takes from colours (*coactus*) against his better judgment. The classes of insects are eight, "Os maxillis palpisque quatuor aut sex." They are named *Eleuterata*, *Ulonata*, *Synistata*, *Agonata*, *Unogata*, *Glossata*, *Ryngota*, *Antliata*. The *Agonata* are defined "Os palpis quatuor, aut sex. Maxilla inferior nulla." This class includes *Scorpio*, *Cancer*, *Pagurus*, *Scyllarus*, *Astacus*, *Gammarus*. Among the definitions of these are "125. CANCER. Palpi quatuor os obtgentes. Antennæ quatuor filiformes; posticis articulo ultimo bifido," and "129. GAMMARUS." "Antennæ quatuor simplicissimæ, sessiles: anticae breviores, subulatæ, posticae setaceæ." This latter contains the species *Gammarus locusta*, *Gammarus pulex*, *Gammarus linearis*, *Gammarus salinus*, *Gammarus stagnalis*, of which the first three correspond respectively to the numbers 82, 81, 83 of the *Systema Naturæ*, ed. xii., the remaining two not belonging to the Amphipoda. It should be remembered that the name *Gammarus*, which had hitherto been a specific name among Stalk-eyed Crustacea, now becomes a generic name among the sessile-eyed.

Among the *Synistata*, "Os palpis quatuor. Maxilla inferior connata cum labio," on page 296, is given a definition of *Oniscus* :—"93. ONISCUS. Labium quadrifidum: laciniis intermediis palpigeris. Antennæ setaceæ." Among the *Onisci*, descriptions referring to Amphipoda (of *Gammarina* 1, *Hyperina* 3, *Caprellina* 1) are given as follows :—

"2 caudatus. 9. O. semicylindricus, caudis duabus longitudine corporis, *Linn. Syst. Nat.* II. 1060. 8. *Fn. Sv.* 2062. Habitat in Oceano Norwegico.

"spinosus. 13. O. oblongus, corpore spinoso, pellucido.

"Habitat in Oceano Atlantico. *Mus. Dom. Banks.*

"Corpus medium, gelatinoso-membranaceum, pellucidum. Caput magnum, rotundatum, obtusum, marginibus spinulosis. Oculi maximi, contigui. Antennæ duæ simplices, setaccæ. Segmenta corporis undecim sensim angustiora, carinata, carina spinulosa. Abdomen subtus foliolis sex ovatis obtgentibus. Cauda brevis, foliolis quatnor bifidis. Pedum septem paria, 1. 2. brevia, chelata, approximata, 3. 4. 5. 6. longiora, angulata, angulis spinulosis, articulo ultimo subulato, simplici, 7. breve, articulo ultimo clavato unguiculato.

"gibbosus. 14. O. oblongus, gibbus, antennis plicatis, longissimis.

"Habitat in Oceano Lusitanico. *Fig. pict. in Mus. Baukiano.*

"Corpus parvum, glabrum, lœve, flavescens, punctis fuscis irroratum. Caput crassum, obtusum, oculis duobus maximis approximatis, macula magna viridi. Antennæ duæ setaceæ, sub corpore inflexæ et plicateæ, corpore triplo longiores. Thorax gibbus, segmentis septem, primo brevissimo. Abdomen segmentis' quatuor. Cauda foliolis tribus, acuminatis, fissis. Pedes 14, intermediis sublongioribus.

"quadricornis. 15. O. oblongus, stylis caudalibus senis, antennis quaternis. Habitat in mari Atlantico. *Mus. Banks.*

"Corpus parvum, gibbum, glabrum. Caput retusum. Oculi maximi, macula magna lunata,

viridi. Antennæ quatuor setaceæ, longitudine corporis. Corpus segmentis duodecim, ultimo planiuseulo, ovato, integro. Canda exserta, stylis sex acutis, integris. Abdomen subtus foliatum. Pedes 14. subequales.

“*Ceti.* 16. O. ovalis, segmentis distinctis, pedibus tertii quartique paris linearibus, muticis. *Linn. Syst. Nat.* 11. 1060. 6, *Fn. Sv.* 2056 : *Mus. A. F.* 1. 89. Habitat in Balaenis. Ab hoc genere differre videtur mihi haud rite notus.”

Among the Antiata the definition of *Pediculus* is as follows:—“184. *Pediculus*. Os haustello atque proboscide. *Haustellum* retractile, recurvum. *Antennæ* subulate.” Under this genus, on p. 810, though, as will be seen, with doubts, he retains the confusion which Linnaeus had introduced between Martens’ whale-louse and Brünnich’s *Pycnogonum*, in the following entry:—“*Balaenarum.* 35. P? abdomine dilatato, muricato, rostro porrecto, subulato.

“*Phalangium balæharum*, *Linn. Syst. Nat.* 11. 1028. 6.

“*Pediculus ceti*, *Mart. Spitz.*, 85, Tab. Q. fig. d.

“*Pedienlus ceti*, *Bast. subs. v. 2. tab. [pars] 3.* 146. [156] *tab. 12. fig. 3.*

“*Phalangium littorale*, *Stroem. Søndm.*, 209. *tab. 1. fig. 17.*

“*Pycnogonum*, Brünnich. *Ins. tab. 1. fig. 17.*

“Habitat in Oceano Norwegico.

“Hujus generis videtur mihi haud rite notus.”

Cystisoma neptuni, Guérin, 1842, which had anticipated *Thaumops pellucida*, Willemoes-Suhm, must obviously itself yield priority to *Oniscus spinosus*, Fabr., above-described.

1776. PALLAS, P. S.

Reise durch verschildene Provinzen des Russischen Reichs. Dritter Theil. Vom Jahr. 1772, und 1773. St. Petersburg, 1776.

On page 709 he describes *Oniscus muricatus*—“*Magnitudo* fere *Squillæ vulgaris*, sed conformatio quæ *Oniscis* squilliformibus reliquis. *Segmenta* corporis scptem, caudæ tria priora utrinque ad dorsum aeuleo conico mucronata. *Pedes* 4 priores elhiferi, primi minores. *Cauda* stylis sex terminata, quorum duo medii breviores, crassioresque. *Color* vivi cinerascente-albidus; sieati, coeti vel a liquore spirituoso conditi coccineus. In Angara inferiore circa mortieinia et quisquilias aquæ injectas colligitur copiose.” He appends a note that a description of this species is to be found in the ninth fasciculus of the *Spicil. Zool.*, p. 52, but that the figure there is not a good one, in particular the dorsal spines being omitted. It seems therefore clear that *Oniscus cancellus* is here for some reason renamed. Herbst mentions that in the German translation of the Spicilegia *Oniscus cancellus* is called *Oniscus muricatus*.

1776. BOMARE, JACQUES CHRISTOPHE VALMONT DE, born 1731, died 1807 (Hagen).

Dictionnaire raisonné universel d’histoire naturelle, &c., &c. Troisième Edition, revue et eonsidérablement augmentée par l’Auteur. Tome Septième. A Lyon, M.DCC.LXXVI.

Under “Pou de Balcine, *pediculus ceti*,” p. 314, will be found au account, not of *Cyamus*, but of a Cirripede, probably *Coronula dialema*. It is “un animal testacée, commun dans les mers du Nord.” “Quand on presse avec les doigts ce coquillage eneore vivant, il répand une liqueur noirâtre. Sa tête ne se montre guère à découvert; elle est presque toujours cachée sous son enveloppe pierreuse.” “Cette coquille est percée dans le milieu d’un tron rond; divisée en plusieurs cellules étroites et profondes.” Nevertheless a reference is given

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

to "Seba (*Thes. 1, Tab. 90, n. 5,*)" which is the figure of a *Cyanus*. The writer notices that Seba mentions also "poux marins de Groëuland, qui font la nourriture des baleines." On p. 361, "Puce de mer, *psillus marinus*, est un petit animal carnassier, qui se trouve en grand quantité sur les bords de la mer du Cap de Bonne Espérance." Its name is derived from its power of leaping. It is armed "d'un petit aiguillon," by which it fixes itself on to fish and drives them to desperation. Rondelet's account of the ape-like shrimp is then given, with the concluding remark, "Peutêtre que les puces de mer sont le même animal connu à Amboine et à Banda, sous le nom de Fotock, *voyez ce mot.*" Under "Fotok," Tom. 3, p. 550, he only says, "*Voyez Pou de mer.*" There may be other information of importance in other parts of this work and in the three other editions of it. I have given specimens to encourage research. The Danish translation by H. v. Aphelen is dated, according to Hagen, 1767–1770, and must have been made therefore from the first or second edition.

1776. MÜLLER, OTTO FRIEDRICH, born 1730, died 1784 (Hagen).

Zoologiæ Danicæ Prodromus seu Animalium Daniae et Norvegiæ indigenarum characteres, nomina, et synonyma imprimis popularium. Auctore Othono Friderico Müller. Havniæ, cœ DCC LXXVI.

Animals are here divided into six classes, the Insecta being the fifth. The Insecta include seven orders, of which the Aptera are the last. Among the Aptera (p. xxvii.) he gives "c. *Crustacea*," with the genera *Polyphemus*, *Cyclops*, *Squilla* ("*Peles* 10 vel 14. *Antennæ* 4 integræ"), *Cancer* ("*Peles* 10. *Antennæ* 2 integræ"), *Oniscus* ("*Peles* 14. *Antennæ* fractæ"), *Scolopendra* and *Julus*.

Under the genus *CANCER*, pp. 196–197, he gives:—

- " 2353. *C. glacialis*, semicylindricus, corporis segmentis octo subæqualibus.† LINN., Mant. 542.
- " 2354. *C. macrourus teretiusculus*, corporis segmentis octo, pedibus duobus chelatis. LINN. Mant. 542. bini hi *Squillis* potius annumerandi, ultimus *S. lobata* affinis videtur.
- " 2355. *C. Medusarum* antennis brevissimis, corpore latiorc. Gr. *Urksursak*. STR. S. 1. p. 188. t. 1. f. 12, 13.
- " 2356. *C. macrourus thorace antrorsum aculeato*, pedum paribus 10; cauda foliacea. I. *Kampa-Lampa*. Isl. R. 899.*†
- " 2357. *C. macrourus articulatus*, manibus adactylis, femoribus posticis orbicularibus, spinis caudæ bifidis. Act. Havn. 9. p. 588. t. 8.
- " 2358. *C. macrourus articulatus*, dorso carinato serrato, spinis caudæ bifidis. A. Havn. 10. p. 5. t. 2. f. 1–8. Cancer STR. S. 1. p. 180. 4. Gr. *Arksegiansoak* quiuan? *Krabbe* nom. gen. APH. 4, 451."

Under the genus *SQUILLA*—

- " 2359. *SQUILLA lobata* pallida pellucida, lobis intermediis quatuor, pedibus decem unguiculatis. Gr. *Napparseria* vel *Illærak*. Cane. *linearis* vel *filiformis* perillustris a LINNÉ.
- " 2360. *S. ventricosa* rubra depressa, pedibus quatuordecim setaceis secundo pari clavato. A. Helv. 4. t. 4. f. 8, 9, 10*."

Under the genus *ONISCUS*—

- " 2362. *O. volutator* antennis crassis abdominis longitudine. *O. bicaud.* LINN. autellas vero pro cauda sumsis."
- " 2366. *O. pullex* compressus; pedibus quatuor anticis cheliformibus. N. *Marflue*. I. *Marflo*. Gr. *Kinguk* STR. S. 188. APH. 2, 399; 5, 235. Cancer LINN. In littore maris & in ripis amnium & lacuum frequens."

Aph. stands for "Bomares Natur-historie af H. von Aphelen."

On p. 280 Müller says, with a reference to No. 2358, "Arksegjarsoak augmentativum ex Arksegiaak nom. Cancer gener." On p. vii, abbreviations, &c., are thus explained, "Species asteriseo* notatae in scriptis perillustris equitis a LINNE frustra queruntur, signo † impressae a civibus, signo + a me, detectae indicantur. Nomina vernacula, quibus nulla litera majuseula anteponitur Danis et Norvegii communia sunt, reliqua D. Danos, N. Norvegos, I. Islandos, L. Lappones, Gr. Groenlandos significant."

Of these species No. 2355 is generally accepted as *Hyperia medusarum*, Müller; No. 2356 remains obscure; No. 2357 repeats Ström's description from the Acta Havn., 1765, of what is probably *Orchestia gammarellus*; No. 2358 in like manner refers to Ström's species of 1770, now become *Amathilla homari*, Fabr.; No. 2359 is synonymous with *Caprella linearis* (Linn.), Bate; No. 2360 is now called *Proto ventricosa*, Müller; No. 2362 answers to *Corophium volutator*, Pall.; No. 2366 includes probably two or three species, such as *Gammarus locusta* and *Gammarus pulex*. No. 2353, *Cancer g(l)acialis*, is probably not an Amphipod; No. 2354 may be a *Caprella*.

1776. FORSKÅL, PEHR.

Icones rerum naturalium, quas in itinere Orientali depingi curavit Petrus Forskål, Prof. Haun. Post mortem auctoris ad REGIS mandatum aeri incisas edidit Carsten Niebuhr. Hauniæ, MDCCCLXXVI.

In the Explicatio Tabularum, under Tab. xli., is given the reference, "D. d. CANCER sedentarius. Pag. 95, n. 59." Figure "d" is a recognisable figure of *Phronima sedentaria* free; figure "D" represents it in its semitransparent case. For the description of this species, see note on Forskål, 1775.

1777. FABRICIUS, J. C.

Genera Insectorum eorumque characteres naturales secundum numerum, figuram, situm et proportionem omnium partium oris adjecta Mantissa specierum nuper detectarum. Chilonii. (Prolegomena dated Kiliae die xxvi Deeem. 1776.)

Here the genus *Scorpio* is transferred to Class V., the Unogata. The other five genera of the Agonata are retained in the same order as in his earlier work. The account of the genus *Gammarus* is as follows:—"GAMMARUS. Cancer Linn. Geoff. Oniscus Pallas. Os mandibulis palpisque absque maxillis. Palpi sex, inaequales, filiformes; anterioribus quatuor porrectis, os obtentibus. anteriores longiores, compressi, bifidi: laenia interiori quadriarticulata; articulo ultimo ineervo, exteriori breviori, vix articulata. medii paullo breviores, bifidi; laeniis subaequalibus; interiori triarticulata, exteriori subulata, acuta. posteriores breves, filiformes, triarticulati mandibulae dorso inserti. Mandibula brevis, cornea, crassa, fornicata, obtusa, vix dentata, dorso palpigera. Labium tripes membranaceum. exterius quadrifidum: laeniis subaequalibus, linearibus. medium bifidum: laeniis rotundatis, divisus, aequalibus. interius bifidum; laeniis aequalibus, rotundatis, extrorsum erassioribus, divisus. Antennæ quatuor inaequales, pedunculatae, simplicissimæ. anteriores breviores, subulate; pedunculo biarticulato. posteriores longiores, setaceæ; pedunculo triarticulato. Metamorphosis completa larva puppaque omnibus partibus completis, agilibus. Victus e rapina minuimorum aquatilium plantisque aquaticis," pp. 142, 143. The species *grossipes* is

thus entered ou p. 248 :—“*grossipes*. I. GAMMARUS mauibus adactylis longitudine corporis. *Cancer grossipes*, Linn. Syst. Nat., 2, 1055, 80. *Astacus muticus* pede antico subulato edentulo longissimo crassissimo, Gronov. Zooph., 989, tab. 17, fig. 7. *Oniscus volutator* Pallas Spic. Zool. fascic. ix. p. 59. tab. 4. fig. 9. Habitat in Europæ aquis stagnantibus.”

1777. PENNANT, THOMAS, born 1726, died 1798 (Webster).

British Zoology, vol. iv., Crustacea, Mollusca, Testacea. London, MDCCCLXXVII.

In his advertisement he says, “In my arrangement of the present work, I have taken the liberty of making a distinct class of the Crustaceous Animals; and separated them from Insects, among which they are usually placed.” Among the lobsters, *Astacus*, which he defines with the words “Cylindric body. Long antennæ. Long tail,” he places “*Cancer linearis* Lin. syst. 1056. Lesser garnet or shrimp. Martens, Spitzberg. 115. tab. P. fig. 1,” “with long slender claws, placed very near the head.” From the figures, pl. xvi. fig. 31, it is pretty clear that these “claws” are the antennæ, and that *Corophium volutator*, Pallas, is intended, the two references being quite inappropriate. He next gives “*Cancer atomos*. Lin. syst. 1056. Mirum animalculum in corallinis, &c., Baster, 1, 43, tab. iv. fig. 11.” He mentions for this “a slender tail between the last pair” of legs, which would apply to *Cercops*, but the figure, pl. xii. 32, gives no pleon. He gives “*C. Pulex*. Lin. syst. 1055, No. 81,” “very common in fountains and rivulets,” probably *Gammarus pulex*, and “*C. locusta*. Lin. syst. 1055, No. 82,” “which leaps about with vast agility,” and which may therefore refer to *Orchestia* or *Talitrus*, or both.

1778. DE GEER, CARL, born 1720, died 1778 (Biographie Universelle).

Mémoires pour servir à l'histoire des Insectes, Par M. le Baron Charles De Geer. Tome septième. Ouvrage posthume. A Stockholm, M.DCC.LXXVIII.

On pages 525–533 he describes “*Squilla (Pulex) aquatica*, corpore compresso, pedibus quatuor anticis, chelatis, cauda setis sex bifurcis terminata,” with references to Gronovius, Zooph. 990., Linn. Syst. Nat., ed. 12, p. 1055, 81. Geoffr. La crevette des ruisseaux, Ray, Frisch, Klein, Roesel, and Baster. From the remarks which he quotes from various authors, we may suppose that he regarded *Orchestia*, *Talitrus*, *Gammarus locusta*, and the like as all agreeing with *Gammarus pulex*, which is apparently the actual subject of his description and of plate 33. On pages 540–544 he describes “*Squilla (Balæni) corpore ovali depresso; segmentis distinctis, pedibus cheliferis: tertii quartique parvis linearibus muticis*,” with references to “*Oniscus (Ceti) ovalis*,” &c., Linn. Syst., ed. 12, p. 1060, No. 6, and Martens Iter Spitsb., Tab. Q, fig. D. This he figures on pl. xlvi. figs. 6–10. In the detailed description, in regard to “les pattes de la troisième et quatrième paire,” he says, “Elles sont longues, déliées, filiformes et très-flexibles, de grosseur partout égale et à l'extrémité arrondie, où l'on ne trouve ni ongle, ni crochet, en sorte qu'elles ressemblent plutôt à de longs filets qu'à des pattes.” Nevertheless, in the enlarged figure he gives them the appearance of being triarticulate, probably under the impression that if they were feet, they must be jointed. He also quotes the observation from Martens, that when the animal is sucking the skin of the whale, these four filiform feet are elevated over the back, so as to touch from opposite sides, and specimens, he says, in his own collection show them in this position.

1779. FABRICIUS, JOHANN CHRISTIAN.

Reise nach Norwegen, mit Bemerkungen aus der Naturhistorie und Oekonomie.
Hamburg, 1779.

At page 247 Fabricius says, "Unter den Insekten ist nichts seltenes; doch fand ich eine Menge kleiner Krebse, in Weingeist aufbewahrt, die in Norwegen unter den Namen Aat bekannt sind. Dieses Aat schwimmet in Sommer bey warmer Witterung in unendlicher Menge in der See. Man kan keiner Eimer voll Wassers schöpfen, ohne Millionen dieser Thiere mit herauszuziehen. Diese sind es, welche den Fischen, insonderheit den Heringen, zur Nahrung dienen, sie unter das Land locken, da sie ihnen immer folgen, wie der Wind und der Strohm sie treiben. Dieses Aat oder diese Krebsarten scheinen daher wenigstens mit die Ursache zu seyn, warum sowol die Menge der Fische, als das Glück der Fischereyen sehr vom Strohme und dem Winde abhängt. Ich beschrieb hier

"*Astacus Homari* antennis posticis bifidis, corporis segmentis dorso subspinosis, caudæ stylis serratis.

"*Cancer* dorso carinato, serrato, Stroem. Act. Hafn. x. pag. 5. tab. 2.

"*Cancer macrourus* articulatis, dorso crenato serrato, spinis caudæ bifidis, Müll. Zool. Dan. 197. 2358.

"*Hummer Aat* Norvagis.

" Magnitudine differt; mox maior, mox minor invenitur. Antennæ quatuor pedunculatae, setaceæ posticae bifidæ lacinia exteriore minore. Caput ouatum absque vlo rostro. Corpus segmentis 13. ultimis dorso eleuatis, acutis, subspinosis. Pedes vnguiculati septem parium, interne lamina magna, ouata, obtusa suffulti; Natatorii trium parium apice fissi. Caudæ stylis plures, serrati."

This species Fabricius seems afterwards to have regarded as the type of his genus *Gammarus*, and since the references identify it with what has since been known as *Amathilla sabini*, Leach, with which the description fairly corresponds, there seems no reason for withholding from the specific name given by Fabricius its right of priority. The species should therefore be called *Amathilla homari*, Fabr.

On page 258, after mentioning the occurrence of *Gammarus locusta* in great numbers at small depths, he describes:—

"*Gammarus longicornis* manibus adactylis, antennis corpore longioribus cauda obtusa.

"*Gammarus crassipes* Gen. Ins. App.

"*Cancer crassipes* Linn. Syst. Nat. 2. 1055. 8o.

"*Oniscus volutator* Pall. Spicileg. Zool. fasc. ix. p. 59. tab. 4. fig. 9.

"*Astacus muticus*, pede antico subulato, edentulo, longissimo, crassissimo Gronov. Zooph. 989. tab. 17. fig. 7.

"Paruus. Antennæ anticæ breves subulatae, posticæ porrectæ, crassæ, corpore longiores. Articulus secundus apice interiori vnidentatus. Corpus griseum, immaculatum. Pedes trium parium adactyli. Cauda obtusa: lamella vtrinque vnicæ."

Why he rejects the earlier specific names, he does not explain. In the synonymy he seems to have used the word *crassipes* twice by mistake for *grossipes*, misled perhaps by Gronov. See Note on Pallas, 1766. What is meant by "Gen. Ins. App." I have not been able to discover. It may refer to some appendix prepared but not published. In the Species Insectorum, 1781, the reference is not repeated.

On page 326, he says, "Unter den grossen *Medusis* hielt sich ein kleiner *Gammarus* auf, der mir noch gleichfalls unbekannt war.

"*Gammarus medusarum*, manibus quatuor monodactylis, capite obtusissimo.

"*Pulex cancriformis*, Stroem Sundm. Tab. 1. figs. 12. 13.

"*Cancer medusarum*, antennis brevissimis, capite latiore. Müll. Zool. Dan. 188. 2355.

"Corpus paruum, incuruum, antice obtusissimum. Antennæ quatuor breuissimæ, filiformes, simplices. Abdomen postice attenuatum. Cauda filiolis quatuor bifidis. Pedes septem parui, breues. Natatorii utrinque tres."

This description is accepted as applying to *Hyperia medusarum*, O. F. Müller.

At page 383 he describes the new species :—

"*Gammarus corniger* manibus adactylis, rostro incurvo subulato, thoracis lateribus cornu dupli.

"Medius in hoc genere. Antenne quatuor æquales filiformes, simplices, albæ. Rostrum breve, subulatum, acutum inter antennas incuruum. Oculi magni, sessiles, cinnabarini. Corpus segmentis vndeclim breuibus albidis margine sanguineis, posticis quinque dorso carinatis, spinosis. Sub thoracis lateribus vtrinque cornua duo basi connata, valida, subulata, acuta : anteriori arcuato. Cauda stylis pluribus bifidis."

This has since been recognised by Boeck as identical with *Epimeria tricristata*, Costa, and is accordingly named *Epimeria cornigera*, Fabr.

1780. FABRICIUS, OTTO, born 1744, died 1822 (Hagen).

Fauna Groenlandica, systematice sistens Animalia Groenlandiæ occidentalis hactenus indagata, quoad nomen specificum, triviale, vernacularumque ; synonyma auctorum plurium, descriptionem, locum, victum, generationem, mores, usum, capturamque singuli, prout detegendi occasio fuit, maximaque parte secundum proprias observationes Othonis Fabricii. Hafniæ et Lipsiae, MDCCCLXXX.

On pp. 212, 213, No. 179, he describes a *Podura maritima* from the sea shore, with a reference to Ström, Act. Hafn. ix. p. 582, Tab. v. (?), which does not appear to be a Crustacean, and must therefore be distinguished from Poda's *Podura maritima*.

Squilla lobata, p. 248, for which he refers both to *Squilla lobata*, Müller, and to *Cancer filiformis*, Linn., Pall., may be either *Caprella septentrionalis*, as supposed by Krøyer in 1838, and afterwards by Boeck, probably on Krøyer's authority, or *Caprella linearis*, as Mayer seems to prefer, while half inclined to make *septentrionalis* itself a synonym of *linearis*.

The *Oniscus ceti*, No. 230, as Lütken points out, is not entirely free from the early confusion about *Cyamus*. The definition is taken with slight change from Linnaeus, and the description by Pallas is referred to as making further details needless, although both Linnaeus and Pallas had to do with *Cyamus mysticeti*, while Fabricius was evidently concerned with what Lütken has named *Cyamus boopis*, as shown by the statement "mea exemplaria accepi in balaena boope." Lütken remarks also that Fabricius is wrong in the detail supplied by the words "femora postica biaculeata."

Oniscus pulex, No. 231, is no doubt, as Krøyer and Boeck say, *Gammarus locusta*. Fabricius himself in the synonymy gives "*Cancer Locusta*, Syst. nat. 1, 1055, Faun. Suec. 2041. indice Pallade l. c. hue pertinet; et certum est, descriptionem cancri coerulei It. Gothl. 260. ibi citatam Onisco pulici omnino convenire, licet ab autore ipso pro distincto habitus."

Oniscus medusarum, No. 232, is by Bovallius (1886), called "*Hyperia Kroeyeri*."

Oniscus cicada, No. 233, with "color totus pulchre rubicundus, oculis sanguineis," is considered by Krøyer, in 1838, to be probably the same as his own *Amphithoë inermis*. Milne-Edwards, in 1840, Hist. des Crust., iii. p. 25, thinks that it is very likely the same as the *Amphithoe serra* of Krøyer, which he would place in the genus *Acanthonotus*, Owen and Ross. But on p. 34 of the same volume he questions whether it may not be the same as *Amphithoë inermis*, Krøyer. Krøyer himself, Tidssk., iv. 161, note, in 1842, repudiates Milne-Edwards, first suggestion, and says, "*Oniscus cicada* is probably a species of the genus *Anonyx*." In

Tidsskr., ser. 2, vol. i. p. 611, in describing the new species *Anonyx gulosus*, he remarks in a note, "It is, however, possible that this species is not new. Fabricius' *Oniscus cicada* seems in many, if not in all, respects to come very near to it, and is obviously in any case an *Anonyx*. By means of the Greenland name this doubt seems capable of solution, at least if the name applies to but one species." With such testimony from Krøyer himself, it seems only just to reduce his *Anonyx gulosus* to a synonym of *Anonyx cicada*, O. Fabricius. It shares with the so-called *Gammarus arcticus*, Scoresby, the reputation of exercising extreme voracity upon dead seals.

Oniscus abyssinus, No. 236, Krøyer in 1838 identifies, though very hesitatingly, with his own *Amphithoë crenulata*. Subsequently Krøyer united *Amphithoë crenulata* and *Amphithoë inermis* as the two sexes of one species, which Boeck places in his genus *Pontogeneia*, as *Pontogeneia inermis*.

Oniscus serratus, No. 237, Krøyer, in 1838, renamed *Amphithoë serra*, and afterwards *Acanthonotus serra*. Boeck calls it *Acanthonotozoma serratum*, the generic names *Acanthonotus*, Owen, and *Vertumnus*, White, to which this species had been successively assigned, being both preoccupied.

Oniscus arenarius, No. 234, is defined as "Oniscus canceriformis, antice depresso-ovalis, postice carinato-subseratus, pedibus 4 anticis cheliformibus levibus, antennis subaequalibus," followed by Ström's definition in the synonymy, "Cancer macrourus articularis, manibus adactylis, dorso carinato serrato, spinis caudae bifidis, Act. Hafn. x. 5. Tab. ii. f. 1-8 et Müll. prodr. 2358 ?" The references imply that *Amathilla homari*, Fabr., 1779, is intended, a species as to which Krøyer, Grönl. Amph., expresses his surprise that one so large should not have been noticed by Otto Fabricius. The name *Oniscus arenarius* is preoccupied by Slabber.

Oniscus Stroemianus, No. 235, is defined as "Oniscus canceriformis compressus, pedibus 4 anticis cheliformibus subdentatis, antennis summis brevissimis," followed by Ström's definition, Act. Hafn. ix. 588, Ström being spoken of as the discoverer. Ström's species is identified by Boeck with *Orchestia (littorea) gammarellus*.

1780. DE QUÉRONIC.

Description d'un Insecte singulier trouvé dans la rade de Lomariaker. Mém. de Math. et de phys. prés. à l'Académie Royale des Sciences, Paris; Tom. IX. Paris. M.DCC.LXXX., p. viii. and pp. 329-330. (Présenté le 4 Juillet 1767.)

The "insect" from Morbihan which he figures, and describes as Puce de mer *arpenteuse*, giving the latter epithet from its mode of walking, is clearly the skull-headed skeleton shrimp, *Caprella acanthifera*, Leach. Boeck says that de Quérone "figures a *Caprella* which seems to be the female of *Caprella linearis* and a variety of it, which has been made a separate species, *Caprella acuminifera*." This latter Mayer identifies with *Caprella acanthifera*, but inclines to regard de Quérone's species as the two sexes of *Caprella tuberculata*, Bate and Westwood. It is, however, only the *Caprella acanthifera* which has the peculiar skull-like head figured by de Quérone. There is nothing in his paper, either in the description or the figures, which are here reproduced, that refers to more than a single form. He draws it, indeed, in two postures, but without any intimation that the figures are taken from more than one specimen. His actual words are, "Notre insecte est couvert d'une écorce semblable à celle des Puces de mer, de même consistance, et aussi d'un rouge lavé, sur-tout après la mort de l'animal. C'est ce qui me porteroit à lui donner le nom de Puce de mer, auquel j'ajouterois celui d'*arpenteuse* pour caractériser sa marche. La figure A, représente l'animal de grandeur naturelle, et à-peu-près dans l'attitude où on l'a vu marcher.

B, est le même insecte vu à la loupe, et dessiné avec toute l'exactitude possible. L'œil qu'on lui voit à chaque côté de la tête, est pendant sa vie, ainsi que lorsqu'il est mort, du rouge le plus vif, semé de petits points jaunes. Sa gueule est ouverte comme celle des poissons, et non comme celle des crabes, écrevisses, etc. On l'a vu remuer les mâchoires qui ont plusieurs plis tels qu'ils sont représentés ; mais il n'a pas été possible d'apercevoir si l'intérieur est garni de dents, comme l'insecte de Ceylan. *CC*, sacs membraneux, velus, et

Fig. 14.

blancs, dont il y a deux de chaque côté, en dessous l'un du second, l'autre du troisième annneau. Ces sacs servent probablement à l'insecte, à se soutenir dans l'eau et à nager. *D*, bras garnis chacun d'un gros crochet, parfaitement semblable à celui qui termine tous les pieds de l'insecte de Ceylan. La comparaison de notre figure avec celle de M. le Commandeur *Godeheu*, page 276 du troisième volume des *Savans Etrangers*, fera voir en quoi ces animaux se ressemblent, et en quoi ils diffèrent l'un de l'autre."

1780. LEPECHIN, IAN. Lepekhin, Ivan Ivanovich (or Lepechin, Ivan), born "vers le milieu du 18^e siècle," died 1802 (Biographie Universelle), born 1737, died 1802 (Hagen).

Tres oniseorum species descriptæ. Ab I. Lepechin. Acta Academiæ Scientiarum Imperialis Petropolitanae. pro Anno MDCCCLXXVIII. Pars prior. Petropoli. MDCCCLXXX.

Of these three species, the second, *Oniscus scorpioides*, Tab. viii. fig. 2, is not an Amphipod; the first and third are described as follows:—"Oniscus aculeatus. Tab. viii. Fig. 1. *Oniscus*

thorace nudo, dorso tribus ordinibus cuspidum notato. Descriptio. longitudo totius animaleculi, exceptis antennis, XI linearum. Caput hemisphericum, oculi magni, protuberantes, coerulei. Os inferius situm in fouea rotundata pone insertionem antenuarum, protuberans denticulis quatuor, quorum duo superiores, maxillam efficientes, validiores sunt, instructum. Antennae IV. per paria dispositae: par inferius magis validum quadriarticulatum: articulus capiti proximus breuissimus, secundus longior crassior que complanatus, tertius breuior secundo et debilior, quartus longissimus setaceus. Thorax semiouatus gibbus, segmentis VI. quorum vnumquodque in medio tuberculo, vix nudo oculo conspieuo, notatur; at in ultimo segmento inferior margo evidentibus cuspidibus armatur; reliquum corpus tribus constat scutis, quorum latera sunt plana in formam semilunae effecta, in abdomine appendicibus trium parium pediformibus, articulatis, extremo setaceis, instructa; in dorso autem tribus ordinibus cuspidum armata, quorum debiliores medium dorsum, fortiores vero vucinatae, latera, occupant. Pedes VII. parium, quorum duo anteriora cheliformia, vno acuto terminata, breuiora, reliqua longitudine crescunt, ita ut ultimum sit longissimum, quadriarticulatum, femora latiora fere triangularia."

"Oniscvs cvspidatvs. Tab. viii. Fig. 3. Oniscus thorace articulato, tuberculoso, segmentis dorsalibus VI, cuspidatis. Descriptio. Caput prominulum a thorace distinctum inaequale, oculis distinctis protuberantibus. Antennae IV, quarum bases constant articulis cylindricis breuioribus, apex vero exit in setam longam attenuatam. Os inferne situm, instructum maxillis hamatis evidentibus. Thorax articulatus oblongus, segmentis IV, quorum vnumquodque tuberculis III, sat eleuatis, uedio oblongiore, notatur; ultimum vero segmentum, praeter tubercula, cuspidibus IV dorsum respicuitibus instructum. Dorsum et abdomen constat itidem segmentis IV, quae sulcis profundis atque evidentioribus distinguuntur. Margo inferior anteriorum segmentorum armatur cuspidibus VI, ratione magnitudinis corporis, validis, ultimum vero segmentum, nou nisi vnicam cuspidem in medio gerit. Cauda in formam penicilli efformatur ex laminibus attenuatis mollioribus. Pedes VII parium, quatuor articulis constantes. Horum anteriores teneriores, hispidi; ultimi vero validiores, femoribus crassioribus, complanatis. spina notatis; abdomen tegunt tria paria appendicium pediformium, basi solidiore sulcata, apice bifido filiformi. Longitudo totius, exceptis antennis, X linearum; color lateritius; locus, mare album."

The first of these Arctic species was again described as a new species by Sabine in 1821, under the name *Talitrus Edwardsii*, which Owen in 1834 changed to *Amphithoë Edwardsii* Milne-Edwards, probably by an oversight, omitted it from his *Hist. des Crustacés*. Krøyer in 1846 fully described it, but without reference to Lepechin, under the name *Amphithoë Edwardsii*, while Spence Bate in 1862, without reference to Krøyer, transferred it to Costa's genus *Amphithonotus* as *Amphithonotus Edlicardii*. Goës in 1865 gave it the name *Amphithonotus aculeatus*. Boeck in 1870 renamed it *Tritropis aculeata*, under the impression that Costa's *Amphithonotus*, 1851, was preoccupied, for he says in his larger work, p. 510, "Jeg har i 1870 iudskrænket denne Slægts Omfang til de Arter, der staa nær *A. cataphractus*, Stimp., og ombyttet Slægtsnavnet, da det allerede forheu, i 1843, er af Fitz benyttet til et Reptil." Curiously enough, it is *Tritropis*, not *Amphithonotus*, which, not Fitz but Fitzinger uses for a genus of reptiles. In 1883 S. I. Smith changed Boeck's *Tritropis*, because it was thus preoccupied, into *Rhachotropis*. In 1874, that is, before the second volume of Boeck's last work was published, Buchholz restored the name *Amphithonotus aculeatus*, uniting with this species Boeck's *Tritropis Helleri*, but retaining the name *Tritropis fragilis* which Boeck had given to *Paramphithoë fragilis*, Goës. *Amphithonotus*, though not preoccupied, lapsed at its first institution as a synonym of *Dexamine*.

Fig. 3.

Fig. 15.

Oniscus cuspidatus, the remaining species, was supposed by Boeck in 1870 to be identical with Owen's *Acanthosoma hystrix*, 1835, which was renamed *Amphithoë hystrix* by Kröyer in 1838, and *Paramphithoë hystrix* by Bruzelius in 1859. The latter name was accepted in the Brit. Mus. Catal., the authors before Boeck not taking notice of Lepechin's *Oniscus*. Owen's name *Acanthosoma* being preoccupied, among Hemiptera in 1824 and elsewhere, was changed by Boeck into *Acanthozone*, who therefore calls Lepechin's species *Acanthozone cuspidata*. Under this name the species still stands, but upon the synonymy above-mentioned from Owen, Kröyer, and Bruzelius, which was accepted by Buchholz in 1874, E. J. Miers has since thrown doubt. See his Spitzbergen Crustacea, 1877, in which he points out that *Oniscus cuspidatus*, Lepechin, *Acanthosoma hystrix*, Owen, and *Acanthozone hystrix*, Buchholz, though all belonging to the genus *Acanthozone*, are probably distinct species.

1781. FABRICIUS, J. C.

Species Insectorum exhibentes eorum differentias specificas, synonyma Auctorum, loca natalia, metamorphosis adjectis observationibus, descriptionibus. Tom. I. Hamburgi et Kilonii, MDCCCLXXXI.

The Agenata are here still the fourth class, with the genera, *Cancer*, *Pagurus*, *Scyllarus*, *Astacus*, *Squilla*, *Gammarus*.

On page 511, *Astacus* includes the following entry:—

“*Homari*. 7. A. antennis postieis bifidis, corporis segmentis dorso subspinosis, cauda fasciculata, stylis serratis. Iter Norwag. d. 18. Iul.*

“*Cancer* dorso earinato serrato. Stroem. Act. Hafn. X. pag. 5. tab. 2.

“*Cancer* macrourus articularis, dorso earinato serrato, spinis caudæ bifidis. Müll. Zool. Dan. 197. 2358.

“Habitat in Oceano Norwagico.” For the probability that this species is in fact an Amphipod, the type-species of Bate and Westwood's genus *Amathilla*, see notes on Fabricius, 1779 and 1798.

On pages 515–518, *Gammarus* includes twelve species answering respectively to:—1. *Cancer ampulla*, Phipps; 2. *Cancer nugax*, Phipps; 3. *Oniscus cancellus*, Pallas; 4. *Cancer grossipes*, Linn., and *Oniscus volutator*, Pallas, but with the specific name *longicornis*; 5. *Gammarus locusta*, Syst. Ent. 418. 1., with references to Linnæus, Pallas, Sulzer, Friseh, Roesel, Klein, and the remarks, “Habitat sub Europæ maritimis frequentissimus, dorso innatans, etiam in fontibus et fossis. Conf. *Oniscus gammarellus*, Pall. Spicil. Zool. fase. 9. 57. tab. 4. fig. 8.;” 6. *Gammarus pulex*, Syst. Ent. 418. 2. with references to Degeer, Ray, Baster, Gronov, and the remark, “Habitat ad Oceani littora frequentissimus, saliens, piceibus infestus, in branchiis vleera eaussans;” 7. *Gammarus corniger*, Iter Norwag.; 8. *Gammarus linearis*, Syst. Ent. 419. 3., with references to *Cancer linearis*, Linn., *Oniscus scolopendroides*, Pallas, to “*Mart. Spizb. tab. P. fig. I. Bast. subs. 1. 32. tab. 4. fig. 2.*,” and the observation “*Cancer atomos*, Linn. Syst. Nat. 2. 1056. 84. vix differt.;” 9. *Gammarus salinus*; 10. *Gammarus stagnalis*; 11. *Gammarus esca*; the last-mentioned three not being Amphipoda; 12. *Gammarus* “*Medusarum*,” Iter Norwag., with references to *Pulex*, *cancriformis*, Stroem, and *Cancer Medusarum*, Müll. Zool. Dan. Prod. 2355. Of *Gammarus salinus* he notes two varieties and adds “An potius Monoeulus?”

Among the Synistata, Class III., *Oniscus* includes, on pages 377, 378, the same Amphipods as in the Syst. Ent. of 1775. These are, 10. *Oniscus bicaudatus*; 14. *Oniscus spinosus*, which is Guérin's *Cystisoma*; 15. *Oniscus gibbosus*, transferred in 1787 to *Gammarus*, but properly, like the next species, belonging to the Hyperina; 16. *Oniscus quadricornis*, subsequently recognised as a synonym of *Gammarus medusarum*; 17. *Oniscus ceti*. While

curtailing some of the descriptions previously given, Fabricius enlarges that of *Oniscus ceti* with the following synonymy:—

“ *Squilla Balænæ* corpore ovali depresso, segmentis distinetis, pedibus cheliferis, tertii quartique parvis linearibus mutieis. *Degeer Ins.* 7. 541. 6 tab. 42. fig. 6. 7.

“ *Pediculus Ceti*. *Martens Spitzb.* tab. 8. fig. D.

“ *Seb. Mus.* 1. tab. 90. fig. 5.

“ *Pall. Spicil. Zool.* fasc. IX. 76. tab. 4. fig. 14.

“ *Egelse Groenl.* tab. 37.

“ Habitat in Oceano boreali balænis molestus.

“ Ab hoc genere differre videtur vterius examinandus.”

Thus Martens' whale-louse is rightly placed, and not, as in the earlier work, erroneously referred to *Pediculus (?) Balænarum*.

1781. ÖDMAN, SAMUEL, born 1750, died 1829 (G. O. Sars).

Grundmårglan, *Cancer pulex*. Kongl. Vetenskaps Academiens Nya Handlingar För Månaderne Aprilis, Majus, Junius, År 1781, pp. 163–168.

For the *Cancer Pulex* here described he gives references to “Fauu. Sv. N:o 2041. S. N. N:o 81. II : r Ströms Sönd.-Mör -1, p. 188. *Marflue*. Hammers Faun. Norv. N:o 735.” The description is as follows:—“Cancer maerourus, manibus adactylis, thorae nullo. Antennæ IV, setaeæ, artieulis 3 primis longioribus. Oeuli nigri lunulati. Segmenta corporis XIII, capite excepto. 5 primis squama lateralí munitis; 8, 9, 10, puneto sanguineo notatis (in vivo). Pedes primarii, 4 parium, quorum 2 par. antiea chelifera, eum pollieis immobilis rudiumento, inter squamas laterales latent. Pedes medii 3 par. longiores, ad segmentum 6 ineipiunt. Pedes postiei 2 par. minimi, bidigitati, sub ipsa cauda, reetrieas. Styli 3 par. setaeæ, mutici sub abdomine (hi sunt pedes spurii LINNEI Loeustæ, S. N. N:o 82). Cauda bifida, chela dupliei polliee sursum posito. Corpus vivi fuseum, mortui rufescit, pellucidum. Magnitudo maris $\frac{2}{3}$ poll. Foem. dimidio minor. Wermloensibus *Grundmårgla*.” Ödman was doubtful whether the Crustacean mentioned in Linne's Ölands-resa, p. 42, and Gothlands-resa, p. 260, should be called *Pulex* or *Locusta*. It is clear from the account he gives of his own species that it is marine, and therefore not *Gammarus pulex*, but in all probability *Gammarus locusta*. See his further account 1799.

1781. SCHRANK, FRANZ VON PAULA, born 1747, died 1835 (Hagen).

Enumeratio insectorum Austriae indigenorum. Avgystæ Vindelieorum, MDCCCLXXXI.

On page 535, under “CANCER, Krebs,” he gives “1114. Astacus, Flusskrebs followed by

“ 1115. PULEX, Seitling.

“ Cancer maerourus artieularis compressus, manibus quatuor adactylis, pedibus decem.

“ Cancer Pulex. Scop. carn. n. 1137.

“ Krebsförmiger Wasserwurm. Frisch. Ins. Deut. part. 7. p. 26. § 18.

“ Habitat in aquis, rivis, fontibus; albissimus, dum natat; einereus, dum in aere exsiccatur; si vel modicus accedit ealor, rubescit.

“ Nomen germanicum Austriae usitatum.”

From the habitat “in rivis,” it may be inferred that Sehrank was acquainted with *Gammarus pulex*. From the habitat “in fontibus,” coupled with the remark “albissimus, dum natat,” it seems fair to suppose that he had also seen one of the well-shrimps, such as *Niphargus aquilex*.

1782. BERKLEY, LEFRANCQ DE. LE FRANCQ VAN BERKHEY (Carus. Bibl. Zool.). JOHN LE FRANC VAN BERKLEY, born 1729, died 1812 (Maunders).

Johann Franz van Berkhey's *Naturgeschichte von Holland, aus dem Holländischen übersetzt*, has the first volume dated Leipzig, 1779, the second, Leipzig, 1782. This German translation of the work is the only one I have been able to obtain, and in the second volume the translator gives notice that he has taken the liberty of considerably curtailing the original. In point of fact, all the zoology seems to be omitted. From local notices in the work it may be inferred that the author's name was certainly van Berkhey.

"He published in Dutch a history of Holland, geographical, physical, natural, and civil, of which a French translation appeared in 1782. He was the first to change the Linnean classification of the Crustacea, forming them into a separate class, which he placed immediately before that of the Insecta. But besides that he only characterised his divisions in a complicated, vague, and often unmeaning way, he departs from the natural order, by placing the Testacea below the insects, so that the Crustacea come next to the bony fishes." Latreille, Consid. gen., pp. 18, 19, 1810. Compare note on Brisson, 1756, in regard to the question of priority, since in regard to arrangement the classifications by Brisson and Berkhey seem to have been practically the same.

1786. MOHR, NICOLAS.

Forsøg til en Islandsk Naturhistorie, med adskillige økonomiske samt andre Anmærkninger. Kjøbenhavn, 1786.

Among the Apterous Insects he gives, on page 107, "243, *Cancer pulex* (Faun. Svec. 2041). Marflo," which, he says, is not only in very great numbers on the strand, but also out in deeper water, where it does great damage, as well to the nets as to what is caught in them. He thinks that it would be difficult to get a sufficient supply of horse-hair for making the under part of the nets, which was the preventive believed in against these predators.

For "244, *Cancer medusarum*," he refers to "Strøm's Søndm. Beskr. 188, Tab. 1, fig. 12, 13," and considers that the description and figures given by Strøm are very accurate, he himself having had the opportunity of comparing them with specimens taken from *Medusa aurita*.

246 is given as "Cancer macrourus articularis manibus adactylis femoribus posticis orbicularibus spinis caudae bifidis (Act. Soc. Sc. Hafn. 9, D. 588, Tab. viii.), Ogn, Aat." It is like a little Marflue, but nearly white, with red eyes, and is much fatter, though smaller than the Marflue. Another species, like it, but much larger, is called by the inhabitants, Grønlands-Ogn, the presence of which indicated the speedy arrival of fish and whales. 247 is "*Cancer filiformis* (Syst. Nat. 1056), *Sqvilla lobata* (Müll. Prodr. Zool. Dan. 2359)."

The Latin description of 246 relates to Strøm's *Orchestia*, 1765, whereas Mohr's own account of it probably refers to some species of *Anonyx*, at any rate not to an *Orchestia*. 247 is identified by Boeck with *Caprella septentrionalis*, Krøyer, but for this identification there seems to be no adequate ground. Mohr's own references have to do with *Caprella linearis*, Liun.

1787. FABRICIUS, J. C.

Mantissa Insectorum sistens eorum species nuper detectas adjectis characteribus genericis, differentiis specificis, emendationibus, observationibus. Tom. I. Hafniæ MDCCCLXXXVII.

The Agonata here comprise seven genera, *Cancer*, *Pagurus*, *Hippa*, *Scyllarus*, *Astacus*, *Squilla*, *Gammarus*. *Gammarus* contains the same list of species as in the Species Insectorum of 1781, with the addition of *Gammarus gibbosus*. The reference to its synonym *Oniscus gibbosus* in the earlier work is misprinted 577 for 377. *Cancer linearis*, Pennant, is given as a synonym of *Gammarus longicornis*. *Oniscus bicaudatus* is retained among the Synistata, where also *Cyamus* is still represented by *Oniscus ceti*.

1788. MÜLLER, OTHO FRIDERICUS (Otto Friedrich), born 1730, died 1784 (Hagen).

Zoologica Danica seu Animalium Daniae et Norvegiae rariorum ac minus notorum Descriptiones et Historia. Volumen secundum explicationi iconum fasciculi secundi ejusdem operis inserviens. Ad formam tabularum denuo edidit frater auctoris. Havniae, MDCCCLXXXVIII.

On pp. 20–21 is described *Squilla ventricosa*, “*Squilla rubra* deppressa, pedibus quatuordeem setaceis secundo pari clavato. Zool. D. pr. 2360.” On pl. lvi. this is figured together with *Squilla quadrilobata*. For the latter, on pp. 21–22, references are given to “Zool. D. pr. 2359.” “Faun. groenl. 225.” “Act. helv. 5. p. 368.” “Cancer atomos, Linn. Syst. p. 1526.” “Brit. Zool. 4, p. 17 f. 32.” “Baster subsecis, i. t. 4 f. 2.” “Oniseus Scolopendroides, Pall. specil. 9. p. 78.” The description is followed by these remarks: “Descriptio Caneri linearis et filiformis Linneani, synonymonque a Martens petitum nostræ Squillæ æque convenienti, at citata BASTERI figura Cancerum atomum esse jubet; in aquis dulcibus fluctuantibus habitare hallucinatione dictum est; cur in fluctuantibus non percipio. Cauda in figura Basteri certe errore delineata Linneum, ut has species cauda prorsus carentes macrouras seu longieudas dieeret, seduxit. Exactissimam clariss. viri PALLAS, GRONOVIA et OTHO FABRICIUS descriptionem dedere; ille a Cancer jure semovens Onisco junxit, hie meeum Squillæ vindicavit. GRONOVIA his insectis olim Squillæ, LINNÆUS dein Cancer, PALLAS Onisci nomen constituerant: minus bene igitur in systemate entomologiae novum Gammari nomen et quidem inseeti maximi valde minutis effictum est. Vesiculos GRONOVIA pedes, pedum vicarias claris. PALLAS quidem nominant, at nec pedes sunt, nec horum vices gerunt. Animal Zeylonicum G. de Riville in Mem. de Mathem. et Physique vol. 3 et Berl. Samml. vol. 9. p. 42, t. 1, f. 6 nostram vesieulis orbata sestit.” Müller’s indignation at seeing the name *Gammarus*, which belonged specifically to that “very large insect,” the common lobster, applied to a genus of “very minute” shrimps, does not appear wholly unreasonable. But if Fabricius committed an error of judgment in this respect, it is too late now to correct it.

1788. LINNÆUS. GMELIN, JOHANN FRIEDRICH, born 1748, died 1804 (Hagen).

Systema Naturæ, editio decima tertia, aucta, reformata, cura Jo. Frid. Gmelin. Lipsiæ, 1788.

In this edition the Insecta Aptera are to be found at the end of “Tom. I. Pars. V.” On page 2963, to the definition of *Cancer* is added, *Palpi* sex inæquaes, *Mandibula* cornea, erassa,

Labium triplex. Under this extensive genus "Cancer," in the groups of species corresponding to the "Astaci Fabricii," is given, "*homari*. 155," with references to Fabricius, Müller, and Stroem, and the observation "Habitat in Oceano norwegico, *minutus*" (p. 2987). The epithet *minutus* would be inapplicable to *Amathilla sabini* as an Amphipod, but would very well apply to it when grouped among the *Astaci*. It gives, therefore, an additional reason for supposing that *Astacus homari* was originally misplaced. See the note on Fabricius, 1779 and 1798. Under the same genus "Cancer," the group of species headed "*anlennis pedunculatis simplicissimis*, Gammari Fabricii," (p. 2991), includes, with the addition of *atomos* and *filiformis*, the same list as that given for *Gammarus* by Fabricius in his *Mantissa*, 1787. The Linnean name *grossipes* is reinstated for the species *Gammarus longicornis*. For "Cancer Pulex," besides the references in Fabricius, Spec. Ins., the following are given "Geoffr. ins. par. 2. p. 667. t. 21. f. 7. Cœdm. nov. act. Stockh. 1782. II. 9. *Hablibz ap. Pall. n. nord. Beytr.* 4. p. 396. *Habitat frequentissimus ad Oceani littora, etiam in fontibus, fossis, lacubus adeo Sibirix salsis, dorso innatans, saliens, in piscium branchiis ulcera excitando piscibus, et invisis retia destruendo piscatoribus infestus, a recurvirostra comedens, noctu lucens.*" After *Cancer linearis*. 83., is given "Atomos, 84. C. linearis, manibus adactylis, pedibus undecim. Brit. zool. 4. t. 12. f. 32. *Habitat in Europæ aquis fluctuantibus dulcibus, nudo oculo vix visibilis, an vere a linearis distinclus?*" and "filiformis. 85. C. linearis, pedibus decem, mediis majoribus. Amœn. acad. 6. p. 415. n. 99. *Habitat in Malacca, pollicis longitudine, debilis.*" For *Cancer medusarum* reference is made to "Fabr. sp. ins. 1. p. 378. n. 16. *Oniscus (quadricornis) oblongus, stylis caudalibus senis, antennis quaternis,*" as well as to "Fabr. sp. ins. 1 p. 518. n. 12. *mant. ins. 1. p. 335. n. 13. Müll. zool. dan. prodr. 2355.*" and "Stroem sundm. 118. t. 1. f. 12. 13. *Pulex cancriformis.*"

The genus *Oniscus* contains the Amphipod, *Oniscus ceti*, 6. with references to Linnaeus, Fabricius, Degeer, Martens, Seba, Pallas, Egede, and the remark, "Habitat in Oceano boreali, balanis molestus, an hujus generis?" p. 3011. It contains also Lepeschin's two Amphipod species, *Oniscus aculeatus*, 26. p. 3013, and *Oniscus cuspidatus*, 28. p. 3014, and concludes with the following notices, of which the first, not being an Amphipod, is only here inserted for the sake of comparison with Turton's Linnaeus:—

- "fuscus. 32. O. fuscus, crusta carinata, macula thoracis alba. Müll. zool. dan. prodr. 2376. *Habitat in Dania.*
- "Medusarum. 33. O. compressiusculus, fronte obtusa, antenuis brevissimis nutantibus, manibus quatuor compresso-incisis. Fabr. fn. groenl. p. 257. n. 232. Müll. prodr. zool. dan. 2355. Stroem sundm. 1. p. 188. t. 1. f. 12. 13. *Cancer medusarum.*
- "*Habitat sub medullæ capillatae folimentiis, 10 lineas longa.*
- "Cicada. 34. O. compressus sublinearis, manibus quatror spinris, antennis summis brevioribus, caudæ dorso laevi. O. Fabr. fn. groenl. p. 258. n. 233. *Habitat in mari Groenlandiam alluente, polissimum ad oslia rivorum, 5 lineas longus.*
- "arenarius. 35. O. anterius depressiusculus, posterius carinato-subserratus, pedibus quatuor anterioribus cheliformibus laevibus, antennis subæqualibus. O. Fabr. fn. groenl. p. 259. n. 234. Müll. zool. dan. prodr. 2358. Stroem act. Hafn. 10. t. 2. f. 1-8.
- "*Habitat in Groenlandiæ littoribus arenosis, supra ulvam umbilicalem, cum 2 præcedentibus et 3 insequentibus canceris, præsertim pulici affinis.*
- "Stroemianus. 36. O. compressus, pedibus quatuor anterioribus cheliformibus subdentatis, antennis summis brevissimis. O. Fabr. fn. groenl. p. 261. n. 235. Müll. zool. dan. prodr. 2357. Stroem act. Hafn. 6. p. 588. t. 8. *Habitat ad Groenlandiæ littora, violaceus.*
- "abyssinus. 36. O. subcylindricus, pedibus quatuor anterioribus cheliformibus unidentatis, antennis subæqualibus setiferis margine baseos interiore serratis. O. Fabr. fn. groenl. p. 261, n. 236.

"Habitat in fundo maris Groenlandiam alluentis, supra ulvas marinas, minimus, vix 4 lineas longus.

"serratus. 38. O ventricosus supra carinato serratus, rostro corniformi deflexo, manibus duabus spinis; antennis summis longioribus. *O. Fabr. fn. groenl. p. 262. n. 237.*

"Habitat in profundis maris Groenlandiam alluentis, ex albo crocoque fasciatus, egregie in aqua sultans, saepius pronus natans, pedes, antennas, caudamque sub abdomine condens."

In the foregoing list *Oniscus ceti*, as Lütken points out, is no longer confused with *Pycnogonum*.

On the other hand *Cancer "medusarum"* and *Oniscus "Medusarum"* are curiously entangled. Although they are retained in different genera, the same references to Müller and Ström are given for both, except that in regard to Ström, by an obvious slip, "p. 118" appears in one reference and "p. 188" in the other. At the same time, to the second of these references the words "Cancer medusarum" are added, probably to warn the reader that if the last six species of *Oniscus*, praesertim pulici affines, should be transferred to the *Gammarus*-group, *Oniseus Medusarum* would then become one with *Cancer medusarum*. Bovallius now distinguishes them by calling the *Oniscus* in question "*Hyperia Kroeyeri*," while the *Cancer* is named *Hyperia medusarum*, O. F. Müller.

1789. RÖMER, JOHANN JACOB, born 1761, died 1819 (Hagen).

Genera Insectorum Linnaei et Fabricii iconibus illustrata a Johanne Jacobo Roemer. Vitoduri Helvetorum, MDCCCLXXXIX.

In the Systema Linnaei here given the Aptera are on pages 32–36, not including any Amphipoda.

In the Systema Fabricii, the Agonata, pages 61–63, include "137, GAMMARUS, antennæ quatuor simplicissimæ pedunculatæ: anticae breves subulatae: posticæ setaceæ. *Longicornis*, FABR. Sp. Ins. I. p. 516, n. 4. Manibus adactylis, antennæ corpore longioribus, cauda obtusa. Tab. xxxiii. f. 6. Habitat in Europæ oceano." This is *Corophium volutator*, Pall. The Antiata, pages 82–86, include "193, PYCNOGONUM, *Haustellum* tubulosum, eonicum, absque setis, *Palpi duo* ad basin haustelli. *Balænarum*, FABR. S. Ent. 810, 35. Sp. Ins. II. p. 475, n. 1. *Phalangium LINN.* *Pediculus* FABR, in Syst. Palpis duobus, corpore ovato. Tab. xxxvi. f. 17. Habitat in Occano Norwagico." The figure is obviously borrowed from Brünnich, although that author is not mentioned. In the figures of *Cyamus* by Martens, Egede and Adelung, the head is represented pointing downwards, as though the artists did not know which was the head and which was the tail, since the general rule in older, as well as in recent, times is to give vertical figures with the heads uppermost. Brünnich figures his *Pycnogonum* head downwards, perhaps for purposes of comparison with the old figures of *Cyamus*, since he at any rate well knew the structure of the creature he was drawing.

1789. MÜLLER, OTHO FRIDERICUS. ABILDGAARD, PETER CHRISTIAN, born about 1740, died 1808 (Nouvelle Biographie générale).

Zoologia Daniea seu Animalium Daniae et Norvegiae rariorum ac minus notorum Descriptiones et Historia. Volumen tertium explicationi iconum faseieuli tertii ejusdem operis inserviens. Auctore Othono Friderico Müller. Descripsit et Tabulas addidit Petrus Christianus Abildgaard. Havniæ, MDCCCLXXXIX.

He figures, pl. ci., and on pp. 33–34 describes, *Gammarus pedatus*, "GAMMARUS linearis corpore articulis sex, pedibus quatuordecim unguiculatis ultimis quatuor longioribus, cauda nulla

distincta," referring to " *Squilla acaudata pedibus quatuordecim* GRONOVIVS *in Actis Helv.* 4, p. 39, t. 4, figs. 8, 9?" and " *Cancer linearis*, LINN. *Syst. nat.* p. 1056, n. 83?" To the fuller description he appends the observation, " Ad genus Gammarorum Celeb. J. C. FABRICII hoc insectum refero, quia primus certis caracteribus cancerorum familiam ab oniscis distinxit; proprium tamen genus cum *Squilla quadrilobata* et *ventricosa* MÜLLERI, quibus cauda nulla et pedes omnes unguiculati constituere videtur." It is now recognised as *Proto ventricosa*, O. F. M. On pl. cxiv., figs. 11, 12, and p. 58, he figures and describes *Gammarus quadrilobatus* ♀, with references to " *Squilla lobata*, Zool. Dan. prodr. n. 2359." " FABRICII Faun. Groenl. n. 225." " *Squilla quadrilobata*, Zool. Dan. fasc. 2, p. 21, tab. 56, fig. 4-6." On pl. cxvi, figs. 1-6, and p. 59, *Gammarus podurus* is given, considered by Milne-Edwards to be an *Amphithoë*, by Spence Bate a *Pherusa*, by Boeck with more probability an undoubted *Gammarus*. It has a red spot on each of the seventh, eighth, ninth, and tenth segments. Dorsal spines are shown on the penultimate and antepenultimate segments. *Gammarus mutilus*, figured on pl. cxvi., figs. 1-11, described on p. 60, in Boeck's opinion is like but not the same as *Gammarus locusta*. Milne-Edwards compares it with his *Gammarus savii* (called *Mæra savii* by Spence Bate), but thinks it distinguished by the long accessory flagellum, the narrow first joint of the hind legs, and the large rami of the last uropods. He says, Hist. des Crust., iii. 53 n., " La première figure représentant cette crevette de grandeur naturelle est très-mauvaise, et a été reproduite dans l'Encyclopédie, Pl. 336, fig. 43 ; mais les autres, qui peuvent réellement être très-utiles pour la détermination de l'espèce, n'ont pas été données dans cet ouvrage." The name *mutilus* is itself not very easy to understand. It agrees, indeed, very well with the fig. 1 which Milne-Edwards censures, for in that the animal abruptly ends with the third pleon-segment. It might have been suggested that the other three segments were accidentally missing, but that Abildgaard has carefully figured the first, second, and third uropods. In the enlarged figure of the antennæ, the flagella of the upper and lower are drawn as equal in length, and the accessory flagellum has about four and twenty joints. If this figure can be trusted, it should be of essential service for determining this still doubtful species. There are dorsal spines or teeth on the hind margins of the last segment of the pereion and the first three of the pleon, which constitute an additional mark of distinction between this species and *Mæra savii*. *Gammarus spinicarpus*, pl. cxix., figs. 1-4, pp. 66-67, is known now as *Leucothoë spinicarpa*. *Oniscus ceti*, pl. cxix., figs. 13-17, pp. 69-70, with references to numerous authors and the synonyms " *Oniscus Ceti*, LINN.," " *Pediculus Ceti*, MARTENS," " *Squilla Balænæ*, DEGEER," corresponds with *Cyamus nodosus*, Ltk., according to Lütken, the synonymy being erroneous.

1791. OLIVIER, ANTOINE GUILLAUME, born 1756, died 1814 (Hagen).

Histoire Naturelle. Insectes. Par M. Olivier. Tome sixième. A Paris, M.DCC.XCI. Encyclopédie méthodique, ou par ordre de matières ; par une société de gens de lettres, de savans et d'artistes.

The article Crevette extends from page 182 to page 190. The genus is thus defined :—
 " CREVETTE. *Gammarus*, Fab. *Cancer*. Lin. *Geoff.* *Squilla*, Deg. Caractères génériques. Quatre antennes setacées, plus courtes que le corps ; les deux inférieures plus longues que les deux supérieures. Bouche formée d'une lèvre supérieure, de deux mandibules, de deux mâchoires divisées, d'une lèvre inférieure très-avancée, et de huit antennules courtes. Yeux immobiles, point du tout saillants. Pattes ordinairement au nombre de quatorze."

After describing the upper lip and mandibles he says, p. 182, "les pièces qui se trouvent au dessous, et que M. Fabricius a pris pour une lèvre inférieure, me paroissent devoir être

regardées comme des mâchoires. Elles sont au nombre de six, trois de chaque côté. Elles sont larges, aplatis, un peu ciliées à leur extrémité interne.

“La lèvre inférieure qui se trouve en-dessous, est longue, recourbée, et couvre presque toute la bouche. Elle est membraneuse, échancrée, et terminée par deux petites antennules.

“Les antennules sont au nombre de huit ; elles sont courtes, presque setacées, et composées de trois ou quatre articles peu distincts. Les deux antérieures sont inserées au dos des mandibules. Les quatre qui suivent, ont leur attache au dos des mâchoires, et les deux dernières sont placées à l'extrémité de la lèvre inférieure.”

The species are given as follows :—“1. Crevette ampoule, *Gammarus ampulla*; 2. C. folâtre, *G. nugax*; 3. C. eanelle, *G. cancellus*; 4. C. longicorne, *G. longicornis*; 5. C. santeuse, *G. locusta*; 6. C. gammarelle, *G. gammarellus*; 7. C. des ruisseaux, *G. pulex*; 8. C. cornue, *G. corniger*; 9. C. linéaire, *G. linearis*; 10. C. saline, *G. salinus*; 11. C. filiforme, *G. filiformis*; 12. C. maréeageuse, *G. stagnalis*; 13. C. bossue, *G. gibbosus*; 14. C. appât, *G. esca*; 15. C. des méduses, *G. medusarum*;” all of which have been already discussed.

Some of the subsidiary observations show that the author was not fully aware of the distinction between the Orchestidæ and the Gammaridæ, nor is any special criticism exercised upon the synonymy. Faxon, Bibl. Embryol. 1882, calls attention to his “observations on young *Gammarus*, p. 183.”

1791. WULFEN, FRANZ XAVIER L. BARON VON, died 1805 (Hagen).

Dn. FRANCISCI XAVERII L. B. DE WULFEN *Descriptiones Zoologicae Ad Adriatici littora maris concinnatae*. Nova acta physico-medica Academiæ Caesareæ Leopoldino-carolinæ naturæ curiosorum exhibentia Ephemerides sive observationes historias et experimenta a celeberrimis Germaniæ et exterarum regionum Viris habita et communicata singulari studio collecta. Tomus Octavus. Norimbergæ, Anno MDCCCLXCI. (“Præfatio” dated XXII. Jul. MDCCCLXXXI.). pp. 235–359.

From the subjoined account of “*Cancer Pulex*,” it would seem that this author has carried to the highest point the confusion of species under this title, which to his apprehension probably included almost all the Gammarina. At page 312, he gives :—

“52. *Cancer Pulex*.

“*Cancer macrourus incurvus articularis compressus*; pedibus quatuordecim; antieis duorum parium subcheliformibus, retractili-uncinatis; stylis caudæ bifurcis trium parium.

“*Cancer macrourus articularis*, manibus quatuor adactylis, pedibus decem. *Linn*, Syst. N. T. I. P. 2. p. 1055. N. 81. *Rösel*, Ins. 3. Supl. Tab. 62. *Baster*. Subs. II. p. 31. Tab. 3. fig. 7. *Geogr. Ins.* II. p. 667. N. 2. Tab. 21. fig. 6. *Frisch*. Ins. T. 7. p. 26. Tab. 18. fig. 1. *Scopol. Ent.* N. 1137.

“*Squilla Pulex*. *De Geer*. Ins. 7. p. 193. N. 4. Tab. 33.

“*Oniseus Pulex*. *Fabric*. Faun. Groenl. p. 254. N. 231.

“*Caneer Locusta*. *Linn*, Syst. N. T. I. P. 2. p. 1055. N. 82. *Scopol. Entom.* p. 411. N. 1136.

“*Vulgatissimus ad maris littora sub lapidibus*; adhærens etiam passim Fucis Ulvis Spongiis. In dulcibus item fluviorum lacuum stagnorum aquis frequentissimus. Non differt *Cancer Linnaei Scopoliique Locusta*, ab eorumdem *Cancro Pulice* specific. Magnitudine, colore, etc. variat admodum. Vidi aquose virentem, excolorem alias, et transparentem, nunc album, jam et aquose fuscescentem, subnigricantem interdum etiam; communiter aquose grisescit; exsiccatione plus minus flavens semper. Nunc non nisi tres quatuorve lineas est longus; alias octo, deceunve, pollicaris reperitur etiam, ac eum proportione magis, minusve corpulentus. Bini quoque extimi caudæ styli longiores quandoque, alias contra adeo parvi, ut vixdum liberis

videantur oculis, et duo tantum eorumdem paria, pro tribus, adesse credantur. Ex quo forsitan præcipua Locustam inter et Pulicem desumpta fuerit diversitas? Corpus anomalo huic Cancro est oblongum, semitereti-compressum, lunato-incurvum, nudum, lœve, nitens, semi-diaphanum, articulare; constans capite absque thorace, tum suturis quatuordecim, utrinque ad latera deflexis; quarum anteriores, septem abdominalis, longius tantisper utrinque procurrentes, marginibus lateralibus rotundatae; posteriores septem caudæ, magis, magisque attenuatae, caudam formant longiusculam, incurvam, apice acutiusculam, sursumque subre-curvam; dorso cæterum, longitudinaliter convexum sed teretiusculum est corpus, subtus concavo-canaliculatum. Caput inflexum, oblongum, declive, fronte longitudinaliter convexa, compressum, os versus obtusum, nec rostratum; oculis binis, oblongo-ovalibus, atris, nitentibus, ad summa capitum latera, inter superiores, et inferiores postice antennas, sitis. Antennæ duorum parium, seu quatuor, ex summo frontis vertice, antrorsum porrectæ et incurvæ, setaceæ, paribus approximatis; singulis quadriarticulatis; superiores longiores, tertiae parti corporis subæquales; articulis tribus inferioribus crassioribus, teretibus, inæqualiter oblongis, ramulo laterali mouiliformi-setaceo ad apicem appendiculatis; articulo extimo reliquis omnibus longiore moniliformi-setaceo, ciliis adperso. Inferiores breviores, non nihil superioribus crassiores, iis cætera simillimæ, dempto ramulo laterali. Os inforcum, maxillo-sdentatum. Palpi duo, os versus porrecti, articulati, apice nuncinati. Pedes quatuordecim, utrinque septem, sub suturis abdominalibus, quorum quatuor antica paria antrorsum, tria vero postica, eaque longiora, retrorsum versa. Prima omnium duo paria brevissima, quadri-articulata, articulo extimo subcheliformi, tumidiusculo, ovato, extrorsum compresso, apice ungue hamato-uncinato retractili armato; binis insequentibus paribus sexarticulatis, articulis oblongis, inæqualibus, extimo in nnguem subulatum abeunte. Tribus denique posticis paribus, et ipsis sexarticulatis, articulis oblongis, tereti-compressis, fenoribus solis iucrassatis, ovato-oblongis; ungue extimi subulato. Pedes omnes per latera ciliati. Suturæ tres caudæ anteriores singulæ subtus pari pinicularum pediformium, tcretiu, scimbifidaru, brevium instructæ; extimæ contra itidem tres, et ipsæ quoque ad lateralem utrinque marginem pinnula pediformi natatoria terete bifurca longiuscula retrorsum versa, et velut adscedente, ciliisque adspersa, instructæ."

The above carefully detailed account probably refers to *Gammarus pulex* alone, without taking any notice of the other Amphipoda, differing in colour, size, and shape of tail which Wulffen supposed to be merely varieties of it. The Crustacean which he next describes, he calls "*Cancer Locusta*," the largest of all the *Cancri* he had ever seen, and a specimen of which had cost him two florins in the market of Trieste. He thought Linnaeus unlucky in having attributed the name *Locusta* "non tam peculiaris Cancri alicujus speciei, quam exiguae verius Cancri Pulicis varietati."

1792. OLIVI, GIUSEPPE, born 1769, died 1795.

Zoologia Adriatica ossia Catalogo ragionato degli Animali del Golfo e delle Lagune di Venezia; preceduto da una Dissertazione sulla Storia fisica e naturale del Golfo; e accompagnato da Memorie, ed Osservazioni di Fisica Storia naturale ed Economia. Bassano, MDCCXCII.

The Insecta Aptera of the genus *Cancer* are discussed on pages 41-61. Only two Amphipods are spoken of, one under the title *Cancer "Locusta, Linn. sp. 82,"* the other *Cancer "linearis, Linn. sp. 83."* Of "*C. Locusta*" he says "this is the only species of *Gamberi* or *Squille* indigenous to the Terme Aponesi," and infers therefore that it must be the species inaccurately described and obscurely figured by Sig. Vaudelli in the first of his

three dissertations "De Apon. Thermis Patav. 1758." G. D. Nardo, 1869, explains it by "Orchestia littorea," a designation which he also applies to the *Cancer locusta*, L., of Chiereghin, but the figure which he gives of that species shows that the doubts which he expresses about it are well founded, since it is certainly not an *Orchestia*. Olivi is not sure of the specific determination of the little marine animals which he had found akin to *Cancer linearis*, but he takes the opportunity of stigmatising the method of Linnæus as artificial, better suited to facilitate the knowledge of the student, than to show the progression of nature. Hence in the present instance he approves the separation of these insects from the other *Cranchj*, either as was done by Pallas in a separate order of *Onischi cancriformi*, or as by more recent naturalists in a genus expressly instituted, which he thinks still more convenient.

1793. FABRICIUS, J. C.

Entomologia Systematica emendata et aucta. Secundum Classes, Ordines, Genera, Species adjeetis synonymis, locis, observationibus, descriptionibus. Tom. II. Hafniae. MDCCXCIII.

The Agonata are here the eighth class, with eleven genera, *Limulus*, *Monoculus*, *Cymothoa*, *Cancer*, *Pagurus*, *Scyllarus*, *Hippa*, *Galathea*, *Astacus*, *Squilla*, *Gammarus*. *Gammarus* has fourteen species, *Gammarus carinatus* being now included, of which the present name is *Atylus carinatus*. The account of *Gammarus gibbosus* does not vary from that which Fabricius gave of the same species in 1775, under the name *Oniscus gibbosus*. It belongs to the Hyperina, possibly Boeck suggests, to *Amphipronoë*, Sp. Bate, a genus which Claus, 1879, though with much hesitation, supposes to be perhaps the same as his own *Parapronoë*. Opposed to Boeck's suggestion are the facts that in *Amphipronoë* and *Parapronoë* the pereon is not especially gibbous, its first segment is not very short, and the pleon has five distinct segments besides the telson, with which the fifth and sixth are not coalesced as in *Dithyrus* or *Hemityphis*. To *Cymothoa*, a new genus among the Agonata, Fabricius in this work refers "*Oniscus ceti*, Mant. Linn. p. 509." The genera *Oniscus*, *Scolopendra* and *Julus* form the class Mitosata. For "*Astacus Homari*" of this work, see notes on Herbst, "58," and on the Supplementum Ent. Syst. 1798.

1796. HERBST, JOHANN FRIEDRICH WILHELM, born 1743, died 1807 (Hagen).

Versuch einer Naturgeschichte der Krabben und Krebse nebst einer systematischen Beschreibung ihrer verschiedenen Arten. Zweyter Band mit xxv Kupfer-Tafeln und Register. Krebse. Berlin und Stralsund, 1796.

In this volume, pages 2, 3, Herbst quotes the definitions given by Fabricius in his *Mantissa* of *Cancer*, *Gammarus*, and the intermediate genera, and rejects them on the ground that they draw marks of distinction only from the antennæ. He himself makes six divisions of Crustacea (das ganze Krebsgeschlecht), the sixth of these divisions being the *Garnelasseln*, with the definition "diese haben mehr als acht Füsse, und oft gar keine Scheeren."

On page 105 the Garnelasseln are also called "*Onisci gammarelli*," the name given by Pallas. Of these he forms two families, the first "mit ungetheiltem Brustschild" containing no Amphipods, unless, as seems most probable, *Amathilla sabini*, Leach, be in reality the

subject of No. 58, which Herbst, combining scraps of information after his usual method, thus describes:—

- “ 58. Der Hummeraat. Cancer (*Gammarellus*) *homari*.
- “ *Fabric. Spec. Ins.* 511. 7. Astac. antennis posticis bifidis, corporis segmentis dorso subspinosis, cauda fasciculata, stylis serratis. *It. Norwag. Mant.* I. 332. 9. *Fig. 1-8.*
- “ *Ström Acta Hafn.* 10. *pay. 5. Tab. 2.* Cancer dorso carinato serrato.
- “ *Müller Zool. Dan.* 197. 2358. C. macrourus articularis, dorso carinato serrato, spinis caudæ bifidis.
- “ *Grönl. Arksegiansoak.*
- “ Bey diesem Krebse haben die Abschnitte des Schwanzes auf dem Rücken einige schwache Dornen, auch ist er kielförmig erhöhet; Am Ende stehen Büschel und gespaltene Dornen. Die hintern Fühlhörner sind doppelt. Man findet ihn im Norwegischen Meere.” In this passage, “ Fig. 1-8,” attributed to the *Mantissa* of Fabricius, no doubt properly belongs to the next reference, as given where that reference is repeated under “ Cancer (*Gammarellus*) *arenarius*.”

The second family of Garneelasseln “ haben einen aus mehreren Gliedern bestehenden Brustschild, grösstentheils festzitzende Augen und 7 Paar Füsse.” These appear in the Table of Contents as “ Zweyte Familie, mit gegliedertem Rückenschild,” the generic name *Cancer* being in that table applied to all the species not only of this but of all the other divisions. Pages 116-146 contain the “ Garueelasseln mit getheiltem oder gegliedertem Rückenschild,” as follows:—

- “ 61. Der Flaschenkrebs. Cancer (*Gammarellus*) *ampulla*,” Phipps.
- “ 62. Der Sonderling. Cancer (*Gammarellus*) *nugax*,” Phipps.
- “ 63. Der Pfützenkrebs. Cancer (*Gammarellus*) *paludosus*,” O. Müller; not an Amphipod.
- “ 64. Der Poduruskrebs. Cancer (*Gammarellus*) *podurus*,” Müller. See *Abildgaard*, 1789.
- “ 65. Der Verstümmelte. Cancer (*Gammarellus*) *mutilus*,” Müller. See *Abildgaard*, 1789.
- “ 66. Der Sumpfkrebs. Cancer (*Gammarellus*) *stagnalis*,” Linn. *Syst. Nat.* 87; not an Amphipod
- “ 67. Der Dickfuss. Cancer (*Gammarellus*) *grossipes*,” with references “ to *Lin. Syst. Nat.* 80. Astac. *muticus*,” &c.; “ *Fabric. Spec. Ins.* 816. 4. *Gamma. longicornis.* Iter Norweg. 258.” *Mantiss. I. 334. n. 4.* “ *Gronov. Zooph.* 989. tab. 17. fig. 7.” “ *Pallas Spicileg. Zool. Fasc.* 9. 59. tab. 4 fig. 9. *Oniscus volutator*;” “ *Pantopp. It. T. 2 p. 334*, Räger, Hopper;” and “ *Fabric. Gen. Ins. Append. Gammarus crassipes*.” *Pantopp.* is for Pontoppidan.
- “ 68. Das Krebschen. Cancer (*Gammarellus*) *cancellus*,” with the references “ *Fabric. Spec. Ins.* 510. 3. *Gamma. manibus quatuor monodactylis, pedibus sedecim.* *Mant. I. 334. n. 3,*” and “ *Pallas Spicileg. Zool. Fasc.* 9. 53. tab. 3. fig. 15, *Oniscus cancellus*; und in der deutschen Uebersetzung *Oniscus muricatus*.” Steller, he says, calls this Siberian fresh-water species “ *Squilla fluvialis* or *phryganea fluvii Angara*.” Dybowsky, in 1874, mentions that the form from the river Angara differs from that out of Lake Baikal by having shorter upper antennæ and the lateral spines on the fifth segment of the trunk less developed.
- “ 69. Die Heuschreckengarnäle. Cancer (*Gammarellus*) *locusta*,” with references to “ *Fabric. Spec. Ins.* 516. 5;” “ *Mant. I. 334, 5;*” “ *Pallas Spicileg. Zool.* 9. 56. tab. 4. fig. 7;” “ *Gesner aquatil. 894.*” Upon this species he remarks: “ This kind (Gattung) is Bellon’s, Mouffet’s and Gesner’s sea-flea, in *Ray. hist. Ins.* 43, and is reckoned by Linnaeus’s *Syst. Nat.* he has attempted to distinguish the two kinds by the number of the feet, and to the species which he calls *locusta* he attributes, including the four gnathopods (Fangfüsse), eighteen feet, a number due probably to some mistake, and thus far not discovered to exist in any single related genus. Still more incorrect are the citations of authors under the same heading of *locusta*; for Rösel’s figure T. 3 Tab. 62, here cited, obviously represents C. *pulex*, as also

Frisch. 7. Tab. 18; indeed, in the twelfth edition Rösel's figure is actually referred to two species, to locusta and to pulex, and yet it can only represent one species; as also the figure referred to in Sulzer's Kennz. Tab. 23. Fig. 152. represents Rösel's C. pulex. Klein's bad description and figure in his Dub. circa Lin. class. quadr. et amphib. p. 36. tab. fig. δ. ε. ζ. might appear doubtful, but because in the Baltic (Ostsee) only *pulex* but not *locusta* is commonly noticed, Klein's figure will have to be referred to *pulex*, as well as that in *Klein hist. pisc. Miss. V.* p. 9. tab. 4. A. B. C. Consequently not one of Linnæus's references is left for *locusta*; he must therefore either have taken the larger Pulex-species occurring in the Baltic (in der See) for *Locusta*, or have intended a quite unknown *Locusta*. I therefore here describe under the name *Locusta* not Linnæus's, but the species found in Pallas Spicileg. Zool. Fasc. 9, and really distinct from *C. pulex*; of which no author makes mention unless it be *Ray. hist. ins.* p. 44; who distinguishes a sea-water flea from that in fresh water, and refers to a figure in *Dodonæus pemptad.* p. 4, 76." The species here discussed is now known as *Talitrus locusta*, Pallas. *Ray's Dodonæus* should be *Dodonæus*, i.e., Rembert Dodoens.

- "70. Die Gammarelle. *Cancer gammarellus*," with references to Pallas, Gronovius, Baster, and Scopoli. This is the *Oniscus gammarellus* of Pallas, now known as *Orchestia gammarellus*. Herbst gives Pallas the credit of having distinguished it from *Cancer pulex*, and it will be noticed that he omits the generic (*Gammarellus*), perhaps not knowing exactly what to do with a generic name the same as the specific.
- "71. Der Seefloh. *Cancer (Gammarellus) pulex*," with references to fifteen authors and eighteen different works, beginning with "*Lin. Syst. Nat. 81*," and ending with "*Scopol. Ent. Carn. 1137*." He ends his description by saying, "whether the *Cancer pulex* of Linné be the same as *C. pulex* of *Scopoli*, may rightly be doubted, since the latter lives always in fresh water." Herbst borrows his figure from Rösel, but neither makes his description tally with the figure, nor takes notice of the differences.
- "72. Die Sandgarneele. *Cancer (Gammarellus) arenarius*," with references to "*Ott. Fabric. Fauna Grönl. 259. n. 234*," and "*Acta Hafn. X. 5 tab. 2. fig. 1-8*," which is perhaps *Amathilla homari*, J. C. Fabr.
- "73. Das Dickhorn. *Cancer (Gammarellus) crassicornis*. *Fabric. Syst. Ent. 415. 7. Spec. Ins. 511. 9.* Ast. antennis posticis bifidis, thorace articulato, pedibus sexti paris longissimis. *Mant. 1. 332. 11. Mus. Banks.*" This is, apparently, not an Amphipod, unless it be one of the Hyperina in disguise.
- "74. Die Strömische Garueelassel. *Cancer (Gammarellus) strömianus*. *Ott. Fabric. Fauna Grönl. 261. n. 235.*
- "75. Die Dornhand. *Cancer (Gammarellus) spinicarpus*, with a reference to "*O. Müller Zool. Dan. p. 66. tab. 119. fig. 1-4.* *Gammarus brachiis quatuor chelatis, in spinam productis*," this being the *Gammarus spinicarpus* of Abildgaard in the third volume of the Zool. Dan.
- "76. Der Mönch. *Cancer (Gammarellus) sedentarius*, Forskål.
- "77. Die Cicadengarneele. *Cancer (Gammarellus) cicada*. *Ott. Fabric. Faun. Grönl. 258. n. 233.*
- "78. Der Sägerücken. *Cancer (Gammarellus) serratus*. *Ott. Fabric. Faun. Grönl. 262. n. 237.*
- "79. Die Medusenassel. *Cancer (Gammarellus) medusarum*," with references to J. C. Fabricius Ström, O. F. Müller, Otto Fabricius, and Bomare, v. 235. He here therefore combines the species now named respectively *Hyperia medusarum*, O. F. Müller, and *Hyperia kroeyeri*, Bovallius.
- "80. Der Hornträger. *Caeuer (Gammarellus) corniger*, *Fabric. Spec. Ins. 517. 7.*
- "81. Der Abyssiner. *Cancer (Gammarellus) abyssinus*. *Ott. Fabric. Fauna Grönl. 261. n. 236.*
- "82. Der Fadenkrebs. *Cancer (Gammarellus) linearis*," with references to the species *linearis*

and *atomos* in *Linn. Syst. Nat. n. 83. n. 84*; *Gammar. linearis* of J. C. Fabricius; *atomos* of Pennant; *Squilla lobata*, Müller *prodrom.* 2359; *Ott. Fabric. Faun. Grönl.* 248. n. 225; *Oniscus scolopendroides* of Pallas; *Martin Spizberg. tab. B. fig. I. p. 115. Granat.*; *Baster opusc. subsec.*; and “*Müller Zool. Dan. p. 21. tab. LVI. Squilla quadrilobata mas, gammarus quadrilobatus, tab. CXIV. foem. anteced.*” It is in all probability the *Caprella linearis* (Linn.) Bate, the figure 9. A, agreeing very fairly with that of *Caprella lobata* in the *Brit. Sess. Crust.*, vol. ii. p. 57.

“83. Der Bauchichte. *Cancer (Gammarellus) ventricosus*,” O. F. Müller.

The section or family concludes with three species which are not Amphipoda.

“84. Die Salzgarnele. *Cancer (oniscus) salinus*.

“85. Die Cylinderassel. *Cancer (oniscus) cylindricus*.

“86. Der Heringfreund. *Cancer (oniscus) esca*.”

Figures are given on pls. xxxv. and xxxvi., from various sources, for all the species except those numbered 72, 73, 74, 77, 78, 79, 80, 81, and the last three.”

Herbst's work is spoken of with great commendation by Milne-Edwards, but it must be confessed that, however great its merits may be in regard to Crustacea in general, ou the Amphipoda this compilation throws but little light.

1796. LATREILLE, PIERRE ANDRÉ, born 1762, died 1833 (Hagen).

Précis des Caractères génériques des insectes, disposés dans un ordre naturel.
Par le Citoyen Latreille. A Paris, et à Brive, an 5 de la R.

In the preface Latreille defines the word *insecte*: “*Animal sans vertebres, dont le corps et les pattes sont de plusieurs pièces.*” The work opens with a Tabular “*Division générale des insectes,*” showing fourteen classes, the first seven belonging to the Ailés, the remaining seven to the Aptères. Classe xii. is formed by the “*Entomostraca, Mull.*” corresponding to “*Synistates, Agonates, Fab.*” Classe xiii., containing “*Crustacés, Crustacea. Agonates, Fab.*” is defined:—“*Tête confondue avec le corps renfermé ordinairement sous une caparace. Autennes. (Quatre)*

“*Plusieurs rangs de feuillets maxillaires et d'antennules, dont deux insérées et couchées sur les mandibules. Lèvre inférieure. o.*

“*Dix pattes communément.*”

Classe xiv. containing “*Myriapodes, Myriapoda. Synistates, mitosates, Unogates, Fab.*” is defined:—“*Tête distinguée du corps, antennifère.*

“*Mandibules ayant un avancement conique à leur base; des dents éailleuses implantées sur le contour de l'extrémité.*

“*Deux rangs de mâchoires au plus. Une lèvre inférieure. Quatorze pattes et plus.*”

On pages 193–201 the genera of the two last classes are given. Under “*CRUSTACÉS. (Cancer Linn. Geoff.)*” are given *Cancer, Pagurus, Scyllarus, Hippa, Galathea, Astacus, Squilla, Gammarus, Carcinus, Entomon.* Of these the eighth and ninth are thus described:—

“*CREVETTE. GAMMARUS, Fab. Oliv., Squilla, Fab.*

“*Antennes pédonculées, très-simples; antérieures courtes, subulées; postérieures sétacées. Antennules bifides. Feuillots maxillaires extérieurs ayant plus de divisions que les intérieurs.*

“*C. H. [Caractères habituels.] Corps petit, alongé, comprimé, glabre, agile, de plusieurs segmens. Tête distinguée du corelet; yeux souvent petits, arrondis et sessiles. Antennes rapprochées, insérées dans l'entre-deux. Pattes de dix à seize; antérieures quelquefois en pince ou en faux. Queue terminée par plusieurs poiutes ou styles.*

“**CARCIN. CARCINUS. Gammarus, Fab. Oliv.*

"Antennes pédunculées très-simples, sétacées; antérieures plus longues. Antennules entières. Toutes les pièces maxillaires bifides.

"C. H. Corps allongé, comprimé, arqué. Tête distincte; yeux sessiles, immobiles. Dix pattes comprimées; les premières et les dernières plus longues. Derniers anneaux ayant chacun un appendice bifide articulé. Queue terminée par deux appendices presque semblables, plus longs, et une petite pièce conique, ciliée de chaque côté."

In the Myriapodes the genera are *Asellus*, *Cyamus*, *Oniscus*, *Julus*, *Scolopendra*. The second of these is thus described:—

"*CYAME. CYAMUS. *Oniscus*, Linn. Fab. *Squilla*, Géé.

"Quatre antennes très-courtes; antérieures coniques, de quatre articles, dont le dernier fort court; postérieures insérées inférieurement, plus courtes que la tête, de trois articles. Antennules obsolètes.

"C. H. Corps ovale, déprimé, crustacé. Tête distincte. Six anneaux. Quatorze pattes; les deux premières plus petites, inserées sous la tête; les 1, 2, 5, 6, et 7^e paires terminées par un crochet."

The genera called in French *Carcin*, *Entomon*, and *Cyame* are marked each with an asterisk to show that they are new, instituted by Latreille himself. The first two have not maintained their ground against earlier designations.

1797. Anonymous.

Epitome Entomologiæ Fabricianæ sive Nomenclator Entomologicus emendatus sistens Fabriciani systematis cum Linneano comparationem adjectis characteribus ordinum et generum, speciebus novis aliorum entomologorum, insectorum habitationibus, nominibus Germanorum Francogallorum Anglorum. Cum indicibus et Bibliotheca Fabriciana. Lipsiae, 1797.

This work refers to another apparently of the same character, entitled "Nomenclator entomologiens secundum entomologiam systematicam ill. Fabricii. Conscriptus a Friderico Webero. Chilonii et Hamburgi. 1795." Among other derivations it gives, together with the definitions, for Synistata, "palpi quatuor maxilla connata cum labio. *Kieferlippen a συνίστημαι*," to unite; for Mitosata, "palpi duo maxilla filiformis membranacea, *Fadenmäuler a μίτος*," a thread; for Unogata, "palpi duo porrecti, maxilla cornea rugulosa, *Haakenmauler ab ὄνυξ*," a nail; and for Agonata "palpi saepius sex, maxilla omnino nulla. *Kinnlose ab ἀγόνατος*," which properly means without a knee or without joints, but is here seemingly taken to mean without a jaw, as though from γένειον instead of γόνη.

Among the Agonata are given *Astacus homari* on page 117, *Cymothoa ceti* on page 119, and on the same page a list of the species of *Gammarus* in accordance with the Ent. Syst. emend. et anct., of 1793. In another list, among the "Agonata sec. Daldorfium," on page 125, "G. Homari (Ast. F.)" is added to the previous catalogue of Gammari.

1797. CUVIER, GEORGES (alias LÉOPOLD-CHRÉTIEN-FRÉDÉRIC-DAGOBERT), BARON, born 1769, died 1832 (Encycl. Brit. 9th Ed.).

Tableau élémentaire de l'histoire naturelle des animaux. Par G. Cuvier. A. Paris, an 6.

In the seventh book, which treats "des insectes et des vers," at page 450 Cuvier says, "Swammerdam divise les insectes d'après la métamorphose; Linnæus, d'après la présence

ou l'absence des ailes, leur nombre, et leurs tégumens ; *Fabricius*, uniquement d'après leurs organes de la mastication ou de la déglutition. Nous adopterons une méthode combinée d'après ces trois points de vue, de manière à faire connoître les classes établies par ces trois auteurs, et nous les subdiviserons jusqu'à ce que les réunions de genres nous paroissent entièrement naturelles." This notice is followed by a chapter headed "Des insectes pourvus de mâchoires, et sans ailes." In this order he includes—"A. *Les crustacés, qui ont plusieurs paires de mâchoires.* (*AGONATA*, Fabr.)." "B. *Les MILLEPIEDS, qui ont le corps composé de beaucoup de segmens, portant des pieds, mais qui n'ont pas plusieurs mâchoires.* (*Mitosata*, Fabr.)." "C. *Les ARACNÉIDES : une seule pièce pour la tête et le corslet, portant huit pieds ; l'abdomen sans pieds.* (*UNOGATA*, Fabr.)." "D. *Les PHTYRÉIDES : à tête distincte ; corslet portant six pieds ; abdomen sans pieds.*" Section A. comprises—"I. *LES MONOCLES.* (*Monoculus*)."
"II. *LES ECREVISSES.* (*Cancer*)."
"III. *LES CLOPORTES.* (*Oniscus*, Lin.)." These divisions are again divided and subdivided, but in none is any reference of any kind made to the Amphipoda, a curious omission on the part of an author on terms of intimacy, as he explains in his preface, both with Fabricius and Latreille. Among "*LES ECREVISSES proprement dites.* (*ASTACUS*, Fabr.)," are included "*Le homar.* (*Cancer gammarus*, Lin.)" and "*La crevette ou salicoque.* (*C. squilla*, Lin.)," two stalk-eyed Crustacea, in describing which, the names *gammarus* and *crevette* might naturally have called Cuvier's attention to the sessile-eyed legion, especially as in regard to the insects he says that Fabricius has helped him with the mouth-organs, "et, en général, il a bien voulu parcourir toute cette portion de l'ouvrage, et m'aider de ses conseils."

1798. FABRICIUS, J. C.

Supplementum Entomologiae Systematicae. Hafniæ, MDCCXCVIII.

In the preface Fabricius says "Agonatorum classem imprimis et nomine et charactere e speci minibus bene conservatis ab amicissimo Daldorffio ex India orientali allatis mutavi, divisi et classes magis naturales characteresque firmiores obtinui." He is here referring to Baron Dagobert Carl de Daldorff.

The Agonata no longer appear, but in their place Classis VIII. Polygonata, "maxillæ plures intra labium," containing *Oniscus*, *Ligia*, *Idotea*, *Cymothoa*, and *Monoculus*; Classis IX. Kleistagnatha, "Maxillæ plures extra labium os claudentes," the genera beginning with *Cancer* and ending with *Limulus*; Classis X. Exochnata, "Maxillæ plures extra labium tectæ palpis," the genera included being *Albunea*, *Scyllarus*, *Palinurus*, *Palæmon*, *Alpheus*, *Astacus*, *Penæus*, *Crangon*, *Pagurus*, *Galathea*, *Squilla*, *Posydon*, *Gammarus*. The old definition of *Gammarus* is given, based only on the antennæ; and a single species, "*Gammarus Homari*," is thus described:—"15. Corporis segmentis dorso subspinosis, cauda fasciculata : stylis serratis. *Astacus Homari* Ent. Syst. 2. 481. 10. Stroem. Act. Hafn. 10. 5. tab. 2. Myll. Zool. Dom. 197. 2358. Habitat in Oceano Norwegico. Antennæ simplices hand bifidæ." These references to Ström and Müller's Zool. Dan. prodr., as earlier notices have stated, are probably concerned with *Amathilla Sabini*, Leach, while "*Astacus Homari*," Fabr., has apparently nowhere found admittance into the ranks of the Amphipoda. Milne-Edwards and Spence Bate do not include it in their lists, Boeck definitely, de Skand. og Arkt. Amph., p. 38, rejects it from his. But from the fact that Fabricius here singles it out as an example of the genus *Gammarus*, it is not unreasonable to suppose that he had changed his mind about its systematic position, especially as we find him adding the remark, "antennæ simplices haud bifidæ," as though to correct an error in his previous description, which contains the expression, "antennis posticis bifidis." By *antennis posticis* Fabricius apparently means the *upper* antennæ, not, as might more naturally be supposed,

the lower. *Amathilla sabini*, it is true, has an accessory flagellum on the upper antennæ, but of that feature Fabricius took no notice in his definition of the genus *Gammarus*. On page 570, in Classis XIII. Antliata, "Os haustello inartieulato," the genus *Pycnogonum* is given and defined as having "*Haustellum tubulosum*, eonium absque setis. *Palpi ad basin haustelli.*" The only species mentioned is *Pycnogonum ceti*, with *Cymothoa ceti*, Ent. Syst., and *Oniscus ceti*, Linn., as its synonyms. In the *Systema Antliatorum*, 1805, *Pycnogonum* no longer appears.

1799. ÖDMANN, SAMUEL (*alias* ÖDMAN).

De Canero Puliee, Linn. *Gammaro*, Fabr. (Svet. Grundmårgla.) et noxa, quam retibus piseatorum infert, experimenta olim instituta communieat Samuel Ödmann. Nova Aeta regiae Societatis Scientiarum Vpsaliensis. Vpsaliae, MDCCXCIX.

On the much disputed question whether the Crustacean in question does or does not injure fishing nets Ödmann pronounces most decidedly that it does, on the ground of repeated experiments. With equal decision he denies that it attacks live fish. "Ipsos autem a piscibus minoribus copiose deglutiuntur, in culina diseuntur quotidie. Præ primis vero generi *anatino* sapidas exhibent dapes." He says that at the beginning of November they come in from the deeper sea to the sheltered parts of the shore in incredible numbers, and that it is from then till May that their destructive industry chiefly needs guarding against by steeping the nets in a decoction from the bark of the alder (*Betula Alnus*). In January and February he repeatedly saw the *Sturnus Cinclus* spend the morning hours, from 7 to 10, in catching these *Cancri Pulices* before his windows in the island of Ingårö.

1799—CUVIER and DUMÉRIL.
1800.

Leçons d'anatomie comparée, tom i. Paris, An viii.

The tableau septième of this work, as quoted by Desmarest, Cons. gén., 1825, shows "CRUSTACÉS. Classe VII^e. Animaux invertébrés, ayant des vaisseaux sanguins, une moelle épinière noueuse, et des membres articulés," including "1. MONOCLES. *Limulus*, *Caligus*, *Apus*, *Cyclops*, *Polyphemus*. 2. ECREVISSES. *Cancer*, *Inachus*, *Pagurus*, *Astacus*, *Palinurus*, *Scyllarus*, *Squilla*." These are followed by "INSECTES. Classe VIII^e. Animaux invertébrés, dépourvus de vaisseaux sanguins, ayant une moelle épinière noueuse, et des membres articulés," of which section A are provided with "mâchoires." Of these a subsection are "sans ailes," one division of which are "GNATHOPTÈRES. Plusieurs paires de mâchoires," containing the "POLYGNATHES. *Asellus* ou *Physodes*, *Oniscus*, *Cymothoa*."

On this classification Milne-Edwards, Hist. nat. des Crust., i. p. 207, observes that the progress of science has withdrawn the Polygnathes from the Insecta, and has necessitated the employment of additional characters to distinguish the Crustacea from the Arahnida, which also have blood-vessels.

1801. PALLAS, P. S.

Bemerkungen auf einer Reise in die südlichen statthalteryschaften des Russischen Reichs in den Jahren 1793 und 1794. Zweyter Band. Leipzig, 1801.

Of Crustacea in the Crimea he says, page 475, "in den Flüssen endlich häufige Krebse von gutem Geschmacke, und in der See zwey Arten von Taschenkrebsen, deren die eine im (ZOOL. CHALL. EXP.—PART LXVII.—1887.)

Sommer bey Nacht zur Begattung auf den Strand heraus kommt und bey Fackeln mit Händen gefangen wird, sonst aber zwischen den Felsen zu hausen pflegt; eiuig besondere Asseln so wohl auf dem Lande, als in der See, und einer kleinen bläulichen Garneele nicht zu erwähnen."

1801. LAMARCK, JEAN-BAPTISTE-PIERRE ANTOINE DEMONET, CHEVALIER DE, born 1774,
died 1829 (Hagen).

Système des Animaux sans vertébres, ou Tableau général des classes, des ordres et des genres de ces animaux; présentant leurs caractères essentiels et leur distribution, d'après la considération de leurs rapports naturels et de leur organisation, et suivant l'arrangement établi dans les galéries du Muséum d'Hist. Naturelle, parmi leurs dépouilles conservées; Précédé du discours d'ouverture du Cours de Zoologie, donné dans le Muséum National d'Histoire Naturelle l'an 8 de la République. A. Paris. An IX-1801.

Lamarck here divides invertebrate animals into seven classes, les mollusques, les crustacés, les arachnides, les insectes, les vers, les radières, les polypes. The Crustacea he divides into Crustacés pédioctes, forming two groups, and Crustacés sessiliocles, also with two groups. For the class at large he gives this description, "Curact. Le corps et les membres articulés. Peau crustacée que l'animal quitte et renouvelle à certaines époques. Organ. Un cerveau et des nerfs. Des branchies pour la respiration. Un cœur musculaire et des vaisseaux pour la circulation." "Ils engendrent plusieurs fois pendant leur vie." He considers that "les balanites et les anatifis" form the passage from the Mollusca to the Crustacea in a remarkable manner. The respiration by branchiae instead of by stigmata and tracheæ, the muscular heart, and the capacity for repeated procreation strongly in his opinion distinguish the Crustacea from the Insecta.

He thus defines the Crustacés sessiliocles, his second order of Crustacea:—"Ils ont deux yeux distincts ou réunis en un seul, mais constamment fixes et sessiles." In this order the Première Section, pp. 164-168, is defined:—"Corps couvert de pièces crustacées nombreuses, soit transverses, soit longitudinales." It includes:—

"XXV^e Genre. CREVETTE. *Gammarus*. Quatre antennes simples, inégales, sétacées, articulées, disposées sur deux rangs. Deux yeux distincts et sessiles. Corps allongé, couvert de pièces crustacées transverses. Des appendices bifides sur les côtés de la queue et à son extrémité. Des pattes articulées et onguiculées.

"**Gammarus pulex*. Fab. *Squilla pulex*. Degeer, ins. 7, p. 525, t. 33, f. 1, 2. *C. pulex*. Lin. Geoffr., ins. 2, p. 667, t. 21, f. 6. Herbst, t. 36, f. 4, 5. La crevette des ruisseaux."

"XXVII^e Genre. CHEVROLLE. *Caprella*. Quatre antennes inégales. Corps lisse et avec des renflements irréguliers, articulé, à segments plus longs que larges. Queue nulle ou très courte et dépourvue d'écaillles ou d'appendices quelconques. Pattes articulées, disposées par paires irrégulièrement distantes.

"**Caprella scolopendroides*. n. *Cancer linearis*. Lin. Bast. op. subsesc. 1, t. 4, f. 2. Pennant, Zool. Brit. 4, t. 12, f. 32. Herbst, p. 142, t. 36, f. 9, 10.

"**Caprella ventricosa*. n. *Squilla ventricosa*. Mull. Zool. Dan. p. 20, t. 56, f. 1-3. *C. ventricosus*, Herbst, t. 36, f. 11, A, B."

"XXVIII^e Genre. CYAME. *Cyamus*, Lat. Quatre antennes inégales: les deux antérieures plus longues, sétacées. Un sucoir simple, rétractile, sortant d'une fente courte située sous la tête. Deux antennules insérées à la base de la bouche. Deux yeux. Corps ovale,

déprimé, à six segmens pédifères. Six paires de pattes; chaque patte terminée par un crochet.

“**Cyanus ceti*. n. *Squilla balænæ*. Degeer, ins. 7, p. 541, t. 42. f. 6, 7. Pall. Spic. Zool., 9, p. 76, t. 4, f. 14, A. B. C. *Oniscus ceti*, Lin. *Pyenogonum ceti*, Fab. Suppl. 570.”

The remaining genera in this section, 26. *Asellus*, 29. *Ligia*, 30. *Oniscus*, 31. *Forbicina*, 32, *Cyclops*, are not Amphipoda.

1802. BOSC D'ANTIC, LOUIS AUGUSTIN GUILLAUME, born 1759, died 1828 (Hagen).

Histoire naturelle des Crustacés, contenant leur Description et leurs Mœurs. 2 vol. Paris. An X. (1802).

The first edition of this work has some historical interest, as being perhaps the first popular treatise ever written in the vernacular on Crustacea. The introduction remarks on the extreme and unjust neglect which had been shown by science to this branch of natural history. The author remarks that the Greek and Latin writers, as Aristotle, Athenaeus, Hippocrates, and Pliny, had all considered the Malacostraca as fish, or intermediate between fish and shell-fish, that the earliest modern naturalists who had written upon them, such as Rondelet, Bélon, Gesner, Aldrovandus, Jonston, had placed them immediately after fish or Molluscs, that even the great Linnæus, who classed them with apterous insects, had left their genera and species in its primitive chaos, merely distinguishing *Crustacea brachyura* from *Crustacea macroura*, and leaving out of sight almost all the minute species. The improvements in classification introduced by Fabricius, Daldorf, Müller, Geoffroy, Cuvier, Lamarck and Latreille, are then explained. An account follows of the different organs of the mouth and the limbs, of the muscles as described by Cuvier, of the viscera after Roesel, of the renovation of limbs, and the phenomena of exuviation after Réaumur. In regard to the fierceness and size of Crustacea in warm countries there is a remark worth citing in the words of the original, “on dit qu'ils sont d'une grandeur si démesurée, qu'ils attaquent les hommes, et en ont mangé plusieurs, entre autres le fameux navigateur François Drake, qui, quoique armé, ne put éviter ce sort.” Of this great sailor's death on the Isthmus of Darien, Hume says, “Drake himself, from the intemperance of the climate, the fatigues of his journey, and the vexation of his disappointment, was seized with a distemper, of which he soon after died.” A rationalist would perhaps attempt to reconcile the two accounts by suggesting that Drake may have died of cancer.

Of Amphipods Bosc gives four genera, *Gammarus*, Fabr., *Talitrus*, Latr., *Caprella*, Lamarck, and *Cyanus*, Latr., with coloured figures of one species of each genus on pls. xiv., xv., and xvi. He describes one new species from North America, *Talitre grillon*, *Talitrus grillus*, with the reference “voyez pl. 15. et fig. 2.” At the foot of pl. xv. we read, “1. 2. Thalitre terrestre.” In accordance with the suggestion of Milne-Edwards, Spence Bate, in the Brit. Mus. Catal., names this *Orchestia gryllus*, with a synonym “*Scamballa Sayana*, Leach, MS.” Bate and Westwood, vol. i. p. 14, note that the name *Talitrus* first appears in the year 1802, both in Latreille's Hist. Gen. des Crust. et Ins., vol. iii., and in Bosc, vol. ii. the latter writer giving Latreille the credit of the invention, while Latreille subsequently, in 1806, refers the genus *Talitrus* to Bosc as its author. This may be explained by the fact which Bosc mentions, vol. i. p. 48, that Latreille had given him permission to use the classification of Crustacea which the lender had prepared for a new edition of his own work. Thus Latreille's *Talitrus* makes its first appearance in Bosc's treatise. It is defined as follows:— “Quatre antennes simples; les intermédiaires, supérieures, plus courtes que le pédoneule des inférieures. Corps alongé, couvert de pièces crustacées, transverses, presque égales, et appendiculées sur leurs côtés. Dix à quatorze pattes; les antérieures terminées par des mains. Des appendices bifides à l'extrémité du corps.”

Under CREVETTE, *Gammarus*, Fabricius, Bosc gives the species *ampulla*, Phipps; *nugax*, Phipps; *carinatus*, author not named; *cancellus*, Pallas; *longicornis*, with references to Gronw., Pallas, Pennant, Herbst; *pulex*, Crevette des ruisseaux, defined as having "Quatre pinces sans doigts; dix pattes," with references to "Baster. Subs. 2. tab. 3. fig. 7. Geoff. Ins. 2. tab. 21. fig. 6. Degeer. Ins. 7. tab. 33. fig. 1, 2. Herbst. Canc. tab. 36. fig. 4, 5." and to his own fig. 4 on pl. xiv., which is in fact a representation of Rösel's species; the account concluding with the remark "se trouve en Europe dans les eaux douees, elle est fort commune aux environs de Paris"; *corniger*, no author named; *gibbosus*, no author named; *esca*, no author named; *medusarum*, with reference only to Stroem, Sundm. tab. 1, figs. 12, 13, where the word "Sundm." is spelt as it is in Herbst's account of *medusarum*; and lastly *homari*, also with reference only to "Stroem, Act. Afr. 10. tab. 2."

Under TALITRE, *Talitrus*, Latreille, Bosc gives *locusta*, with references to "Pallas, Spicil. Zool. 9. tab. 4. fig. 7. Roesel. Ins. 3. tab. 62. Frisch. Ins. 7. tab. 18. Herbst. Canc. tab. 36. fig. 1;" and *grillus*, his own species, figured pl. xv. fig. 2.

Under CHEVROLLE, *Caprella*, Lamarck, he gives *Caprella linearis*, "Quatre mains à un seul ongle; dix pieds dans le mâle," with references to "Cancer linearis. Linn.—*Gammarus linearis*. Fab. Pallas, Speicil. Zool. 9. tab. 4. fig. 15. Pennant. Zool. Brit. 3. tab. 12. fig. 32. Martin. Spitz. tab. P. fig. 1. Herbst. Canc. tab. 36. fig. 9 et 10, A. B.," his own figure, Pl. 15. fig. 5, being presumably borrowed from Herbst, who copies from the Zool. Dan. tab. 56. fig. 5; he also gives *Caprella ventricosa*. "Deux mains avec un seul ongle; quatorze pieds," with references to "Müller, Zool. Dan. tab. 56. fig. 1, 3. Acta Helv. 4. tab. 4. fig. 8, 9, 10." In his general remarks on "les chevrolles" he says, "La première espèce, qui a été observée par Müller, présente un phénomène remarquable; le mâle est fort différent, et a un plus grand nombre de pattes que la femelle." Bosc thinks that Müller must here have confounded two species. The confusion, however, must be laid to the charge of Bosc himself.

After chapters on *Asellus*, *Idotea*, *Sphaeroma*, *Ligia*, *Caligus*, *Binoculus*, Bosc comes to CYAME, *Pygnogonum*, Fabricius, for which he borrows from Lamarck without acknowledgment the following definition:—"Quatre antennes inégales; les deux antérieures plus longues, setaeées. Un sucoir simple, retractile, sortant d'une fente courte, située sous la tête. Deux antennules insérées à la base de la bouche. Deux yeux. Corps ovale, déprimé, à six segmens pédifères. Six paires de pattes; chaque patte terminée par un crochet." Lütken criticises the inapplicable expression *sucoir*, and is of opinion that by the two *antennules* at the base of the mouth, the first gnathopods, not the maxillipeds, must be understood here; he notices also the attribution of a *crochet* to each foot of six pairs. In the specific account Bosc clearly distinguishes the shape of what he supposed to be the third and fourth pairs of feet from that of the other five pairs. He speaks of the species as *le pou de baleine*, and figures it, pl. xvi. fig. 2, as *le Cyame des Cétacés*, representing, according to Lütken, a female (?) of *Cyamus mysticeti*. Bosc himself gives no Latin name either for this species, or for the *Pycnogonum* that has been confused with it. To the *Pycnogonum* he refers as "le eyame des baleines," and after finishing his account of "le eyame des cétacés," he says, "La seeonde espèce avoit été placée par Linnaeus parmi les *phalangium*; par Pallas parmi les *acarus*; par Fabricius, d'abord parmi les poux, et en dernier lieu, avec la première, parmi les *pygnogonum*, sous le nom spécifique de *balenarium*. Bruniek la regarde comme formant un genre nouveau, et probablement il a raison; car cet animal paraît bien différer par la description du pou de baleine."

1802. SCHOUSBOE, P. K. A.

Jagttagelser over tvende sieldne og lidet bekjendte Krebsarter. (Oplaest den 24 May 1799.) Skrivter af Naturhistorie-Selskabet. 5te Bind. 2det Hefte. Kiøbenhavn, 1802.

The two Crustacea in question are here called *Dromia clypeata* and *Gammarus sedentarius*.

The latter, Forskål's now well-known species, is fully described and fairly figured. Of it the author says, "In mari Tingidem alluente unica tantum vice plura specimina inveni mense Febr. 1793." He criticizes Herbst's rendering of Forskål's account, and his copy of Forskål's figure, as not quite accurate. He suggests that some unknown Mollusc may have been the first and original owner of the dwelling in which the creature is found.

1802. TURTON, WILLIAM.

A general system of Nature, etc., etc. Translated from Gmelin's last Edition of the celebrated *Systema Naturae*, by Sir Charles Linné. Amended and enlarged by the improvements and discoveries of later naturalists and societies, *with appropriate Copper-plates*, by William Turton, M.D. Vol. iii. London, 1802.

Among the Insecta Aptera, following "118. Scropio," comes "119. CANCER. Legs, 8 (rarely 6 or 0) besides 5 chelate hands or claws furnished with a moveable thumb: *feelers* 6, unequal: *eyes* 2, distant elongated moveable, and generally placed on peduncles: *mandibles* horny thick; *lip* triple; *tail* articulated and unarmed."

Under *Cancer*, Section "F. Antennæ pedunculate and very simple. *Gammarus*," contains the following information:—

"*Ampulla*. Hands without fangs: legs 14: hind-thighs compressed dilated.

Inhabits the *Northern Ocean*. *Phipps*. tab. 12. fig. 3.

Body nearly white; *proboscis* short incnrvd and very sharp: *tail* with 6 leaves, the last joint bifid.

"*Nugax*. Hands without fangs: legs 14: 6 hind-thighs compressed dilated.

Inhabits *North Seas*. *Phipps*. tab. 12. fig. 3.

"*Carino-spinosus*. Hands without fangs: legs 14; back carinate and spinous.

Inhabits —— In the *British Museum*.

Body whitish subcompressed; the hind segments a little spinous.

"*Cancellus*. Hands 4 without fangs: legs 16.

Inhabits *Siberia*. *Pall. Spic. Zool.* 9. tab. 3. fig. 18.

First pair of antennæ incnrvd.

"* *Grossipes*. Hands without fangs: antennæ longer than the body: tail obtuse.

Inhabits *Europe*. *Brit. Zool.* iv. tab. 16. fig. 31.

"* *Locusta*. Hands 4 without fangs: legs 14: thighs simple: tail with bifid spines. *Roes. Ins.* 3. tab. 62. *Sulz. Ins.* tab. 23. fig. 152.

Inhabits *Europe* on sandy shores and in stagnant waters; leaps about with great agility.

"* *Pulex*. Hands 4 without fangs: legs 10.

Degeer. Ins. 7. tab. 33. fig. 1. 2. *Bast. tab.* 3. fig. 7.

Very common in fountains and rivulets, and swims in an incurved posture upon its back: is very troublesome to fish by getting between their gills, and is said to shine by night.

- “*Corniger*. Hands without fangs: proboscis incurved subulate: sides of the thorax with a double horn.
 Inhabits the *Norway Seas*.
 Body of 11 short segments, whitish edged with red, the 5 hind ones carinate and spinous on the back: under the *thorax* each side are 2 horns united at the base: *tail* with numerous bifid styles.
- “**Linearis*. Hands 4 with a single fang: legs 10.
Pall. Spicil. Zool. 9. tab. 4. fig. 15, *Baster*, tab. 4. fig. 2.
 Inhabits the shores of *Europe* and *America*.
- “**Atomos*. Hands 4 with a single fang: legs 14, with two oval vesicles each side between the fourth and fifth pair.
Pennant Brit. Zool. iv. tab. 12. fig. 22.
 Inhabits *Europe*, in running water, and is so very minute as to be seldom visible to the naked eye.
- “**Salinus*. Legs 20 spreading: tail subulate,” &c. (not an Amphipod).
- “**Stagnalis*. Hands without fangs: legs 22: tail cylindrical bifid,” &c. (not an Amphipod).
- “*Gibbosus*. Oblong, gibbous; antennæ folded and very long.
 Inhabits *Portugal*; small.
 Body smooth yellowish speckled with brown: *head* thick obtuse with a large green spot: *antennæ* bent under the body, folded and 3 times as long as the body: *tail* with 3 sharp cleft leaves.
- “*Esca*. Hands without fangs: tail jointed subulate and cleft at the tip,” &c. (not an Amphipod).
- “*Medusarum*. Hands 4 with a single fang: head very obtuse.
Stroem, Sundm. 188. tab. 1. fig. 12, 13.
 Inhabits *Norway*, under Medusæ.
- “*Filiformis*. Linear; legs 10, the middle ones larger.
 Inhabits *Melacea*. *Amoen. Acad.* 6. p. 415. n. 99.”
- After “120. *Monoculus*” comes “121. *ONISCUS*. Jaw truncate denticulate: *lip* bifid: *antennæ* setaceous, 2–4: *body* oval, consisting of about 14 transverse segments: legs 14.” Under section “A. *Feelers* 0: *antennæ* often 4, sessile: *Cymothoa*,” are given among many others:—
- “*Ceti*. Ovate with distinct segments: third and fourth pair of legs linear and unarmed.
Seba, Mus. 1. tab. 90. fig. 5. *Degeer*. 7. t. 42. t. 6, 7.
 Inhabits the *Northern Seas*, on Whales.”
- “*Aculeatus*. Thorax naked: back with 3 rows of spines.
Act. Petrop. 1778, 1. p. 247. tab. 8. fig. 1.
 Inhabits the *White Sea*. *Body* carmine.”
- “*Cuspidatus*. Thorax articulate tuberculate: the 6 dorsal segments cuspidate.
 Inhabits the *White Sea*. *Act. Petrop.* 1778. tab. 8. fig. 3.
Antennæ 4: *tail* tufted at the sides.”
- “*Fuscus*. Brown; shell carinate with a white spot on the thorax.
 Inhabits *Denmark*. II. *Mull. Zool. Dan.* 2476.
- “*Medusarum*. A little compressed: front obtuse; antennæ very short and pendant: hands 4 compressed and ent.
Stroem, Sundm. 1. p. 188. tab. 1. fig. 12, 13.
 Found under the folds of the *Medusa Capillata*.
- “*Cicada*. Compressed, sublinear with four spurious hands: upper antennæ shorter: tail smooth on the back.
 Inhabits *Greenland Seas*. *Fab. fn. Groen.* p. 258. n. 233.

“*Arenarius*. Slightly depressed before, carinate and subscrate behind : 4 fore-legs cheliform and smooth : antennæ nearly equal. *Stroem. Act. Hafn.* 10. tab. 2. fig. 1-8.

Inhabits the Sandy Shores of *Greenland*, on the *Ulva umbilicalis*.

“*Stroemianus*. Compressed ; 4 fore-legs cheliform and slightly toothed : upper antennæ very short.

Stroem. Act. Hafn. 9. p. 558. tab. 8.

Inhabits the Shores of *Greenland*. Body violet.

“*Abyssinus*. Subcylindrical ; 4 fore-legs cheliform and 1-toothed : antennæ subequal setiferous and serrate at the base on the inner margin.

Inhabits *Greenland*. *Fab. fn. Groen.* p. 261. n. 236.

Body with white and saffron bands : darts with great velocity in the water.

“These 6 last might probably be referred to the genus *Cancer*.”

In this list, *Cancer (Gammarus) carino-spinosus*, being without references, is apparently intended for a new species. In the Brit. Mus. Catalogue, Spence Bate names it *Amathia carino-spinosa*, distinguishing it from *Amathia sabini* “more in deference to the opinions of Rathke, Liljeborg, and Bruzelius, than from a conviction of there being any real distinction between them.” Boeck accordingly makes “*Cancer carino-spinosa*, Turton, Linn. Syst. Nat. III. p. 760. (ifølge Spence Bate)” a synonym of *Amathia sabini*, without observing that Bate and Westwood, vol. i. p. 362, declare that Turton’s species is *Atylus carinatus*. On page 363, they say further, “it is quite evident that the latter [Turton] never examined the animal of unknown habitat in the British Museum, which he cites, but that his knowledge was derived from the Fabrieian description of *Atylus carinatus*, the name of which he unnecessarily altered.” The species, *Cancer (Gammarus) corniger*, though also without references, is clearly the *Gammarus corniger* of Fabricius, now called *Epimeria cornigera*. It will be observed that for *Cancer (Gammarus) medusarum* and for *Oniscus (Cymothoë) medusarum*, Turton gives the same reference to Strom without any attempt at explanation.

1802. LATREILLE, P. A.

Histoire Naturelle, générale et particulière des Crustacés et des Insectes. Ouvrage faisant suite aux Œuvres de Leclerc de Buffon, et partie du Cours complet d’Histoire naturelle redigé par C. S. Sonnini. Tomes I.-IV. A Paris. An X.

In vol. i. p. 45, he recognises that the Stalk-eyed Crustacea or *pédioctes* of Lamarek have an organization evidently distinct from insects, but the Sessile-eyed Crustacea come so near the insects, by the form of the vessel regarded as the heart, that he would have been well content for the present to leave the Crustacea at the head of the insects, only forming a subclass of them.

Vol. ii. opens with a table giving “Divisions générales des animaux invertébrés et pourvus de pattes.” The Crustacés, Class I. have “Mandibules palpigères. Des pièces articulées doubles ou bifides, disposées sur plusieurs rangs, et fermant la bouche. Quatre antennes.” These form two orders, Les Décapodes, “Tête confondue avec le corps. Branchies cachées,” and Les Branchiogastres, “Tête distincte. Branchies extérieures.” The Insectes, Class II., include four subclasses, the first of which is named les Tetraères, and the fourth les Entomostracés.

An explanation of earlier classifications is given pp. 292-365. After Aristotle he considers that Aldrovandus was the first systematist to make any advance, then Willughby

[Willughby], whose method is more commonly attributed to Ray, who adopted and developed it.

In vol. iii. p. vii. n. 1, Latreille remarks that, since the publication of his *Précis* in 1796, the name *insect* had been restricted in its application, he therefore now says, "je nomme *Condylipodes* les animaux que Linnaeus appelle *insectes*, et qui forment, dans la méthode du professeur Lamarck, trois classes; les *crustacés*, les *arachnides* et les *insectes*." He alters the classification of the preceding volume, making the Entomostraca now the first subclass of the Crustacea, the second subclass being the Malacostraca. In these latter the Branchiogastera, p. 35, are the second order, with two families; 1. Squillaires; squillares; including the genera *Squilla* and *Mysis*; 2. Crevettines; *gammarinæ*, thus defined:—"Corps formé d'une suite d'articles de longueur à peu près égale, ou dont le premier du moins n'est pas beaucoup plus grand que les autres. Yeux sessiles. Extrémité postérieure du corps sans appendices, ou à appendices styliformes," and including the genera *Phronima*, *Talitrus*, *Gammarus*, *Caprella*, *Cyamus*.

The new genus "Phronime; phronima," is thus defined:—"Antennes apparentes au nombre de deux, presque sétacées, de trois articles. Des palpes saillants, sétacés. Dix pattes; les quatre antérieures et les quatre postérieures terminées par une pièce conique, un peu arquée; celles de la troisième paire les plus longues, et terminées par une main ayant deux pinces. Derniers anneaux étroits; plusieurs styles allongés, articulés et bifides, à l'extrémité du corps. Corps mou. Tête fort grande. Animal vivant dans un corps ovalaire, transparent, presque gélatineux, (*Cadavre d'un béroë?*). Exemple. *Cancer sedentarius*, Forsk."

Next he defines "Genre. Talitre; talitrus. Antennes simples: les intermédiaires supérieures et plus courtes que le pédoncule des latérales et inférieures. (Dix à quatorze pattes.) Une queue; des pièces articulées au bout. Exemples. *Gammarus locusta*, Fab. *Oniscus gammarellus*, Pall." He then proceeds to define the genus "Crevette; gammarus," adding a remark on this and the preceding genus:—"Othon Fabricius a décrit plusieurs crustacés qu'il faut, je pense, rapporter à ces deux genres. On placera parmi les talitres les suivans: *oniscus serratus*, *cicada medusarum*; avec les crevettes les autres: *oniscus arenarius*, *stræmianus*, *abyssinus*."

He defines "Chevrolle; caprella, Lam." with *Gammarus linearis*, Fab., and *Squilla lobata*, Oth. Fab. as examples.

He defines "Genre. Cyame; cyamus. Corps large, court. Pattes courtes, dont quatre au moins fausses vers le milieu du corps; les autres terminées par un crochet. Point de queue ni de pièces articulées au bout. Exemple. *Oniscus ceti*, Linu. Remarq. Je ne suis pas sûr que les deux genres précédens soient de cet ordre."

Then follow the Insecta as Classe Seconde, with the Tetracera as first subclass, containing the two families "*asellota*" and "*oniscides*."

At the opening of vol. iv. Latreille repeats his reasons for using, instead of the Linnaean *insectes*, the denomination *Condylipodes*, *condylipoda* (pattes noueuses), and for placing the Crustacea at the head of the division. As before, he relies on the observations especially of Swammerdam in olden times, and of Cuvier and Lamarck, his contemporaries. Among other remarks on classification he says, p. 8, "Si j'examine attentivement, en effet, la série naturelle des genres, je vois que les crabes me conduisent aux écrevisses, que de celles-ci j'arrive presque sans saut aux crevettes (*gammarus* F.); de là aux aselles, aux cloportes, enfin aux iules et aux scolopendres; et comme je découvre dans ces derniers animaux des stigmates, je dois penser que les arachnides, les insectes proprement dits doivent leur succéder."

1803. LATREILLE, P. A.

Histoire naturelle, etc. Tomes V.-VI. A Paris. An XI.

This volume opens with the Histoire des Malacostracés, notices how little attention was paid them from the time of Aristotle till we come to Belon, Rondelet, Gesner, Aldrovandus, with whom they still remain between the Mollusca and the Testacea. Jonston was only a compiler. Swammerdam in *bernard l'hermite* discovers a heart or at least a principal organ of circulation "différent du vaisseau dorsal et noueux des insectes. Ce crustacé trouve son rang avec eux; il est compris avec les insectes du premier ordre, ou ceux qui sortent de leur oeuf parfaitement formés et pourvus de tous leurs membres." Kleiu rejected Linnæus's arrangement of Aptera. "Ses animaux multipèdes sont partagés en deux sections. La première est destinée à ceux qui sont cuirassés, *loricata*; elle est remplie par six ordres, dont les cinq premiers appartiennent aux crustacés, et le deruier aux scorpions. La seconde section est celle des insectes; là se voient les scolopendres, les iules, les cloportes, les araignées, etc." Latrcille then gives the system of Lefraucq de Berkley, who, he says, "de nos jours, a le premier séparé les malacoderimes ou les crustacés des naturalistes des insectes." But this seems to be an error, as, except that he places Man in a first division by himself, the nine groups of his second division correspond with those of Brissone.

Vol. vi., pp. 270-331, contains the fuller account of the Branchiogastra. The species given are *Phronima sedentaria*, Forsk., *Talitrus locusta*, Fabr., *Talitrus gammarellus*, Pall., *Talitrus grillus*, Bosc., *Talitrus medusarum*, Fab., *Talitrus cicada*, Oth. Fab., *Gammarus pulex*, Fab., *Gammarus cancellus*, Fab. (with a suspicion that it is the same as *Gammarus carinatus*, Fab.), *Gammarus ampulla*, Fab., *Gammarus nugax*, Fab., *Gammarus longicornis*, Fab., *Gammarus corniger*, Fab., *Gammarus esca*, Fab., *Gammarus spinicarpus*, Müller, *Gammarus homari*, Fabr., Suppl. ent. syst. p. 418, Stroem. Act Hafn. 10. 5. tab. 2. *Gammarus arenarius*, Oth. Fab., *Gammarus abyssinus*, Oth. Fab., *Gammarus serratus*, Oth. Fab., followed by the remark "Les crevettes suivantes de Fabricius ou de l'Encyclopédie méthodique appartiennent à d'autres genres; *Gammarus linearis*, Fab. Voyez chevrolle. *Gammarus filiformis*. Oliv.—*Cancer filiformis*. Lin. Voyez Tom. IV de cette Histoire, p. 330, le second entomostracé décrit par Godeheu Riville. Je crois en effet que c'est une crevette. *Gammarus stagnalis*. Fab. Voyez branchiopode. *Gammarus salinus*. Fab. Idem. Les autres appartiennent au genre *talitre*, ainsi que le cloporte de Stroemius d'Othon Fabricius, Fauna Groenland. no. 235, et dont nous n'avons point parlé." He proposes to call it *talitre stroemien*. In Müller and in Herbst, he says, there are two Crustacea which belong to this genus, *cancer podurus*, *cancer mutilus*, but their specific characters do not appear to be well established. Under *Caprella* he gives *Caprella linearis*, Linn., and *Caprella ventricosa*, Müller. Under *Cyamus*, "cyamus ceti, Lin." On pl. lii he figures Cyame de la Baleine. On pl. lvi. he professes to figure *Phronima sedentaria*, but it does not appear there. On that plate are Talitre sauterelle and Talitre gammarelle, the latter being an *Orchestia*, the figure of it not original. On pl. lvii. are Crevette puce, representing Roesel's dentate species, and Chevrolle linéaire. In the discussion of *Gammarus pulex* an account is given of some original observations in regard to the heart and other internal organs.

1803—BOSC and LATREILLE.
1804.

Nouveau Dictionnaire d'Histoire naturelle, appliquée aux arts, principalement à l'agriculture et à l'économie rurale et domestique. Par une Société de naturalistes et d'agriculteurs, avec des figures tirées des trois règnes de la nature. Paris, 1803—1804. (Twenty-four volumes).

In this work the Crustacea are described by Bosc, who, it is said, merely repeats what had already appeared in his Histoire naturelle des Crustacés. Desmarest says that "Latreille a inséré dans le dernier volume un tableau méthodique de ces animaux." The work must not be confounded with the so-called new edition in thirty-six volumes, Paris, 1816—1819, for which the Crustacea were described by Latreille.

1804. MONTAGU, GEORGE, born 1751, died 1815 (W. Pengelly, e Biblio. Cornub.).

Description of several Marine Animals found on the South Coast of Devonshire. By George Montagu, Esq., F.L.S. Read December 7, 1802. The Transactions of the Linnean Society of London. Volume vii. London, MDCCCIV., pp. 61—85, Pls. vi., vii.

In this paper three Amphipods are described:—

"CANCER PHASMA. Tab. vi. Fig. 3. Cancer linearis, *Linn. Syst.* p. 1056, *Gmelin Syst.* p. 2992. *Bast. Op. Subs.* 1, p. 32, t. 4, f. 11. *Turton Linn.* iii. p. 761. *Oniscus scolopendroides.* *Pall. Spic. Zool.* 9, t. 4, f. 15. *Cancer atomos.* *Linn. Syst.* p. 1056. *Gmel. Syst.* p. 2992. *Brit. Zool.* iv. t. 12, f. 32. *Turt. Linn.* iii. p. 761." Montagu thought he had good reason for uniting the species mentioned in the synonymy with his *Cancer phasma*, but nevertheless thought it well to retain the new specific name to prevent further confusion. This species was named *Astacus phasma* by Pennant in 1812, referred to *Caprella* by Leach in 1814, and to *Protella* by Spence Bate in 1862, where it still stands (see Mayer, *Caprell.*, p. 29) at the head of a long list of synonyms, though one quite different from Montagu's list. His imperfect description is as follows:—"With a slender body of six joints, independent of the head: on the first joint are two spines, a third on the fore part of the second joint, and a fourth on the head, all pointing forwards: the rest of the body smooth: antennæ four, the upper pair nearly as long as the body; lower pair half that length, and the extreme joint of each pectinated with bristles: eyes fixed, reticulated, usually of a reddish colour: close to the mouth are two very short palpi, or feelers, with hooked claws; behind these are two others much longer, armed with single moveable fangs: on the first joint of the body are two long arms, with very large oblong oval hands, furnished with a strong spine on the inside, and a long moveable fang, which is capable of closing upon the spine, in order to secure its prey: the front of the hand in some is also narrowed and elongated into a spine; the second and third joints of the body are each provided with a pair of flat oval fins; the three posterior joints are each furnished with a pair of long slender legs, with a single hooked claw; the hindmost are the longest, and originate from the extremity of the body, the animal being destitute of tail. Length rarely exceeds three-quarters of an inch, and seldom so much: colour various, sometimes red, but more commonly pellucid olive green. The female differs in possessing several plates or valves beneath the body, situated between the two pairs of fins: the office of these is to carry and protect its eggs or young, at which time they extend very considerably, and form a kind of pouch. We have seen this receptacle distended with ova, from fifteen to twenty, readily distinguished through the transparent plates. In this part a very strong pulsation is observable."

"CANCER PALMATUS, Tab. vi. Fig. 4. With a smooth, somewhat compressed body, with thirteen joints : colour, when dead, pale yellowish brown : antennæ four, superior pair longest, half the length of the body ; each pair composed of three large joints, with several small articulations at the end : eyes large, fixed : arms two ; hands remarkably large, flat, triangular, furnished at the upper angle with a moveable fang, capable only of closing upon the middle or palm, which is formed a little concave ; the back of the hand convex ; joint of the wrist deeply cut or indented on the lower side : legs six ; thighs broad, flat : caudal fins two pairs, subulate, with two joints each ; the extreme joint of the tail is furnished with two small appendages ; the next joint with two minute spines ; the third joint with a single spine. Length, three-eighths of an inch." This is now called *Melita palmata*.

"CANCER ARTICULOSUS, Tab. vi. Fig. 6. With an oblong, smooth, glossy body, a little compressed on the sides, with eleven joints, of a cream colour when dead : antennæ four, the upper pair longest, but not half so long as the body : eyes large, of a garnet colour, immovable : arms four, of a very singular form ; the foremost pair with a subglobose, cheliform hand, with the fixed claw very slender, and the moveable one, or thumb, long and double-jointed, or furnished with an additional hooked fang at the end : second pair with an ovate, oblong hand, furnished with one long moveable hooked fang ; at the wrist arises a compressed slender plate, projecting forward, and almost meeting the fang when closed : legs five pairs, small, subulate : tail terminated by several slender, flat, caudal fins. Length, half an inch. Inhabits the deep : taken by the dredge amongst shells and algae." This, having since been identified with *Gammarus spinicarpus*, Abildgaard, 1789, and made the type of a new genus, is now called *Leucothoë spinicarpa*.

1805. VIVIANI, DOMENICO.

Phosphorescentia maris quatuordecim lucecentium animalculorum novis speciebus illustrata a Dominico Viviani. Genuæ, 1805.

In his discussion of the causes of the phosphorescent appearance of the sea, Viviani says "Lucescentibus animalculis immixtæ, nonnullæ reperiuntur in mari species, quæ licet ob parvam

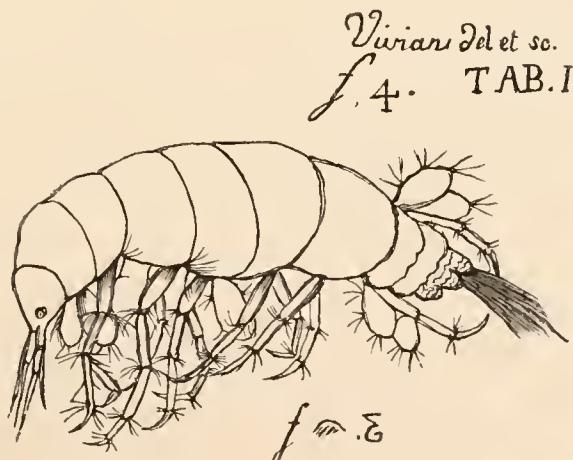

Fig. 16.

corporis molem, et reliquam ejusdem compagem, maxima adfinitate uniantur, nulla vero phosphorica facultate gaudent. (*Gammarus crassimanus* nob. *Gammarus Pulex*, stagnalis,

- Locusta: *Fabric.*)." On the other hand Desmarest, Consid. gén sur la Cl. des Crust., p. 267, says of *Gammarus locusta*, Leach, "M. Suriray, du Havre, a remarqué qu'elle est phosphorescente." Viviani has brought his species into the Fabrician genus of *Gammari*, he tells us, by their coniformity in the number and shape of the antennæ. These he calls "*longissimas* cum corporis longitudinem duplo superant, *brevissimas* cum corporis medium longitudinem non attingunt," always making his comparative measurements with the longer pair. The descriptions are as follows:—"Gammarus caudisetus. (*Tab. I. Fig. 3, 4*). *Gammarus Antennis* (4) *brevissimis*, subæqualibus: annulo caudali medio setiger. Reperi in aquis Portus Genuæ: *Sotto il Molo Vecchio*. *Corpus* oblongum, rubescens, decem segmentis compositum, capitis segmento obusé [obtuse] conico. *Oculi* duo nigrescentes, turgidi, secus autenuas siti. *Antennæ* quatuor, quadruplò corpore breviores. In antenuis superioribus, articuli duo primi elongati, medium earumdem longitudinem æquantes; ultra medium setaceæ. *Inferiores* basi a superioribus ita tectæ, ut nunquam earumdem structuram perlustrare potuerim, ultra medium tamen et ipsæ setaceæ. *Pedes* duodecim, 3-4 articulati; in articulatione verticillato setigeri; apice uncinulo recurvo armati. *Laminæ* natatoriae ovatae, margine setigeræ, utrinque subtus secundum, et quintum segmentum erumpentes, in segmento octavo utrinque geminæ. *Caudæ* segmentum superné squamulosum, quadrilobum, emarginaturā mediâ setularum fasciculo valde mobilium munita. *Color* pallide rubescens."
- "*Gammarus longicornis* (*Tab. II. Fig. 3, 4*). *Gammarus Antennis* longissimis, capite attenuato; pedibus anticis iuarticulatis, brevissimis. Reperi in maris sinibus algosis prope Genuam. A. S. Nazzaro. *Corpus* oblongum, 13 segmentis compositum, utrinque attenuatum, dorso emarginatum; capitis segmentum subcylindricum, incurvatum, apicem versus paulò angustius. *Antennæ* 4 longissimæ; articulus primus in singulis extuberans brevissimus, duo subsequentes quadruplo longiores, tenues, reliqui brevissimi, setulis binis ad interuodia muniti, articulis ita sensim diminutis, ut post tertium, antennæ setaceæ evadant. *Oculi* inter antennaruum superiorum, et inferiorum basim siti. *Pedes* sex biarticulati, apice uncinati. *Pedes branchiales* inarticulati, apice longe setigeri. Capitis segmentum, et subsequens tribus utrinque muniuntur falsis pedibus brevissimis, unico cylindrulo formatis, apice brevissimis setis ciliato; ad cibum captandum fortasse accommodatis. *Cauda* laminulis ellipticis setulosis sex componitur, ex ultimo corporis segmento prodeuntibus. *Color* dilutè flavescens.
- "*Gammarus truncatus* (*Tab. II. Fig. 5, 6*). *Gammarus capitis* segmento antice truncato, caudæ recurvo, antennis superioribus duplo brevioribus. Reperi cum præcedenti. *Corpus* subcylindricum, posticé attenuatum, segmentis duodecim, caudalibus recurvis, caput anticé truncatum, subtus coaretatum. *Antennæ* quatuor: inferiores superioribus duplo longiores, corporis totius medium longitudinem non excedunt; in utroque pari articuli primi paulo extuberantes, reliqui breviores, sensim tenuiores, iu articulationibus setigeri. *Oculi* pone antennas inferiores siti. *Tentacula* duo cylindrica, filiformia, inarticulata. *Pedes* decem, triarticulati, brevi uncinulo muniti, hispida: *Branchiales* sex, è tuberculo prodeentes, cylindrici, apice setularum longo fasciculo muniti. *Caudæ appendices*, cylindruli quatuor recurvi, hispida, peullimum inter, et anterius caudæ segmentum inserti. *Color* dilutissime flavescentes.
- "*Gammarus circinnatus* (*Tab. II. Fig. 9, 10*). *Gammarus subcylindricus*, segmentis 2-6 ad latera utrinque in appendicem circularem excurrentibus, caudalibus reliqua subæquantibus. Reperi cum præcedente. *Corpus* subcylindricum, segmentis decem conflatum, tribus caudalibus latere inferiori postico angulatis, reliqua fere magnitudine subæquantibus. Capitis segmentum cylindricum, anticé rotundatum. *Antennæ* superiores, corpore duplo breviores, ultra medium setaceæ. Articuli tres primi sensim minores, spinulis setulisque in articulatione armati. Par inferiorius, superiori duplo brevius; post primum articulum elongatum antennæ setaceæ evadunt. *Tentacula* duo triarticulata: articulo primo cylindrico, altero

cordiformi, tertio ovato, uncinulo instructo. Segmenta 2, 3, 4, 5, 6 utrinque in appendicem rotundum exent pellucidum ovolorum glomerem tegentem (*Fig. a*). *Caudales appendices*: cylindrula duo recurva, quinque articulata, quibus duo tenujora, inarticulata spinulosa, longitudine subæqualia, adiiciuntur. *Pedes* decem, quorum duo anteriores, articulo primo cylindrico, duobus subsequentibus majoribus apice emarginatis, ultimo oblongo, uncinulo armato componuntur. *Pedes* reliqui triarticulati, longo uncinulo aucti: *Branchiales* sex, unico articulo formati: apice setigeri. *Color* ex flavescenti dilutissime rubescens."

"*Gammarus heteroclitus* (*Tab. II. Fig. 11, 12*)," appears to be a species of *Tanais*. Of it

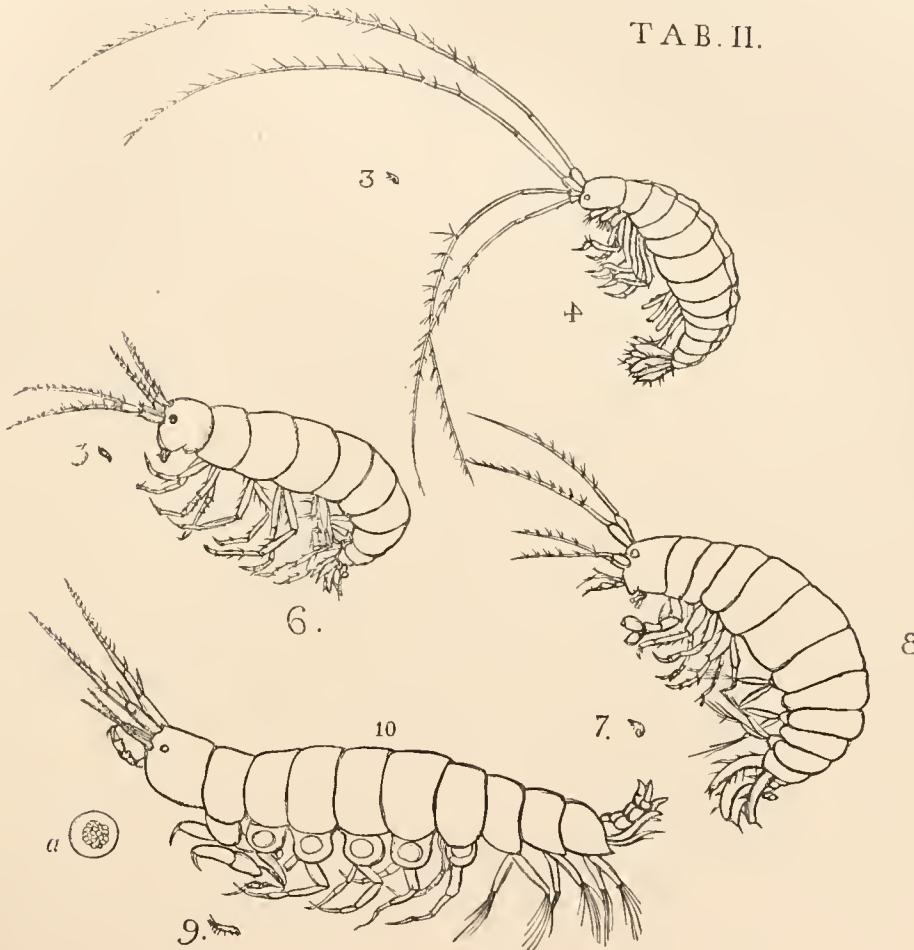

Fig. 17.

Viviani says "Antennarum formâ et insertione species hæc novum fortasse genus exposceret. quod habitus totius corporis a *Gammaris* diversissimus confirmaret."

"*Gammarus crassimanus* (*Tab. II. Fig. 7, 8*). *Gammarus ventricosus*: caudâ reflexâ; anterioris pedum paris tarsis incrassatis, chelâ granulatâ. Reperi cum precedentibus. *Corpus* oblongum, ventricosum, antice truncatum, in cauda attenuatum recurvum, segmentis 17 compositum. *Capitis* segmentum subcylindricum, subtus veluti in rostrum breve coarctatum. *Antennæ* quatnor, medianam totius corporis longitudinem paulò excedentes, setaceæ, articulo primo brevi ventricoso, subsecente elongato tenui, reliquis sensim tenuioribus brevissimis.

Antennæ inferiores duplo breviores, structurâ superioribus conformes. Oculi inter utrumque antennarum par siti, latiusculi, nigri. Tentacula quatuor, quorum antica duo biartieulata, articulo primo cylindrico, extimo falcato, ramulosé pilifero. Inferiora subtus caput prorumpentia filiformia, inarticulata, flexilia. Pedes octo, duo anteriores crassiores, articulo priuno cylindrico, duobus subsequentibus obcordatis, extimo seu chelâ, obovato, turgido, granulifero: reliqui triarticulati, uncinulo armati. Pedes branchiales sex, articulo unieo elongato formati apice setigero, é tuberculo eaudali prodeentes. Appendices caudales quatuor, cylindrici, recurvi, hispidi, inter duodecimum et tredicesimum segmentum erumpentes."

It might be possible for some one residing at Genoa to identify these Genoese Amphipoda. The figures given to represent the natural size are so minute as to suggest some error. Fig. 4, pl. i. is suggestive of *Hyperia medusarum*, though the eye is represented only by a small o. Fig. 6, pl. ii. may represent *Hyale* sp. Fig. 4, pl. ii. ought to be capable of identification by the extreme length of the antennæ of both pairs, but of the upper pair especially. The name *Gammarus longicornis* is preoccupied among the synonyms of *Corophium volutator*. Spence Bate has suggested the identity of *Gammarus crassimanus* with *Mæra truncatipes*. Desmarest, Consid. gén. sur la Cl. des Crust., p. 265. n., also thinks it probable that it belongs to the same genus as *Mæra grossimanus*. Boeek thinks it is perhaps a *Gammarus*. In his view, *Gammarus circinatus* seems to be a species of *Amphithoë*. Milne-Edwards and Spence Bate alike omit Viviani's species from their general lists of Amphipoda, and in the special lists of Mediterranean species by Costa, 1830, by Hope, 1851, by Stalio, 1877, and by Carus, 1885, no notice is taken of them.

1806. DUMÉRIL, ANDRÉ MARIE CONSTANT, born 1774, died 1860 (Hagen).

Zoologie Analytique, ou Méthode Naturelle de Classification des Animaux, rendue plus facile à l'aide de tableaux synoptiques. Paris. M.DCCC.VI.

Duméril rejects the precept of Linnæus and Fabricius to draw the characters of classes, orders, and genera from one and the same part, as inapplicable to zoology, however suitable it might be to botany. He prefers the natural method, which studies all the parts of an organism, with a view to its classification. In regard to the Crustacea he follows Latreille and Lamarck. He makes nine "general divisions" or classes, the Crustacea being the sixth, between the Mollusca and the Insects. The Crustacea are defined as "Animaux sans vertèbres, munis de vaisseaux et d'organes respiratoires sous forme de lames ou de branchies; pattes le plus souvent au nombre de dix." They form two orders, Entomos-tracés and Astacoides. The latter, "à croûte caleaire," contain four families, Maeroures, Carcinoïdes, Oxyrinques, and Arthrocephalés. These last, "à tête séparée du eorcelet," correspond to the Branchiogastres of Latreille. The name is derived "De Αρθρον membre qui se meut, et de Κεφαλη tête." An alternative name is Capités. The following definition and table is given:—"Crustacés à pattes ordinairement au nombre de quatorze; à branchies apparentes vers la queue et à tête articulée sur le eorcelet.

	Genres.
pedonculés ;	<i>Mysis.</i>
sessiles; la troisième paire de pattes,	<i>Squille.</i>
	<i>Plironime.</i>
	<i>Crevette.</i>
	<i>Thalitre."</i>

He makes the following remarks upon the Amphipoda—"Le genre *phronime* (*phronima*) est encore du même naturaliste [Latreille]. Il comprend un animal très-singulier, qu'on a observé dans un corps gelatinous transparent, qui n'a que deux antennes et dix pattes dont la troisième paire, plus longue que les autres, est armée de deux pinces ; le corps se termine par plusieurs filets fourchus. Le genre *thalitre* (*thalitrus*, du même auteur) ressemble beaucoup à celui des crevettes. Les *crevettes* (*gammarus*, Fab.) diffèrent de tous les autres astacoides par la forme du second segment du corps, lequel n'est pas plus long que ceux qui viennent immédiatement après, par les appendices fourchus qui se remarquent à l'extrémité et sur les côtés de la queue ; enfin par l'immobilité des yeux, qui sont à-peu-près disposés comme ceux des aselles et des cloportes, insectes avec lesquels les crevettes semblent se lier. Ces crustacés vivent dans les eaux douces et salées ; ils nagent fort rapidement et toujours sur le côté."

The sixtieth or last family of the Insects, among the Aptera, is called Quadricornes or Polygnates, and contains three genera, *Physode*, *Cloporte*, *Armadile*, with the remark that *physode* (*physodes*, Fab.) answers to the *asellote* family of Latreille. He considers that the "Polygnates semblent faire le passage des insectes aux crustacés, dont ils diffèrent seulement par le défaut de branchies."

1806. LATREILLE, P. A.

Genera Crustaceorum et Insectorum secundum ordinem naturalem in familias disposita, iconibus exemplisque plurimis explicata. Tomus Primus, Parisiis et Argentorati, 1806. (The other three volumes 1807, 1809.)

Of the twelve classes into which Latreille here distributes animals, the Crustacea are the eighth, invertebrates with distinct nerves, "Cor ; branchiæ ; medulla spinalis gangliis plurimis ; pedes." Of the Crustacea, the Malacostraca form the second Legion ; containing two Orders, the Decapoda and the Branchiogastera, the latter thus defined, "Caput a thorace distinctum ; branchiæ externæ, inferæ ; pedes saepissime quatuordecim." Of the Branchiogastera, the first Family are called *Squillares*, the second *Gammarinae* or *Crevettines*. These latter include the genera *Phronima*, *Talitrus*, *Gammarus*, *Corophium*, *Caprella*, *Cyamus*. The new genus *Corophium* is thus defined :—*Cauda* appendicibus articulatis, subcylindricis. *Antennæ* inferæ crassissimæ, articulis quinque, seta nulla articulata apicali. *Pedes* duo antici manu parva (ungue mobili, pollice iuncta)." The type species is *Corophium longicorne*, taking its specific name from the synonym, *Gammarus longicornis*, Fab., instead of taking it, as it should do, from the earlier synonym, *Oniscus volutator*, Pall. A final note remarks, "Genera *Symethis*, *Posydon*, mihi ignota." *Phronima sedentaria* and its habitation are figured on pl. ii.

The Tetracera are the first Legion of the Ninth Class, Apterous Insects, and comprise two Families, the Asellota and the Oniscidae.

1808. MONTAGU, GEORGE.

Description of several Marine Animals found on the South Coast of Devonshire. Transactions of the Linnean Society, vol. ix., London, MDCCCVIII. pp. 81–114, pl. ii.–viii. (Read June 18, 1805).

At page 92 Montagu gives "CANCER GAMMARUS LOCUSTA. Tab. iv. Fig. 1. Cancer Locusta. Gmel. Syst. p. 2992. Turt. Linn. iii. p. 760. Oniscus Gammarellus. Pallas Misc. Zool. t. 14. f. 25. Id. Spic. Zool. 9. t. 4. f. 8." Although the accessory flagellum of the upper

antennæ is not noticed, this is clearly *Gammarus locusta*, Linn., and as Montagu professedly mentions it only to clear it from confusion with other species, it is singular that he should place in the synonymy *Oniscus gammarellus*, Pallas, which is an *Orchestia*. He describes the eyes as "lunated, fixed," with an explanatory note, "Not pedunculated, or moveable, but fixed under the shell of the thorax; a circumstance common, I believe, to all this family." The epithet in "hands sub-cheleferous" he also explains in a note, as "A term adopted for a single fang capable of closing upon the hand, answering the purpose of a fixed claw, in contradistinction to cheleferous, or such as are formed with double claws."

On page 93 he gives "CANCER GAMMARUS PULEX. Tab. iv. fig. 2. Cancer Pulex. Gmel. Syst. p. 1055. Turt. Linn. iii. p. 760. Brit. Zool. iv. p. 21. No. 33." This, he remarks, "is as incapable of living in salt water as the *C. Locusta* is in fresh, although we have the authority of Linnaeus and many of his disciples to the contrary. It is also incapable of leaping, and very soon dies when taken out of water."

On page 94 is "CANCER GAMMARUS SALTATOR. Tab. iv. fig. 3. Cancer Locusta. Brit. Zool. iv. p. 21. No. 34. Oniscus Locusta. Pallas Spic. Zool. 9. t. 4. f. 7. Misc. Zool. t. 14. f. 15." Of this Montagu says, "The *C. Saltator* is without doubt the animal referred to by Pallas, and this confirms the opinion that Gmelin has confounded it with his *Cancer Locusta*, having quoted both the *Oniscus Gammarellus* and *O. Locusta* of that author for it. That it is Pennant's *C. Locusta* there can be little doubt, as he particularly mentions the quality of leaping, a power denied to the other species." Montagu's figure very clearly depicts what is now known as *Talitrus locusta*, Pallas. As he makes no reference to Klein's *Squilla saltatrix*, 1743, the specific name *saltator* was probably not borrowed from that source.

On page 96 he gives "CANCER GAMMARUS LITTOREUS. Tab. iv. fig. 4. Pulex marinus. Baster Op. Subs. ii. p. 31. t. 3. f. 7. 8." "The *C. littoreus*," he says, "is doubtless the species figured by Baster as above referred to, and which Gmelin has erroneously quoted for the Linnean *Cancer Pulex*." This is pretty clearly the *Oniscus Gammarellus* of Pallas, which Montagu himself has erroneously quoted for the Linnean *Cancer locusta*. Its name, therefore, should be, as Boeck gives it, *Orchestia gammarellus*, Pallas.

On page 97 he gives "CANCER GAMMARUS GROSSIMANUS. Tab. iv. fig. 5." This is a new species. It is now called *Mæra grossimana* (? better, *grossimanus*).

On page 98, "CANCER GAMMARUS TALPA. Tab. iv. fig. 6," now called *Apseudes talpa*, belongs to the Tanaidæ.

On page 99, "CANCER GAMMARUS RUBRICATUS. Tab. v. fig. 1." is a new species, which was referred by Leach to his genus *Amphithoë*. It includes, I believe, *Amphithoë littorina*, Sp. Bate, and three or four other synonyms from species founded chiefly on immaterial distinctions in colouring.

On page 100 is given the new species "CANCER GAMMARUS FALCATUS. Tab. v. fig. 2." This Leach considered to belong to the genus *Jassa*, which he instituted with the species *Jassa pulchella* and *Jassa pelagica*, establishing at the same time the genus *Podocerus* with the species *Podocerus variegatus*. Milne-Edwards gave *Cancer falcatus* and *Jassa pelagica* to *Cerapus pelagicus*, to *Podocerus variegatus* he left its name, and changed *Jassa pulchella* into *Podocerus pulchellus*. Spence Bate gave the four as separate species of *Podocerus*, to which more recently all four have been assigned as a single species. Boeck united the names *pelagicus* and *pulchellus* as synonyms to Montagu's *falcatus*, no doubt correctly, but it seems curiously perverse that he should assign Leach's three species of *Jassa* to *Podocerus* and Leach's species of *Podocerus* to *Janassa*, altered without due reason from *Jassa*. *Janassa* may well fall to *Podocerus* as being too near for generic distinction, but, if not, the species in question would have to be named *Jassa falcata*, Montagu, and *Podocerus variegatus*, Leach. It is rather singular that Montagu should finish his account with the words "This curious and rare species inhabits the deep, amongst *Sertularia*, and *Algæ*, and has

only been taken by dredging at Torcross." As a matter of fact now-a-days at Torquay and Ilfracombe, in shore-pools, the *pelagicus* and *pulchellus* forms are extremely, not to say tiresomely, abundant.

After describing two species of *Phalangium*, on page 102 Montagu gives "ONISCUS TESTUDO Tab. v. fig. 5. Body sub-ovate, composed of eight joints rising to a ridge on the back; the plates elevated at their edges; the four first fall very low on the sides, and obscure the anterior legs; along each side of the body a row of small tubercles; the frout sub-bifid; antennae four, very short, lower pair hid beneath: eyes prominent, black: posterior end obtusely pointed; caudal fins beneath, obscure: legs fourteen, short and strong, the three posterior pairs longest; all furnished with a simple claw. Length two lines. Colour dull red, with a white spot on the anterior part of the back, but as the insect dies this mark is lost. Rare." By Bate and Westwood, Brit. Sess. Crust., vol. i. part 5, p. 228, 1862, this is made the type of a new genus *Pereionotus*. See also Brit. Mus. Cat., p. 375, 1862. These authors recognise that "this genus bears a near relationship to that of *Phlias* of Guérin," 1836. They only find indeed one distinction of importance, that while *Pereionotus testudo* has the last uropods uniramous, *Phlias serratus*, taken on the voyage from the Falklands to Port Jackson, has these uropods biramous. A specimen from the Mediterranean which Spence Bate has named *Phlias rissoanus*, he unfortunately left unexamined in regard to the last uropods. Grube's genus *Iridium*, 1863-4 would seem undoubtedly synonymous with *Pereionotus*, but that its author declares that his *Iridium fuscum* has no telson. Carus, Prodr. Faun. Medit., 1885, gives under "Iridium GRUBE (*Phlias* GUÉR.)," "I. Rissoanum CATTA (*Phlias Rissoana* SP. B., *I. fuscum*, GR.). ♀." That further investigation will unite *Phlias*, *Pereionotus*, and *Iridium* in one genus seems not improbable. In that case *Phlias*, Guérin, will take precedence, with *Oniscus testudo*, Montagu, for the type species.

1810. LATREILLE, P. A.

Considérations générales sur l'ordre naturel des Animaux composant les classes des Crustacés, des Arachnides, et des Insectes; avec un tableau méthodique de leurs genres, disposés en familles. Paris, 1810.

The first part, pages 9-87, reviews in general the work that had been done up to that time in regard to the classification of the groups mentioned in the title. In the second part, the Crustacea are divided into two Orders, Entomostraca and Malacostraca. The Malacostraca are divided into seven families, the first five with "tête confondue avec le corcelet," the sixth and seventh with "tête distincte du corcelet." The sixth, or *Squillares*, has "Yeux pediculés." The seventh, Crévettines, *Gammarinx*, has "Yeux sessiles." In this last, two groups are formed, the first containing but a single genus, the second much subdivided, as follows:—

- "I. Dix pates. G. 49. PHRONIME, *Phronima*."
- "II. Douze à quatorze pates. 1. Des appendices articulés et saillans au bout de la queue.
A. Les quatre antennes terminées par un filet articulé. G. 50. CREVETTE. *Gammarus*."
"G. 51. TALITRE, *Talitrus*." "B. Antennes inférieures très-grosses, point terminées par un filet, et formées de quatre articles (les deux pates antérieures terminées par une main, avec un doigt ou crochet mobile). G. 52. COROPHIE. *Corophium*. 2. Point d'appendices articulés et apparaissant au bout de la queue. G. 53. CHEVROLLE. *Caprella*." "G. 54. CYAME. *Cyamus*."
On pp. 422-3, species are given for these genera as follows:—" *Phronime. *Cancer sedentarius*, Forsk. Crevette. *Gammarus pulex*, Fab. Talitre. *Oniscus gammarellus*, Pall. *Corophie. *Gammarus longicornis*, Fab. Chevrolle. *Cancer linearis*, L. *Cyame. *Pycnogonum ceti*, Fab." The asterisks indicate the genera instituted by Latreille himself.

1811. STEWART, CHARLES.

List of Insects found in the Neighbourhood of Edinburgh. Memoirs of the Wernerian Natural History Society, vol. i. For the years 1808-9-10. Edinburgh, 1811. Pp. 566-577.

Among the Aptera, under the genus *Cancer*, he gives the names *Gammarus*, *Puler*, and *Locusta*. *Cancer gammarus* of Linnaeus, it should be remembered, is not an Amphipod.

1812. THOMAS PENNANT.

British Zoology, a new edition. In four volumes. Vol. iv. Class v., Crustacea. vi. Vermes. London, 1812.

He here adds to his *Astacus linearis* the reference "Herbst. Canc. ii. 142. t. 26. f. 9. A. 10. B." *Astacus atomos* is now called *Astacus phasma* or Phantom Lobster. The figure is on pl. xiii. 2. *Astacus locusta* now has the references "C. locusta, Gm. Lin. 2992." "Faun. Suec. 2042." "Oniscus gammarellus. Pallas Misc. Zool. t. 14. f. 25." "Linn. Trans. ix. 92. tab. 4. fig. 1." Additional references are given for *Astacus pulex*. *Astacus saltator* appears with references to "C. saltator. Linn. Tr. ix. 94. t. 4. f. 3." "Oniscus locusta. Pallas Misc. Zool. t. 14. f. 15." "Roesel Insect. iii. tab. 62." "C. locusta. Br. Zool. iv. 21." "Herbst. Canc. ii. 127. t. 36. f. i." Under the generic name of *Astacus*, Montagu's species *littoreus*, *grossimanus*, *rubricatus*, *falcatus*, *palmatus*, are given from the "Linn. Tr. ix. 91-100," and *articulosus* from "Linn. Tr. vii. 70," whence in reality *palmatus* also comes. On p. 40, *Oniscus testudo*, Montagu, is given. It is clear that for his fresh references, as well as for the new species, Pennant is indebted to Montagu's papers.

1813. MONTAGU, GEORGE.

Descriptions of several new or rare Animals, principally marine, discovered on the South Coast of Devonshire. Transactions of the Linnean Society. Vol. xi. First Part. MDCCCXIII. Pp. 1-26, pls. i.-v. Read April 7, 1807. (The bound volume is dated 1815, but the separate first part as above.)

On page 3 Montagu gives "CANCER GAMMARUS SPINOSUS. Tab. II. fig. 1," which Leach afterwards called *Dexamine spinosa*. He hints that Turton's briefly described *Cancer gammarus carinospinosus* may be the same species, but this is decided by Bate and Westwood to be *Atylus carinatus*, Fabr.

On page 4 is given "CANCER GAMMARUS GALBA. Tab. II. fig. 2. Body ovate, somewhat elongated at the tail, smooth, glossy, and when alive of an olive-green minutely speckled with brown, but by drying becomes rufous-brown; antennæ of the male remarkably short; in the female two pairs extremely long and slender, nearly equal to the length of the body; joints of the body, independent of the head, and the joint to which the caudal fins are attached, eleven; the head is large, and much resembles that of a maggot, and in the male appears to have no division between the eyes, but a continuation of the same transparent membrane covers the whole; the eyes of the female are very large, but distinctly marked by a division; the two pairs of anterior legs, like those of *C. spinosus*, are small, and not subcheliferous, but occupy the place of arms, and scarcely differing in any respect from the other five pairs, all of which are furnished with a very small claw; abdominal fins three pairs; caudal fins

five, flat, and bifid; the middle one very broad, concealing the others which are capable of spreading laterally. Length, half an inch or more. The female is rather more slender in the body, and does not so suddenly decrease towards the tail. The eyes, as before-mentioned, are distinct, and are of a bright red when alive, reticulated, and marked with two streaks of black, one on each side of the eye, probably the reflection of a pupil. This is another species of *Cancer* that very nearly approaches the genus *Oniscus*, and is readily distinguished by the larva-like appearance of its head. It is not uncommonly taken with the last." It should be noticed that this description differs strikingly in some respects from that given of *Hyperia galba* by Bate and Westwood. Their species is fawn or faint yellow speckled with red, and has green eyes. Montagu's species is olive-green speckled with brown, and has red eyes. Boeck unites both of them as synonyms of *Hyperia (Cancer) medusarum*, O. F. Müller, but does not notice the colouring, nor that in the expression five caudal fins. Montagu attributes to his species only two instead of three pairs of uropods, nor that he gives the long antenæ to the female instead of the male. Montagu's remark that his species is not uncommonly taken together with *Dexamine spinosa*, if applied to *Hyperia medusarum*, seems scarcely in accord with common experience, although various Gammarina are occasionally taken upon *Medusæ*. In the figure, it is the first uropods, not the last, that extend furthest backwards.

On page 5 he gives "CANCER GAMMARUS MONOCULOIDES. Tab. II. fig. 3." "This species," he says, "seems to connect the *Cancer* with the *Monoculus*, but is more allied to the former in the conformation of its members." Its name at present is *Stenothoë monoculoides*. On the same page is given "CANCER GAMMARUS OBTUSATUS. Tab. II. fig. 7," now known as *Melita obtusata*.

On page 6 he gives "CANCER GAMMARUS PEDATUS. Tab. II. fig. 6. Gammarus pedatus. *Mull. Zool. Dan.* iii. t. 101." He does not seem to have been aware that this had been earlier described by Müller as *Squilla ventricosa*. It is now known as *Proto ventricosa*, Müller.

1813—LEACH, WILLIAM ELFORD, born 1790, died 1836 (Webster).
1814.

Crustaceology. The Edinburgh Encyclopædia, conducted by David Brewster, L.L.D., &c., &c., with the assistance of gentlemen eminent in science and literature. In eighteen volumes. Vol. vii. Edinburgh, M.DCCC.XXX. (The issue of the work lasted from 1810–1830, but the title page for each volume bears the date 1830. The earlier numbers ran through several editions. Leach's article, Crustaceology, is referred to by Desmarest, 1825, and others, with the date 1813–1814. Whether it originally appeared with or without the appendix seems uncertain.)

Leach in this article considers that Crustaceology treats of two classes, Crustacea and Arachnides, as distinct from Insecta. Of Brisson he does not as yet seem to have heard, as he thinks that Pennant first separated the Crustacea from insects, although capriciously. Leach himself takes from the Arachnides the orders Tetracera and Myriapoda of Latreille to add them to the Crustacea, and Latreille's Parasita to add them to the Insecta. He divides the Crustacea into three orders, Entomostraca, Malacostraca, Myriapoda; the Malacostraca into three tribes, Brachyuri, Macrouri, Gasteruri. The Gasteruri are thus defined, "Eyes sessile. The joint of the body which receives the head, of the same size with the rest." This tribe contains the following families, Gnathonii (also spelled Gnathionii), Gammarini, Corophionii (also spelled Corophini), Caprelliui, Apseudii. Of these the first, with the genus *Gnathia*,

since called *Anceus*, and the last with the genus *Apseudes*, are not usually considered Amphipod families.

In this system we have the following arrangement of the genera and species which came soon after to be called Amphipoda.

“Family XIV. GAMMARINI.

- “1. Superior antennæ shorter than the peduncle of the inferior antennæ. Feet fourteen.” “Genus LIII. TALITRUS.” “Sp. 1. *Locusta*.” “*Cancer locusta* of Pennant and Gmelin. *Oniscus locusta* of Pallas. *Gammarus locusta* of Fabricius? *Cancer gammarus saltator* of Montagu. *Talitrus locusta* of Latreille.” “Sp. 2. *Littoralis*.” “*Talitrus littoralis*. Leach’s MSS.” This was afterwards dropped. “Genns LIV. ORCHESTIA.” “Sp. 1. *Littorea*.” “See Plate cxxxi. fig. 6. *Pulex marinus* of Baxter [Baster]; *Cancer gammarus littoreus* of Montagu; *Orchestes littorea*, Leach’s MSS.; *Talitrus gammarellus*, Latreille?” “Latreille quotes Baxter’s figure which renders it highly probable that this may be his *Talitrus gammarellus*; but as he quotes also the *Oniscus gammarellus* of Pallas, it still remains in some doubt.” This confusion on Leach’s part probably originates with Montagu. See Note on Montagu, 1808.
- “2. Superior antennæ longer; or at least as long as the inferior. Fourteen feet, the third and fourth pair smallest.” “Genus LV. GAMMARUS.” “Fresh water. Sp. 1. *Pulex*.” “*Cancer pulex* of Linné and Pennant; *Gammarus pulex* of Fabricius and Latreille.” “A species which Mr. Leach considers as distinct from *pulex*” is then mentioned, but not numbered. It came from a well in London. “It differs principally from *Gammarus pulex* in having the upper process of the tail much longer. The colour, when alive, was cinereous, but so translucent, that the eyes could not be discovered; it stands in Mr. Leach’s cabinet, under the specific name *subterraneus*.” This is probably the same as *Niphargus aquilex*, Schiødte. The species of *Gammarus* are continued under the heading “Marine.” “Sp. 2. *Locusta*.” “*Cancer locusta* of Linué. Is it *Cancer gammarus locusta* of Montagu? *Linn. Trans. vol. ix.*” “Sp. 3. *Camylops*.” This is probably only a casual variety of *Gammarus locusta*. “Sp. 4. *Rubricatus*.” “*Cancer gammarus rubricatus* of Montagu. *Ampithoe rubricata*, Leach’s MSS.” “It is a rare species, and possibly does not belong to this genus.” “Genus LVI. MAERA. Anterior pair of feet with a moveable nail; the second pair with a compressed hand and moveable thumb. Peduncle of the antennæ with three joints; the superior antennæ longest.” “Sp. 1. *Grossimana*.” “*Cancer gammarus grossimanus* of Montagu. *Mæra grossimana*, Leach’s MSS.” “Genus LVII. MELITA. Anterior pair of feet very small; second pair with a compressed hand, and moveable nail which bends on the palm. Superior styles of the tail very long and large.” “Sp. 1. *Palmata*.” “*Gammarus palmata*, Montagu, *Linnean Transactions*, vol. vii. tab. 6. *Melita palmata*, Leach’s MSS.” “Genus LVIII. LEUCOTHÖE. Anterior feet with a finger and thumb; the thumb jointed; second pair with a moveable thumb but no finger. Peduncle of the antennæ with two joints. Superior antennæ longest.” “Sp. 1. *Articulosa*.” “*Cancer articulosus* of Montagu. *Leucothoe articulosa*. Leach’s MSS.” This is now known as *Leucothoe spinicarpa* (Müller) Abildgaard.

Leach then observes that *Phronima sedentaria* of Latreille, “*Cancer sedentarius* Forsk. F. Arab. page 95,” probably forms a distinct family, but as he had never seen a specimen, he merely quotes some remarks of Latreille upon it, and then proceeds to give:—

- “Family XV. COROPHINI. Genus LIX. COROPHIUM.” “Sp. 1. *Longicornes*.” “*Cancer grossipes* of Linné; *Oniscus volutator* of Pallas; *Gammarus longicornis* of Fabricius; *Astacus linearis* of Pennant; and *Corophium longicorne* of Latreille.”
- “Family XVI. CAPRELLINI,” with a note:—“The body of these animals, exclusive of the head, is composed of six joints, all except the second and third bearing feet. The second and third segments furnished on each side with two processes, which probably serve as fins.

Feet ten, all armed with a moveable nail; the anterior pair very small, and originating from the head. Mouth with two jointed palpi, armed at the point with a little hook. The female is furnished with a pouch, situated between the fins, in which she carries about the eggs and her young after their exclusion, until they are enabled to shift for themselves." "Genus LX. CAPRELLA." "Sp. 1. *Linearis*." "Head with one little tubercle. Hand of the second pair of feet with three teeth on the inner edge. *Cancer linearis* of Linné; *Astacus atomos* of Pennant; *Caprella linearis* of Latreille; *Oniscus scolopendroides* of Pallas." This Mayer is unable to identify, but the tridactyl hand points pretty clearly to Müller's *Squilla quadrilobata*, Zool. Dan., pl. lvi, figs. 4-6. "Sp. 2. *Phasma*," Montagu, Liun. Trans., vol. vii., which is now *Protella phasma*, Montagu. "Sp. 3. *Pennantis*." "*Astacus atomos* of Pennant." This has since been identified with *Caprella acutifrons*, Latreille. "Sp. 4. *Acanthifera*." "*Caprella acanthifera*, Leach's MSS." "Genus LXI. PANOPÆ. Body depressed. Eyes situated on the vertex of the head. Antennæ four-jointed; the upper pair, with the basilar joint, largest; the second and third equal, but rather shorter than the first; apical joint very small; inferior pair also composed of four joints, shorter than the first joint of the upper pair. Feet compressed and armed with strong nails; the anterior pair situated on the base of the head, the wrist jointed. Fins of a leathery-membranaceous substance, cylindrical and elongated. Anus produced, having a few obscure small tubercles on each side and under. The pouch of the female with four valves." "Sp. 1. *Ceti*." "*Oniscus ceti* of Linné; *Pycnogonum ceti* of Fabricius; *Panope ceti*, Leach's MSS." Latreille's authority is quoted for the (erroneous) statement that it attaches itself to fishes of the genus *Scomber*, as well as to whales, but no notice is taken of Latreille's name for the genus, *Cyamus*.

Under "Order III. Myriapoda. Family XVIII. ASELLIDES," upon "Genus LXVI. CYMOTHOA," the observation is made:—"It is highly probable that *Oniscus testudo* of Montagu (*Transactions of the Linnean Society of London*, vol. ix. page 102, tab. 5, fig. 5) is referable to a genus akin to this." Leach having never himself seen the species, merely quotes Montagu's description.

1814. LEACH, W. E.

Article Crustaceology. Appendix. The Edinburgh Encyclopædia. Vol. vii. pp. 429-437. (That the date of this Appendix is not later than 1814 may be inferred from the fact that the genera *Pherusa* and *Proto* appear in it as new, without any reference to the mention of them in the Tabular View read before the Linnean Society in April, May and June of 1814.)

Leach has here "divided the Tribe MILLEPEDA from the Crustacea, and considered them as a distinct class, under the title of MYRIPODA, and has placed the ONISCIDES and ASELLIDES with the GASTERURI." The two orders Entomostraca and Malacostraca are now considered as sublasses. The three Tribes of the Malacostraca are called orders. The Gasteruri now include seven Tribes called Gnathides, Gammerides, Phronimarides, Caprellides, Apseudides, Asellides, Oniscides. Of these we find that the second, third, and fourth, belong to the Amphipoda. The Tribe Gammerides, answering to the previous Family Gammarini, is thus divided:—"Family I. ORCHESTIDÆ," "Genus I. TALITRUS," in which Leach has discovered that *Talitrus littoralis* is only the other sex of *Talitrus locusta*; "Genus II. ORCHESTIA." "Family II. DEXAMERIDÆ. Antennæ three-jointed, the last joint composed of several other minute articulations; upper ones longest," with two sections, "*Two anterior pairs of feet

monodactyle. Genus III. DEXAMINE. Four anterior feet nearly equal; hands sub-ovate, compressed and filiform," type species *Dexamine spinosa*, Montagu; " * * *Anterior pair of feet didactyle; second pair monodactyle.*" Genus IV. LEUCOTHOE."

"Family III. GAMMARIDÆ. Last joint of the antennæ composed of several minute articulations; upper pair longest, four-jointed; under ones five-jointed," with three sections, " * *Second pair of feet larger than the first, with a compressed hand.* Genus V. MELITA," "Genus VI. MAERA." " * * *Four anterior feet nearly equal in size and form with ovate hands.* Genus VII. GAMMARUS." "Genus VIII. AMPITHÖE superior antennæ, without a seta at the base of the last joint; back of the tail without fasciculi of spinules." " * * * *Four anterior feet with a filiform hand.* Genus IX. PHERUSA," left otherwise without definition, the type species *Pherusa fucicola* receiving this description:—"Colour whitish, nutted with reddish. Found on the rocky shores of Devon, under stous at low tide, on fuci."

"Family IV. PODOCERIDÆ. Superior antennæ shortest four-jointed, the last joint solid or obscurely articulated; inferior antennæ five-jointed, with the last joint solid, or very obscurely articulated." In the first section, " * *Superior antennæ very short, the last joint composed of many minute articulations,*" he places "Genus X. COROPHRIOUM [i.e., *Corophium*]"; in the second, " * * *Superior antennæ shorter than the under ones; the last joint scarcely articulated,*" he places "Genus XI. PODOCERUS," "Eyes hemispherical and somewhat prominent; four anterior feet didactyle, anterior pair smallest with an elongate sub-ovate hand; second pair with an ovate hand, and the internal side nearly straight," type-species, *Podocerus variegatus*; "Genus XII. JASSA, eyes not prominent; four anterior feet didactyle with ovate hands; the anterior pair smallest; the hand of the second pair with the internal edge furnished with teeth," with two species, *Jassa pulchella*, var. α , var. β , and *Jassa pelagica*, both these species being referred to as already established in the genus *Iassa*, Leach, "Mem. Wern. Soc. vol. ii." He adds that "*Cancer gammarus falcatus* of Montagu, *Lin. Trans.* vol. ix. tab. 5. fig. 2. seems referable to this genus." Modern opinion groups all the four last-mentioned species under the name *Podocerus falcatus*, Montagu. *Jassa* or *Iassa* would claim priority as the generic name, only that there seems to be nothing in the Mem. Wern. Soc. corresponding to Leach's reference. Tribe III. PHRONIMARIDES, only contains the genus *Phronima*. Of Tribe IV. CAPRELLIDES, Leach says, "This includes our family CAPRELLINI, to which we can add another genus, differing from *Caprella* in having true legs instead of the gelatinous fine [fin]-like legs, which is named Gen. PROTO. Sp. 1. *Pedata. Cancer gammarus pedatus*, Montagu, *Linn. Trans.* vol. xi. p. 6. tab. ii. fig. 6." This is *Proto ventricosa*, O. F. Müller.

1814. The Entertaining Magazine; or, Repository of General Knowledge, &c. By the Most Celebrated Modern Authors. Vol. II. London. Preface dated Dec. 31, 1814.

The Article "Animal Biography" concludes in July 1814, on page 354, with giving in Class V., Insecta, "Order VII. APTERA, or insects without wings. The genera are:—1. *Podura*, spring-tail. 2. *Pediculus*, louse. 3. *Pulex*, flea, chigger. 4. *Acarus*, tick, mite. 5. *Aranea*, spiders. 6. *Scorpio*, Scorpion. 7. *Cancer*, crab, lobster, crawfish, shrimp. 8. *Monoculus*, water-flea. 9. *Oniscus*, wood-louse. 10. *Scolopendra*, centipede." This contribution, "by the most celebrated modern authors," or some one of them, is a high compliment to the enduring influence exercised by Linnæus, whose earliest views on this portion of the animal kingdom are here reproduced, in spite of all that had been done in the interval by his distinguished successors throughout Europe.

1814. RAFINESQUE-SCHMALTZ, CONSTANTIN SAMUEL, born 1783, died 1840 (Hagen).

Précis des découvertes et travaux Somiologiques entre 1800 et 1801, ou choix des principales découvertes en zoologie, et en botanique. Palerme, 1814.

Somiologie is explained by this eccentric author to mean "la Science des Corps vivans," applying both to botany and zoology, to each of which he assigns two classes, which he sets one over against the other. The Crustacea are placed in the fifth class, the Plaxolia, in which he had observed about 180 species, nearly half of them new, to be described and figured in his *Plaxologie Sicilienne*. He describes a new genus *Pisitoe*:—"Antennes nulles, yeux irréguliers, bouche sous la tête, recourbée postérieurement, munie de crochets; Corps à 6 articles et 6 paires de jambes inégales, la quatrième paire la plus grande, queue à 4 articles, les 3 antérieurs à appendices.—Obs. Il appartient à l'ordre *Bragasteria*, et famille *Phronimia*, il diffère particulièrement du *G. Phronima* par son moindre nombre de jambes," with the species, "*Pisitoe bispinosa*, Front à deux épines antérieurement, les trois premières paires de pattes à un seul ongle," and "*Pisitoe levifrons*. Front lisse, sans épines, les trois premières paires de pattes à deux ougles." Boeck thinks that this genus may be the same as *Phrosina*, Risso. Costa makes *Pisitoe levifrons* a synonym of *Phronima sedentaria*, and regards *Pisitoe bispinosa* as equivalent to Risso's *Phrosine semilunata*, though apparently not thinking it right to displace Risso's name in favour of Rafinesque's inaccurately described genus and species.

1815. TILESUS VON TILENAU, WILHELM GOTTLÖB, born 1769, died 1857 (Hagen).

De Canceris Camtschaticis, Oniscis, Entomostracis et Cancellis marinis microscopicis noctilucentibus. Cum tabulis iv. aenca et appendice adnexo de Acarisi et Ricini Camtschaticis. Auctore Tilesio. Conventui exhibuit die 3 Februarii 1813. Mémoires de l'Académie Impériale des Sciences de St. Pétersbourg. Tom. 5. St Pétersbourg, 1815, pp. 331–405.

This author divides the Crustacea into three orders—1°) *Entomostraca*, "2°) *Astacoidea*, quorum corpus et cauda elongata et crusta calcarea obiectum est," 3°) *Carcinoidea* seu Brachiuri. A note to the *Astacoidea* says, "Palinurus, Astacus, Hippa, Squilla, Gammarus Palæmon, Crago Penæus et plura genera ad formandam familiam Astacoideorum microscopicorum vel Arthrocephalorum Dumerillii ad maximam partem noctilucentium marinorum subjungenda, v. g. Caprella Lamarkii, Mysis Latreillii ejusque Phronime vel Cancer sedentarius Forskålii, Thalitrus Latreillii, Amblyrrhyncotus vel obtusirostris, Erythrocephalus, Acanthocephalus, Anarthrus, Symphysopus et alii, quorum sermo erit in Sectione VIII. de Entomostracis inscripta."

At page 369, section IX. is devoted to the Onisci, in regard to which he prefers the views of Pallas to those of Linnæus. He gives a description of "*Oniscus scolopendroides*, Pallas, spicil. Zool. fasc. IX. tab. 4, fig. 15. Martens, Spitzb. t. P. f. 1. a.b.c. Longitudo digitus transversi, rarissime pollicaris. Corpus filiforme varicosum, septem articulorum, e quibus posteriores sensim minores. Antennæ majores dimidia corporis longitudine, interiuediae sub majoribus dimidio breviores, exiliiores. Palpi ad os exiles et prope os brachiola minuta elhelifera, qui primum par efficiunt pedum. Ad finem articuli secundi prelongi brachia duo insignia chelis magis ventricosis instructa. In tertio et quarto articulo utrinque vesicula ovata loco pedum, et in fæmellis ovariorum receptacula foliacea. Articuli posteriores pedibus ambulatoriis iuncti in postremo articulo longioribus parva chela

terminatis. Hæc onisorum species a Cancro linearis atomos et filiformi *Linnxi* vix differt, jam a *Stellero* nostro 1741 in portu divi Petri et Pauli Camtschatico observata et a me in fruticosis Sertulariae longissimæ et spinosæ fasciculis per ancoræ dentes avulsis, et cum ancora sublatis visa."

1815. RAFINESQUE-SCHMALTZ, C. S.

Analyse de la Nature ou Tableau de l'Univers et des corps organisés par C. S. Rafinesque. Palerme, 1815.

In the "Tableau des Classes Somobiques," the Règne Animal is divided into ten classes, of which four belong to the first Sous-Règne, "Zostolia;" the remaining six to the second Sous-Règne, the "Anostia, Anostiens," which have "Poiut de squelette osseux, ni d'épine dorsale vertébrée, uu cerveau ou une moelle longitudinale noueuse centre du système nerveux." The first "Sur-Classe" is the "Condylopia, Condylopes," with "des membres articulés et une tête; jamais de coquille." This contains Class V., the "Plaxolia, Crustacés," with "des Branchies, un cœur et des vaisseaux sanguins," and Class VI., "Entomia, Insectes." He disapproves the classifications of the Crustacea made respectively by Fabricius and Latreille, preferring Lamarck's division of them into Pédiocles and Sessiliocles.

The subclass Sessilioclia he thus defines:—"Yeux sessiles, non mobiles, ou effacés ou un seul ou aucun; tête articulée; ordinairement plus de 10 pattes exongulées et chaque paire inserée à un article." He includes in it the orders "4, Ostracina," "5, Pseudopia," "6, Branchypia." The sixth order, "Branchypia, Les Brauchypes" contains the following:—

- "14. Famille. PHRONIMIA. Les *Phronimiens*. Deux antennes ou aucunes, quelques pattes chéliformes ou pincifères.
- "1. S. F. ELAPHALIA. Les *Elaphales*. Point d'antennes. G. I. *Callirhoe* R. (*Heterelos* R.)
2. *Pisitoe* R.
- "2. S. F. CEROPHALIA. Les Cérophales. Deux antennes. G. 3. *Phronima* Foskael. 4. *Cerophas* R. 5. *Protonia* R.
- "15. Famille. GAMMARIA. Les *Gammariens*. Quatre antennes, quelques pattes chéliformes ou pincifères, corps ordinairement cylindrique ou comprimé, la tête plus longue du dernier article caudal.
- "1. S. F. TALATRIDIA. Les Talitrides. Queue terminée par des appendices ou soies. G. 1. *Talitrus* Bosc. 2. *Corophium* Latr. 3. *Gammarus* Fabr. 4. *Asope* R. sp. do. 5. *Plexaura* R. sp. do. 6. *Hippias* R. sp. do. 7. *Cychreus* R. sp. do. 8. *Steryllos* R. sp. do. 9. *Pepluredo* R. sp. do. 10. *Dinoa* R. sp. do. 11. *Thiella* R. 12. *Aglaura* R. 13. *Isolus* R. 14. *Eratea*. 15. *Zacoreus* R.
- "2. S. F. CYAMIDIA. Les *Cyamides*. Queue sans appendices ni soies. G. 15. *Caprella* Lam. 16. *Cyamus* Latr.

"16. Famille. ONISCIA. Les *Onisciens*. Quatre antennes, quatorze pattes, dont aucunes chéliformes ni pincifères, corps déprimé, le dernier article de la queue plus long que la tête et à appendices articulés.

- "1. S. F. ASELLOTA. Les *Asellotiens*. Quatre antennes très-apparentes. G. 1. *Asellus* Geofr. 2. *Idotea* Fabr. 3. *Sphaeroma* Latr. 4. *Cymothoa* Fabr. 5. *Tyronia* R. 6. *Primno* R. 7. *Psamathe* R.

"2. S. F. LYGIDIA," in which all the genera mentioned are Isopods, as indeed also are those under Asellota, although *Cymothoa* at one time included *Cyamus* and the name *Primno* was subsequently used by Guérin for one of the Hyperina.

It will be understood that the letters S. F. stand for sous-famille, R. for Rafinesque, G. for genre or genus.

1815. LEACH, W. E.

The Zoological Miseellany ; being Deseriptions of new, or interesting Animals, by William Elford Leach. Illustrated with coloured figures, drawn from nature, by R. P. Nodder. Vol. ii. London, 1815.

On page 21 Leach defines the new genus *Atylus* ;—“*Antennæ* 4-articulatae segmento ultimo e plurimis artieulis minutis efformato ; *superiores* sub-breviores artieulo secundo tertio longiore ; *inferiores* artieulo secundo tertio sub-breviore. *Oculi* sub-prominentes rotundati inter antennas in capitib processum inserti. *Pedes* 14 ; paria 1 et 2 monodactyla manu parvula, compressa, 3, 4, 5, 6 et 7 ungue simplici instruta. *Cauda* utrinque stylis duplicitis tribus et superne stylulo utrinque mobili instruta. *Corpus* (capitē ineludente) 12-articulatum.” Stylos duplicitis tribus is translated “with a triple series of double styles,” and (capitē ineludente), “(including the head).” The type species *Atylus carinatus* is figured the natural size, and the desription is taken from the specimens of *Gammarus carinatus* described by Fabricius, Ent. Syst. 2. 515, 3, so that Leach feels justified in correcting that author’s statement that the hands are simple, “*G. manibns adactylis*.” On page 23 the genus *Dexamine*, already established in the Edin. Encycl., vol. vii. p. 432, is here more fully characterised :—“*Antennæ* triarticulatae segmento ultimo e plurimis artieulis minutis efformato, segmento primo secundo breviore ; *superiores* longiores. *Oculi* oblongi hand prominentes ponc antennas superiores inserti. *Pedes* 14 ; paria 1 et 2 monodactyla manu parvula, compressa, 3, 4, 5, 6 et 7 nngue simplici instructa. *Cauda* utrinque stylis duplicitis tribus, superneque stylo ntrinque mobili instructa. *Corpus* (capitē includente) 12-articulatum.” The type-species is Montagn’s “Caneer *Gammarus spinosus*,” now *Dexamine spinosa*.

1815. LEACH, W. E.

A Tabular View of the external Characters of Four Classes of Animals, which Linné arranged under INSECTA ; with the Distribution of the Genera composing Three of these Classes into Orders, &c., and Deseriptions of several New Genera and Species. The Transactions of the Linnean Society of London. vol. xi. Part the Seeond, MDCCCXV. pp. 306–400. (Read April 19, May 3, and June 1, 1814.)

He here proposes to include in a new class the *Syngnatha* and *Chilognatha* of Fabricius [the Myriapoda], which Latreille and Lamarck had arranged with the Arachnides. He therefore distinguishes into four classes the Crustacea, Myriapoda, Arachnides and Insecta. The Crustacea with “Branchiis pro respiratione,” form two subclasses, the Entomostraea and the Malaeostraea ; to the latter he unites the Tetraecra, whieh Latreille had placed with the Arachnides, and divides the subclass into two Legions, the Podophthalma and the Edriophthalma, the latter being defined as having “oculi sessiles.” This Legion comprises three sections, the first with “corpus lateraliter compressum. Pedes 14. Antennæ 2 in frontem insertæ, unâ utrinque. (*Cauda stylis instructa*),” one genus. The second section has “corpus lateraliter compressum. Pedes 14 coxis lamelliformibus. Antennæ 4 per paria insertæ. (*Cauda stylis instructa*).” It includes five divisions with thirteen genera. The third section has “corps depresso. Antennæ 4. Pedes 14.” with four groups, seven divisions and twenty-four genera, the first division with two subdivisions and three genera belonging to the Amphipoda.

Sectio I. contains only “Gen. PHRONIMA, Latr.” which is fully described, and has “Spec. 1. *Phronima sedentaria*.”

Sectio II. has the following arrangement: "Divisio I. *Antennæ* 4-articulatæ, articulo ultimo e plurimis segmentis minutis efformato; *superiores* brevissimæ, inferiorum pedunculo breviores." Gen. 2. *TALITRUS*, *Latr.*, *Bosc.* *Pedes* quatnor antici in utroque sexu subæquales, mouodactyli. *Antennæ* superiores articulis duobus inferiorum basilaribus breviores. "Spec. 1. *Talitrus locusta*." "Gen. 3. ORCHESTIA," Leach's own genus re-defined:— "Pedum paria qnatuer antica MARIS monodactyla, pari secundo manu compressâ magnâ; FÖMINÆ pari antico monodactylo, secundo didactylo. *Antennæ* superiores articulis duobus basilaribus inferiorum hand longiores. Spec. 1. *Orchestia littorea*."

"Divisio II. *Antennæ* quadriarticulatæ, articulo ultimo e segmentis plurimis aliis distinctis efformato; superioribus subbrevioribus. Gen. 4. ATYLUS," with the observation, "Generi Dexamini valde affine est hoc genus," and "Spec. 1. *Atylus carinatus*," Fabr.

"Divisio III. *Antennæ* triarticulatæ, articulo ultimo e plurimis aliis distinctis confecto, superioribus longioribus. Gen. 5. DEXAMINE." Spec. 1. *Dexamine spinosa*; "Gen. 6. LEUCOTHÖE." Spec. 1. *Leucothöe articulosa*.

"Divisio IV. *Antennæ* 4-articulatæ, articulo ultimo e plurimis articulis efformato; *superiores* longiores. Subdivisio I. *Pedum par secundum maris manu dilataâ compressâ*. Gen. 7. MELITA." Spec. 1. *Melita palmata*; "Gen. 8. MAERA." Spec. 1. *Maera grossimana*. "Subdivisio 2. *Pedum paria duo antica in utroque sexu monodactyla conformia*. Gen. 9. GAMMARUS, *Antennæ* superiores ad basin articuli quarti setâ parvulâ articulatâ instructæ. *Cauda* superne fasciculato-spinosa. * *Cauda stylis geminatis superioribus stylo supero brevisimo*. Spec. 1. *Gammarus aquaticus*. G. processu inter antennas obtuso rotundato," with the synonym "Gammarsus Pulex. Leach, Edin. Encycl. vii. 402-432." "Spec. 2. *Gammarus marinus*. G. processu inter antennas subacuminato." ** *Cauda stylis geminatis superioribus stylis subæqualibus*. Spec. 3. *Gammarus Locusta*." Spec. 4. *Gammarus Campylops*;" "Gen. 10. AMPITHÖE." Spec. 1. *Ampithöe rubricata*; "Gen. 11. PHERUSA." *Antennæ* superiores setâ nullâ ad artienli quarti basin. *Cauda* superne haud fasciculato-spinosa. *Manus filiformes*," a definition which differs from that of *Ampithöe* only in the substitution of filiformes for ovatæ. The type-species, *Pherusa fucicola*, is still only described by its colour, which, according to Leach's own rendering of his Latin, is "testaceous-cinereous, or gray-cinereous, mottled with reddish."

"Divisio V. *Antennæ* 4-articulatæ, inferiores longiores, pediformes. (*Pedes* quatnor antici monodactyli.) Subdivisio 1. *Pedum par secundum manu magna*. Gen. 12. PODOCERUS." Spec. 1. *Podocerus variegatus*; "Gen. 13. JASSA." Spec. 1. *Jassa pulchella*. Var. α . manu secundâ dente elongato, obtuso ad interni lateris basin. Var. β . manu secundâ latere interno tridentatâ; Spec. 2. *Jassa pelagica*, and the observation, "Gammarus falcatus, Montagu, Trans. Linn. Soc. ix. ad hoc genus pertinere videtur." Subdivisio 2. *Pedum par secundum manu haud magnâ*. Gen 14. COROPHIUM. *Latr.*, Spec. 1. *Corophium longicorne*.

"Sectio III. *Corpus* depresso. A. *Cauda inermis*. Divisio I. *Corpus* 6-articulatum, segmentis omnibus cum capitib basi pedigeris. *Pedes* 14; *paria duo antica* ungue mobili, (pollice) instructa; *par anticu* minus, ad caput annexum, carpo articulato; *paria tertium* et *quartum* sæpius spuria; *paria sex posteriora* coxis aliquot prodnetis, *unguis* validis armata. *Antennæ* qnatuer, superiores longiores. *Os* palpis dnobns apice unguulatis. *Anus* tuberculis parvis obscuris. *Bursa* (*uterus externus*) valvulis imbricata inter fœminæ pedum paria tertium et quartum sita est, quâ ova, pullique post exclusionem educantur. Animalia parasitica in Oceano degentia, Fucis, Cetaceis (Piscibusque?) arcte affigentia. Subdivisio 1. *Corpus lineare*. *Oculi pone antennas superiores siti*. *Antennæ* 4-articulatæ, *superiores* segmento ultimo aliorum longitudine, e plurimis aliis compositis; *inferiores* subcompressæ, superioribus dimidio minores. *Pedum par anticu* (*Palpi* Montagu) *os prope situm*: *secundum manu sibi intus dentatâ*." Gen. 15. PROTO. *Pedum paria secundum, tertium* et *quartum* basi appendiculata. *Pedes* omnes validè unguiculati. Ad hoc genus pertinet

Squilla pedata, forte etiam *ventricosa*? Müller." "Gen. 16. CAPRELLA." with the note, "ad hoc genus *Astacus atomos*, Pennant, *Squilla lobata*, Müller, et *Cancer Phasma* Montagu pertinent," but Leach declines to disentangle the confused synonymy.

"Subdivisio 2. *Corpus latum, Oculi in verticem siti. Antennæ 4-articulatæ, superiores longiores, articulo basilari paulo majore, secundo tertioque aequalibus basilari paululum minoribus, ultimo minuto penultimo quadruplo minore; inferiores articulo basilari superiorum breviores articulo ultimo minuto. Pedes compressi valide unguiculati; paria duo antica police instructa; par anticum minimum ad capitis basin adnexum, carpo articulato, secundum majus manu intus dentata, tertium et quartum coriaceo-membranacea, cylindrica, elongata, spuria. Anus productus, tuberculis obscuris parvis. Bursa (uterus externus) valvulis quatuor imbricata.*" Gen. 17. LARUNDA, with *Cyamus*, Latreille, Lamarck, and *Panope*, Leach, for synonyms. *Larunda ceti*, the only species.

There are thus no new genera properly speaking in this paper, but Leach probably regarded those which had just been instituted by him in the appendix to his Article Crustaceology in the Edinburgh Encyclopædia as practically new. These are *Dexamine*, *Ampithoe*, *Pherusa*, *Podocerus*, *Jassa*. In the Encyclopædia he refers to Mem. Wern. Soc., vol. ii., for *Jassa*, but apparently by mistake, as the genus does not appear in that volume, and the reference is not repeated in the Linnaean Transactions. *Atylus* was instituted in the Zool. Misc., vol. ii. *Proto* appears here as a new genus, or at least without reference to any previous work. It appears indeed in the appendix above-mentioned, but that appendix may have been in fact contemporaneous in its production with the present "tabular view."

Leach does not give any reasons for rejecting the earlier name *Cyamus*, Latreille, or his own *Panope*, in favour of *Larunda*. *Panope* he may have thought too near to *Panopea* or *Panopaea* employed among Mollusca in 1807. *Cyamus* he perhaps rejected as a name already employed in botany, but Lütken points out that, so far as the Linnaean era is concerned, its zoological use takes precedence of the botanical.

1816. LEACH, W. E.

Annulosa. Encyclopædia Britannica. Supplement., pp. 401-453.

The Annulosa are explained to comprehend five classes—Crustacea, Myriapoda, Arachnides, Insecta, Vermes. The Crustacea are distinguished as having "Branchiæ or gills for respiration. Legs for motion." By "legs" are meant "those organs which actually perform the functions of legs." A review is given of the earlier systems of classification for the Crustacea, concluding with that adopted by Leach himself in the Linnean Society's Transactions, vol. xi. part 2, which was read in 1814, and published in 1815. This system is here repeated, in English instead of in Latin, but otherwise as far as the Amphipoda are concerned, practically unaltered; two or three immaterial observations are added, and in Section III., the definitions of Divisio I. and its two subdivisions are omitted. In both papers *Phronima* is sometimes spelled *Phronyma*, and in the English notes on *Phronima sedentaria* Leach observes that "all authors have erred in giving but ten legs to this animal." This is unjust to Forskål who attributes to the species "pedes utrinque decem: paria enim septem thoracis septem articulis adhærent." To *Gammarus pulex* of his earlier work, Leach, in this and the preceding paper, gives the name *Gammarus aquaticus*, as a new species distinct from the *Gammarus pulex* of Latreille and Bosc, arguing from their borrowed figures, which represent the hands much dentated within. That, however, is very little to the purpose, since their figures are only taken from Rösel's *Squilla fluvialis* without regard to the creature described. On Plate XXI., *Melita palmata*, *Pherusa fucicola*, and *Larunda ceti* are figured.

1816. SAVIGNY, MARIA JULES-CÉSAR LELORGUE, born 1777, died 1851 (Hagen).

Mémoires sur les Animaux sans vertèbres. Première partie. Description et Classification des animaux invertébrés et articulés, connus sous les noms de Crustacés, d'Insectes, d'Annélides, &c. Premier fascicule. Mém. 1-2. Théorie des organes de la bouche des Crustacés et des Insectes. *Insecta*, Linn. A Paris. Janvier 1816.

Savigny tells us in the preface that he based his theory on the examination of some 1500 species of insects and crustacea, most of them scarcely four or five lines in length, and some far smaller. These were carefully dissected, and complete descriptions drawn up and accurate drawings made of the organs of nutrition, motion, sensation, respiration, &c.

The theory in brief is, that whatever form of mouth the insects may take, it is always composed of the same elements. In the second memoir he divides the Insecta of Linnaeus into two classes, 1. insectes *Hexapodes*, which in the perfect state never have more than six feet attached to the first three rings of the body, including all the winged insects with "la Puce, le Pou, le Ricin, les Forficules, les Podures," the latter two more doubtfully added; 2. insectes *Apiropodes*, with more, sometimes many more, than six feet, including "les Entomostracés, les Crustacés, les Pycnogonum, Scorpions, Araignées et autres insectes sans antennes, les Scolopendres, les Iules." He shows that in the mouth of the crab are to be found the elements which constitute the mouth of the Hexapod insect, but in addition other elements which must of necessity be analogous to the six feet of the Hexapods. All doubt on this point, he says, is removed by what we find in *Gammarus*. This, like the crab, has two compound eyes, four antennae, a large upper lip, a tongue deeply bifid (the labium inferius), two mandibles, two first maxillæ, two second maxillæ free, not forming together a lower lip. Behind these second maxillæ are not found six auxiliary maxillæ as in the crab, but two only united at the base and exactly imitating a lower lip surmounted by its two palps. But these palps are armed with strong hooks or nails. After them come not ten but fourteen feet, four more than in the crab, a number just equal to the auxiliary maxillæ which *Gammarus* has fewer than the crab. In truth, he says, all Crustacea properly so-called have sixteen feet, of which more or fewer are converted into auxiliary maxillæ. He noticed that in removing the head from some of the smaller Crustacea, the *Cymothoæ* for example, the maxillipedes remain attached to the first ring of the body. This I have found with some of the Amphipoda.

The mistake which Fabricius made in placing in the same genus the *Pycnogonums* without antennæ, and the *Cyami* which have four, Savigny attributes to the real relations "in the habitation, mode of life, and above all, the general form of body of these parasitic insects." But in a note he says, "les Pycnogonum ne sont point parasites à la manière des Cyamæ. Il paraît qu'ils s'attaquent principalement aux coquillages bivalves." In comparing *Cyamus*, a close relation of the *Gammari*, with *Nymphon* of the *Pycnogonum* family, Savigny hopes to show how Nature passed from the mouth of the Crustacea to that of the Arachnides. He states that the head of *Cyamus* is "pourvue de gros yeux composés," and in describing the eyes of *Nymphon*, "très-petits, lisses et groupés près de la tête sur le dos," he adds "ce qu'il y a de singulier, c'est qu'on trouve aussi deux petits yeux lisses au Cyame. Ce sont même les seuls que les naturalistes aient aperçus." The singularity, however, is on the part of Savigny, who, Lütken says, introduced the fiction of the large compound eyes. He does not figure them either in the upper or under view which he gives of the animal. In the "Rapport fait à la première Classe de l'Institut," by the "commissaires MM. Cuvier, de Lamarck et Latreille, rapporteur," Savigny's mistake was accepted without question, to

judge by the quotation he gives from it on page 72, "On n'avait encore aperçu que les deux petits yeux lisses des Cyames, et M.S., en découvrant les yeux ordinaires ou composés, nous montre un fait dont nous n'avions pas encore d'exemple parmi les Crustacés, et qui indique un nouveau rapprochement des Cyames avec les Arachnides sans antennes."

In Plate IV. "*Gammarus . . . Cymadusa filosa*," n.s., now called *Amphithoë filosa*, and "*Gammarus . . . Lycesta furina*," n.s., now called *Leucothoë furina*, are figured in part; and on Plate V. *Cyamus ceti*, Latreille, which is *Cyamus mysticeti*, Lütken. In the description of details it may be noticed that the lower lip or labium is called *langue*, the maxillipeds lèvre auxiliaire, and to the six free joints of the legs are given the designations, 1. hanche, 2 and 3. cuisse, 4 and 5. jambe, 6. tarse.

1816. POLLINI, CIRO.

Viaggio al Lago di Garda e al Monte Baldo in cui si ragiona delle cose naturali di quei luoghi aggiuntovi un cenno sull'curiosità del Bolea e degli altri monti Veronesi. In Verona, 1816.

He remarks, pages 22, 23, "Oltre del Gambero comune, *Cancer Astacus*, rinvengansi al nostro Lago due granchietti. L'uno è il *Cancer Squilla* (Gamberozoli volg.), che abita infra l'erbe palustri tanto del Benaco, quanto delle risaie nostre, ed è la varietà a rostro dritto. L'altro è il *Cancer Pulex* (Saltercello volg.); ritrovasi nel greto a quattro dita, dove si moltiplica prodigiosamente. Dalla sua bocca esce un umore corrosivo, alto a sciogliere la terra. E poichè nelle ore calde suole uscire dal covacciolo, reca sommo danno alle tele di lino e di canape, che si stendono dai benaccensi ad asciugare ed imbiancare sulla spiaggia, mentre le foracchia di mille modi con l'umore onde si prepara l'alimento. Fu scoperto anche in alcuni pozzi di Verona, e nelle terme di Caldiero." G. D. Nardo, in 1868, states that the "Gambazzolo" is *Anchystia palustris*, Heller, but of the *Cancer pulex* so destructive to linen on the beach, when it issues from its burrows in the heat of the day, he gives no explanation. It may be conjectured that this burrower is one of the *Orchestidae*, and that when Pollini speaks of its being found also in wells and warm springs, he is confounding it with other Amphipods, such as *Niphargus puteanus* and *Gammarus pungens*.

1816. BLAINVILLE, MARIE HENRY DUCROTAY DE, born 1778, died 1850 (Hagen).

Prodrome d'une nouvelle distribution systématique du règne animal. Bulletin des Sciences, par la Société Philomatique de Paris. Année 1816, Paris, pp. 105 [113]–124.

De Blainville declares his object to be to group animals "d'après l'ensemble de leur organisation." For the purposes of his system, he says, "Je suis arrivé à mettre en première ligne la disposition des différentes parties ou la forme générale des animaux, ce qui se trouve concorder avec celle du système-nerveux quand il existe. Puis l'organe qui soutient cette forme ou la peau et ses annexes. Après cela les appendices qui s'y ajoutent, et s'y développent. Enfin, les différentes modifications et combinaisons de ces modifications des appendices, c'est-à-dire des organes des sensations, de la locomotion, dans ses différentes espèces, de la mastication, et jusqu'à un certain point de la respiration."

In the Tableau Analytique he divides "ANIMAUX" into "I^e Sous-règne *Pairs* ou ARTIOMORPHES. II^e Sous-règne *Rayonnés* ou ACTINOMORPHES. III^e Sous-règne sans forme régulière."

lière ou HÉTÉROMORPHES." The first subkingdom is again divided into "Type I. Vertébrés ou OSTÉOZOAIRES. Type II. Invertébrés ou ANOSTÉOZOAIRES." This second type has three subtypes, I^e Sous-type. non-articulés; Mollusques MALACOZOAIRES. II^e Sous-type. Sub-articulés ou SUB-ENTOMOZOAIRES. III^e Sous-type. Articulés à Append. ENTOMOZOAIRES." The second of these contains Classe VIII. POLYPLAXIPHORES. Classe IX. CIRRHOPODES. For the third subtype the following Table is given :—

Cl. X.-XVII. INSECTES ET VERS. A. Articulés, Entomozooaires.	ORD.		
<i>Entomozoologie ou Entomologie.</i> <i>Entomologistes.</i>			
Classe I ^e . 6 pieds HÉXAPODES ou Insectes.	Sous-Cl. I ^e . TÉTRAPTERES, Sous-Cl. II. DIPTERES, Sous-Cl. III. APTÉRES.		
II ^e . 8 pieds OCTOPODES ou Arachnides.	LÉPIDOPTERES. COLEOPTERES. ORTHOPTERES. HÉMIPTERES. NÉVROPTERES. HYMÉNOPTERES.		
Plus petit que les anneaux. Articulés ou de pieds en nomb. Munis d'appa- ndices.	III ^e . 10 pieds DÉCAPODES ou Crustacés. IV ^e . Pieds var. HÉTÉROPODES. V ^e . 14 pieds TÉTRADÉCAPODES. VI ^e . MYRIAPODES. VII ^e . SÉTIPODES ou Annélides. Sans appendices latéraux,	Sous-Cl. I. ACÉRES. Sous-Cl. II. TÉTRACERES, ATHORACIQUES. Sous-Cl. I. Sous-Cl. II. Sous-Cl. I. Les TÉTRACERES. Sous-Cl. II. Les EPIZOAIRES. Sous-Cl. I. Les SANG-SUES. Sous-Cl. II. Les ENTOZOAIRES.	BRACHYURES. MACROURES. BRANCHIOPODES. SQUILLAIRES. CREVETTINES. ASELLES. CLOPORTES.

In the notes, he says, "Dans cette nouvelle distribution des animaux articulés, qui fait le sujet d'un Mémoire communiqué à M. Latreille, le 19 Juin 1815, et lu à la Société philomatique le 24 du même mois, on voit que le principe a été de ne tirer les caractères que des organes de la locomotion, on mieux, de la combinaison des différentes espèces d'appendices dont peut être accompagné chaque anneau du corps." Note 4, to les EPIZOAIRES, says, "Cette sous-classe, dont j'ai fait le sujet d'un travail particulier, contiendra, outre les Lernées et plusieurs genres nouveaux que le Dr. Leach et moi avons cru devoir établir, les Calyges, Cyames, Chévroles, etc., de manière à passer insensiblement aux Tetracères."

1816. BLAINVILLE, M. H. D. DE.

Sur une nouvelle distribution des classes des Crustacés, des Myriapodes, et des Arachnides ; par le docteur WILLIAMS ELFORD LEACH. Bulletin des Sciences, par la Société philomatique de Paris. Année 1816, Paris.

This is merely a report of Leach's paper in the Linnean Society's Transactions, as the title intimates.

1816—
1817. LATREILLE, P. A.

Nouveau Dictionnaire d'histoire naturelle, appliquée aux arts, à l'Agriculture, à l'Économie rurale et domestique, à la Médecine, &c. Par une Société de Naturalistes et d'Agriculteurs. Nouvelle Édition. A Paris. M DCCC XVI. (Thirty-six volumes, of which the first seven belong to 1816, the remainder to 1817, 1818, 1819. The Crustacea are by Latreille.)

In the first volume, pp. 467–469, Latreille institutes the order of Amphipoda, with the following divisions:—

I. *Deux antennes.* Le genre PHRONYME. II. *Quatre antennes.* A. *Les quatre antennes presque semblables pour la forme; les inférieures, n'imitant pas des espèces de pieds.* a. *Antennes supérieures plus longues que les inférieures.* Les genres CREVETTE, MÉLITE, PHÉRUSE, DEXAMINE, LEUCOTHOÉ. b. *Antennes supérieures plus courtes que les inférieures.* ATYLE, ORCHESTIE, TALITRE. B. *Antennes inférieures en forme de petits pieds.* Les genres COROPHIE, PEDOCÈRE. Voyez aussi: AMPHITHOÉ, JASSE, MERA.

In the fifth volume under “Chevrolle, *Caprella*, Lam.” Latreille refers to the genus “*Proton*,” as containing “les espèces qui ont dix pieds attachés successivement par paires, et sans discontinuité, à autant d’anneaux,” while “le genre des Leptomères” contains the species “où les pieds sont au nombre de quatorze.” Of *Caprella* he makes two groups:—

“I. *Tête ovale pointe peu rétrécie postérieurement,* containing *Caprella acutifrons*, Leach, and *Caprella acuminifera*, thus described:—“Les quatre antennes presque sans cils; corps ayant en dessus de petits tubercules pointus; premier segment renflé, en forme de noeud, vers son extrémité postérieure, à l’insertion de la seconde paire de pieds, avec deux tubercules en dessus; les pieds allongés, avec leur serre échancree en forme de croissant et armée d’une forte dent en dessous; leur doigt ayant aussi une dent au même côté. Je l’ai reçue de M. Leach sous le nom d’*acuminifera*.” This is probably *Caprella acanthifera*, Leach.

Group “II. *Tête allongée et rétrécie postérieurement*” contains *Caprella linearis*, Linn., and *Caprella mantis*, n. sp., thus described:—“La seconde paire de pieds est plus courte; ses articles inférieurs sont comprimés et anguleux; leurs fesses ont à leur base et à l’extrémité opposée, une dent assez forte; ou en distingue une troisième, mais plus petite, sous celle de bout. Sur nos côtes baignées par l’Océan.”

He adds that “il faut encore rapporter à ce genre le *cancer fitiformis* de Linnaeus. Forskaël en décrit une autre espèce, comme une larve d’un genre incertain, *Faun. arab.*, pag. 87.”

In the eighth volume the article Crustacés extends from p. 487 to p. 494. It contains a brief history of Carcinology, and definitions of the five orders into which Latreille at this epoch divided the class. The situation and form of the branchiæ, the manner in which the head articulates with the trunk, and the masticatory organs, have, he says, furnished the principal characters for his classification. He explains the name Amphipoda, which he gives to the third order (see Glossary). He supposes them to have two kinds of branchiæ, the one set vesicular, placed at the inside of the base of the leg, the other set setaceous, under the tail (“en forme de poils ou de soies, annexés à des espèces de fausses pattes, situées sous la queue”).

The article “CYSTIBRANCHES, *Cystibranchia*, Latr.” receives what are now called the Caprellina as a “section des crustacés, de l’ordre des isopodes,” but distinguished from other Isopods by so many characters that Latreille thinks they might well form a separate order. Hence in the seventeenth volume, 1817, we find the article “LEMODIPODES, *Lemodipoda*. (Gorge à deux pattes.) Ordre de crustacés qui, dans l’ouvrage de M. Cuvier, sur le Règne animal, compose la section des cystibranches de l’ordre des isopodes, mais que j’en ai ensuite séparé

pour en former un ordre spécial. Ses caractères ont été développés à l'article CYSTIBRANCHES. V. ce mot." Already to the article on the Isopods, his fourth order, he had appended a note, "On pourroit former un ordre particulier, sous le nom de *læmodipodes* (*læmodipoda*), des *isopodes cystibranches*. Leurs quatre mâchoires sont disposées sur le même plan transversal, en forme de lèvre, comme celles des myriapodes; la première paire de pieds proprement dits est annexée à la tête; ils n'ont point de branchies sous la queue; de petits corps vésiculeux, analogues à ceux qu'on voit à la base des pieds des amphipodes, paroissent en tenir lieu."

These *Læmodipodes*, he thinks, lead towards the Myriapods or the Pyenogonides.

Throughout the work the various genera of Amphipoda and Læmodipoda accepted at this period are discussed in the alphabetical order of their French names, but without, so far as I have seen, any novel information being contributed. In most instances the French and Latin names begin with the same letter, but *Gammarus* is an exception, being in French Crevette or Chevrette. Of the "CREVETTINES, *Gammarinæ*," Latreille says, "J'ai, dans mes ouvrages précédens sur l'entomologie, désigné sous ce nom une famille de crustacés composée de ceux qui forment aujourd'hui l'ordre des *amphipodes* et la division des *isopodes*, que j'appelle *Cystibranches*."

1816. RISSO, A., born 1777, died 1845 (Hagen).

Histoire naturelle des Crustacés des environs de Nice. Par A. Risso. Ornée de gravures. A Paris, 1816.

Risso begins with a quotation from Cuvier, "La détermination précise des espèces, et de leurs caractères distinctifs fait la première base sur laquelle toutes les recherches de l'Histoire Naturelle doivent être fondées," &c. Risso's own intention, doubtless, was to act in accordance with this maxim. Nevertheless, the species he established have in several cases caused great perplexity, owing in part, perhaps, to the want of repeated researches in those localities in which Risso's specimens were taken. In discussing the habitations of Crustacea, he regards *Talitrus* as amphibious, delighting in the rocks; *Caprella* (les chevrolles) hides under stones covered with fucus; *Cyamus* attaches itself to cartilaginous fishes; *Phronima* floats on the surface, leaps lightly out, or penetrates to small depths below. *Typhis* is found beyond the *Zostera* zone.

He divides the class Crustacés into two orders, the first "Cryptobranches. Tégumens durs; branchies cachées sous le corcelet; yeux pediculés; sans palpes ou antennules; dix pattes foliacées ou mutiques," subdivided into two sections (1) Brachiures, with two families containing between them eleven genera, and (2) Macroures, with three families containing among them seventeen genera; the second, "Gymnobranches. Tégumens coriaces; branchies cachées ou inconnues; yeux le plus souvent sessiles; mandibules palpigeres; dix pattes ou plus; terminées par des crochets," subdivided into three sections (1) "Squillines. Tête distinct du corcelet;" (2) Tétracères; (3) Entomostracés. The Squillines include two families, "Squillares. Queue munie de lames ou de filets, yeux pediculés," with the genera *Squille* and *Mysis*; "Crevettines. Queue avec ou sans appendices foliacés, yeux sessiles," with the genera, "31. Phronime. 32. Typhis. 33. Euphée. 34. Talitre. 35. Crevette. 36. Chevrolle. 37. Cyame." The second section, Tétracères, contains two families, Asellotes and Cloportides, each with six genera; the third section, Entomostracés, contains two families, the Clypéacés with one genus, and the Ostracodes with two genera.

The Isopod *Anceus*, it may be noticed, is here given as a new genus, among the third family, Paguriens, the first of the Macroures. It is, in fact, a synonym of the genus *Gnathia*,

named by Leach in his Article Crustaceology, 1813-1814. Leach himself appears for some unexplained reason to have allowed his genus *Gnathia* to drop, but the name retains its right of priority notwithstanding.

Pages 119 to 132, and Pl. II. figs. 3, 9, are concerned with Amphipoda, arranged as follows:—
 “Septième Famille. CREVETTINES. (1) *Antennes n'étant point terminées par des filets. A. Queue sans appendices* [which is inconsistent with the descriptions that follow]. G. xxxi.
 PHRONIME. *Phronima*, Latr. Les pattes des deux premières paires monodactyles. LATR.”
 Espèces. (1) “*P. Sedentaria*, Latr.” “(2) *P. SENTINELLE*. N. *P. custos*, N. Planch. 2, fig. 3. *P. Corpore linearis, albissimo; pedibus decem, tertio pari longiore aequali, didactylis*, N. Cette phronime a le corps linéaire, cylindrique et blanchâtre. Son corcelet est formé de très-petits segmens. Sa tête est conique, plane sur le devant. Ses yeux sont noirs et sessiles. Ses pattes sont filiformes ; la troisième paire est un peu plus longue que les autres et armée de pinces égales, les postérieures sont courtes et grêles. L'abdomen est composé de quatre longs segmens. La queue se termine par une petite plaque qui sert de support à des appendices bifurqués. *Dimens. long. 0,040. larg. 0,004. Séjour : dans les équorées et geronies. (Genres de meduses.)*” This species is, in Claus's opinion, the same as the preceding. “G. xxxii. *TYPHIS*. N. *Typhis*. N. Corps arrondi, abdomen plié sous le corcelet dans le repos ; pattes de la première paire didactyles ; celles des deux dernières en forme de lames avec un ongle crochu à l'extrémité. Espèce. T. OVOIDE. N. *T. Ovoides*.

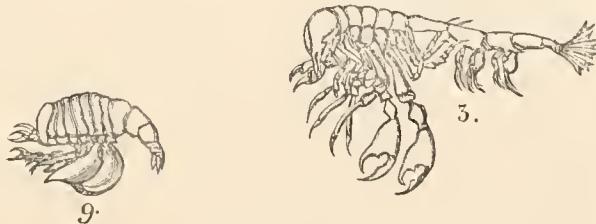

Fig. 18.

N. Planch. 2, fig. 9. Cette espèce ne peut entrer dans aucun des genres connus de la classe des Crustacés. Son corps est ovoïde, lisse, d'un beau jaune clair et luisant, parsemé de petits points rougeâtres ; sa tête est oblongue, très-large et tronquée sur le devant. Ses yeux sont petits ainsi que ses antennes. Sa bouche est garnie des palpes soyeux. Son corcelet est composé de segmens très-rapprochés, qui sont munis sur leurs bords de lamelles, sur lesquelles les pattes s'articulent. La première paire est presque aplatie, à cinq articles dont le dernier est didactyle : la seconde et la troisième paires sont petites, monodactyles, et les deux dernières, consistent en deux grandes et larges lames terminées par un crochet. L'abdomen est convexe, composé de cinq segmens. Les écailles caudales sont arrondies, ciliées ; la pièce du milieu est conique et aiguë.” “*Dimens. long. 0,024. larg. 0,012. Séjour : dans le golfe de Nice.*” This species has been called *Thyropus ovoides* by Spence Bate, and *Eutyphis ovoides* by Claus, but *Dithyrus*, Dana, being the earliest synonym of the preoccupied name *Typhis*, will take precedence for the genus, and the species will be *Dithyrus ovoides*. Risso's own figures are drawn with very fine lines and give the details more clearly than might be supposed from my copies of them.

Risso continues as follows:—“2. *Antennes terminées par des filets. A. Queue ayant des appendices.* G. xxxiii. EUPHÉE. N. *Eupheus*. N. Corps cylindrique, terminé par de longs filets ; pattes de la première paire didactyles.” This genus is now generally regarded as belonging to the Isopoda, and its one species, *Eupheus ligoides*, as being identical with the earlier *Cancer (Gammareus) talpa* of Montagu, Leach's *Apseudes talpa*. “G. xxxiv.

TALITRE. *Talitrus*. Latr.," contains two species, "1. T. GAMMARELLE. *T. Gammarellus*, Latr," which is *Orchestia gammarellus*, Pall., and "2. T. TACHETÉ DE ROUGE. N. *T. rubropunctatus*. N. *T. Chelis minimis; pedibus secundo pari longissimis apice ovatis, acutis*. Cette nouvelle espèce a le corps comprimé, d'un jaune clair, transparent ; composé de dix segments tachetés de rouge. Sa tête est presque triangulaire, ses yeux sont réniformes, réticulés ; ses antennes supérieures presque aussi longues que les inférieures, avec les deux premiers articles très-gros et fort longs. Le premier de ces inférieures est court et renflé. La première paire de pattes est grêle, courte ; la seconde est longue avec leur dernier article ovale, tacheté de rouge et terminé par un érochet. La femelle porte des œufs blanchâtres, en avril. *Dimens. long. 0,015. larg. 0,004. Séjour : dans le golfe de Nice.*" This species is not included in the general lists either of Milne-Edwards or Spence Bate, although the latter writer notices *Enone punctata*, which is evidently the same species, renamed but treated as new, by Risso in 1826. That it is not a *Talitrus* may be inferred as well from the description of the antennae as from Risso's preliminary remark, evidently referring to this species, "une des deux espèces que je vais décrire se tient en pleine mer, et saute toujours à la surface de l'eau pendant les calmes de l'été." "G. xxxv. CREVETTE. *Gammarus*. Fabr." "Espèce. G. PUCE, *G. Pullex*. Fab." "Var. A. On trouve des individus coloré d'un rouge pâle au vallon obscur." *Pullex* in the errata is corrected to *Pullex*.

After *Gammarus* follows "B. Queue sans appendices. G. xxxvi. CHEVROLLE. *Caprella*. Latr." "Espèces. 1. C. LINÉAIRE. Latr. *C. Linearis*. Latr.," "2. C. PONCTUÉE. N. *C. Punctata*. N. *C. Pedibus anticis brevibus; secundo tertioque pari longissimis monodactylis*. N." These two species of *Caprella* are given up by Mayer and V. Carus as incapable of determination." "G. xxxvii. CYAME. *Cyamus*. Latr." "Espèce. C. DE LA BALEINE. *C. Ceti*. Latr." Of this Lütken thinks that Risso's description is original, though possibly he may have described a northern specimen, and taken for granted that the species occurred in the Mediterranean. After the specific description Risso adds, "Les cyames paraissent présenter les mêmes mœurs et les mêmes habitudes que les caliges. Ces animaux se fixent indifféremment sur les cétaées ou sur les poissons pour se nourrir à leurs dépens. Les thons qui en sont quelque fois atteints paraissent souffrir beaucoup de ces hôtes incommodes, et lorsqu'ils en ont un très-grand nombre, ils sont saisis d'une sorte de fureur qui les porte à sauter très-souvent hors de l'eau. *Dimens. long. 0,012. larg. 0,008. Séjour : sur les Baleinoptères et les Scombrés.*"

1816.—TREVIRANUS, GOTTFRIED REINHOLD, born 1776, died 1837 (Hagen).
1817.

Abhandlungen über den innern Bau der ungeflügelten Insekten. Siebente Abh.
Die Walfischlaus. (Vermischte Schriften anatomischen und physiologischen
Inhalts. Von Gottfried Reinhold Treviranus und Ludolf Christian Treviranus. 2ter
Band (1817) S. 3. t. 1.). Göttingen, 1816.

Boeck says that the anatomy of *Cyamus* is given, with figures of the male and female, the mouth-organs, and intestines. The mouth-organs are considered to resemble those of *Oniscus*, but to be simpler in construction. The author was uncertain as to the form of the second maxilla, and could not make out whether the mandibles had a palp or not. The stomach he found to be quite simple, without salivary or biliary duct. To the nerve-cords he attributes seven knots or ganglia; the heart he describes as an organ broad in front, narrow behind. He also describes the cylindrical branchiae. He considers that the genus may stand in the same family with *Oniscus*, and that it does not belong to *Squilla*, as de Geer, or to *Cancer*

mulex, as Latreille supposed. In full accordance with Boeck's account of this paper, Lütken says that the figure and description given of the exterior of the animal are good, the account of the mouth-organs very incomplete, and the contributions to the knowledge of the internal structure, if on the whole correct, not very far-reaching.

1817. LATREILLE, P. A.

Le Règne animal, distribué d'après son organisation, pour servir de base à l'histoire naturelle et d'introduction à l'anatomie comparée. Par M. le Ch^r. Cuvier. Avec Figures, dessinées d'après nature. Tome III. contenant les Crustacés, les Arachnides et les Insectes, Par M. Latreille, de l'Academie des Sciences, &c. A Paris, 1817. (pp. 44–53.)

Latreille here divides the class of Crustacea into five orders—Decapods, Stomopods, Amphipods, Isopods, and Branchiopods. In regard to his order of Amphipods, after giving a general description of the structure and habits, he says we might embrace this order under the generic name of *GAMMARUS*. He then proceeds to distinguish Les Phronimes (*Phronima*, Latr.), les Chevrettes (*Gammarus*, Lat.), which include, with various characteristics, les *Leucothoés* and les *Dexamine* of Leach, les *Melite*, les *Mærsa*, the Chevrettes, properly so-called, or *Gammarus*, les *Pherusa* and les *Amphitoe*, all of Leach, and la *Chevrette des ruisseaux* of Geoffroi. These are followed by les *Talitres* (*Talitrus*, Latr.), which, he says, Leach subdivides into his *Atyles*, *Talitres*, and *Orchesties*. Finally, les *Corophies* (*Corophium*, Lat.) are mentioned, with *Cancer grossipes* of Liunæus for the type, and to this group he refers "les *Podocera* et les *Jassa* de M. Leach."

The Isopods he divides into three sections, according to the form and position of the branchiæ. The first section, les Cystibranches (compare page 95), contains the genera *Leptomera*, Latr., and *Proto*, Leach, which are in fact identical, *Caprella*, Lam., and *Cyamus*, Lat., with *Larunda*, Leach, given apparently as an alternative name. In the second section, the Phytibranches, *Typhis*, Risso, is included with other genera usually reckoned as Isopods. The third section, the Pterygibranches, contains only Isopods. In a note on page 7, he recognizes that the branchiæ in *Cyamus*, *Caprella*, and *Proto* were not thoroughly understood, but makes a good guess as to their true position.

1817. RAFINESQUE-SCHMALTZ, C. S.

Synopsis of four New Genera and ten new Species of Crustacea, found in the United States. The American Monthly Magazine and Critical Review. Vol. ii. New York, 1817, pp. 40–43.

The portion of this paper apparently referring to the Amphipoda is as follows:—

"III. PSAMMYLLA. (N. Order *Branchypia*, N. Family *Gammaria*.) The two upper antennæ, with two long segments at the base, and many small articles at the top; lower antennæ very short; all the feet with one nail, the last pair much longer and larger: each segment of the body with a lateral appendage, tail with four bifid unequal filaments.—Obs. The name is abbreviated from *Psammopsylla*, which means sand-flea. The family *Gammaria* is the fifteenth in my natural classification, and is distinguished by fourteen feet, four antennæ, body not depressed, etc.

"1. *Psammylla littoralis*. Longer antens doubly than the head, short autens not longer than their first segment; last pair of feet double in length; body rufous above, white beneath.—Obs. I have found this animal in great numbers on the shores of Long-Island and New-York, and ou the Hudson river, jumping about like fleas, whence its vulgar name Sand-flea; it jumps by means of its liud feet and tail, like locusts. Length about half an inch, often less; eyes large and round.

"IV. PEPHREDO. (Natural order and family of the foregoing.) The two upper antens longer and with six long segments; all the feet with one nail, and nearly equal, the two first pairs with thick swelled hands; body without lateral appendages, tail with simple filameuts.—Obs. This genus was noticed in my Analysis of nature, and formed on an European species; the uame is mythological. It may be deemed a singularity in this family, that this genus should be a freshwater one, aud the last a land one !

"1. *Pephredo potamogeti*. Long antens, scarcely longer than the head and double of the short ones; body fulvous, transparent, with a central brown or longitudinal stripe.—Obs. It lives on the *Potamogeton perfoliatum* in the Hudson and the Fishkill, near Newburg. Length three lines, creeper, eyes very small."

Psammylla littoralis is obviously one of the Orchestidæ, a "beach-flea." The upper and lower antens of Rafinesque's terminology would be respectively the lower and upper antennæ of ordinary language. If the two genera *Psammylla* and *Pephredo*, could be identified, they might probably enough fall as synonyms to others already known. It is possible that the acute American observers of the present day will be able to identify the two species here given with some that have been since named.

1817. SAY, THOMAS, born 1787, died 1834 (Hagen).

On a New Genus of the Crustacea, and the Species on which it is established.
Read July 8, 1817. Journal of the Academy of Natural Sciences of Philadelphia.
Vol. i. Part 1, No. 4. August 1817. Philadelphia, 1817. pp. 49–52.

The new genus *Cerapus*, assigned to the order Macrouri, is thus defined:—"Essential Character.—Thumb of the second pair of feet bi-articulate; interior antennæ four-jointed, exterior ones five-jointed. Artificial Character.—Antennæ subequal, interior ones 4-jointed, exterior ones 5-jointed. Two anterior pairs of feet monodactyle, the second pair with a two-jointed thumb. Natural Character.—Body semicylindrical, somewhat linear, decreasing towards the tail, ten-jointed. Head distinct from the first joint and larger, quadrate, a little elongated into an angle near the base of the interior antennæ, each side, for the reception of the eyes, which are hardly prominent. Antennæ nearly equal, very large, interior ones with the first joint thick, second and third nearly equal; exterior antennæ five-jointed, the first joint placed in a deep sinus bencath the eye, short, not projecting beyoud the margin of the head above, secoud joint hardly longer than the first, third and fourth equal to the second and third of the interior antennæ. Anterior pair of feet moderate, with a small ovate hand and moveable nail, not closing on the hand, attached to the first segment of the body; second pair with the basal joint attached to the edge of the body (as in *Cymothoa*, &c.), second joint broad, compressed, with an incisure near the base before, third small, medioliform, carpus cylindrical, narrower than the preceding joint; hand very large, compressed, subtriangular, attached to the carpus by the inferior edge of the acute angle, which is a little curved, tip emarginate and armed with a stroug, acute spine on the anterior angle, thumb two-jointed, first joint incurved, linear, second acute, closing on the spine of the hand. Third and fourth pairs of feet equal, similar to each

other, first joint dilated, equal to that of the preceding feet, remaining joints small, nearly equal to each other, submoniliform; two posterior pairs of feet reflected above the back; tail incurved, furnished on each side near the tip with a pedunculated bifid process, and a minute, conic, acute papilla." The type species, *Cerapus tubularis*, is further described thus:—"Head with a mucronate carina before; eyes oval, black. Hand and first joint of the thumb of the second pair of feet with one or two obtuse teeth within. Body above blackish, with irregular paler spots; antennæ and feet white, joints tipped with blackish; two hind pairs of feet and tail white. Inhabits a tube. Length about one-quarter of an inch." Say would place it between *Gammarus* and *Caprella*, next to *Jassa* in the family Podoceridae of Leach. He cannot believe that the tube is fabricated by the Crustacean itself, though he notices that it is always proportioned to the size of the inhabitant, which moves actively with its neatly fitting house, making use of its four antennæ as feet, and deftly turning within its tube, if any impediment is offered to its progress in one direction. It is figured in the following number of the Journal for September, 1817.

1817. STEWART, CHARLES.

Elements of the Natural History of the Animal Kingdom: comprising the characters of the whole genera, and of the most remarkable species, particularly those that are natives of Britain; with the principal circumstances of their history and manners. The second edition. In two volumes. Edinburgh, 1817.

In the preface Stewart says that, as editor, "he has, with Cuvier and others, disjoined the Crustaceous Animals from the Class of Insects, in which they had been included by Linnaeus. In vol. ii. p. 308, after the Insects, he places the Class Articulata, containing "two Orders, viz. 1. Crustacea, or those animals which constituted the genus Cancer of Linnaeus; and, 2. Arachnides, including the genera Aranca, Phalangium, etc." For this arrangement he gives references to Latreille, Lamarck, and Leach (Edin. Encycl. vol. vii. Crustaceology, and Mal. Pod. Brit. London, 1815. On pp. 316, 317, he gives under *Cancer* the following section or group of species:—

- "D. Antennæ pedunculated and simple.
- "32. *Cancer grossipes*. The claws want the finger; the antennæ the length of the body; the tail obtuse. Inhabits the European Ocean. B.—Pennant British Zool. 4. pl. 16. f. 31. The *linearis* of Pennant. Found in the sand on the shore of Flintshire and other places.
- "33. *Cancer Pulex*. With four claws which want the finger; ten feet. Inhabits Europe. B.—Degeer, Ins. 7. tab. 33. f. 1, 2. This species is very frequent on the shores of the sea; likewise in fountains and rivulets; it swims on its back, and leaps; it causes ulcers on the gills of fishes, and destroys the nets of fishermen; it is eaten by the Avosetta; it shines in the night.
- "34. *Cancer Locusta*. With four claws, which want the finger; fourteen feet; the thighs simple. Inhabits Europe. B.—Frisch. Ins. 7. tab. 18. Found very frequently on the sea shore; also in fountains and ditches, swimming on its back, and leaping.
- "35. *Cancer Atomos*. Linear; the claws wanting the finger; with eleven feet. Inhabits Europe. B.—Pennant Brit. Zool. 4. pl. 12. f. 32. Found in fresh waters; hardly visible by the naked eye; a slender tail between the last pair of feet, makes the eleventh foot; in the middle two pair of oval vesiculae.
- "36. *Cancer lobatus*. Linear; four claws wanting the finger; ten feet. Inhabits Europe. B.—Muller, Zool. Dan. Icones, tab. 56. f. inf. This is the *Squilla lobata* of Muller's Zoologia

Daniea ; it is found among the confervæ on the sea-shore at Leith ; but, perhaps, is not really different from the preceding species." The two remaining species in the group are "Caneer *salinus*" and "Caneer *stagnalis*," not Amphipoda.

1818. SAY, THOMAS.

An Account of the Crustacea of the United States. Read June 10, 1818. Journal of the Academy of Nat. Sciences of Philadelphia. Vol. i. part ii. Philadelphia, 1818. pp. 313-319.

Here assigned to Order III. Amphipoda, Latr., is the new genus *Lanceola*, thus described :—

"*Essential Characters*.—Antennæ four, terminal joints not articulated; *antenniform processes* above the mouth; *caudal styles*, three pairs, peduncle depressed linear, supporting two lanceolate lamellæ. *Natural Character*.—*Body* soft, external covering membranaceous; *head* very short, transverse; *eyes* longitudinal, placed opposite the base of the superior antennæ; *clypeus* projecting into an acute angle; *front* concave; *antennæ* four, unequal, inferiores longest, four-jointed, compressed, basal joints very short, third and fourth longer, equal, the latter entire, superiores abbreviated, compressed, triarticulate, basal joints short, robust, concealed by the clypeus, terminal joint not articulated, linear, compressed, obtuse; *mouth* protuberant; *labrum* emarginate, supporting two filiform, triartieulate processes, of which the first joint is very short, second linear, third shorter, subulate; *labium* (pedipalpi) bifid, closing the mouth, laciniae linear, inner edges hirsute, tips rounded; *thorax* oval convex above and beneath, seven-jointed, sutures imbricate; *feet* fourteen, simple, two anterior pairs compressed, terminal joints conic compressed, remaining pairs somewhat cylindric, armed with a minute subterminal nail, sixth pair much the longest; *vesicular branchiæ* oblong, distinct, placed at the inner base of the feet, excepting the first and seventh pairs; *abdomen* abruptly much narrower than the thorax, of three subcylindrical segments, each furnished with natatory feet; *tail* depressed, three-jointed, joints furnished each with a lateral style, which consists of a foliaceous linear peduncle, supporting two acute lanceolate, subequal lamellæ, two anterior styles equal, posterior pair rather shorter, terminal segment attenuated between the posterior styles."

The type species, *Lanceola pelagica*, ♀, is thus described :—"Antennæ, inferiores more than half as long as the thorax, superiores attaining the middle of the third joint of the inferiores; *antenniform processes* surpassing the second joint of the inferior antennæ; *thorax*, first segment shortest, acutely angled before near the clypeus, second and third segments longest, equal; *feet*, anterior pair shortest, third, fourth, and seventh equal, fifth longer, sixth longer than the thorax. Length one inch and one fourth. *Inhabits*—Gulf Stream. Say further says that "it is allied to the Amphipoda by the vesicular branchiæ and by the caudal appendices to the genus *Phronima*, more than to any other of this order; in the external appearance of the mouth there is a great similarity to the Linnean *Onisciti*, the labium being nearly the same in form." Spence Bate, "in consequence of the obscurity of Say's description," makes the genus a synonym of the later *Vibiliæ*, Milne-Edwards. The species he therefore calls *Vibiliæ pelagica*, not as Milne-Edwards had done *Hyperia pelagica*. Bovallius, 1885, reinstates *Lanceola* as a distinct genus, assigning to it six new species.

1818. SAY, THOMAS.

An Account of the Crustacea of the United States. Read July 7, 1818, Journal, &c., pp. 374-401.

Say here describes the new species *Gammarus fasciatus* from the rivers, *Gammarus minus*, found in brooks under stones, *Gammarus mucronatus*, *Gammarus appendiculatus*, which has "caudal segments, and three terminal segments of the body, dentated on their posterior edges." "The remarkable elongation of the inner lamella of the second pair of feet in one sex [♀] is a very striking peculiarity of this species." "It is probable," he adds, "that this animal will form a new or subgenus, which would very probably arrange under *Gammarus*." Spence Bate leaves the name unaltered, but says, "Certainly it does not belong to *Gammarus*. It appears to be related to *Podocerus*." It is more suggestive of *Mæra*.

The new genus *Lepidactylis* is thus described:—"Essential character.—*Antennæ* four-jointed, furnished beneath with plumose eiliae, intermediate ones with an accessory seta placed at tip of the third joint. *Clypeus* produced between the bases of the intermediate antennæ, and acute. *Feet*, two anterior pairs simple, equal, third and fourth subequal, didactyle, fingers lamelliform; remaining feet spinous, without nails. Natural character.—*Body* compressed-oval. *Head* distinct, subquadrate, extended into a short acute rostrum between the intermediate antennæ; *antennæ* subequal, four-jointed, *inferiores* rather longer, incurved, second and third joints dilated beneath, compressed, and ciliated beneath with plumose, elongated hairs, these two joints, when at rest, form a continued oval, the former is dolabri-form, terminal seta eight-jointed, verticillate, *superiores* protracted, basal joint dilated, depressed, second one much smaller, placed on the inner tip of the preceding, and with that joint furnished with plumose eiliae beneath, third joint much smaller than the second, and furnished at the tip with a tri-articulate accessory seta, parallel with the terminal joint; terminal joint of about eight segments, and not longer than the preceding joints conjointly; *eyes* convex, touching the anterior edge of the head; *thorax* with seven segments, and lateral scales; *feet* fourteen, two anterior pairs in each sex simple, filiform, equal, third and fourth pairs equal, didactyle, hands compressed, not dilated, finger rounded, thumb oval, lamelliform, remaining feet gradually larger, compressed, armed with short spines, and destitute of a nail; hind pair largest, antepenultimate joint lengthened above, and nearly attaining the tip of the following joint, which is crenate and spinous on the edge, terminal joint compressed, serrated, and spinous on the edges, and truncate at tip; anterior pairs of feet furnished at their inner bases, with oblong oval moveable lamellæ. *Abdomen* of three segments, abruptly narrower than the thorax, each furnished beneath with natatory feet, consisting of short, rounded peduncles, supporting double setæ, of which the outer ones are longest, third segment abruptly inflected at tip; *tail* inflected, armed with bifid styles." The species *Lepidactylis dytiscus* has "Eyes orbicular; body when recent, white, with an abbreviated internal ferruginous vitta, including the alimentary canal; accessory seta of the intermediate antennæ, attaining the tip of the fourth segment of the terminal joint; anterior pairs of feet hairy. Length, male one-quarter, female three-twentieths of an inch." In shallow pools left by the receding tide "its presence may be ascertained by the numerous and irregular tunnels which it forms in the sand, like miniature representations of those of the mole, only less rectilinear." It is the same as *Oniscus arenarius*, Slabber. See notes on Slabber and P. L. S. Müller.

To the genus *Ampithoe*, Leach, Say assigns the new species *Ampithoe serrata* and *Ampithoe punctata* from Egg-harbor, and *Ampithoe dentata*, "a very common inhabitant of the fresh water marshes of South Carolina." *Ampithoe serrata* is thus described:—"antennæ equal, short, stout; eyes large, approximated, suboval; eighth, ninth, and tenth segments

of the body serrated." "Clypeus acute; antennæ nearly equal, short, stout, attaining the base of the sixth segment of the body; eyes large, black, oval, placed at the outer base of the superior antennæ, and approximated above; hands with about three equidistant, prominent, spinose teeth on the inferior edge or palm, the nail or thumb curved, acute, and attaining the third tooth; eighth, ninth, and tenth segments of the body serrated, the last more conspicuously so. Length, two-fifths of an inch. Remarkable by its large eyes, short, stout antennæ, and serrated appearance of the hind part of the back, occasioned by the elevation of the tip of each of those segments above the base of the succeeding one." Spence Bate renames it *Acanthonotus Sayi*. Say's *Talitrus longicornis* is transferred by Milne-Edwards to *Orchestia*, as his *Talitrus grillus*, Latr. from Bosc, is by Spence Bate. He thus describes his new species, *Podocerus cylindricus*, which S. I. Smith, 1874, withdraws from the synonymy assigned to it in the Brit. Mus. Catal., p. 256, renaming it *Corophium cylindricum*:—"Hands of the second pair somewhat cylindrical; eyes small, not prominent. Inhabits Egg Harbour." "Eyes small; front acute; superior antennæ attaining the tip of the third joint of the inferiores, inferior antennæ much thickened, hairy, the terminal joint shorter than the preceding one; hand of the second pair not larger than the carpus, palm longitudinal, rectilinear, thumb much shorter than the hand; third, fourth, and fifth pairs of feet short, much compressed, nail as long as the preceding joint, which is suboval and narrower than the one before it; sixth and seventh pairs reflected, and of the usual cylindrical, elongated form. Length less than three-twentieths of an inch."

The new genus *Unciola* is described as follows:—"Essential Character.—Antennæ subpediform, superiores with an articulated seta at the base of the fourth joint; anterior feet monodactyle; second pair with adactyle compressed hands; coxa not dilated. Natural Character.—HEAD deeply emarginate beneath the eyes to receive a segment of the base of the lower antennæ (ear ?), and projecting into an acute angle between the bases of the upper antennæ; eyes hardly prominent, placed on a somewhat advanced portion of the head, between the bases of the upper and lower antennæ; antennæ robust, terminal joint of the superiores rather longer than the preceding one, furnished at base with an articulated seta, inferiores rather shorter, thicker, terminal joint shorter than the preceding one; THORAX composed of seven segments, each furnished with feet, of which the first pair are largest, hand dilated, monodactyle, second pair with a dilated, compressed, subequal carpus and hand, the latter simple, with two minute hooks at tip, posterior pair longest; coxa simple or not remarkably dilated; ABDOMEN of three segments; natatory feet with the filaments subequal; tail of three segments, the first and second bearing each a pair of bifid styles, terminal one suborbicular; with a pair of simple, depressed styles, concealed by the others." The type species *Unciola irrorata* is thus described:—"Eyes hemispherical; hands of the anterior feet with a longitudinal palm, and prominent tooth, those of the second pair compressed, ciliated. Inhabits Egg Harbour." "Accessory seta of the superior antennæ, attaining the fifth articulation of the terminal joint; eyes conspicuous, rounded; palm of the anterior feet a little convex in the middle, a large obtuse tooth at base; nail attaining the carpus, which terminates so as to appear like a second tooth of the hand; second pair of feet ciliated, with a subtriangular hand, segments of the abdomen uncinate each side behind; colour when recent, pale with very numerous red points. Length, three-tenths of an inch." Say remarks that it approaches *Gammarus* by the accessory seta to the superior antennæ, *Pherusa* by the form of the second pair of feet, but by various points and general habit "it seems to arrange naturally with *Podocerus*, *Jassa*, *Cerapus*, *Atylus*, etc."

The species next described, *Caprella geometrica*, is identified by Mayer with *Caprella acutifrons*, Latreille; *Caprella equilibra* is still accepted, with the improved spelling, as *Caprella aquilibra*.

In describing the genus *Cyamus*, Latreille, Say mentions "eyes two; stemmata two," apparently borrowing an error from previous writers, instead of observing his own specimens. On

these, which were "less than one-tenth of an inch," he finds the species *Cyamus abbreviatus*, from a Balæna, species unknown. This *Cyamus* Lütken considers scarcely recognisable. Spence Bate says of the specimens in the British Museum "they appear to me to be only the young of *Cyamus ovalis*."

Milne-Edwards, 1840, takes it for granted that Say's *Gammarus minus* is merely a slip of the pen for *Gammarus minimus*, and inclines to identify the species with *Gammarus fasciatus*, which in its turn he considers very near to the French "crevette des ruisseaux." *Gammarus mucronatus* is transferred by Sp. Bate to *Gammarecanthus*, but S. I Smith, 1874, objects to this, "for the dorsal margin is not distinctly carinated, and the third, fourth, and fifth segments of the abdomen are furnished with fascicles of spines;" he therefore restores the species to *Gammarus*.

1818. CHIEREGHINI, STEFANO, born 1745, died 1820 (Nardo).

Deserizone de' erostaei, de' testaei e de' pesei ehe abitano le lagune ed il golfo Veneto rappresentati in figure a chiaro-scuro ed a colori. Manoscritto in foglio in vol. 12, esistente presso il R. Liceo di Venezia (Santa Catterina, ora Marco Polo).

G. O. Nardo assigns to this work, though still in manuscript, a quasi publication in 1818, about which date it was acquired by the imperial government and consigned to the public library in Venice, where it has been, and still is, consulted by naturalists. The first two volumes, Nardo says, treat of Crustacea, one containing the descriptions, the other the figures. The species there described and figured by Chiereghini are sixty-four, thirty-three of which bear the Linnean names, while thirty-one he considered to be new. After certain necessary deductions from this number, Nardo allows Chiereghini the credit of having described and figured twenty-four species, either new, or till then obscure. Among these are two Amphipods, called respectively "Cancer Salectus" and "Cancer Algensis," for which see note on Nardo, 1847.

1818. LAMARCK.

Histoire naturelle des Animaux sans vertèbres, présentant les caractères généraux, et particuliers de ces animaux, leur distribution, leurs classes, leurs familles, leurs genres, et la citation des principales espèces qui s'y rapportent, etc. Tome cinquième. Paris. Juillet, 1818.

The Crustacea are the eighth class. The Isopods, the second section, contain, among the Ionelles, corresponding to the Phytibranches of Latreille, Risso's *Typhis ovoïdes*, which is an Amphipod, along with *Anceus*, *Praniza*, *Apseudes*, and *Ione*. Risso's *Eupheus ligioïdes* becomes *Apseudes ligioïdes*. The "2.^{me} Coupe" of the Isopods contains *les Caprellines*, answering to the cystibranches of Latreille. In this group *Proto* is dropped from the synonymy of *Leptomera*. The species are *Leptomera rubra* and *Leptomera pedata*, both synonyms of *Proto* (*Squilla*) *ventricosa*, O. F. M.; *Caprella scolopendroïdes*, which Boeck and Krøyer identify with *Caprella (lobata) linearis*, but which Mayer thinks undecipherable; *Caprella phasma*, now known as *Protella phasma*, Montagu; and *Cyamus ceti*, which Lamarck says has fewer relations with "Pycnogonon" than was generally supposed. He notes a second very small, still undescribed species, from the East Indies, as known to

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

Xxx 14

Latreille. His third section, the Amphipods, contains four genera, 1. *Phronima*, with the species *sedentaria* and *custos*; 2. *Gammarus*, with the species *pulex*, *spinosus*, *articulosus*, *palmatus*, *grossimanus*, *pherusa*, and the remark, "etc. Le *gammarus rubricatus*, Montag. Trans. Soc. Linn. 9, p. 99, tab. 5. f. 1. est encore de ce genre. *Anaphithoë*, Leach"; 3. *Talitrus*, with the species *locusta*, *gammarellus*, *carinatus*, and an "etc."; 4. *Corophium*, with the species *longicorne*, and the final "etc. Rapportez aux corophies les genres *podocera* et *jassa* de M. Leach."

1818. LATREILLE, P. A.

Tableau Encyclopédique et méthodique des trois règnes de la nature. Vingt-quatrième partie. Crustacés, Arachnides et Insectes, Par M. Latreille. A. Paris, M.DCCCXVIII.

The Amphipoda, of which figures from various sources are given in this volume, are thus named in the "Explication des Planches":—Planche 327. 3. *Atylus carinatus*, Leach. "Planche 328. 1 et 2. *Gammarus ampulla*, Fabricius. 3. Appendices de sa queue. 4 et 5. *Gammarus nugax*, Fabricius. 6. *Gammarus cancellus*, Fabricius. 7 et 8. *Gammarus* (*corophium*, Latreille;) *longicornis*, Fabricius. 9. *Talitrus Locusta*, Latreille. 10. *Talitrus gammarellus*, Latreille. 11 et 12. *Gammarus pulex*, Fabricius. 13.—grossi. 14. Ses œufs, de grandeur naturelle. 15.—grossis. 16. Item, lorsqu'ils sont plus avancés et que le fœtus commence à s'y montrer. 17 et 18. *Phronima* , Latreille. 19. Appendices de sa queue, très-grossis. 20. *Gammarus* (*caprella*, Lamarek;) *linearis*, Fabricius." In this list 1. 2. 3. belong to *Stegocephalus ampulla*, 4. 5. to *Anonyx nugax*, 6 to *Pallasea cancellus*, 7. 8. to *Corophium volutator*, 9 to *Talitrus locusta*, 10 to *Orchestia gammarellus*, 11. 12. 13 to Rösel's *Gammarus fluviatilis*, 17. 18. 19 to what Latreille afterwards named Hypérie de Lesueur, 20 to *Caprella*, sp?

Planche 329 has "14 et 15. *Cyamus ceti*, Latreille. 16. La femelle, en dessous." Planche 330 has "3. *Oniscus arenarius*, Slabber; nouveau genre, voisin de celui que j'ai nommé *ione*. (Cuvier, *Règne animal*, tom. iii. p. 54). 4.—très-grossi." This is Slabber's figure, of which Latreille subsequently complains that it only exhibits eight legs. Nevertheless, the figure is sufficiently characteristic.

Planche 336 contains "18. *Phronima sedentaria*, Latreille; grossi. 19. Appendices de l'extrémité de sa queue, très-grossis. 20. Sa tête, très-grossie. 21. Ce crustacé dans son habitation formée du cadavre d'un zoophage (béroé?). 22. Cette habitation sans l'animal." "29. *Gammarus obtusatus*, Montagu; grossi, représenté (observation de M. Léach) sur un individu altéré: 30. *Leucothoe articulata*, Léach; grossi. 31. *Melita palmata*, Léach. 32. *Gammarus pelagicus*, Montagu; grossi; *jassa pelagica*? Léach. 33. *Ampithoe rubricata*, Léach; grossi. 34. *Talitrus locusta*, Latreille; grossi. 35. *Orchestia littorea*, Léach; grossi. 36. *Typhis ovoides*, Risso. 37. *Cancer* (*caprella* Lamarek;) *plasma*, Montagus; grossi. 38. *Proto* Léach." "43. *Gammarus mutilus*, Müller. 44. *Gammarus polurus*, Müller. 45. *Mæra grossimana*, Léach; grossi.

1818. O'REILLY, BERNARD.

Greenland, the adjacent seas and the north-west passage to the Pacific Ocean illustrated in a voyage to Davis's Strait, during the summer of 1817. London, 1818.

In the "Journal in Davis's Strait" it mentions for June 2, "a male whale killed this morning measured seventy feet;" "groups of the oniscus ceti, whale-louse, attached to the epi-

dermis of this whale, particularly about the fins and anns," p. 166. For July 18 it says, "The monodon appeared in great number this day, and the Thomas's men succeeded in killing one male and two females: the latter were destitute of the tooth: they are always taken without that instrument, which is solely conferred on the male either for ornament or annoyance: a female whale (*balaena mysticetus*) killed this day, measured sixty feet: it received the harpoon but once, and dived away under the ice, drawing down three boats' lines, being 1080 fathoms, and died at the bottom: immense groups of the *oniseus ceti* attached to the under lip and to the under part of the flukes: the edge of the fleshy covering embracing the root of the monodon's tooth was covered with insects of the same description."

1818. LEACH, W. E.

Crustacés, Crustacea. Dictionnaire des Sciences Naturelles, dans lequel on traite méthodiquement des différens êtres de la nature, &c. Tome douzième. Strasbourg, Paris, 1818. pp. 69-75.

The Crustacea are said to form two great groups or subclasses, of which the first comprises the Malacostraca, which has a pair of mandibles, and two pairs of maxillæ, furnished with palps, and eight pairs of feet provided with branchiæ at their bases. All the genera devoid of these characters belong to the second group, the Entomostraca. Leach then briefly reviews the various classifications of Crustacea, including those by himself, that had been proposed up to the date of this article. He gives a list of authors who have written on Crustacea, and deferring the details about genera and species to the articles on the several families, he winds up with an alphabetical list of the Crustacean genera recognized at that date, including for the Amphipoda, *Aerope*, *Ampithoe*, *Atyle*, *Caprelle*, *Cerapode*, *Corophie*, *Crevette*, *Dexamine*, *Jassa*, *Larunde*, *Leucothoe*, *Melitée*, *Orchestie*, *Pheruse*, *Plironyme*, *Podocère*, *Proto*, *Talitre*, *Typhlis*, mixed up in alphabetical order with the rest. That *Aerope* belongs to the Amphipoda, my only authority is Desmarest.

1818. LEACH, W. E.

Memoirs of the Wernerian Natural History Society. Vol. II. For the years 1811-1816. Edinburgh, 1818.

Leach refers to this volume for his species, *Jassa pulchella* and *Jassa pelagica*, but since the references occur in the Appendix to his Article, Crustaceology, in the Edinburgh Encyclopædia, which cannot well be of later date than 1814, and these memoirs seemingly were not published till 1818, he probably refers to some paper intended for this volume, but withdrawn before publication.

1819. LEACH, W. E.

Zoological Memoranda. Descriptions of the New Species of Animals, discovered by His Majesty's Ship Isabella, in a Voyage to the Arctic Regions. By Dr. W. E. Leach. A Voyage of Discovery, made under the Orders of the Admiralty, in His Majesty's Ships Isabella and Alexander, for the purpose of exploring Baffin's

Bay, and enquiring into the probability of a North-West Passage. By John Ross, K. S., Captain Royal Navy. Second Edition. Vol. II. London, 1819. Appendix No. IV.

Under "Type Annulosa," "Class Crustacca," is given "Genus, GAMMARUS, *Latreille*. Species 1. *Sabini*, segmentis dorsalibus postice falcato-productis. Baffin's Bay, Captain Sabine." This is the Amphipod, so often described both before and after this date, called *Amathilla sabini* by Bate and Westwood, and in this Report identified with *Gammarus homari*, Fabricius.

1819. SAMOUELLE, GEORGE.

The Entomologist's Useful Compendium; or an introduction to the knowledge of British Insects, comprising the best means of obtaining and preserving them, and a description of the apparatus generally used; together with the genera of Linné, and The Modern Method of arranging the Classes Crustacea, Myriapoda, Spiders, Mites and Insects, from their Affinities and Structure, according to the views of Dr. Leach. Also an explanation of the terms used in entomology; a calendar of the times of appearance and usual situations of near 3000 species of British insects; with instructions for collecting and fitting up objects for the Microscope. London, 1819.

The preface explains that "The Modern System is nearly the same as that given in the Supplement to the Encyclopædia Britannica, article Crustaceology, and Dr. Brewster's Edinburgh Encyclopædia, article Entomology, with the exception of the foreign Genera and the alteration of Tribes to Families, terminating in *idæ*." Notwithstanding this notice, the three Families belonging to the Amphipoda are given, pp. 101-106, as "Fam. I. PHRONYMADEÆ. Leach's MSS." "Fam. II. GAMMARIDÆ. Leach's MSS." "Fam. III. CAPRELLADÆ. Leach." All the information is derived from the papers by Leach. The articles referred to in the Preface are probably the Crustaceology of the Edinburgh Encyclopædia and the Annulosa of the Supplement to the Encyclopædia Britannica.

1819. SAMOUELLE, GEORGE.

A nomenclature of British Entomology, or a Catalogue of above 4000 species of the classes Crustacea, Myriapoda, Spiders, Mites and Insects, alphabetically arranged, and intended as labels for cabinets of British insects, etc. From the Entomologist's Useful Compendium. London, 1819.

This work is merely the index of the preceding, adapted for the purpose mentioned in the title.

1819. TILESIIUS, W. G.

Ueber das nächtliche Leuchten des Meerwassers. Neue Annalen der Wetter- und Gesellschaft für die gesammte Naturkunde. Erster Band. Frankfurt am Main, 1819. pp. 1-10. Pl. XXI.

Tilesius says that the sea-water is illuminated not only by the Mollusca contained in it, but also by the marine insects or microscopically luminous shrimps (Krebschen). Of these he

figures and describes several, with a warning that the figures indicating the natural size are in reality somewhat exaggerated. The following portion of his account is worth quoting here:—

- “Fig. 4. *Amblyrrhyncotus glaucus*. Der blaue Stumpfrüssel, einer von der grössern Art, bisweilen von der Grösse eines Hirsenkornes. Der ganze Raum zwischen dem Bauche und Schwanz war mit blauen Eiern angefüllt, welche in einer Haut verschlossen zu liegen schienen.
- “Fig. 5. *Erythrocephalus melanophthalmus*. Der Rothkopf mit den grossen schwarzen Augen, gehört zu denjenigen *Astacoidea*, welche keinen soliden *Thorax* oder kein besonderes Bruststück, sondern viele fast gleichgrosse Glieder längst dem ganzen Körper haben, wie die *Arthrocephali* oder Gliederköpfe DUMÉRIL, und wie der *Cancer sedentarius* FORSKAELLI. Der unsrige aber steht mit jenem der Grösse nach in keinem Verhältnisse. PALLAS hatte diese vielgliedrigen kleinen Krebse als die *Squillæ* und *Gammari* des FABRICIUS, *Thalitras* und *Mysis* des LATREILLE schon alle unter das Geschlecht der *Scolopendren* gebracht.

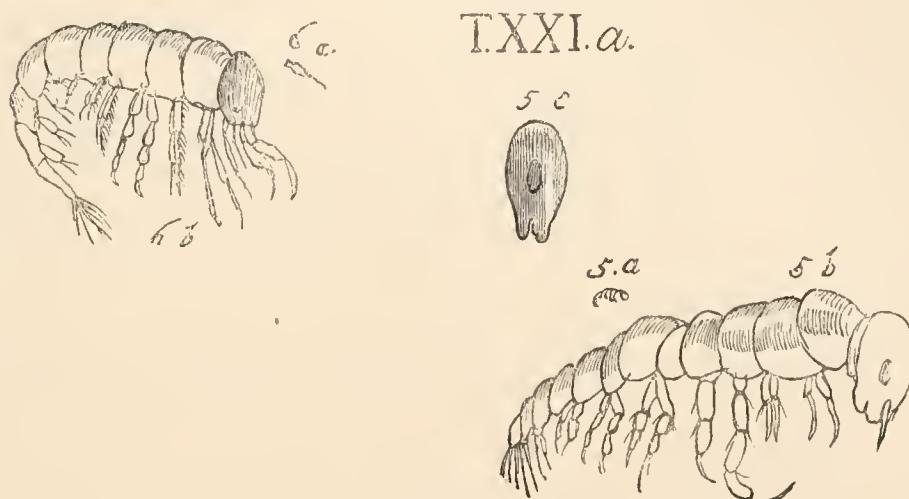

Fig. 19.

“Fig. 6. Der blinde Rothkopf, *Erythrocephalus caecus*, er hat zwei grosse dreigliedrige Klauen am Kopfe und statt der Augen zwei kleine kaum merkliche Sternchen.

“Fig. 7. Der fusslose Sägerüssel, *Prionorhyncotus Apus*.”

“Fig. 8. Der Sprützenkrebs mit dem Stachelkopfe, *Acanthocephalus syringodes*.”

“Fig. 9. Der blaue Fadenkrebs, *Phasmatoecrinus glaucus*, ebenfalls ein sehr dünner und langer, aber vielgliederter und vielfüssiger Krebs, welcher den LINNEE'schen Fadenkrebsen (*Cancer linearis* L.), oder Gespensterkrebsen (*Gammarus pedatus* O. MÜLLER, *Squilla quadriloba* und *ventricosa* (Zool. Dan. Tab. LVI. u. CXIV.) und den Caprellen oder Chevrollen des Lamarck am nächsten steht, so wie auch der folgende Fig. 10, nämlich der langhalsige gehörnte Gespensterkrebs oder das Scheibenauge, Fig. 10.

“Fig. 10. *Phasmatoecrinus discophthalmus*. Sie haben zwar alle Stielenaugen (*podophthalmi*); aber dieser trägt anstatt des Augen-bulbus, eine breite platte Scheibe auf dem langen Augenstiele, (aus der Südsee, bei den Marquezasinseln).”

Fig. 4 represents rather a *Nebalia*-like form than an Amphipod.

Fig. 5 belongs no doubt to the Hyperina. Templeton thought that it might be the same as his

Thaumalea depilis, which Spence Bate considers to be a *Vibilia*. But while *Thaumalea* appears to have the characteristic antennæ of a *Vibilia*, this *Erythrocephalus* is certainly without them, so that Templeton's guess must be wide of the mark. In the figure here copied from Tilesius we may probably recognise the first two pairs of pereopods, one limb of the third pair, and one of the fourth. If this be correct, it may be inferred that the gnathopods and fifth pereopods were either wanting in the specimen examined or, from their position and insignificant size, escaped the attention of the draughtsman. In addition to the appendages above mentioned, I interpret the figure as showing a vertical head produced below the pereon, a pereon of six segments, without side-plates, and a pleon of six segments and a telson, with pleopods attached to the first three segments and uropods confusedly in attachment with the fifth and sixth segments and the telson. It will be observed that the third pereopods, as in *Pronoë capito*, Guérin, and many other Hyperina, greatly exceed in size the other pairs. In saying that Pallas referred such animals to the genus *Scolopendra*, Tilesius has fallen into error, and should have said *Oniscus*.

Fig. 6 evidently belongs to the Hyperina and probably to the Hyperidae. The front pereopods not unfrequently lie across the sides of the head and protruding beyond it. They have apparently here been mistaken for antennæ. The species intended remains for the present uncertain. It can scarcely belong to the same genus as the preceding species, and the want of well-developed eyes, to which the specific name refers, must itself be regarded as very doubtful.

Figs. 7 and 8 appear remote from the Amphipoda. Figs. 9 and 10, with the large stalked eyes, to which Tilesius himself refers, can have no connection with the Caprellina, though they show a general resemblance. *Amblyrrhyncotus* and *Phasmatocarcinus*, occasionally referred to as if among the Amphipoda, have evidently no right to be so placed.

1820. RAFINESQUE-SCHMALTZ, C. S.

Annals of Nature or Annual Synopsis of New Genera and Species of Animals, Plants, &c., discovered in North America by C. S. Rafinesque, Professor of Botany and Natural History in Transylvania University, at Lexington in Kentucky, and member of several Learned Societies in the United States and in Europe, &c. *Exertion unfolds and increases knowledge.* First Annual Number, for 1820. Dedicated to Dr. W. E. Leach, of the British Museum, London. Printed by Thomas Smith, Lexington, Ky. (16 pp. 8o. In the Library of the New York Academy of Sciences.)

For the title page and other extracts from this rare little book I am indebted to my friend and former pupil, William Bradford, Esq., Counsellor at Law, New York. In the course of his plaintive preface Rafinesque remarks, "I shall not be prevented from publishing my new species because it may happen that one out of fifty may be previously noticed in some costly and inaccessible work."

On p. 2 he gives "Animals. I Class. Mastosia—the Sucklers;" on p. 4 "II Class. Ornithia—the Birds," "III Class. Erpetia—the Reptiles;" on p. 6 "IV Class. Ichthyosia—the Fishes;" V Class. Plaxomia—the Crustacea." In this Class he enters:—

"iii. N. G. SPERCHIUS: Antenna double than the head, four nearly equal, with two long trunecate articles, the upper pair rather broader and longer. Body compressed, with seven segments, each with a large lateral appendage or scale. The fourth larger and with an additional posterior appendage, the corresponding feet larger and with a large rounded and

thick hand, all the feet with only one claw. Rump with four large segments, without lateral appendages, but with the usual ones beneath. Tail with short and recurved appendages.—It belongs to the family *gammaria*, the name was that of an ancient fluvial God of Thessaly.

“39. *Sperchius Lucidus*. Shining brown, eyes black, nearly round; appendages of the tail shorter than the last article, curved outwards, with two articles and a terminal filament. Discovered in the springs and brooks near Lexington, Ky. Length about one-third of an inch, almost black when in the water, oliveaceous brown when out of it, and pale when dry. Body arched, antenna descending. It swims well.

“iv. N. G. LEPLEURUS. Four antenna shorter than the head, nearly equal, truncale, with a single segment. Body rather compressed and straight, with twelve segments, all with a large lateral scale except the three anterior and the last, posterior segments and scales longer. First pair of feet with a large oblong cheliform and euspidate band; the second and third pair cylindrical pincerous or with two cylindrical and truncate fingers, the four other pairs slender; all the feet without real claws. Appendages beneath the rump almost similar to the hind feet; those of the tail short and with single segments.—Another fresh-water genus of shrimps, of the family *Gammaria*. The name means lateral scales.

“40. *Lepleurus Rivularis*. Oliveaceous, eyes very faint irregular; appendage of the tail truncale straight oblique; antenna nearly horizontal, feet longer than the breadth of the body.—I have detected it in the brooks of the mountains of Pennsylvania and at Shannon run, near Bedford Springs. Length about half an inch; it crawls on the stones rather than swims or jumps.”

He then describes the new genus *Lirceus* in the family *Oniscia*. His remaining Classes are, Entomia, the Insects; Helminthia, the Worms; Apalosia, the Mollusca; Polypia, the Polyps; Porostomia, the Porostomes.

Desmarest objects to the name *Sperchius* as too near to the *Sperchæus* of Fabreius, among the Coleoptera. Neither *Sperchius* nor *Lepleurus* has yet been identified. In the descriptions of both there are perplexing obscurities. The short antennæ of *Lepleurus* are suggestive of *Hyalella*, but the identification must be left to naturalists in Kentucky.

1820. SCHLOTHEIM, ERNST FRIEDRICH, Baron von, born 1765, died 1832.

Die Petrefaetenkunde auf ihrem jetzigen Standpunkte durch die Beschreibung seiner Sammlung versteinerter und fossiler Überreste des Thier- und Pflanzenreichs der Vorwelt erläutert. Gotha, 1820.

At page 41 he gives “5. Trilobites problematicus. Aus Höhlenkalkstein von Glücksbrunn, der Gebirgsart aufstiegend.

“Höchst wahrscheinlich gehört dieses kleine sonderbare Geschöpf ebenfalls zu den Trilobiten. Leider ist es etwas verdrückt, übrigens aber fast ganz vollständig erhalten. Es ist krumm zusammengebogen, aber die Schilder sämmtlich sehr flach, bloß der Rücken wenig gewölbt. Die Kopfbuckeln sind klein und stehen ziemlich eng, nach dem vordern Rande des Brustschildes zu, zusammen, in der Mitte wieder etwas vertieft, das Kopfschild verhältnismäsig sehr schmal, und die Rückenschilder am Seitenrand mit kleinen Strichen gesäunt. Nur erst bey der Auf-findung recht vollständig erhalten Exemplare wird sich ausweisen, ob er wirklich zu dieser Familie gerechnet werden muss, womit er allerdings grosse Ähnlichkeit zeigt.” See note on Schlotheim, 1822.

1820. SCORESBY, WILLIAM, born Oct. 5, 1879, died March 21, 1857 (Encycl. Brit., 9th Edition).

An account of the Arctic regions, with a history and description of the northern Whale-fishery. In two volumes. Edinburgh, 1820.

At page 541 he gives in the Class Articulata, "GAMMARUS *arcticus* (Leach).—The characters of this animal (Pl. XVI. Fig. 14), I have been favoured with from Dr. Leach. They are as follows:—"G. oculis sublunatis; pedum pari tertio, secundo majori." The actions of this species suggest as a familiar name, the *mountebank shrimp*. It frequently turns over when in the water, with singular celerity, and swims with equal ease in every position. The four feet raised in the figure above the back are made use of in that position, whenever its back comes in contact with any solid substance. This species occurs in all parts of the Spitzbergen Sea, and at the greatest distance from land; it inhabits the superficial water, and affords food for whales and birds.

"GAMMARUS——? —Another small species of this family, was found in large quantities in the stomach and mouth of some mysticete. It is remarkable for the largeness of its eyes."

He also mentions "CANCER *Pulex* (Linné)," "CANCER *Ampulla* (Phipps)," from the stomach of a shark, "CANCER *Nugax* (Phipps)," and "ONISCUS *Ceti*. (Lin.), LARUNDA *Ceti* (Leach), *Whale's louse*.—This little animal, about half an inch in diameter, firmly fixes itself by its hooked claws, on the skin of the mysticetus. It is found principally under the fin, or in other situations where the skin is tender, and where it is not liable to be dislodged. A similar animal, but smaller, is sometimes found on the body of the narwal."

Boeck judges that *Gammarus arcticus* is identical with *Gammarus locusta*. The tolerably useless figure shows some seventeen or eighteen segments besides the head. The large-eyed *Gammarus* is probably one of the Hyperina.

1821. D'ORBIGNY, CHARLES, born 1806.

Notice sur le *Corophium longicorne*, Latr. Crustacé observé dans les Bouchots à moules, des ecommunes d'Esmeudes et Charon près la Roehelle. Journal de Physique et Chimie, d'histoirc naturelle et des Arts. 1821. Tom. 93, pp. 194–200.

He gives an accurate description of *Corophium longicorne*, which is *Cancer grossipes*, Linné; he enters into details as to its mouth-organs, omitting to notice the under-lip. In regard to its mode of life he states that about winter-time it leaves the strand and goes out into the deep water, returning in the spring and occupying during the summer its holes in muddy shores. The structure of its body is evidently adapted for this mode of life (Boeck).

In the British sessile-eyed Crustacea, vol. i. p. 495, it is not considered certain whether the small tubular galleries in which this *Corophium* spends the summer "are perforated by these Crustacea or by the numerous Annelids that it preys upon." No one, however, who has examined these creatures in their own home could have the smallest doubt that the galleries are perforated by the Crustacea themselves. A stretch of mud may sometimes be seen speckled all over with asterisks, formed by these creatures turning round in their tubes with their antennæ projecting on the surface and marking the mud much as a cook marks pastry with the prongs of a fork. That they prey on Annelids is a very doubtful opinion. An Annelid and a *Corophium*, which I kept for some time alive together in a bottle, made no attempts to injure one another.

1821. SABINE, SIR EDWARD, born October 14, 1788, died May 26, 1883 (Encycl. Brit., 9th Edition), died June 26, 1883 (Friedländer, *Naturae novitates*).

An account of the animals seen by the late northern expedition whilst within the Arctic Circle Being No. X., of the Appendix to Capt. Parry's Voyage of Discovery. By Capt. Edward Sabine, R.A., F.R.S., & F.L.S. London, 1821. pp. 51–57.

After mentioning the *Cancer nugax* and *Cancer ampulla* of Phipps respectively as *Gammarus nugax* and *Gammarus ampulla*, Sabine proceeds to describe *Gammarus boreus*, with a reference to "Squilla Pulex. Degeer Ins. v. 7, p. 525, t. 33., f. 1. and 2." "Individuals, vary in size from half an inch to an inch and half." The fourth, fifth, and sixth segments of the tail, he says, are "slightly tricarinate on the back, and spinous." In general his account of it agrees well with *Gammarus locusta*, with which it is united by Boeck. The remarks with which Sabine winds up his account are of some interest. "The Squilla Pulex," he says, "figured by Degeer, l. c., differing in no respect from the above description, is considered to have been an individual of the same species, and it is therefore believed to be common to the northern shores of Europe and America; the Squilla Pulex has been considered a synonym of the *Gammarus Pulex* of modern authors, but erroneously, as may be seen by comparing the figure in Degeer with that of the *Gammarellus Pulex*, Herbst., vol. ii., 130, tab. 36, fig. 4 and 5, which is the *Gammarus Pulex* of J. C. Fabricius, *Ent. Syst.*, and of Latreille, *Encycl. Méth.* pl. 328, figs. 11–15; the species are very distinct, differing in the lateral lobes, in the mucronate production of the caudal segments, in the absence of the carinae and spines on the three posterior segments of the latter, and in the shape of the eyes; the *Gammarus Pulex* of Montagu, *Linn. Tr.* ix, t. 4, f. 2, is a third species, differing not merely in appearance, but in its habits, being found only in fresh water. The *Oniscus Pulex* of Otho Fabricius, *Faun. Græn.*, No. 231, differs from the present species in the relative proportions of the three posterior pairs of legs, the last pair being described by Fabricius as less than the two preceding, whereas in the *Boreus* the seventh are longer than the fifth and sixth pairs. The *Oniscus Cancellus* of Pallas, *Spicil. Zool.* ix, p. 53, tab. 3, f. 18, is distinguished by the lateral scales on the segments of the body, but in other respects is not very dissimilar to the animal under description; it may not be amiss to notice incidentally that an error has crept into the specific character of the *Cancellus* in the writings of modern authors, commencing it is believed with J. C. Fabricius, of describing it with sixteen legs, instead of fourteen, which is the usual number in the genus; in the original account of the *Caneellus*, *Spicil. Zool. l. c.*, the number of legs is fourteen, both in the description and figure." The figures cited from Herbst and Latreille are in fact copies of Rösel's *Squilla fluvialis*, with which Sabine seems to have been unacquainted. The description of Amphipoda with sixteen legs, occasionally met with in the old writers, may have arisen from their including the maxillipeds among the legs. Savigny, it will be remembered, regarded sixteen as the normal number of legs both for the Decapoda and the Tetrade-capoda, the difference between those two groups being that in the former three pairs, and in the latter only one pair, of the legs were transferred to the service of the mouth.

The species next described has since been made by Spence Bate the type of the genus *Gammaracanthus*. Sabine's account is as follows:—"GAMMARUS LORICATUS. G. Rostro corniformi deflexo, dorso carinato, segmentis posticè et acutè productis. Plate 1, fig. 7. This species was found associated with the preceding, and of the same size, but less abundant; body laterally compressed, especially the posterior segments; shell smooth,

and much harder than in its congeners, resembling a coat of mail, whence the specific name; back carinate, the segments increasing in length from the first to the tenth, from whence they decrease; and beginning with the third or fourth, are produced in sharp and strong points directed backward: lateral lobes oblong, enlarging from the first to the fourth segment, and decreasing to the seventh; those of the three first caudal segments are larger than those of the body, and are acuminate; head produced into a strong, arched, carinate, and sharp-pointed rostrum, curving down between the antennæ; eyes large, black, lateral, prominent and reniform; beneath the eyes is a small lateral lobe; antennæ four-articulate, the upper pair having a small seta at the base of the fourth articulation; legs fourteen, two first pair with a large compressed monodactyle hand, those of the anterior pair being smaller than the others; third and fourth pairs of the same length as the preceding, slender, terminating in a nail; the three posterior pair directed backward, similar in formation, but differing in size, the middle and longest pair being as long as the body, and the seventh pair shorter than the fifth, all terminating in a nail; colour in some individuals pale, in others varied red and white." He points out that it differs from *Oniscus serratus* of O. Fabricius, from *Gammarus carinatus* of J. C. Fabricius, and from *Gammarellus pulex* of Herbst. *Atylus carinatus* is mentioned as the name given by Leach to the species *Gammarus carinatus*.

Sabine next gives "GAMMARUS SABINI. Leach in Ross's Voyage, Ed. 8vo., Vol. 2, page 178. G. segmentis dorsalibus postice falcato productis, capite inter antennas acuminis minuto. Plate 1, fig. 8-11. On the shores of Bathurst Bay, but not met with in the Polar Sea: the head of this species which terminates in a point between the antennæ, instead of being produced in a rostrum, readily distinguishes it from the preceding species, and has been added to the specific character assigned by Dr. Leach, in whose arrangement it was unnecessary, the formation of the head making part of the character of the genus."

The next species, "TALITRUS EDWARDII, T. Rostro corniformi, antennis subæqualibus, corpore ovato depresso, caudâ compressâ tricarinatâ spinosâ. Plate II, fig. 1-4," though here described as new, is the *Oniscus aculeatus* of Lepechin, now *Rhachotropis aculeatus*. The remarks which follow the description bear upon classification. "In conformity," the author says, "with the arrangement which is followed in the present account, this species has been considered a Talitrus, as the inferior antennæ are somewhat longer than the superior; this character is, however, by no means remarkable either in this species, or in some others, which are distributed by it into the respective genera of Talitrus and Gammarus; if a subdivision be desirable in the well-defined and natural genus comprehending all these animals which so nearly resemble each other in general appearance and habits, the prolongation of the anterior part of the head into a rostrum, would seem preferable to a distinction founded on the relative length of the antennæ, which in many of the species are so nearly the same; or, the genus Talitrus might be limited to those species in which the superior antennæ are very short, not exceeding the length of the two first articulations of the inferior pair." He adds that "this species has been named in compliment to John Edwards, Esq., surgeon of the Hecla."

The remaining species "TALITRUS CYANÆ. T. capite obtusissimo, antennis subæqualibus, corpore latiore, pedibus quatuor anticis inunguis latis. Plate 1, fig. 12-18," was taken "parasitic on the Cyanea Arctica, the individuals varying in length from two to eight-tenths of an inch: colour pale yellowish red, sprinkled with innumerable minute spots of deeper red; in about half the specimens, the number of which was considerable, the antennæ were equal in length to the five first segments of the body; in the others they were scarcely one-fifth as long, but otherwise similar; there was no other perceptible difference in the specimens." The eyes are "extremely large, innate, of a brownish red colour." In the further course of the description he mentions "legs fourteen, the four anterior equal and

similar, five-jointed, being a long compressed thigh with four much shorter articulations, hirsute, and unarmed; the ten posterior legs similar and equal in size, five-jointed, the thigh being long and much compressed, followed by three short fleshy joints, (the first of which is the shortest,) and by a long and curved member, terminated by a nail." He concludes by observing, "this description differs from that of the Cauer Medusarum, Otho Fabricius, *Faun. Græn.*, No. 332, in the number of joints of the legs, and in the four anterior being unarmed; the conformation of these legs distinguishes it also from the Gammarus Medusarum of J. C. Fabricius, of which a part of the specific character is 'mauibus quatuor monodaetylis.'" It is with the latter species nevertheless that Boeck identifies it, under the name *Hyperia medusarum*, O. F. Müller. Milne-Edwards, *Hist. des Crust.* iii. p. 78, under the genus *Metæcus*, after describing *Metæcus medusarum*, Kröyer, says of it, "Le Talitrus eyaneæ de Sabine, que nous avions d'abord considéré comme une Hypérie, semble se rapprocher davantage des Métoèques, mais devra peut-être former un genre particulier, car d'après l'auteur qui l'a fait connaître, cette Hypérine aurait les pates des deux premières paires obtuses et adactyles; mais la division en pinces a peut-être échappé à son attention. Du reste, cette espèce se distingue de la précédente, et des Hypéries mentionnées ci-dessus, par la longueur beaucoup plus considérables de ses antennes, dont le filet terminal est grêle et multi-articulé." Spence Bate, in the *Brit. Mus. Catalogue*, p. 294, retains the species as *Hyperia cyanex*.

1822. MANDT, MARTIN WILHELM, born 1799, died 1858 (G. O. Sars).

Observationes in historiam naturalem et anatomiam comparatam in itinere Groenlandico factæ. Dissertatio inauguralis quam consensu et auctoritate gratiosi medicorum ordinis in universitate literaria berolinensi ut summi in medicina et chirurgia honores rite sibi concedantur die xxii. M. Julii A. MDCCCXXII. H.L.Q.S., publice defendet auctor MARTINUS GULIELMUS MANDT Beyenburgensis.

In 1821 Mandt went in the "Blüeher," Captain John Rose, past Spitzbergen to the 81° of north latitude. He here makes record of his acquisitions, material and scientific, in those regions. In describing "Balœna Mysticetus," he says, page 10, "Partibus tenerioribus cutis, axillis, pudendis Oniscus eeti adhæret, præsertim si tempus iustat editionis," and "Vulva præcipue hoc tempore iis obsessa appetet." The *Oniscus ceti* here mentioned is the *Cyamus mysticeti* of Lütken.

On pp. 31-37 he describes two Amphipods, of which the first has since been referred to Guérin's *Themisto*, and is the earliest described species of that genus, while the second has become the type of Lilljeborg's genus *Eurythenes*. The original account as drawn up by Liechtenstein is here subjoined.

"E crustaceorum ordine duas ex itinere retuli species, Oniscis marinis Lin: aut Gammaris Fabricii aeneendas nec ab ullo auctore hucusque descriptas. Quæ eum museo locupletissimo hujus Universitatis a me oblata essent, a viro celeberrimo hujus Musei directore Lichtenstein aeneaturi examinatae, dignæ visæ sunt quarum descriptio amplior huic dissertationi inseratur. Qualem vir doctissimus benevole meeum communieavit lectoribus naturæ curiosis hic offero.

"I. Gammarus Libellula N.

"G. capite magno globoso, corpore segmentis undecim, pedibus quatuordecim, octo anticis brevibus, uneinatis, raptatoriis, sex posticis elongatis, saltatoriis.

"*Longiludo tota æquat pollicem et dimidium.*

- “*Corpus* compresso-cylindracēum, incurvatum, saltatorium. *Caput* globosum, utrinque inflatum, hemisphērio utroque oculum magnum sessilem mentiente.
- “*Antennæ* breves, serobiculis profundis frontalibus implantatæ, superæ breviores, (sesquilineares) articulo basali et seta apicali subtriquetra, couflatae, inferæ paullo longiores, bilineares, triarticulatæ.
- “*Mandibulæ* exiguae, iuæquales, argute dentatae. Palpi mandibularum lateri externo inserti, quadriarticulati, in fossulam inter antennas inferiores reclinandi. *Segmenta* corporis primum, secundum, tertium quartumque, angusta (*Notetur terminos angustum et latum hic a dimensione singuli segmenti, minime autem a latitudine corporis esse intelligendos.*), sensim latiora utrinque in appendicem foliaceum articulatum producta, subtus pedes gerentia breves raptatorios, fe-indè [?perinde] e primo pari sensim maiores, femoribus complanatis, manibus incrassatis subtus spinescentibus, pro recipiendo unguiculo valido, elongato. *Segmenta* quiutum, sextum et septimum paullo latiora, lateribus vix appendiculatis, margine externo cum *pedibus* articulo iuncta elongatis, saltatoriis, postice complicandis, corpore incurvato pedes octo anticos inter se occultantibus. Horum femora complanata, margine postico foliaceo pro tegenda tibia reclinanda, tibiæ geniculo basali brevi, elongatae, compressæ, antice spinescentes, postice glaberrimæ; tarsi graciles, subcylindrici, rigidi, margine antico spinescente tibiis applicandi, apice unguiculo minuto acutissimo instructi. Pedum par quintum omnium longissimum fere pollicare, tibiis quatuor et dimidiam lincas lougis, sextum, septimum sensim breviora, postremo octo lineas longo.
- “*Segmenta* octavum, nonum et decimum, *caudalia* omnium latissima fere cylindrica subtus appendicibus ovigeris natatoriis, in singulo biuis bifidis, articulo basali valido, conico, subtus unisulcate, lacinia terminali dupli, acuminata, subtriquetra, ciliata.
- “*Segmenta* undecimum duodecumque, flabellum caudale efformantia, appendicibus utrinque tribus bifidis conflatum, quorum articuli basales elongati, compressi; laciniæ terminales, in singulo binæ inæquales, altera longiore foliacea, altera breviore accessoria teretiuscula. *Color* flavescente lividus.
- “Affinis haec species 1) Ovisco Cicadæ Oth. Fabricii *¹ a quo tamen differt capitis pedumque forma, colore et magnitudine;
- “2) Onisco Medusarum O. Fabricii, cuius tamen oculi lineares, arcuati, coerulei, lateribus frontis innati, nimis discrepant. Cum hac utraque Gammarus Libellula peculiare genus constituat, in familie hujus descriptione monographica arctius definiendum.
- “Unicum hujus animaleculi specimen die vicesimo nono mensis Iunii anni præterlapsi accepi vivum e mari prope insulam Ian Meyen protractum, plura autem mense insequente mortua in stomacho Procellariae glacialis reperi, integra quidem et digestione vix læsa, nisi quod pedum subtilissima pubes detrita esset.
- “Inter hæc juvenilia quoque, dimidiæ reliquorum magnitudinis, cæterum simillima illis.
- “II. Gammarus Gryllus N.
- “G. Corpore segmentis tredecim, pedibus quatuordecim, quorum par secundum longissimum, debile multiarticulatum, scutis lateralibus maximis pedes obtegentibus.
- “Lougïtudo tres pollices æquat (corporis duos et quadrantem, caudæ incurvatae tres quadrantes poll.) circumferentia media duos pollices quadrantemque.
- “*Corpus* compressum, dorso fornicato, rectiusculum, cauda brevi incurvata.
- “*Caput* cylindricum quasi primum corporis segmentum, antice obtusum, antennis quatuor conicis, brevibus ?*² superis pedunculo triarticulato bifidis, iuferis longioribus quadriarticulatis, articulo secundo seta parva, postremo cæteris longiore.

¹ “*O. Fabricii Fauna groenlandica, pag. 257-258. Præter hunc reliqui auctores omnes (Pallas, Müller, Stroem, Leach) de simili specie tacent. Unicam ob oculos amplos insignem Scoresby (Account of the arctic regions pag. 542) commemorat, cæterum sibi minus notam.”

² “* Antennæ in specimine nostro vix integræ, apice obtuso detrito.”

- “*Oculi* satis ampli, ovati, laterales, sub insertione antennarum inferaruu, (in mortuo) albicantes.
- “*Os productum compressiusculum, anticum, labro tuberoso corneo, mandibulis validis osscis, margine antico serrato.*
- “*Maxillarum* par primum elongatum, apice tricuspidatum utrinque palpo triarticulato et basi lamina foliacea, apice ciliata. Par secundum inferum mento amplo geniculato, labio bifido utriusque palpo coiplanato triarticulato, apice obtuso ciliato.
- “*Segmentum corporis* primum latum, margine antico caput postico segmentum secundum excipiens, appendice scutiformi laterali exiguo, cuius paginæ internæ pedes primi paris inserti sunt compressi, molliuseuli, palpiformes, quiuquearticulati, articulis (basali femore excepto) unispinosis, teruinali ciliato.
- “*Segmentum* secundum reliquis angustius, scuto lateralí ampliore fere quadrato, eius paginæ internæ infixum par pedum secundum, qui structura prioribus similes omnium longissimi (quatuordecim lineas) quinquearticulati, antice complicandi et abscondendi inter membra uam teuuem, a ventrali buiuis segmenti pagiuia tendentem, scutum magnitudine adæquantem.
- “*Segmenta* tertium quartumque æque lata, scutis lateralibus maximis, rotundatis, postice emarginatis, e quorum basi interna tendunt pedes, æque longi (decem lineas) antrorsum versi, quiuquearticulati, unguiculo termiali iuncti. Acedit ad singulum pedem a latere interno membrana tenuis, lanceolata, marginie ciliis longis obsita.
- “*Segmenta* quintum, sextum et septimum eiusdem latitudinis, pedes gerunt retrorsum versos quasi saltatorios, præcedentibus vix longiores, inter se æquales, scuto amplissimo triarticulato iunatos, ut cuiusvis scuti articulum dignoscas femorale, tibialem et tarsi. Inde femur, tibia, tarsus vere alati. Non nisi extimus siuguli pedis articulus cum unguicolo liber emergit. Par quintum intus membrana linearis.
- “*Segmenta* octavum, nonum et decimum latissima postremum antice gibbum, pro iuecurvanda cauda, subtus gerunt appendices natatorios, singulum binos bifidos satis elongatos. Horum quoque margo lateralis foliaceus, protensus sed cum parte dorsali conuatus, haud articulo inctus uti priorum.
- “*Segmenta* undecimum, duo-decimum, decimum tertium incurvata, vix erigenda, sensim angustiora laminas caudales gerunt corneas, rigidas, biarticulatas, bifidas sex, quibus accedit septima intermedia, miuita, duplex e parte dorsali postremi segmenti oriens. Segmentum undecimum medio impressum quasi bituberculatum.
- “Color speciminiis nostri fere carueus.
- “Uuicum quod ex itinere rectuli specimen a Procellaria glaciali, hamulo capta vomitu eiectum est, quum ictu lethali in occiput percussa esset. Testa animaleculi vix nisi forte apice antennarum laesa, sed quasi inanis non nisi adipe oleoso, piscini illius odoris tota repleta. Celerrimam igitur mutationem omnia ingesta vel tegumentis solidioribus inclusa in his avibus subire videntur.”

It would seem fair to accredit these two very interesting species to Lichtenstein, since Mandt expressly acknowledges his indebtedness to that professor for the descriptions just as they are here given. *Gummarus gryllus* was redescribed by Milne-Edwards in 1848 as a new species under the name *Lysianassa magellanica*.

1822. RISSE, A.

Mémoire Sur quelques nouveaux Crustacés observés dans la mer de Nice.
Journal de Physique, de Chimie et d'Histoire Naturelle. Tome XCV. Octobre. An
1822. pp. 241–248.

The new genus *Phrosina* is thus defined:—“Deux antennes à peine apparentes; yeux sessiles; tête prolongée sur le devant en forme de museau; mandibules palpigères; corps oblong,

un peu arqué, sub-arondi sur les côtés, à segments crustacés transverses, dix pattes monodactyles, dissemblables, le dernier article falciforme, aigu au sommet." The type species is *Phrosina semilunata*. *Phrosina macrophtalma*, n. sp., is also described, a doubtful species which, in the opinion of Spence Bate, probably belongs to the genus *Anchylomera*.

1822. SCHLOTHEIM, E. F.

Nachträge zur Petrefaetenkunde. Gotha, 1822.

In this work, at p. 38, Schlotheim places *Trilobites problematicus* among the doubtful species. He gives figures of it, which are here reproduced, on Pl. XXII. fig. 8, a, b. He remarks further, "Ausser dem Kopfschild mit dem beyden augenähnlichen Wärzchen scheinen noch zwey Reihen anders gestellter Schilder zwischen dem Kopfschild und den sehr schmalen Rückenschildern zu liegen, welche letztere an den Seiten mit einem durch feine Striche ausgezeichneten Saum versehen sind. Es hat den Anschein, als wäre der

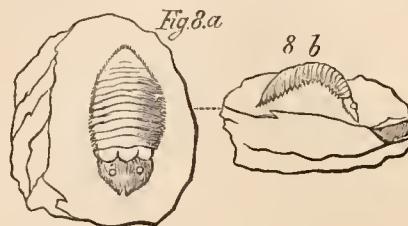

Fig. 20.

Hinterleib, nach Art des Asaphus, mit einem besondern Schwanzsilde bedeckt; doch ist diess in der Versteinerung nicht deutlich genug ausgedrückt. Das Kopfschild scheint vorn mit kleinen Zähnen, vielleicht aber auch mit Fresswerk-zengen und Fühlspitzen ausgerüstet zu seyn." It seems a somewhat wild conjecture that has placed this specimen, since mislaid or lost, in the ranks of the Amphipoda, and identified it with the *Palaeocrangon problematicus* of Schlauroth, and the *Prosoponiscus problematicus* of Kirkby.

1823. BLAINVILLE, M. H. D. DE.

Essai sur une nouvelle classification des Animaux. Les Principes d'Anatomie comparée. Tom. i. tab. 7. Paris, 1823.

This, according to Desmarest, is the same essay, with some modifications, as that already noticed, published in the Bulletin des Sciences, 1816.

1823. DESMAREST, ANSELME GAETAN, born 1784, died 1838 (Hagen).

Dictionnaire des Sciences Naturelles. Tome vingt-huitième. Strasbourg. Paris. 1823. Article Malacostracés. pp. 138–425. Tableaux I–V.

The articles on Crustacea for this dictionary were entrusted to Leach, but while the notices from G to M were being published, Leach was prevented by illness from attending to the work. The word *Malacostraca* gave Desmarest an opportunity, without breaking the alphabetical order of the dictionary, of supplying the past omissions in reference to the Crustacea by

one comprehensive article on the group. In 1825 this article, without material alteration, was converted into a separate volume. Its treatment of the Amphipoda may be understood from the note on Desmarest under that date.

1823. FLEMING, JOHN, born 1785, died 1857 (Rev. J. Duns, in Lithology of Edinburgh).

Gleanings of Natural History, gathered on the Coast of Scotland during a voyage in 1821. By the Rev. JOHN FLEMING, D.D., F.R.S.E., M.W.S., &c. In a letter to Professor JAMESON. The Edinburgh Philosophical Journal, &c., from October 1, 1822, to April 1, 1823. Vol. VIII. Edinburgh, 1823. pp. 296–297.

In *Proto pedatus*, Fleming says that he readily distinguished "the four minute appendiculae of the posterior end, which are figured by Müller, but which Montagu was unable to detect in his specimens." Of Latreille's definition of the genus *Proto*, Leach, he says, "it is true that there are only ten feet, if we exclude the two pairs belonging to the first and last segments of the body; but if these be included, the number of feet should be stated at fourteen. This precision in enumerating the feet becomes the more necessary, since Latreille has added another genus, termed *Leptomera*, to the family CAPRELLADÆ, which, in the character assigned to it, 'Out quatorze pieds, disposés dans une série continue, depuis la tête jusqu'à l'extremité postérieure du corps,' would appear to differ only in having four additional feet. But the *Squilla ventricosa* of Müller (Zool. Dan. tab. 56.), referred to as the type of the genus *Leptomera*, possesses the same number of feet as the *Gammarus pedatus* of the same author, referred to as the type of the genus *Proto*. The feet of the first and last segments of the body, however, have been enumerated by Latreille, in the character of his genus *Leptomera*, while they have been excluded from the character of the genus *Proto*. The two genera, in consequence of this arrangement, seem to differ in a character in which they agree." He criticises Lamarck for retaining "dix ou quatorze pattes" as a character of the genus *Leptomera*, of which he made *Proto* a synonym, instead of giving *Proto* the priority. But Fleming himself would retain both genera on new grounds. "In the *Leptomera*," he says, "the tarsi of the second pair of feet only are furnished with a moveable claw; while in *Proto*, all the feet are unguiculated. In the latter genus, the second, third, and fourth pairs of feet have appendages at the base, which are wanting in *Leptomera*. We are not aware that the *Leptomera ventricosa* has ever been detected on the British shores."

Of *Cancer phasma* of Montagu, which he refers to *Caprella*, he says, "it is subject to considerable variation in the number and position of the spines, and the hairiness of the different parts. In the example now before us, the claw and last joint of the first pair of feet were deeply serrated. It is probable that the *Caprella Pennantii* and *acanthifera* of Dr. Leach (Edin. Eneyelopædia, vol. vii. p. 404), are merely varieties of this species."

1824. MARTENS, GEORGIO.

Reise nach Venedig. Ulm, 1824.

According to G. D. Nardo, he mentions *Gammarus pulex*, Fab., *Oniscus (Caprella) linearis*, Latr., with many other Crustacea. Zenker, 1832, speaking of the universal distribution of *Gammarus pulex* in the rivers and streams of Europe, adds, "vix tamen in tepidis aut calidis inveniatur aquis, licet Martens (*Reise nach Venedig*. Wien, 1824. II., 197) ipsum in thermis Albanis vivere contendit, sine dubio *Gammarum Locustam* cum nostro commutans." Zenker had found that *Gammarus pulex* speedily died in warm water, but he had probably not put *Gammarus locusta* to the test.

1825. AUDOUIN, JEAN VICTOR, born 1797, died 1841 (Hagen).

Expliation sommaire des Planches dont les dessins ont été fournis Par M. J. C. Savigny. Pour l'histoire naturelle de l'ouvrage. [See Note on Savigny, 1825.]

In regard to Pl. XI., which alone concerns the Amphipoda, Audouin assigns to figure 1 the name *Gammarus dulongii*, now known as *Tanaïs dulongii*. Fig. 2. he recognizes as Savigny's *Lycesta furina*, and adds, "Ce crustacé a beaucoup d'aualogie avec la *Leucothoë articulata* de Leach, et appartient certainement au même genre."

He continues for the other figures as follows:—

"La figure 3. 1 représente une espèce fort curieuse, qui doit constituer un petit sous-genre voisin des *Mera* et des *Melita* de M. Leach, et qui se distingue facilement de celui qui précède, par la seconde paire de pieds développée outre mesure et en forme de pince (seulement du côté gauche); nous lui assignerons le nom de M. Fresnel *Gammarus Fresnelii*. Ce crustacé singulier est très-petit, ainsi qu'on peut le voir à la figure 3. 1.

"La figure 4. 1 est encore une Crevette que l'on doit rapporter au sous-genre *Amphithoe*, *Ampithoë* de M. Leach, et qui est très-voisine de deux espèces décrites par Montagu sous le nom de *Cancer Gammarus rubricus* (2), et par Pallas sous celui d' *Oniscus cancellus* (3); M. Savigny l'a mentionné (4) sous le nom de *Cymalusa filosa*.

"La figure 4. 2 représente de profil et au trait une portion de ce crustacé: on a découvert les flancs pour montrer les espèces de lamelles qu'ils renferment; la figure 4. 3 est une de ces lamelles isolée.

"La figure 5. 1 appartient au même genre, et représente peut-être la même espèce, ou bien une variété de sexe. On pourroit croire aussi que la partie postérieure de son corps, qui est tronquée brusquement en dessus, est un caractère spécifique; on retrouve ce caractère dans le *Cancer rubricatus* de Montagu.

"La figure 6. 1 appartient au même genre: cette espèce paraît distincte; elle est plus petite que les deux précédentes. Nous proposerons de lui donner le nom de M. Ramond, *Amphithoe (Gammarus) Ramondi*.

"Genre Talitre, *Talitrus*. Fig. 7, 8 et 9."

"La figure 7. 1 est une espèce d'assez petite taille (7. 1), et qui offre les caractères du sous-genre *Orchestia*, *Orchestia* de M. Leach; mais on doit la distinguer de l' *Orchestia littorea* de cet auteur, ou le *Cancer littoreus* de Montagu; nous lui donnerons le nom de Montagu, *Orchestia Montagui*. Les figures 8. 1 et 9. 1 sont des Talitres qu'on peut rapporter aussi au sous-genre *Orchestia*, à cause de la dissemblance des pieds et du développement de la seconde paire. Ces espèces nous ont paru nouvelles: la première sera dédiée à M. Deshayes, *Orchestia Deshayesi*, et la seconde à notre ami, le docteur Jules Cloquet, *Orchestia Cloquetii*."

The reference (2) is to "Montagu. Linn. Trans. tome ix. pag. 99. pl. v. fig. 1; et Encyclop. méthod. pl. cccxxxvi. fig. 33." The reference (3) is to "Pallas, Spicil. zool. fascic. ix, pag. 52, tab. iii, fig. 18." The reference (4) is to Savigny, Mémoires.

1825. BLUMENBACH, JOHANN FRIEDRICH, born 1752, died 1840 (Eneyel. Brit., 9th Edition).

Handbuch der Naturgeschichte. Eilfte reehtmässige Ausgabe. Göttingen, 1825.

In the preface a protest is raised against the use, affected by zoologists and botanists, of the word *Gattung* to mean *genus*, contrary to the older use of *Gesellschaft* for *genus*, and *Gattung* for *species*.

While following in general the system of Linnæus, Blumenbach agrees with the recent French systematists in separating "die Spinnen- und Krebsartigen Insecten, so wie die Tausend-

füsse etc.,” from the Aptera proper. In Suborder A, Arachnidea, it may be noticed that he includes “*Phalangium Balænarum*, die Wallfischlaus. P. abdomine dilatato muricato, rostro subulato. Penuant’s *British Zoology*. P. iv. tab. 18. fig. 7.” In Suborder B, Crustacea, he gives *Cancer* divided into three Families, Brachyuri, Parasitici, Macrouri, the first with six, the second with one, the third with eight species. The 14th species is thus given:—“*Pulex*. (*Gammarus P. F.*) die Fluss-Garnele. *C. macrourus* articularis, manibus 4 adactylis, pedibus 10. Rösel vol. III. tab. 62.”“Zumahl häufig in der Brunnenfresse. Aber auch in Unzahl an manchen Seefüsten. Sehr gefräßig, was verzehrend.” The genera *Monoculus*, *Oniscus*, *Scolopendra* and *Iulus*, complete the Crustacea. *Oniscus* has for its first species:—“*Ceti*. (*Cymothoa C. F.*) die Wallfischlaus. *O. ovalis*, segmentis distinctis, pedibus tertii quartique paris linearibus ovaticis.”“Pallas spicileg. zoolog. Fasc. IX. tab. 4, fig. 14.”“Zumahl eine Plage der Wallfische, bey welchen dieses Insect, besonders an den Finnen und Zengungstheilen, aufs festeste sich einnistet.”

1825. DE BRÉBISSEON, L. ALPHONSE, born 1798 (Hagen).

CATALOGUE Méthodique des Crustacés terrestres, fluviatiles et marins, recueillis dans le département du Calvados, lu à la séance du 14 mars 1825; Par M. DE BRÉBISSEON. Société Linnaéenne du département du Calvados. pp. 225–270. Caen, 1825.

In the introduction de Brébisson promises a similar work “sur la classe des Arachnides et sur celle des Insectes,” if the years which are accumulating so rapidly on his head, leave him time for it. This seems an odd expression for a man of twenty-seven, which would be his age at this time according to the date of his birth given by Hagen. Further on, in treating of the difficulties of obtaining specimens of marine Crustacea, he says, “En effet, comment parvenir à connaitre celles dont l’existence semble être confinée aux plus grandes profondeurs de l’Océan?” To this question the Challenger and similar expeditions have at least begun the answer.

In “Ordre 3, les Amphipodes. *Amphipoda*,” he gives, with short descriptions of the genera and species, *Gammarus pulex*, Fab. Lat. etc.; *Talitrus locusta*, Lat. Lamk.; *Talitrus gammarellus*, Lat. Lamk., Bosc, etc., the species now generally accepted as *Orchestia gammarellus*; *Melita palmata*, Montagu, sp.: *Corophium longicornis*, Lat. Lamk.

“Order 4. Les Isopodes. *Isopoda*,” begins with Chévrille, *Capreola*, Lat. Lamk., *Caprella* being intended. The species given is “*C. Linearis*. Lat. (*C. Scolopendroides*. Lamk.—*Cancer. Lin.*).” Then follow *Anceus*, Risso, *Jone*, Leach, *Sphaeroma*, Lat., &c.

1825. DESMAREST, A. G.

Considérations générales sur la classe des Crustacés, et description des espèces de ces animaux, qui vivent dans la mer, sur les côtes, ou dans les eaux douces de la France. Ouvrage orné de cinquante-six planches en taille-douce représentant cent quarante genres de Crustacés. Paris. Strasbourg, 1825.

This very useful history of the Crustacea in general discusses, in the first eighty-two pages, their position in the scale of beings, their structure, functions, habits, and utility, together with
(ZOOLOGICAL CHALL. EXP.—PART LXVII.—1887.)

a brief review of the systems successively adopted for their classification. The sixth chapter, containing this review, is admirably illustrated by five "tableaux synoptiques," which precede the plates at the end of the volume.

In Chapter VII. Desmarest gives notice that in his own classification of the Crustacea he proposes to follow essentially that inserted by Leach in the eleventh volume of the Linnæan Transactions, but modified and expanded to adapt it to the improved state of science on the subject. He had already explained in the preface that he had improved Leach's system by grafting upon it that of Latreille. Accordingly, he makes two subclasses, the Malacostraca and the Entomostraca, each divided into five orders. The Malacostraca are divided into two legions, of which the first, the Podophthalma, includes two orders, the Decapoda and Stomapoda; the second, the Edriophthalma, contains three orders, the Amphipoda, Læmodipoda, and Isopoda. As usual at this period, the mandibular palp comes into the definition of the Amphipoda, and is denied to the Læmodipoda. The Amphipoda are said to have five pairs of false feet under the tail.

The distribution of the Amphipoda is as follows:—

"I^e Section. *Deux antennes insérées une de chaque côté du front; queue terminée par des filets styliformes; tête grosse, verticale.*"

This includes *Phronima*, with the species *sedentaria* and *custos*.

"II^e Section. *Quatre antennes; deux feuillets aptatis, servant de nageoires, placés au bout de la queue, et remplaçant les styles; tête grosse, verticale.*" Herein he places *Hyperia*, Latr. "Quatre antennes sétacées. Les dix pieds, proprement dits, médiocrement longs, et tous terminés par un article simple et pointu. Tête assez petite, ronde, plane en devant, point prolongée en rostre. Corps conique, terminé par deux lames triangulaires, allongées, horizontales. *Hyperie de Lesueur; Hyperia Suerii*, Latr.; *Phronima?* ejusd., Encycl. Mét. Crust., tab. 328, fig. 17 et 18. Nota. Je dois la communication des caractères de ce genre inédit à la complaisance de M. Latreille, son fondateur." In this section he also places "PHROSINE (*Phrosine*, Risso; *Dactylocerus*, Latr.)," with the species *Phrosine semilunata* and *Phrosine macrophthalma*.

"III^e Section. *Quatre antennes; queue terminée par des filets styliformes; tête médiocrement grosse, non verticale.*

"I^e Division. *Antennes formées de quatre articles dont le dernier est subdivisé en plusieurs autres fort petits; les supérieures très-petites et plus courtes que le pédoncule des inférieures, qui est composé de trois articles.*" *Talitrus* with the species *locusta*, and *Orchestia* with the species *littorea* occupy this division.

"II^e Division. *Antennes grandes, sétacées, formées de quatre articles dont le dernier est lui-même multiarticulé; les supérieures de bien peu plus courtes que les inférieures.*" This division has only *Atylus*, Leach, with the species *carinatus* of Fabricius. But the remark is added, "M. Latreille présume que le *Gammarus nugax* de Fabricius, figuré par Phipps (Voyage au pôle boréal, pl. 12, fig. 2), appartient au genre Atyle."

"III^e Division. *Antennes formées de trois articles dont le dernier est multiarticulé, et dont le premier est le plus petit de tous; les supérieures étant les plus tongues.*" The genus *Dexamine* is included, with the species *spinososa*, and this is followed by "LEUCOTHOÉ (*Leucothoe*, Leach; *Gammarus*, Latr.; *Cancer*, Montagu; *Cuvieria*, Leach)," with the species *articulosa*, but no explanation is given to show where the synonym *Cuvieria* for the genus is to be met with.

"IV^e Division. *Antennes formées de quatre articles, dont le dernier est multiarticulé; les supérieures étant les plus longues.*

"Subdivision I. *Les quatre premiers pieds monodactyles; ceux de la seconde paire dans les mâles, ayant la main dilatée et comprimée.*" In this subdivision is included "MÉLITE (*Melita*, Leach; *Gammarus*, Latr., Lamck.; *Cancer*, Montagu; *Boscia*, Leach)," with the species *palmata*, and "MAERA (*Mæra* Leach; *Gammarus*, Latr., Lamck.; *Mulleria*, Leach), with

the species *grossimana*. Whence he derives the names *Boscia* and *Mulleria* he does not explain. He adds in a note that probably *Gammarus crassimanus*, Viviani, belongs to the genus *Mara*.

"*Subdivision II. Pieds des deux premières paires monodactyles et semblables dans les deux sexes.*"

In this are included three genera, "CREVETTE (*Gammarus*, Fabr., Latr., Lamek., Leaeh; *Squilla*, Degér; *Cancer*, Linn.; *Carcinus*, Latr.)," with the species *Gammarus pulex*, Fabr., Latr.; *Gammarus marinus*, Leaeh; *Gammarus locusta*, Leaeh; and *Gammarus campylops*, Leach. Among the synonyms of *Gammarus pulex* may be mentioned, "*Squilla fluvialis*, Merret, Pin., pag. 192." Of *Gammarus locusta*, he says, "M. Suriray, du Havre, a remarqué qu'elle est phosphorescente." The next genus, *Amplithoe*, has the species *rubricala* of Montagu and *cancellus* of Pallas. The third genus is *Pherusa*, with the species *fucicola*.

"*V^e Division. Antennes composées de quatre articles ; les inférieures étant les plus longues et pédiformes ; les quatre pieds antérieurs monodactyles.*

"*Subdivision I. Pieds de la seconde paire pourvus d'une grande main ; antennes inférieures de bien peu plus longues que les supérieures.*" *Podocerus* with the species *variegatus*, *Jassa* with the species *pulchella* and *pelagica*, are the genera included, *Corophium*, Latr., being given as a synonym to each.

"*Subdivision II. Pieds de la seconde paire n'ayant pas la main dilatée ; antennes inférieures bien plus longues que les supérieures.*" *Corophium*, with the species *longicornis* and its accustomed synonyms, stands here alone.

"*VI^e Division. Les quatre antennes très-grandes et fortes, presque aussi longues les unes que les autres ; les supérieures formées de quatre articles, et les inférieures ou latérales, de cinq.*" *Cerapus*, Say, with the type species *tubularis*, occupies this division.

In a note Desmarest here gives an account of several genera as probably belonging to the Amphipoda, though from want of figures and sufficient description remaining doubtful. These are *Lepidactylis*, Say, with the species *dysticus*; *Lanceola*, Say, with the species *pelagica*; *Sperchioides*, Rafinesque, with the species *lucidus*, and a complaint that Rafinesque should have chosen a name for his genus so near to *Sperchioides* employed by Fabreius among the Coleoptera; *Lepturus*, Rafinesque, with the species *rivularis*; *Pisitoe*, Rafinesque, with the species *bispinosa* and *laxifrons*. "Enfin, un genre nommé AEROPE, appartenant aussi à l'ordre des amphipodes, a été érigé par M. Leaeh ; mais il m'est inconnu, et M. Savigny a figuré (dans ses Mém. sur les anim. sans vert., 1^{re} part., 1^{er} fasc.), les parties de la bouche des deux autres, qu'il nomme CYMADUSA et LYCESTA. Ce dernier me paraît très voisin du genre MAERA de M. Leaeh."

The fourth order, *Læmodipoda*, Latr., is distributed as follows:—

"*I^{re} Section. Corps très-étroit et linéaire ; des yeux composés situés en arrière des antennes supérieures ; point d'yeux lisses ; antennes supérieures ayant le dernier article aussi long que tous les autres ensemble ; les inférieures un peu comprimées ; pieds en nombre variable ; main de ceux de la seconde paire souvent dentée en dedans.*" To this section he assigns *Leplomera*, Latr., Lamek., with *Squilla ventricosa*, Müller, for type, observing that Latreille founded this genus only upon published figures, and referred to it, besides Müller's species, which has no vesicular appendages figured at the bases of the legs, also Slabber's species, "qui a un appendice en forme de lobe, à tous les pieds, les deux premiers exceptés," and Montagu's *Cancer pedatus*, "qui en a tous les pieds pourvus, moins ceux de la première et des trois dernières paires." To the same Section he assigns "PROTON (*Proto*, Leaeh, Latr.; *Squilla*, Müller; *Leptomera*, Lamek.). Dix pieds disposés dans une série continue depuis la tête jusqu'au quatrième anneau inclusivement, le corps étant terminé par deux ou trois articles, qui forment une espèce de queue," etc., with the type species, "LE PROTON PEDIAIRE, *Proton pedatum*, Nob.; *Squilla pedata* de Müller." Though Desmarest says he had himself found it in abundance at Havre, there can be no

doubt that the account is based on imperfect specimens of *Proto ventricosa*, O. F. M. Lastly, in this section he places *Caprella*, Lamck., with the species *acutifrons*, Latr.; *acuminifera*, Leach, (more correctly, *acanthijera*, Leach); *linearis*, Linn.; “*mantis*, Latr., Nouv. Diction. d’Hist. nat. Tête allongée, rétrécie postérieurement; pieds de la seconde paire plus courts que ceux de l’espèce précédente, avec leurs articles inférieurs comprimés et anguleux. Des côtes de la France baignées par l’Océan”; a species which Mayer considers quite indefinite; *phasma*, Lamck., with *Cancer phasma*, Montagu, for a synonym, this being *Protella phasma*. He concludes by remarking that, “M. Latreille regarde encore comme appartenant à ce genre le *Cancer filiformis* de Linnæus, et le crustacé décrit par Forskal, Faun. Arab., pag. 87, comme une larve d’insecte d’un genre incertain.”

“II^e Section. *Corps large, déprimé; des yeux composés, et en outre deux très-petits yeux lisses disposés transversalement sur le vertex; antennes très-rapprochées à leur base; pieds au nombre de quatorze, dont dix parfaits, et quatre (placés sous le second et le troisième segment du corps), en forme d’appendices grêles, articulés, ou de fausses pattes; anus avancé et pourvu de tubercules peu saillans.*” This section has the one genus *Cyamus*, Latr., with the species *ceti*. The various synonyms of the genus and species are given, followed by the remark, “de l’Océan d’Europe où il vit sur les baleines, et aussi, selon M. Latreille, sur les scombres ou maquereaux. Ce crustacé est vulgairement désigné par le nom de pou de baleine.”

In the fifth order, *Isopoda*, Latr., “I^re Section. Branchies placées sous la queue,” etc., he defines the first division thus:—

“I^re Division. Pieds au nombre de dix seulement; corps formé de trois, cinq ou sept segmens; abdomen (ou queue) en ayant quatre, cinq ou six, et terminé par deux ou quatre lames latérales; deux ou quatre antennes.” In this division he places the genus, now transferred to the Amphipoda, *Typhlis*, Risso, with the species *ovoïdes*, Risso, remarking as to the definition of the genus that “M. Risso n’annonce comme didactyles que les deux premiers pieds; MM. Latreille et de Lamarck indiquent les deux suivants comme présentant le même caractère.” Under the genus “*Jone*, Latr.,” in the Second Division, Desmarest remarks that Latreille (Encycl. Méth., Expl. des pl.) considers Slabber’s *Oniscus arenarius* suited to form a genus near to *Jone*, but Desmarest himself, though he thinks that Slabber’s species has only twelve feet, shows that it is at any rate quite remote from *Jone*.

Pages 396–420 are occupied with a valuable Bibliographie carcinologique. Pages 421–427 contain a supplementary account of various species described by Risso, but not easily to be identified or classified. Among these are his *Talitrus rubropunctatus*, which Desmarest thinks may be an *Orchestia*, and his *Caprella punctata*, which Mayer agrees with Desmarest in thinking quite indefinite.

Figures of Amphipoda, borrowed from various sources, are given on plates 45 and 46. Fig. 1 on plate 45 is described at the foot of the page as “*Phronime sedentaire, gr. nat.*” Yet it has evidently been copied with some care from Pl. 2, fig. 3, of Risso’s Hist. Nat. des Crust. des Environs de Nice, 1816, which represents Risso’s *Phronima custos*, a species, it is true, identical with *Phronima sedentaria*, but none the less distinguished from it by Desmarest, who remarks upon it, “Pattes natatoires caudales paroissant n’être qu’au nombre de quatre,” a mark of distinction which beyond doubt belongs to the figure only, and not to the species. Desmarest’s fig. 8, on pl. 45, of “*Crevette des ruisseaux, gross.*,” is no longer that of Rösel’s species, but no doubt taken from an actual *Gammarus pulex*.

1825. ESCHSCHOLTZ, JOHANN FRIEDRICH, born 1793, died 1831 (Hagen).

Uebersicht der zoologische Ausbeute während der Reise von Kronstadt bis St Peter und Paul. Mit Abbild. Isis. 1825. pp. 733–746.

This work is included in Boeck’s list, but I can find nothing in it relating to the Amphipoda.

1825. LATREILLE, P. A.

Familles naturelles du Règne Animal, exposées succinctement et dans un ordre analytique, avec l'indication de leurs genres. Paris, 1825.

Latreille here divides animals into three great series or divisions, 1. Les *Vertébrés* ou *Spinalcérabraux*. 2. Les *Céphalidiens*. 3. Les *Acéphalés*. The last two include the invertebrates. The *Céphalidiens* he divides into three races, "les mollusques, les elminthoides et les condylopes." Of the condylopes the "première branche" is "Les HYPERHEXAPES, *Hyperexapi*. (Apiopodes, Sav.)." The première classe is *Crustacea*. Of these the première section is *Maxillosa*, with nine orders, Decapoda, Stomapoda, Læmodipoda, Amphipoda, Isopoda, Lophyropoda, Phyllopoda, Xyphosura, Siphonostoma. Of the third of these orders, "LÆMODIPODES. *Læmodipoda* (Isopodes cystibranches; Cuv., *Règne Animal*, tom. 3, pag. 50.)," he says, "la tête était confondue avec le premier segment du tronc, tandis que dans les deux ordres suivants elle est séparée, nous commençons par celui-ci; autrement la série naturelle des amphipodes et des isopodes serait interrompue." Of the Crustacés sessiliocles he had already said in the preface, page 24, "ils composent l'ordre des *amphipodes* et ceux de *læmodipodes* et *d'isopodes*; on aurait pu les réunir en un." This latter opinion has not met with acceptance in its entirety, but the Læmodipoda are now by general consent united with the Amphipoda. Latreille here forms them into two families, the first, Ovalia, with the genus *Cyame*, the second, Filiformia, with the genera *Clievrolle*, *Proton*, *Leptomère*. To the Amphipoda he gives four families, the first, CREVETTINES, *Gammarina*, contains in groups the genera CÉRAPE, LEUCOTHOÉ; MÉLITE, AMPHITHOÉ, DEXAMINE, CREVETTE, PHÉRUSE; ORCHESTIE, TALITRE, ATYLE; COROPHIE, PODOCÈRE, JASSE; PHRONIME. The three remaining families are given as follows:—

"Seconde Famille. UROPTÉRES. *Uroptera*. Les appendices latéraux de l'extrémité postérieure de leurs corps sont eu forme de feuillets et servent de nageoires. Ces crustacés avoisinent les *cymothoa*. Les g. HYPÉRIE, PHROSINE (Riss., Desm.; *Dactylocère*, Latr. *manuse*). 2. Ceux-ci n'ont plus que dix pieds et ue composent qu'une seule famille.

"Troisième Famille. DECEMPÈDES. *Decempedes*. Les g. TYPHIS, ANCÉE, PRANIZE (*Oniscus cœruleatus*, Montag.; Atlas de l'Encycl. méthod., pl. 336, fig. 28, et pl. 329, fig. 24). II. Les autres et derniers amphipodes ont tous leurs pieds (quatorze) ou les quatre derniers au moins simplement natatoires et mutiques.

"Quatrième Famille. HÉTÉROPES. *Heteropa*. Les g. APSEUDE, IONE (*Calino*, Léach). PTÉRYGOCÈRE."

1825. LATREILLE, P. A.

Encyclopédie Méthodique. Histoire Naturelle. Entomologie ou Histoire Naturelle des Crustacés, des Arachnides et des Insectes, Par M. Latreille. Tome Dixième. Par MM. Latreille, Le Peletier de Saint Fargeau, Serville et Guérin. A Paris, M.DCCCXXV.

The articles on Amphipoda signed by Latreille in this volume are to be found under:—

- "1. PHÉRUSE. *Pherusa*. Leach," as to which he does not supplement the scanty information which Leach supplies.
- 2. PHYTIERANCHES, *Phytibranchia*. Of these he says, "dans l'ouvrage sur le règne animal de M. Cuvier, j'ai designé ainsi une famille de Crustacés, de l'ordre des Isopodes, dont les appendices branchifères situés sous la queue ressemblent à de petits pieds articulés ou à des

- tiges ramifiées, tandis que ceux des autres Isopodes sont en forme de lames ou d'écaillles. Ayant, depuis l'impression de cet ouvrage, observé des palpes aux mandibules de divers Phytiphages [Phytibranches], caractère qui distingue les Amphipodes des Isopodes, j'ai transporté cette tribu dans le premier de ces deux ordres. Les autres Amphipodes ayant d'ailleurs sous le post-abdomen des appendices d'une forme analogue, ce groupe ordinal n'en est que mieux assorti. Je le divise en quatre familles." These are 1. Les CREVETTINES, *Gammarinx*, with the genera "Crevette, Talitre, Corophie, Phronime et plusieurs autres établis par M. Léach;," 2. "Les UROPTÈRES, *Uroptera*. Semblables aux précédens par la manière dont se terminent leurs pieds et par leur nombre, mais dont le corps offre à son extrémité postérieure et latérale des appendices en nageoires. Le genre *Phrosine* de M. Risso et quelques autres inédits appartiennent à cette famille." 3. "Les DÉCEMPÈDES, *Decempedes*. Les pieds sont onguiculés, mais réduits à dix. Elle se compose des genres *Typhis*, *Ancée*, *Pranize*." 4. "Les HÉTÉROPES, *Heteropa*. Les pieds sont au nombre de quatorze, comme dans les deux premières familles, mais tous, ou les quatre derniers au moins, sont mutiques et simplement natatoires. Là se placent les genres *Apseude*, *Ione*, *Pterygocère*." Remarks follow in regard to *Anceus*, *Praniza*, *Apseudes* and *Ione*, concluding with the observation "le genre PTÉRYGOCÉRE a été établi sur une figure de Slabber copiée ici, pl. 330, Nos. 3 et 4. Veuillez cet article et celui de TIPHIS [Typhis]."
3. PODOCÈRE. *Podocerus*, Leach, as to which he says, that it might be united to *Corophium*, by this observation leading up to the introduction of a long letter from M. d'Orbigny in regard to the habits of *Corophium grossipes*.
 4. "PTÉRYGOCÈRE, *Pterygocerus*. Genre de Crustacés que j'ai indiqué à l'article Phytibranches de cet ouvrage, et qui est formé d'après la figure de l'*Oniscus arenarius* de Slabber. (*Observ. microscop. tab. XI. fig. 3. 4.*) Quoique nous n'ayons point vu cet animal en nature, il nous paraît cependant qu'on ne peut le rapporter à aucun genre de Crustacé connu. Ses quatres antennes sont très-garnies de poils barbus ou formant des pinuules aux premiers articles qui sont beaucoup plus grands que les autres. Les quatre pattes postérieures présentent les mêmes caractères ; les quatre premières, ou du moins celles qui semblent l'être d'après la figure, sont velues, courbes, et se terminent par une nageoire ou un article arrondi et mutique. L'extrémité postérieure du corps est terminée par plusieurs appendices ou styles velus. Ce Crustacé doit appartenir à l'ordre des Amphipodes ou à celui des Isopodes."

1825. GUÉRIN (later GUÉRIN-MÉNEVILLE), Félix Édouard, born 1799, died 1874 (Webster).

Encyclopédie Méthodique, &c. Tome Dixième, &c. A Paris M.DCCCLXXV.

Latreille's health having failed before the completion of this volume, the remaining articles on the Amphipoda were entrusted to Guérin. This author wishing to bring the Encyclopædia up to the level of knowledge then existing on the subject, subjoins to those species which he is able to mention in their alphabetical order, the notice of various others in the best grouping he can contrive. Under the heading PROTON are given four articles, 1. "PROTON, *Proto*. Léach. Lat. *Squilla*, Muller. *Leptomera*. Lamk." 2. "LEPTOMÈRE, *Leptomera*. Lat. Lamk. *Proto?* Léach." 3. "CHEVROLLE, *Caprella*. Lamk. Lat. Léach. *Cancer*. Linn. *Gammarus*, Fab." 4. "CYAME, *Cyamus*. Lat. Lam. *Oniscus*. Pallas. *Squilla*. De Géer. *Pycnogonum*. Fab. *Larunda*. *Panope*. Léach." No new information is contributed. Rafinesque's PROTONIA is next mentioned, but Guérin says he knows nothing about it. An account is given of "TALITRE, *Talitrus*. Lat. Bosc. Léach. Lamk. *Cancer*. Montagu. *Oniscus*. Pallas," with the species "*Talitrus locusta*, Lat. Léach. Desm," and various synonyms. This is followed by "ORCHESTIE, *Orchestia*, Léach. Latr. (*Fam. nat.*) *Talitrus*. Lat. Bosc. Riss. Lamk. *Oniscus*. Pallas," with the species "*Orchestia gammarella*, Lat.," and its

synonymy. Next is given "ATYLE, *Atylus*, Léach. *Gammarus*. Fab. *Talitrus*, Lat.," with the species *Atylus carinatus*, Léach, having for synonym *Gammarus carinatus*, Fab. The remark is made that "Risso describes a species of *Talitrus* (*T. rubropunctatus*) which might well belong to the genus *Atylus*."

"TYPHIS, *Typhlis*, Risso, Lat. Lamk." is described in accordance with the views of Latreille among the *Decempedes*, where it is placed in company with *Ancus* and *Praniza*.

Under "UROPTÈRE, *Uroptera*. Lat.," the genus *Hyperia*, Lat., is described. Desmarest is referred to for the species "*Hyperia Suerii*." Montagu's descriptions of "*Cancer gammarus Galba*" and *Cancer monoculoides*, are translated in the belief that these species either belong to the genus *Hyperia* or come very near it. *Phrosina*, Risso, is next described, and Risso's accounts given of the two species *Phrosina semilunata* and "*Phrosina macrophthalmus*." Guérin's own genus *Themisto* follows, being very fully described, with *Themisto Gaudichaudii* for the type species. The account was repeated with but slight variation in a separate memoir in 1828. See note on Guérin under that date. In the *Encyclopædia* Guérin appends to his description of *Themisto*, one of "*Rhoë*, *Rhaea*. Milne Edw.," observing, "à la suite des Uroptères, nous devons faire mention d'un nouveau genre que vient d'établir M. Milne Edwards dans les *Annales des Sciences naturelles*. Ce naturaliste pense qu'il forme le passage entre les Amphipodes et les Euphées de M. Risso, que M. Latreille réunit à son genre *Apseude*. M. Edwards croit qu'en modifiant un peu les caractères de la famille des Uroptères, son genre s'y plaiera aisément et d'une manière naturelle." Lastly Guérin gives "*Zuphée*, *Zuphaea*. Risso," and "*Hexone*, *Hexona*. Risso," but he is not able to add anything to Risso's statements about them. The volume ends with an alphabetical table of the articles which come into the dictionary not in their alphabetical order. Here Chévrille appears as Chevralle, Cyame as Cyane, Hypérie as Hyspérie. Phrosine and Themisto are not mentioned.

1825. SAVIGNY, JULES-CÉSAR.

Description de l'Égypte, publiée par les ordres de sa Majesté l'Empereur Napoléon-le-grand. Histoire Naturelle. Animaux articulés. Crustacés. Pl. XI. dessiné et gravé en 1805–1812.

The illness of Savigny prevented him from writing the text to his elaborate Plates. After waiting for many years, the French Government at length entrusted the task to Vietor Audouin. The brief account which he gave of the Amphipoda is quoted in the Note on Audouin, 1825. It may here be mentioned that 2. *Lyceta furina*, Savigny, is now known as *Leucothoë furina*; 3. *Gammarus Fresnelii*, Audouin, is now called *Melita Fresnelii*; 4. *Cymadusa filosa*, Savigny, is now called *Amphithoë filosa*; 6. retains the name *Amphithoë Ramondi*, Audouin, but is not easily to be distinguished from *Amphithoë filosa*, except that it has the ocular lobe of the head more sharply produced between the antennæ; 5. which is not positively named by Audouin at all, though he hints at *Amphithoë rubricata*, Montagu, resembles *Amphithoë filosa* and *Amphithoë Ramondi*, except that the wrist in the first gnathopods is longer in proportion to the hand, the hand of the second gnathopods is rather densely setose on the anterior margin, and the third joint of the peduncle of the upper antennæ is by comparison elongate. 7. *Orchestia Montagui*; 8. *Orchestia Deshayesii*; and, with some authors, 9. *Orchestia Cloquetii*, retain the names assigned them by Audouin. *Orchestia Cloquetii*, the figure of which has met with some mishap in the British Museum Catalogue, was placed by Guérin-Méneville in one of his divisions of the genus *Talitrus*. Savigny's figure of it is here reproduced. It will be seen by the position of the larger

gnathopods that they are probably the first pair, not the second as has been hitherto supposed. The large fourth joint must be the wrist not the hand. The finger is not shown. Judging only by the general appearance, in the absence of other evidence, one may reasonably assign the species rather to *Talitrus* than to *Orchestia*. In fig. 1, which repre-

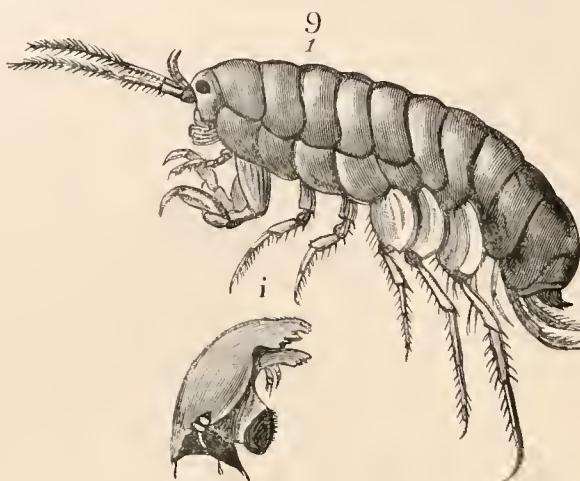

Fig. 21.

sents the mandible of *Orchestia Montagui*, here reproduced, it will be seen that Savigny represents the rudiment of a triarticulate palp. In his figure of the maxillipeds of the same species he represents the outer plate as articulated with the joint of which it is the expansion. This must be an error.

1826. RISSO, A.

Histoire Naturelle des principales productions de l'Europe Méridionale et particulièrement de celles des environs de Nice et des Alpes Maritimes. Tome cinquième. Paris, 1826.

In the preliminary notice Risso observes that "tous les genres d'amphipodes aiment à se laisser balancer mollement par les vagues sur la surface des eaux," a statement which must be received with some reservation in regard to the Orchestidae and others. The crustacés amphipodes here form the third Order. Genera and species, which had been already described in Risso's earlier works, are nevertheless here marked as new, sometimes without a reference to the earlier description. The genus *Phrosina* has the following fresh definition:—"Corps assez solide, oblong; tête moyenne; dix pattes, toutes monodactyles; dernier article de la queue arrondi, sans appendices." The expression "sans appendices" is intended to distinguish *Phrosina* from *Phronima*, in which Risso fancied that the telson had appendages. The genus *Typhis* is re-described:—"Corps solide, ovoïde; tête large; dix pattes, la première paire didactyle; dernier article de la queue conique, aigu, sans appendices." A new species, named *Gammarus marinus*, is thus described "corpore subovato, intus griseo; punctulis saturate griseis ornato; antennis pedibusque pallidioribus." The name being preoccupied by Leach, and the description very inadequate, this species has been allowed to drop by subsequent authors. Under the heading "les antennes supérieures presque aussi longues que les inférieures," the new genus *Enone* is described:—

"Corpus elongatum, compressum, articulatum; styli caudales inferiores, superioribus longiores; oculi magni, reniformes; antennae superiores articulo primo elongato, secundo quintuplo longiore, articulis aliis minutissimis; antennae inferiores articulo priuuo breve, secundo valde elongato, articulis aliis exiguissimis; pedes æquales, monodactyli," with the type species *Enone punctata*, "Corpoë hyalino, lutescente, lateribus rubro punctatis; chelis minimis; pedibus, secundo pari, longissimis, apice ovatis, acutis." This is obviously Risso's *Talitrus rubropunctatus* of 1816. Without noticing this synonym, the British Museum Catalogue names it *Allorchestes punctatus*, as a doubtful species, and with the alternative suggestion that it may be the young of *Ampithoë rubra*; but the description of the antennæ and gnathopods excludes both these identifications. Guérin, 1825, suggests the genus *Atylus* for the species *rubropunctatus*. It is characteristic of Risso that while in the generic description he gives "tous les pieds égaux, monodactyles," in the specific account we find "la première paire de pattes grêle, courte; la seconde fort longue; les autres longues et égales." The species was found in the spring, far from the shore, the female carrying transparent eggs. He says of the animals of this genus (p. 100), that they "restent toujours en pleine mer, et on les voit souvent sautiler à la surface de l'eau pendant les fortes chaleurs." This does not favour Guérin's suggestion above-mentioned.

Talitrus niceensis, n. s., is described as "corpoë glaberrimo, hyalino, vitro, pellucido; oculis purpureo-nigris: antennis, pedibus tarsisque violascentibus." This pellucid species, more likely to be one of the *Hyperina* than a *Talitrus*, might, one would think, be identified and more fully described by some one residing at Nice or in the neighbourhood. The same may be said of *Atylus corallinus*, n. s., which Spence Bate believes to be probably *Dexamine spinosa*. The genus *Eupheus*, Risso, is thus re-described, "Corpus elongatum, postice gradatim acuminatum; caput quadratum; oculi globosi; tentacula duo filiformia, multiarticulata; thorax quinquearticulatus, segmento anteriore majore, filamentis duobus corpore longioribus instructus," with the type species *Eupheus ligoides*, of which its author says, "le corps de cette espèce est composé d'un segment assez large, rattaché à cinq autres plus étroits, qui sont suivis d'un même nombre plus petits, le dernier terminé par deux courts appendices garnis chacun d'un long filet très mince; la tête est tronquée au-devant; l'œil petit, noirâtre; les antennes inégales; les quatre paires de pattes sont ciliées; une belle teinte jaune, blanche et verdâtre le colore de toute part." Risso fancies that the genus has much in common with *Ligia*. Bate and Westwood, following the lead of Desmarest, make it a synonym of *Apseudes*, Leach, in the Tanaidæ, among their *Isopoda aberrantia*.

The Crustacés Lémodipodes form the fourth Order. The first section includes *Caprella*, with the species of his earlier work, "*C. linearis*" and "*C. punctata*," and *Nymphon*, Leach, with a new species "*N. arachnoideus*," quite out of place in this group. The second section includes *Pygnogonum* (Fab.), *Ciame*, with a species "*P. ceti*, *C. de la baleine*," apparently a *Cyamus*, although the habitat assigned "sur les baleinoptères et les scombres" implies some confusion. It includes also the new genus *Hexona*, "Corpus ovatum, postice abrupte acuminatum; thorax sexarticulatus; cauda subtrigona, quinque articulata; pedes sex æquales, unguibus curvatis, acutis, aruati," with the species *Hexona parasitica*. As its habitat is on *Bopyrus*, there seems to be little doubt that it is the male of *Bopyrus* which Risso had observed in its ordinary position. Another new genus included is *Zuphea* "Corpus oblongum, convexum; caput subtriangulare; oculi magni, convexi; thorax quinque articulatus, articulis integris, approximatis; cauda sex articulata, ultimo articulo elongato, triangulare; pedes sex æquales," with the species *Zuphea sparicola*, the habitat of which is sur les spares (gilt-head), "dans le sillon des nageoires dorsales." This, like the preceding genus, is probably an Isopod, the description corresponding with the *Praniza* form of the genus *Anceus*.

1826. Ross, Sir JAMES CLARK, born April 15, 1800, died April 3, 1862 (Encycl. Brit., 9th Edition).

Journal of a third voyage for the discovery of a north-west passage from the Atlantic to the Pacific ; performed in the years 1824-25, in his Majesty's ships *Hecla* and *Fury*, under the orders of Captain William Edward Parry, R.N., F.R.S., London, MDCCCXXVI.

In the Appendix, which is separately paged, under "Natural History" is included a paper entitled "Zoology, by Lieutenant James Clark Ross, R.N., F.L.S.," pp. 91-120. He says that in his "brief notice of the Marine Invertebrate Animals brought home by the late Expedition, the generic arrangement of M. Le Chevalier de Lamarck (*Histoire Naturelle des Animaux sans vertèbres*) has been followed in every instance." On the Amphipoda his notes are as follows :—

- "10. *CAPRELLA SCOLOPENDROIDES*. Caprella scolopendroides. *Lam.* v. p. 174. *Gammarus quadrilobatus*. *Zool. Dan.* iii. p. 58, Plate 114, fig. 11, 12, Female (young?) *Squilla quadrilobata*. *Zool. Dan.* ii. p. 21, Plate 56, fig. 4, 5, 6, Male (young?) *Squilla lobata*. *Fabr. Faun. Grænl.* p. 248, No. 225. Was found abundantly at Port Bowen, but considerably larger than those from which Müller's drawings were taken, and nearly as large as the magnified figures. They also differ in having a great number of small spines along the back, which, however, were not observable on the young ones found attached to the antennæ of the females. They agreed in all other respects. I have therefore considered them to be of the same species, as it is probable that Müller's drawings were taken from the young.
- "11. *CYAMUS CETI*. Cyamus ceti, *Lam.* v. p. 176. *Oniscus ceti*. *Fabr. Fauna Grænl.* p. 253, No. 230. *Zool. Dan.* iii. p. 69, Plate 119, fig. 13-17. Found on a young whale, which was killed in June 1825, near Port Bowen.
- "12. *GAMMARUS SABINI*. Gammarus Sabini. *Leach, in Ross's Voyage*, 8vo ii. p. 178. *Supp. to Parry's First Voyage*. p. cxxxii. Plate i. fig. 8-11. Found on the ice at Port Bowen, but not very abundantly.
- "13. *GAMMARUS LORICATUS*. Gammarus loricatus. *Supp. to Parry's First Voyage*, p. cxxxii. Plate i. fig. 7. In the figure above referred to, each pair of antennæ appear to be placed on a peduncle, which is not the case. They were found in considerable numbers on the ice in Port Bowen.
- "14. *GAMMARUS BOREUS*. Gammarus boreus. *Supp. to Parry's First Voyage*, p. cxxxix. The specimens which I possess differ from Captain Sabine's description in having the superior antennæ as long as the head and six first segments of the body, and the antennæ, legs, and tail being fringed with most beautifully fine ciliae, particularly the plates of the tail. The fifth, sixth, and seventh pair of legs increase successively in length, the fifth pair being the smallest. In all other respects my specimens correspond exactly with his description.
- "15. *TALITRUS NUGAX*. Gammarus nugax. *Supp. to Parry's First Voyage*, p. cxxxix. Cancer nugax. *Philipp's Voyage*, Plate xii. fig. 3. By far the most numerous of the *Crustacea* inhabiting the Arctic Seas. The superior antennæ are shorter than the inferior, which, according to the arrangement followed in this notice, separates it from the genus *Gammarus*, where it has been inadvertently placed.
- "16. *TALITRUS EDWARDSII*. Talitrus Edwardsii. *Supp. to Parry's First Voyage*, p. cxxxiii. Plate ii. fig. 1-4. Was found on the ice at Port Bowen in great numbers. The plate and description above referred to are very exact."

In regard to *Talitrus nugax*, see Note on Goës, 1865. In regard to *Caprella scolopendroides*, see Miers' opinion in Note on Miers, 1877.

1827-JOHNSTON, GEORGE, born 1797, died 1855 (Hagen).
1828.

Contributions to the British Fauna. By George Johnston, M.D., Fellow of the Royal College of Surgeons of Edinburgh. The Zoological Journal, vol. iii. From January, 1827, to April, 1828. London, 1828, pp. 173-181, 490-491.

Under "Class. Crustacea. Order. Heterobranchia. Sect. Amphipoda. Gen. *Gammarus* Lamarck," he described "1. GAM. MACULATUS," from sea coast near Berwick, with the observation, "it belongs to Leach's restricted genus *Gammarus*, of which he has described four species. Three of these are well known to me. His *G. aquaticus* is common here, as everywhere else in our wells and ditches; the *G. locusta* swarms in the pools left on the recess of the tide; and the *G. marinus*, remarkable by its strongly ridged back, is frequently taken here, in great abundance, in the baskets used for catching crabs. Our animal is quite distinct from any of these, nor can it be the *G. Camylops*, which I have not seen, for that is characterized by having 'flexuous eyes,' a character not in the least applicable to our *G. maculatus*."

"2. GAM. PUNCTATUS." "Hab. Amongst confervæ in pools left by the tide, very common near Berwick. Obs. In the arrangement of Dr. Leach this is an *Ampithoë*. He describes one species, the *Cancer Gammarus rubricatus* of Montagu (Linn. Trans. ix. 99, tab. v. fig. 1), which differs from ours in the following particulars:—it is of a "reddish, or pale pink" colour; the eyes are crimson, in ours brown, and so dark that if not attentively examined they might be pronounced black; the hands have no notch or fissure between their articulations; and, if Montagu's figure be correct, the outline of the body is different. Moreover, in the description, Montagu makes no mention of the punctures on the dorsal portion of the segments, a character not likely to have escaped the notice of that excellent naturalist."

"3. GAM. DUBIUS," which Johnston at one time thought synonymous with *Pherusa fucicola*, Leach, but in *Gammarus dubius* "the basilar joint of the superior [antennæ] is longer than the second or third," and this species has "arms with nearly equal hands, monodactyle, oblong, not much dilated, and sparingly ciliated," whereas he observes, "in the figure of the *Pherusa fucicola* given in the Supplement to the Encyclopædia Britannica, the second joint of the superior antennæ is represented as elongated, the first pair of feet or arms filiform without any hand, and the hand of the second pair oval with a very small claw. There is also a considerable difference about the tail, the *Pherusa* having no terminal conical processes. Other distinctions might be mentioned, but those already specified seem of as high a value as many of those which divide the genera of Dr. Leach."

"4. GAM. NOLENS." "Hab. amongst confervæ, not rare. Obs. To the preceding species I gave the specific appellation *dubius*, since it seemed doubtful to which of the genera of Dr. Leach it ought to be referred; this I have named *nolens*, as it will agree with none of them. It seems allied to the *Gammarus monoculoides* (Linn. Trans. xi. 5, tab. ii. fig. 3.) of Mr. Montagu."

He enumerates as also occurring at Berwick, "the *Talitrus Locusta* and *Orchestia littorea* of Leach," the *Mæra grossimana* and *Jassa pulchella* of the same author, "the *Gam. monoculoides* of Montagu," and "the *Corophium longicorne*," all of them in abundance.

At p. 490, the habitat of *Gammarus punctatus* is described.

The description of *Gammarus maculatus* is quoted by Bate and Westwood, vol. i. p. 339, who distinguish it from the later *Gammarus maculatus* of Lilljeborg, but can give no further clue to its identification. There can, I think, be little doubt that it is the same as *Gammarus (Gammaropsis) erythrophthalmus*, Lilljeborg, which must in that case receive the name *Gammaropsis maculatus*, Johnston. *Gammarus punctatus* is identified by Spence

Bate with his own *Amphithoë littorina*; both are by Boeck made synonyms of Rathke's *Amphithoë podoceroides*. All three should in my opinion fall into the synonymy of *Amphithoë rubricata*, Montagu. The description of *Gammarus dubius* is quoted by Bate and Westwood, vol. i. pp. 397-398. It seems likely to remain in the doubt in which both they and the author of the species left it. The description of the antennæ points to some species of *Calliopius* or *Amphithopsis*, but the two "papillæ," which seem to be meant for the telson, would be inconsistent with these genera. *Gammarus nolens* is likewise left among the doubtful species by Bate and Westwood, vol. ii. p. 19. It had been, without sufficient reason, re-named by White *Typhis nolens* and subsequently *Anonyx (?) nolens*. It is as likely to be the *Hyale nilssonii* of Rathke as any other species that I am acquainted with, but the description is not sufficiently definite to entitle it to displace Rathke's specific name.

1827. MEYER.

Supplemente zur Lehre vom Kreislaufe. 1 Heft, Mit 1 ill. Kupfert. Bonn, 1827.

Zenker, 1832, says that this author described the circuit of the blood and of vegetable sap more as a poet than a naturalist, maintaining that not only in the sap of plants, but also in the blood of animals monads are found, and that all trunks are zoophytes, inhabited by hamadryads. He quotes from him the following passages relating to *Gammarus pulux* :—
 " Pag. 56 : Globulos sanguinis, ait, recto pergere tramite et hoc (*i.e.* hanc directionem) ipsis utpote animaleculis prudenteribus ("sinnigen thieren") esse inuatum.
 " Pag. 69 : Succos Gammari Pulicis effusos in monades atque in globulos campanuliformes majores distribui, qui inter se plures haberent monades, idem auctor narrat.
 " Pag. 70 legitnr : Gammari P. corpore disrupto globuli succi duplicitis generis profluent. Majores campanulati lentius moventur, diversas versus directiones, minores monades velociter diversas sequuntur regiones et varia velocitate, et sic plures fluminis instar !
 " Pag. 74. denique prodit auctor noster, *sibi ex Gammari extremitate (pede) abscissa in massu musculari (?) coxae acervum globulorum separatorum et vortice convolutatorum videre contigisse*, cujns rei libenter ipsi fidem habeamus, nam si phantasiae lusibus obtempcremus, tunc omnia cernere possumus, quæ imaginatio nobis proponat."
 Zenker's last observation would apply to his own ternary and quinary distribution of the parts of *Gammarus pulux*.

1828. AUDOUIN, V., et MILNE-EDWARDS, H.

Mémoires pour servir à l'histoire naturelle des Crustacés. Paris, 1829.
 Troisième Mémoire sur l'Anatomie et la Physiologie des Crustacés. Recherches anatomiques sur le système nerveux. Lues à l' Académie royale des Sciences. (Extrait des *Annales des Sciences naturelles*, mai 1828).

The authors here say, p. 115, "parmi les Crustacés des ordres inférieurs que nous avons examinés, ce sont les Talitres qui nous ont offert le système nervenx le plus simple et le plus uniforme. Le corps de ces animaux se divise en trois parties assez distinctes, la tête, le thorax et l'abdomen ; mais chacune d'elles est formée d'anneaux qui ont entre eux la plus grande ressemblance, et dont le nombre total est de treize. Ces divers segmens présentent à leur face inférieure deux ganglions nerveux placés sur les côtés de la ligne médiane, et réunis

entre eux par une petite commissure transversale : chacun de ces petits noyaux communique avec celui du segment qui le suit et qui le précède, à l'aide d'un cordon médullaire, et fournit un certain nombre de nerfs qui vont se distribuer aux différentes parties du corps. Le volume de ces ganglions diffère peu dans les divers segments ; au thorax, cependant, ils sont un peu plus gros que dans l'abdomen. Enfin ils sont tous un peu aplatis et ont à peu près la forme d'un losange.

“Il existe donc dans le Talitre deux chaînes ganglionnaires parfaitement symétriques, distinctes dans toute leur longueur, réunies entre elles par des commissures transversales, et offrant partout une disposition essentiellement la même. La première paire de ganglions, ou la céphalique, est remarquable par sa simplicité, et ne diffère pas essentiellement des ganglions qui suivent ; elle est située, comme dans tous les animaux articulés, au dessus de l’œsophage, et fournit des nerfs aux yeux et aux antennes : ces ganglions que l’on a désignés à tort sous le nom de cerveau, se continuent postérieurement avec les cordons médullaires qui les unissent aux deux ganglions du premier anneau thoracique, en passant sur les côtés de l’œsophage, qu’ils embrassent. Ces derniers ganglions fournissent en dehors deux nerfs, dont l’un pénètre dans la patte correspondante, et dont l’autre paraît se distribuer principalement aux muscles et aux téguments des parties latérales du corps. Les ganglions des autres segments présentent la même disposition ; seulement la distance qui les sépare nous a paru plus grande dans l’abdomen qu’au thorax.” Pl. II. fig. 1 exhibits the “Système nerveux du Talitre.”

The Report on this paper to the Académie Royale des Sciences by M. Geoffroy S.-Hilaire, “lu dans la séance du 25 février 1828,” in describing the results of the investigations made by the two authors, declares the conclusion to be that “the nervous system of all the crustacea, whatever the differences it presents among the species of the various orders, is formed of the same elements : the solitary nerve-nucleus of the crab being practically nothing but an agglomeration of the numerous nerve-ganglia arranged longitudinally in the cray-fish and Talitrus.”

1828. GUÉRIN (afterwards GUÉRIN-MÉNEVILLE), F. É.

Mémoire sur le nouveau genre Thémisto, de la Classe des Crustacés ; par M. F. E. Guérin. (Lu à la Société d’Histoire naturelle de Paris le 29 août 1828.) Extrait du tome iv. des Mémoires de la Société d’Histoire naturelle de Paris. 8 pages. Pl. xxiii.

The genus is described as follows :—“Corps oblong, composé de douze segments ; tête occupée entièrement par deux yeux à réseau, arrondie, non prolongée inférieurement en rostre. Quatre antennes ; les supérieures plus courtes que la tête, courbées au bout ; les inférieures beaucoup plus longues. Quatorze pieds ; les quatre premiers courts, dirigés en avant, couchés sur la bouche, et représentant les deux dernières paires de pieds-mâchoires des Crustacés supérieurs ; les quatre suivants beaucoup plus grands, terminés par un érochet dirigé vers la queue ; la cinquième paire très-longue dirigée vers la bouche, ayant l'avant-dernier article grêle, fort long, garni d'épines en dedans et terminé par un érolet ; les quatre derniers, de moitié plus courts, dirigés et conformés de même, mais sans dents à l'avant-dernier article. Queue terminée par six appendices natatoires longs, aplatis, bifides à l'extrémité ; trois paires de filets également natatoires sous les trois premiers segments de la queue.”

It belongs, Guérin says, evidently to Latreille’s family of Uroptera. The type species is *Themisto gaudichaudii*, found “sur les côtes des îles Malouines par M. Gaudichaud,” that is, at the Falkland Islands. It is well figured and described in much detail. By some misapprehension the mandibular palp is represented as 4- instead of 3-articulate.

1828. MILNE-EDWARDS, HENRI, born October 23, 1800, died July 29, 1885 (Friedländer, *Naturae Novitates*).

Mémoire sur quelques Crustacés nouveaux. *Annales des sciences naturelles*. Tom. 13, pp. 287 to 301. Pl. 13, 14, 15. 1828.

The first of these new Crustaceans is considered by Milne-Edwards to be evidently an Amphipod. He says it resembles the Gammarids by its general form, the disposition of the antennæ, and the appendages under the five first segments of the abdomen; it is separated from them by the structure of the two first pairs of feet, by the form of the terminal segment of the abdomen, and by the long filaments which this latter supports; these characters, he says, bring it near to *Eupheus*, with which it cannot be confounded. *Eupheus* had been withdrawn from the Isopods and placed among the Amphipods by Latreille in his last work, and Milne-Edwards believes that his new genus will here fill up a gap between "les Amphipodes uroptères et les hétérops," though the characters of the Uroptera will require some slight modification. He thus defines the genus *Rhæa*:— "Quatre antennes dont les supérieures sont grosses, bifides, et plus longues que les inférieures, quatorze pattes dont les deux premières terminées par une pinee et les autres par un ongle eroeu; le dernier article de l'abdomen allongé et supportant deux appendices terminés par de longs filamens." The type species *Rhæa latreillii* has now been transferred to the earlier genus *Apsæudes*, Leach, of which Risso's *Eupheus* is considered a synonym. Whether this and the other Tanaidæ should be reckoned as Amphipods is a matter still sub judice.

1828. STRAUS-DURCKHEIM, HERCULE EUGÈNE, born 1790 (Hagen).

Considérations générales sur l'Anatomie comparée des Animaux articulés, auxquelles on a joint l'anatomie descriptive du melolontha vulgaris (hanneton), donnée comme exemple de l'organisation des coléoptères. Paris, Strasbourg, Bruxelles, 1828.

In the introduction the author observes that animals had generally been classified in a simple series, but that the natural method is ramified, as Lamarck had first pointed out in his "*Hist. nat. des animaux sans vertèbres*, 1815; tome 1^{er}, p. 457."

In the "Tableau synoptique des animaux articulés, avec l'indication des genres par lesquels les classes et les ordres s'avoisinent dans l'état actuel de la science," he passes from the first class, Annelids, to the Myriapods as the second class, and from these in a straight line to the third class, the Insects, but through a branching off at the genus *Glomeris* to the fourth class Crustacea, in which the 1^{er} Ordre, ISOPODES" descends through the "P.^{er} G.^{re} *Armadillo*" to *Sphæroma* and *Proto*. At *Proto* branches off the "2.^e Ordre, PARASITES," including the genera *Nymphon* and *Lernæa*, while at *Sphæroma* another branch carries down the lines as follows:—3.^e Ordre AMPHIPODES. P.^{er} G.^{re} *Hiella*. D.^{er} G.^{re} *Phronima*. 4^e Ordre STOMAPODES. P.^{er} G.^{re} *Squilla*. D.^{er} G.^{re} *Erichthus*. 5^e Ordre DECAPODES. 1^{re} Fam. Maeroures. P.^{er} G.^{re} *Mysis*." &c.

He discusses, pages 33 to 38, the chemical composition of the integument of insects and Crustacea, and mentions that what Odier calls *chitine*, Lassaigne proposed to call *Entomeiline*, from ἔντομον, an insect, and εἴλυμα, a covering.

In regard to his order of "Parasites," he says in the introduction, page 17, that in it he places successively "les *Nymphon*, les *Phoxichilus*, les *Pycnogonum*, les *Cyamus*, les *Cecropes*, les *Calygnus*, les *Dichelestion*, les *Chondracante*, et les *Lernæa*," thus mixing up *Cyamus* with animals very differently constructed. For *Limulus* he proposes a separate order with the name GNATHOPODES.

1828. ZENKER, JONATHAN CARL.

Das thierische Leben und seine Formen. Ein zoologisches Handbuch zum Gebrauche academischer Vorträge und zum Selbststudium. Jena, 1828.

Zenker here divides animals into ten classes, of which the Insecta are the fifth between the Vermes and Pisces. The Insecta are divided into two orders, Crustacea, and Insecta vera. The Crustacea include four subdivisions, Branchiopoda, Isopoda, Decapoda, and Octopoda. To the Isopoda he assigns four families, numbered in his system, 55. Pycnogona, 56. Leptomera, 57. Juli, 58. Aselli; and to the Decapoda four, namely, 59. Squillæ, Squillares, Goldf., 60. Paguri, 61. Astaci, 62. Caneri.

At page 342, he assigns to "56. Fam. *Leptomera*," the genera "1. *Leptomera* LATR. 2. *Proto* LEACH. 3. *Caprella* LAM. 4. *Cyamus* LATR." He mentions that Goldfuss calls this family *Cystibranchia*, that *Leptomera rubra* LAM. is *Squilla ventricosa*, that the *Caprellæ*, as *Caprella linearis* Risso, live parasitically on Whales and fish in the European waters, and that "*Cyamus Ceti*," the *Walfischassel* has two great compound eyes on the front side-rim of the head and two small simple (glatte) ones on the head. He says it is also called *Walfischhaas* from its imbedding itself in the fat of the whale.

At page 349 he thus describes "59. Fam. *Squillæ, Squillares*, GOLDF., Heuschreckenkrebse. Kopf dick (1), klein (7). Augen gestielt (4. 6. 7) oder sitzend (1, 2, 3, 5). Fühler 4, untere länger, mit gegliederter Endborste (2) oder ohne dieselbe (3), obere länger (5). Bruststück mit den Leibesringen von gleicher Grösse (1-5) oder viereckig grösser (6, 7). Füsse, fünftes Paar sehr lang mit einer Scheere (1), das zweite Paar (2) oder das vorderste (3), oder auch die zwei vorderen (5) mit solcher, oder ohne Scheere (4). Das zweite Paar der grösseren Kiefernfüsse mit einem glatten (6) oder gezähnelten (7) Endgliede, welches sich in eine Rinne des nachfolgenden Gliedes ein legt. Schwanz mit mehreren stielformigen (1), walzigen, gegliederten (2, 3, 5) Auhängseln oder 2 Schwanzblättchen (4), und 2 oder 5 (6) oder bloss 5 Kiemenfusspaaren auf dem Schwanz. 1. *Phronima* LATR. 2. *Talitrus* LATR. 3. *Corophium* LATR. 4. *Plasmatoecrinus* TILES. 5. *Gammarus* LATR. 6. *Erichthius* LATR. 7. *Squilla* FABR." It will be noticed that the numbers in brackets refer to the numbered genera, and the stalked eyes of (4, 6, 7) will sufficiently point out that the genera so numbered do not belong to the Amphipod-group as now accepted. In the appended observations Zenker takes note of *Phronima sedentaria*, *Phronima custos*, *Corophium longicorne*, which, he says, is "*Cancer crassipes* L.", and of *Gammarus pulex*. He then adds, "Tilesius fand unter den leuchtenden Meerthieren auch mehrere hierher gehörige, wie die *Federkrebse*, *Plasmatoecrinus discophthalmus* und *glaucus*. Andere mikroskopische Thiergeschlechter, wie *Amblyrhincotus*, *Erythrocephalus*, *Acanthocephalus*, u.s.w. verdienen vielleicht hier gleichfalls ihre Stelle. In reality it is only the genus *Erythrocephalus*, in this list from Tilesius, that can be reckoned among the Amphipoda.

1829. AUDOUIN, V., et MILNE-EDWARDS, H.

Résumé d'Entomologie, ou d'Histoire Naturelle des animaux articulés, par MM. V. Audouin et H. Milne Edwards. Tome Premier. Histoire Naturelle des Annélides, Crustacés et Arachnides. Contenant une esquisse de l'Organisation, des Caractères, des Mœurs et de la description de ces animaux; précédée d'une Introduction Historique, et suivie d'une Biographie, d'une Bibliographie et d'un

Vocabulaire ; par M. V. Audouin. Complétée par une Iconographie de 48 Planches. Paris, 1829. (In the Encyclopédie portative, sous la direction de M. C. Bailly de Merlieux.)

The Crustacea occupy pages 95–195. The account of “Ordre III,—Edriophthalmes,” pp. 173–184, is extracted from the work which Milne-Edwards had recently presented to the Académie des Sciences. Planche xxvii. gives figs. 1. 2. “ORCHESTIE de Montagu;” fig. 3. “LEUCOTHOÉ furina;” Planche xxviii. gives fig. 1. “ATYLE caréné;” figs. 2. 3. “COROPHIE longiorue;” figs. 4. 5. 6. 7. “CÉRAPODE tubulaire;” fig. 8. “LEPTOMÈRE pédiaire.”

1829. BOUCHARD-CHANTEREAUX.

Précis de l'histoire physique, civile et politique, de la ville de Boulogne-sur-mer et de ses environs, depuis les Morins jusqu'en 1814; &c., par P.-J.-B. Bertrand. A Boulogne, 1828–1829.

In the second volume (1829), at page 488, is given a catalogue headed “Animaux sans vertèbres Observés par M. Bouchard-Chantereaux. (*Système du chevalier Lamarek*).” In this catalogue among the Crustacés are found the following Amphipods:—“Talitrus locusta, Talitre locuste. Orchestia littorea. Orchestie littorale. Cyamus ceti. Cyame de la bâcine.” No descriptions are given, or remarks of any kind.

1829. JOHNSTON, GEORGE.

Contributions to the British Fauna. The Zoological Journal. Vol. IV. London, 1829. pp. 52–57, 416–421.

He says “In a preceding communication I had occasion to mention that the *Gammarus marinus* of Leach was common in this neighbourhood [Berwick]; but from a subsequent examination of my specimens I am now convinced that I was in error, and that they constitute a distinct and uncharacterized species, which I proceed to describe.

“GAMMARUS CARINATUS. G. corpore maculato, atomisque flavis irrorato; dorsi segmentis valde carinatis, marginibusque posterioribus granulatis. *Hab.* Mare Britannicum.” The English description follows. This species is noticed by White, Pop. Hist. Brit. Crust., p. 183, but not by Spence Bate or Boeck. The name is preoccupied by Fabricius.

At page 417 he describes “GAMMARUS SPINIPES. Gamm. corpore albo, lœvi, lineis rubris transversis picto; palmâ pedis secundi dilatata, apice triangulare, monodactylâ, spinâ validâ infernè terminatâ. *Hab.* Littora maris Britannici.” A description in English is given, and a speculation as to whether it could possibly be the same as *Jassa pulchella* of Dr. Leach. White, *loc. cit.*, p. 199, takes note of it under *Jassa*. Other authors leave it in its pristine obscurity.

1829. LATREILLE, P. A.

Le Règne Animal distribué d'après son organisation, pour servir de base à l'histoire naturelle des animaux et d'introduction à l'anatomie comparée. Par M. le baron Cuvier. Nouvelle édition, revue et augmentée. Tome IV. Crustacés, Arachnides et partie des Insectes. Par M. Latreille. Paris, 1829.

Here Latreille divides the Crustacea into two sections, “les Malacostracés et les Entomostracés.” The former of these comprises five orders, “les Décapodes, les Stomopodes, les Læmodi-

podes, les Amphipodes, et les Isopodes." In the body of the work he transposes the Amphipoda and Læmodipoda. In treating "des Malacostræés à yeux sessiles et immobiles," he says, page 114, "Ces animaux se partagent en trois ordres : ceux dont les mandibules sont unies d'un palpe paraissent se lier naturellement avec les crustacés précédents, tels sont les amphipodes ; ceux où ces organes en sont dépourvus composeront les deux ordres suivants, les læmodipodes et les isopodes. Les eyames, genre du second, étant parasites, nous conduiront naturellement aux bopyres et aux cymothoës, par lesquels nous connemptions les isopodes." That some Amphipoda are without, and that some Læmodipoda possess the mandibular-palp, had not yet been noticed.

Of les Amphipodes (*Amphipoda*), which he here makes the third order of Crustacea, he says, "ils pourraient être compris dans un seul genre, celui DES CREVETTES. (GAMMARUS. Fab.). Que l'on peut partager d'abord, d'après la forme et le nombre des pieds, en trois sections.
 "1^o Ceux qui ont quatorze pieds, tous terminés par un crochet, ou en pointe et au nombre de quatorze.
 "2^o Ceux dont le nombre des pieds est encore de quatorze, mais où ces organes, ou les quatre derniers au moins, sont mutiques et simplement natatoires.
 "3^o Ceux qui n'ont que dix pieds apparents."

The first of these sections he divides into two, the *Uroptera* and the *Gammarinæ*. To the *Uroptera* he assigns *Phronima*, Latr., with the species *Phronime sédentaire*, Forsk., and *Phronime sentinelæ*, Risso ; *Hyperia*, Latr., "dont le corps est plus épais en devant ; dont la tête est occupée, en majeure partie, par des yeux oblongs et un peu échancreés au bord interne ; dont deux des antennes sont aussi longues au moins que la moitié du corps, et terminées par une tige scutacée, longue et composée de plusieurs petits articles," with references to "*Cancer monoculoides*, Moutag., Trans., linn. Soc., XI, ii, 3 ;—*Hypérie de Lesueur*, Latr., Encycl. méthod. atl. d'hist. nat., ccxxviii, 17, 18; Desmar., Consid., pag. 258." The figures in the Atlas of the Encycl. méth. are there called *Phronima*, without any specific name. Here after *Hyperia* he places "Les PHROSINES (PHROSINE. Risso.) Semblables, pour la forme du corps et celle de la tête, aux hypéries, mais dont les antennes sont au plus de la longueur de cette partie, de peu d'articles en forme de stylet, ou terminées par une tige en cône allongée." To this genus he refers, "*Phrosina macrophthalmia*, Risso, Journ. de phys., octob. 1822 ; Desmar., *ibid.*, p. 259 ; *Cancer galba*, Montag., Trans. linn. Soc. XI, ii, 2." Next he places "Les DACTYLOCÈRES. (DACTYLOCERA. Latr.). Dont le corps n'est point épaisse en devant ; dont la tête est de grosseur moyenne, déprimée, presque carrée, avec les yeux petits ; et dont les quatres antennes, fort courtes et de peu d'articles, ainsi que dans les phrosines, sont de formes diverses : les inférieures étant menues, en forme de stylet, et les supérieures étant terminées par une petite lame concave au côté interne, et représentant une cuiller ou une pioche." In a note to this description of *Dactylocera*, he gives references as follows ; "*Phrosina semilunata*, Risso, *ibid.*; Desmar., *ibid.* La tige des antennes inférieures présente deux ou trois articles, au lieu que, dans les phrosines, elle est inarticulée. Ici encore les articles des pédoneules des mêmes antennes sont plus courts." In the corrections and additions at the end of the volume he says, "près des Hypéries, doit être placé un autre genre de crustacés, celui de THÉMISTO, établi par le même naturaliste, et décrirait ainsi que figuré, avec le même soin, dans le Tome IV^e des Mémoires de la Société d'histoire naturelle de Paris." The naturalist thus indefinitely alluded to is Guérin. Latreille adds some remarks on the mouth-organs of *Themisto*.

Under the "CREVETTINES, *Gammarinæ*. Lat.", he places "un sous-genre, que nous avons établi sous la dénomination D'IONE (IONE.), mais uniquement d'après une figure de Montagu (*Oniscus thoracicus*, Trans., linn. Soc., IX, iii, 3, 4)," which, he says, has very special characters, separating it from all the rest of the same order. It is now recognised as an Isopod. After *Ione*, he gives *Orchestia*, *Talitrus*, *Atylus*, *Gammarus*, *Melita*, *Mara*,

Ampithoe, *Pherusa*, *Dexamine*, *Leucothoe*, *Cerapus*, *Podocerus*, *Jassa*, *Curophium*, with references to one species of each genus. Under *Atylus*, besides *Atylus carinatus*, he suggests as possibly a second species, "G. nugax? ejusd.; Phipps, Voy. au Pol. bor., xii, 2?" Under *Ampithoe*, besides *Cancer rubricatus*, Montagu, he gives, as a second species,— "Oniscus cancellus, Pall., Spicil. zool., fasc. IX, iii, 18; Gammarus cancellus, Fab." Les Podocères, "à yeux saillants," are distinguished from les Jasses, "à yeux non saillants." The species mentioned are *Podocerus variegatus*, Leach, and *Jassa pulchella*, Leach.

The second section he calls "HETEROPES, *Heteropa*, Lat." In a note he says, "Cette section et la suivante forment, dans la première édition de cet ouvrage, la seconde des isopodes, celle des phytibranches. Mais outre que nous avons aperçu, dans quelques-uns de ces crustacés, des palpes mandibulaires, la forme des appendices sous-caudaux nous a paru les rapprocher beaucoup plus des amphipodes que des isopodes. Au surplus, ainsi que nous l'observons plus bas, ces animaux, dont nous n'avons vu qu'un petit nombre, n'ont pas encore été bien étudiés." To the *Heteropa* he assigns *Pterygocera*, Lat., and *Apseudes*, Leach. A note to the generic description of *Pterygocera*, says, "d'après la figure de Slabber (*Oniscus arenarius*, Encyclop. méthod., atl. d'hist. natur., ccxxx, 3, 4.), le nombre des pieds ne serait que de huit; mais je présume, par analogie, qu'il est de quatorze; au surplus, si la figure est exacte, ce genre appartiendrait à la section suivante." In Slabber's figure, the animal being viewed from above, many of the limbs are naturally concealed from the observer. The note to *Les APSEUDES* gives "*Eupheus ligoides*, Risso, Crust., III, 37; Desmar., Consid., 285;—*Apseudes talpa*, Leach; *Cancer gammarus talpa*, Montag., Trans. linn. Soc., IX, iv, 6.; Desmar., Consid., xlvi, 9. Voy. aussi le *gammarus heteroclitus* de Viviani, Phosphor. maris, II, 11, 12."

The third section, "DECÉMPÈDES, *Decempedes*. Latr.", includes *TYPHIS*, Risso; *ANCEUS*, Risso.—*Gnathia*, Leach;—*PRANIZA*, Leach. The remark follows that, "À ce même ordre des amphipodes paraissent appartenir divers autres genres de MM. Savigny, Rafinesque et Say, mais dont les caractères n'ont pas été donnés ou suffisamment développés." A note adds, "Je ne puis encore rien dire du *G. ergine* de M. Risso: il semble, par le nombre des pieds, appartenir à la dernière section des amphipodes, et par la manière dont ils se terminent et le nombre des segments du corps, se ranger avec les isopodes."

Of *Les LÆMODIPODES*. (Læmodipoda.), which he here makes the fourth order of Crustacea, he says, "Dans la première édition de cet ouvrage, ils formaient la première section de l'ordre des isopodes, celle des cistibranches. On pourrait n'en former qu'un seul genre, auquel, par droit d'ancienneté, on conserverait le nom "De CYAME. (CYAMUS, Latr.)." He does not, however, carry out this suggestion, but retains the old grouping into *filiformia* and *ovalia*. To the former he assigns three genera, as follows:—"Les LEPTOMÈRES. (LEPTOMERA, Latr.,—*Proto*, Leach.)

"Ont quatorze pieds (les deux annexés à la tête compris) complets et dans une série continue. "Ici, comme dans nos LEPTOMÈRES propres (*Gammarus pedatus*, Mull., Zool. dan., CI 1, 2), tous les pieds, à l'exception des deux antérieurs, ont un corps vésiculaire à leur base. Là, comme dans les PROTOS de M. Leach (*Cancer pedatus*, Montag., Trans. linn. Soc., II, 6; Encyclop. méth., atl. d'hist. natur., ccxxxvi, 38.), ces appendices ne sont propres qu'aux seconds pieds et aux quatre suivants (1). [with a note] (1) Rapportez encore aux leptomères la *squilla ventricosa* de Müller, Zool. dan., LVI, 1-3; Herbst., xxxvi, 11:— le *Cancer linearis* de Linnaeus est peut-être congénère. Il lui donne six pieds, mais sans compter la tête.

"Les NAUPRÉDIES. (Naupredia, Latr.).

"N'ont que dix pieds, tous dans une série continue; les seconds et les deux paires suivantes ont à leur base un corps vésiculaire (1). [with note] (1) Sous-genre établi sur une espèce de nos côtes qui me paraît inédite.

"Les CHEVROLLES. (CAPRELLA. Lamck.)." Of these the generic description is given, and in the note references appear to various species which are, not wholly without reason, criticised as doubtful.

Of the *ovalia* Latreille says, "Ces lœmodipodes forment le sous-genre Des CYAMES proprement dits. (CYAMUS, Latr.,—*Larunda*, Leach.)

"J'en ai vu trois espèces, qui vivent toutes sur des cétacés, et dont la plus connue, le *Cyame de la baleine* (*Oniscus ceti*, Lin.; Pall., Spicil. zool., fasc. IX, iv, 14; *Squille de la baleine*, Degéer, Ins., VII, 6, vi; *Pycnogonum ceti*, Fab.; Savig., Mém. sur les anim. sans vert., fasc. I, v, 1.) se trouve aussi sur le maquereau; les pêcheurs l'ont désignée sous le nom de *Pou de baleine*. Une autre espèce, très analogue, a été rapportée par feu Delalaude de son voyage au cap de Bonne Espérance. La troisième, beaucoup plus petite, se trouve sur des cétacés des mers des Indes orientales."

1829. MÜLLER, JOHANNES, born 1801, died 1858 (Hagen).

Sur la Structure des Yeux du Hanneton (Melolontha vulgaris). Annales des Sciences naturelles. Tome dix-huitième. Paris, 1829. p. 107.

In this letter to the editors Müller criticises Straus-Durckheim's views on the eyes of insects, and Straus-Durckheim replies to him at p. 463 of the same volume. Müller refers to Straus-Durckheim's description of the eye of *Daphnia*, and adds "c'est la même structure que j'ai observée moi-même dans les *Monoculus apus*, *Gammarus pulex* et *Cyamus ceti*," and in a note to this passage he says, "Voyez mon second Mémoire sur la structure des yeux chez les insectes et les crustacés.—Meckel's, *Archiv für Anatomie und Physiologie*. 1829. H. i."

1829 ½ STRAUS-DURCKHEIM, H. E.

Mémoire sur les *Hiella*, nouveau genre de Crustacés Amphipodes. Mémoires du Muséum d'Histoire Naturelle. Tom. xviii. pp. 51–62. Pl. 4. Paris, 1829 ?

This author considers that the Amphipods are distinguished from the Isopods, because "in the Amphipods the mandibles are palpiferous; the front pairs of feet are directed forwards, and the hinder backwards; the abdomen, generally flexed underneath, carries several pairs of bifid false feet, like those of the Decapoda macroura, and the last which corresponds to the lateral appendages of the hinder segment in many Isopods, generally preserves the form of the other false feet, and is not enlarged into swimmerets. The most obvious characters to distinguish the two orders are the presence or absence of the mandibular palp, that presented by the branchiae, and that offered by the form and arrangement of the abdomen," *Hiella* he regards as a link between the two orders. He recognises its affinities with *Themisto*, *Phronima*, *Hyperia*, but is led away from perceiving its identity with the last by the inaccuracy of Latreille's definition. The genus *Hiella* is characterised as follows:—"Tête hémisphérique, quatre antennes courtes en allée de quatre articles; bouche saillante, composée d'un labre, d'une paire de mandibules, de deux paires de mâchoires et d'une lèvre inférieure terminée par deux lobules; le tronc et l'abdomen chacun de sept segments mobiles; sept paires de pattes ambulatoires, dont quatre dirigées en avant et trois en arrière; une paire de fausses pattes à chaque segment abdominal." The type species, "*Hiella Orbignyi*," from near Roehelle, does not appear to be mentioned in the Brit. Mus. Catalogue. Milne-Edwards, 1840, regards it as a synonym of his *Hyperia latreillii*, and both are by Boeck

made synonyms of *Hyperia medusarum*, Müller. Straus-Durckheim gives elaborate descriptions and figures of the structure, nervous system, etc. For the six joints of the leg he uses the terms hanche, trochanter, cuisse, jambe, tarse and crochet.

1830. Bosc, L. A. G.

Manuel de l'histoire naturelle des crustacés, etc., Par L. A. G. Bosc. Édition Mise au niveau des connaissances actuelles, par M. A. G. Desmarest. Paris, 1830.

The Amphipoda are in the second volume of this little work, which, when completely out of date, was refurbished in a confused manner, probably to suit some publisher's purpose rather than the cause of science. The Amphipoda are included in the numbered genera, XLVI. *Corophium*, Latr. XLVII. *Talitrus*, Latr. XLVIII. *Gammarus*, Fabr. XLIX. *Phronima*, Latr. L. *Cyamus*, Latr. LI. *Caprella*, Lam. LII. *Leptomera*, Latr. LVII. *Typhis*, Latreille. At p. 106 Leach's genera "Pherusa, Mæra, Melita, Leucothoe, Dexamine, Atylus, Amphithoe, etc.," are mentioned as "genres que nous n'adopterons pas." Sixteen species are assigned to *Gammarus*, which include *longicornis*, *gibbosus*, "Esca," "Pherusa," "Medusarum" and "Homari." *Corophium longicorne* had been given in advance. *Cyamus ceti* "se trouve dans la mer du Nord, non seulement sur les baleines, mais encore sur les maquereaux et autres scombrés."

1830. ESCHSCHOLTZ, JOHANN FRIEDRICH, born Nov. 12, 1793, died May 12, 1831 (*Encycl. Brit.*, 9th Edition).

A new voyage round the world, in the years 1823, 24, 25, and 26. By Otto von Kotzebue. London, 1830. Appendix. Review of the Zoological collection of Fr. Eschscholtz.

At p. 326, Eschscholtz says that while detained in the Baltic they were enabled to use their deep fishing-nets upon the great banks. These brought to light a considerable number of marine animals. Upon the branches of the *Spongia dichotoma* sat swarms of Star-fishes and Crustacea, the latter including *Caprella scolopendroides*, Lam.

1830. MILNE-EDWARDS, HENRI.

Extrait de recherches pour servir à l'histoire naturelle des Crustacés Amphipodes. (Extrait des Annales des Sciences naturelles, août 1830). Tom. 20. Pl. 10. 11. 48 pages.

The Crustacea are here divided into eleven orders, of which the seventh, eighth and ninth are the Laemipodes, Isopodes and Amphipodes. Milne-Edwards feels bound to observe that at first he had placed the genera *Rhoea* and *Tanaïs* among the Amphipods, but by Latreille's advice had transferred them to the Isopods, being thus enabled to assign more definite characters to these orders, without making them less natural. Some authors think that he was in this respect ill-advised, and that he would have done better to follow his own judgment.

The Amphipods he divides into two families, the *Crevettines* and the *Hypérines*. When he says that the Crevettines are never parasitic, he is naturally passing no judgment on the habits of *Guerinia* and *Lafystius* or other later discoveries, and the relation of *Isæa montagui* to *Maia squinado* seems to be only residential, not parasitic.

The *Crevettines* he subdivides into the tribe of the *Sauteurs* and the tribe of the *Marcheurs*. In the former he includes the following genera, the first two as *arénicoles*, the remainder as *aquatiques* :—

1. *Orchestia*, Leach, to which he transfers *Talitrus longicornis*, Say. He here describes *Orchestia Fischerii*, Milne-Edwards, with a reference to "Mém. de la Soc. d'Hist. nat. de Paris. t. 5. pl. 25, fig. 14." This species Spence Bate refers to *Orchestoidea*.
2. *Talitrus*, Latr., including *Talitrus Beaucoudraui*, n. s., which Spence Bate thinks is probably the female of *Orchestia littorea*, with Klein's *Saltator* and Audouin's *O. Cloquetii*.
3. *Lysianassa*, n. g., thus described :—"Les Crevettines, que nous plaçons dans cette nouvelle division générique, se rapprochent des Talitres par la structure de leurs pattes, dont aucune n'est préhensile ; celles de la première paire sont assez fortes, presque cylindriques dans toute leur longueur et terminées par un article court et presque immobile. La forme des divers appendices de la bouche est au contraire la même que dans les Crevettes et les autres genres de la subdivision des Aquatiques ; les antennes sont quelquefois très-courtes, mais les supérieures sont toujours au moins aussi longues que le pédoneule des inférieures et se terminent par deux tigelles annelées." He describes and figures "*Lysianassa Costæ*," n. s., pl. 10, fig. 17, and gives brief notes upon "*L. Chauseica*," n. s., which he afterwards transferred to a new genus *Alibrotus*.
4. *Gammarus*, Fabr. in which he describes and figures *Gammarus ornatus*, n. s., pl. 10, figs. 1–8, in his account of this species calling attention to what he then thought a unique phenomenon, the *calceoli*, as they were afterwards called, on the flagella of the lower antennæ, "une petite cupule membraneuse, transparente, invisible à l'œil nu, légèrement ciliée sur les bords, fixée à l'antenne par sa base et entourée de quelques poils (pl. 10. fig. 2, b) ;" he describes "*Gammarus Olivii*," n. s., pl. 10, figs. 9, 10, which by both Sp. Bate and Boeck is referred to *Gammarus marinus*, Leach; he describes and figures "*Gammarus Othomis*," pl. 10, figs. 11–13 which by Bate is referred to *Megamæra*, by Boeck to *Mæra longimanus*, Leach; he gives brief distinguishing marks for *Gammarus atlanticus*, n. s., which he afterwards described as *Lysianassa atlanticu*; "*Gammarus Impostii*," n. s. = *Mæra grossimanus*, Montagu (according to Spence Bate in the British Museum Catalogue of Amphipodous Crustacea); "*Gammarus Dugesii*," n. s. = *Melita palmata*, Montagu; *Gammarus podager*, n. s. = *Melita podager* (B. M. C.); "*Gammarus Savii*," n. s. = *Mæra Savii* (B. M. C.), but a doubtful species; *Gammarus brevicaudus*, n. s., afterwards corrected into *Gammarus brevicaudatus* = *Gammarella brevicaudata* (B. M. C.). As "Espèces douteuses" he gives 1. *Oniscus arenarius*, O. Fabr., referring to it *Gammarus Homari*, Fabr., and Strom's *Marflue*; 2. *Oniscus abyssinus*, O. Fabr.; 3. *Gammarus marinus*, Risso, and *Gammarus palmatus*? Montagu.
5. *Amphithoe*, Leach, in which he describes and figures *Amphithoe costata*, n. s., pl. 10, figs. 14–16, a species transferred by Spence Bate to the genus *Pherusa* of Leach, with a note of Milne-Edwards' error in attributing four joints to the mandibular-palp in the text, though he correctly figures only three; he gives very concisely distinguishing marks for "*Amphithoe Marionis*," n. s. = *Dexamine spinosa*, Montagu (B. M. C.); "*Amphithoe Jurinei*," n. s. = *Pherusa fucicola*, Leach (B. M. C.); "*Amphithoe Pausilipæ*," n. s., which he afterwards called *Amphithoe Pausilipii*"; "*Amphithoe Inda*," n. s., afterwards called "*Amphithoe Indica*," and said to be very near the preceding species; "*Amphithoe Reynaudii*," n. s.; *Amphithoe armorica*, n. s., which "appears to belong to the genus *Nicea*," according to the B. M. C., p. 243, note; "*Amphithoe Swammerdamii*," n. s., afterwards called *Amphithoe Swammerdamii* = *Atylus Swammerdamii* (B. M. C.); *Amphithoe pelagica*, n. s.; "*Amphithoe Prevostii*," n. s., on which see below.
6. *Isxa*, n. g., thus described :—"Dans le genre Isxa, la forme générale du corps est la même que chez les Crevettes ; les antennes supérieures se terminent aussi par deux appendices annelés ;

mais, au lieu de n'avoir que les pattes des deux premières paires préhensiles, ces Crustacés les ont toutes terminées par une griffe mobile qui se reploie sur le bord de l'article précédent." The type species "*Isaxa Montagui*" is given without further description.

7. *Leucothoe*, Leach.

In the tribe of the *Marcheurs* are included 1. *Erithonius*, n. g., thus described:—"Les Crevettines appartenant à ce genre nouveau ont beaucoup d'analogie avec les Leucothoés, dont elles diffèrent principalement par l'état rudimentaire des pièces épimériennes des premiers segmens thoraciques. Les antennes supérieures sont simples et à peu près de la longueur des inférieures ; les pattes de la seconde paire sont terminées par une main très-grosse formée par l'antépénultième article, et présentent en avant un prolongement sur lequel s'appuie la griffe qui est composée elle-même des deux derniers articles." This genus has been by some authors made the synonym of *Cerapus*, Say, but is now again separated from it. Of his type species, *Erithonius difformis*, Milne-Edwards says only "point de prolongement spiriforme [spiuiforme] sur l'antépénultième article des pattes antérieures." 2. *Atylus*, Leach, probably placed in this inappropriate position through insufficient knowledge ; 3. *Unciola*, Say ; 4. *Cerapus*, Say ; 5. *Podocerus*, Leach ; 6. "*Corophia*, Latr." in which to "*C. longicornis* Latr." is added a new species "*C. Bonellii*," only distinguished by the words "troisième article des antennes inférieures dépourvu de dents à son bord inférieur," to which in the Hist. nat. des Crustacés is added the further mark of "deux grandes épines au bord inférieur de l'article basilaire des antennes supérieures." Boeck makes the species a doubtful synonym of *Corophium crassicornis*, Bruzelius ; G. O. Sars says it is easily distinguished from that species by the rounded side-lobes of the head and the far weaker structure of the lower antennæ in both sexes (Oversigt, p. 112, 1882).

The family of the Hypérines is divided into eleven genera:—1. *Vibilia*, n. g. thus defined:—"Corps grêle et allongé comme chez les Crevettines de la seconde tribu ; tête petite et tronquée en avant ; antennes supérieures grosses, courtes, non subulées et arrondies au bout ; celles de la seconde paire, courtes et styliformes ; thorax divisé en sept segmens ; pattes de la deuxième paire terminées par une petite main imparfaitement didactyle, dont le doigt mobile est formé par les deux derniers articles ; pattes de la septième paire très-courtes, mais de même forme que les précédentes." The type species "*Vibilia Peroni*" is not further described. Latreille, in his Report upon this paper, supposes *Vibilia* to be a synonym of his own *Dactylocera*, but that genus, as Milne-Edwards points out in a note, corresponds only with Risso's *Phrosine semilunata*.

2. *Hyperia*, Lat., which Milne-Edwards thinks identical with *Lanceola*, Say. Sp. Bate makes *Lanceola* = *Vibilia*, but he also drops the name on account of the obscurity of Say's description, and Bovallius, 1886, vindicates the distinctness of *Lanceola* from both *Hyperia* and *Vibilia*. To *Hyperia* are here assigned "*Hyperia Latreillii*," n. s., pl. 11, figs. 1-7, *Talitrus cyanæ*, Sabine, both synonyms of *Hyperia medusarum*, O. F. M., *Lanceola pelagica*, Say, which is out of place, and *Hyperia cornigera*, n. s., later placed by Milne-Edwards in his new genus *Tyro*.
3. *Phorcus*, n. g., thus described:—"Dans cette petite division générique de la famille des Hypérines, les antennes inférieures sont tout-à-fait rudimentaires ; la tête est très-grosse ; le second segment du thorax est notablement plus développé qu'aucun des autres ; aucune des pattes n'est préhensile, ni terminée par une main ; celles des quatre premières paires sont courtes ; les cinquièmes sont très-longues, mais filiformes, et ne peuvent guère servir à la locomotion ; celles de la sixième paire, encore plus longues, sont, au contraire, très-fortes ; enfin celles de la dernière paire sont rudimentaires ; la structure de l'abdomen est la même que dans le genre Hypérie." The type species is *Phorcus Reynaudii*, n. s.
4. *Lestrigomus*, n. g., thus described:—"Tête très-grosse et renflée ; premier segment du thorax rudimentaire ; abdomen plus grand que le thorax ; antennes à peu près de même longueur,

terminées toutes par une longue tige subulée, multi-articulée. Aucune patte n'est préhensile mais celles de la seconde paire présentent une espèce de petite main formée par l'anté-pénultième article, etc., etc." The type species is *Lestrigonus Fabrei*, n. s., described and figured afterwards in the Hist. nat. des Crustacés. By many authors the genus *Lestrigonus* is considered to represent only the male forms of *Hyperia*, Latr.

5. *Daira*, n. g., thus described :—"Tête grosse et renflée ; antennes styliformes et rudimentaires ; thorax conique, très-étroit postérieurement et ayant le premier segment très-court ; pattes des deux premières paires portant une main imparfaitement didactyle, dont le doigt mobile est formé par les deux derniers articles ; abdomen comme dans le genre Hypérie." Type species "*Daira Gabertii*," n. s., described subsequently in the Hist. nat. des Crustacés. The name *Daira* being pre-occupied is changed by Dana into *Dairilia*, which owing to a misprint in his work is sometimes written *Dairinia*, but Bovallius, 1886, maintains that Dana's *Dairilia* is a distinct genus, and that *Paraphronima*, Claus, is the genus which comes nearest to Milne-Edwards' *Daira*, or is possibly identical with it.
 6. *Themisto*, Guérin.
 7. *Dactylocera*, Latr., which Latreille, as already mentioned, supposed to be the same as *Vibilia*, Milne-Edwards, but which Milne-Edwards, probably against his better judgment and merely out of respect to Latreille, introduces here with the synonym "*Phrosina* ? Risso." He assigns to it only the species "*Dactylocera Nicaensis*," n. s., with the synonym "*Phrosina semilunata* ? Risso." In 1840 he called the species "*Phrosina Nietensis*," and distinguished it, though perhaps needlessly, from *Phrosina semilunata*, Risso, on the authority of Costa's figures of the latter species in the Fauna del regno di Napoli, pl. 4, figs. 1-5.
 8. *Anchylomera*, n. g., thus described :—"Forme générale du corps la même que dans le genre précédent ; antennes très-courtes et styliformes ou nulles ; thorax divisé en six segments ; pattes des deux premières paires terminées par un article aplati et laniéolé ; celles de la troisième et de la quatrième paires terminées par une petite main formée par le troisième article ; pattes de la cinquième paire grosses et subcylindriques ; enfin celles des deux dernières paires terminées par une tige grêle et cylindrique." Two new species, *Anchylomera Blossevillii* and *Anchylomera Hunterii*, are assigned to this genus.
 9. *Phronima*, Latr.
 10. *Typhis*, Risso, to which he assigns *Typhis ferus*, n. s., pl. 11, fig. 8-18, and *Typhis rapax*, n. s. Of *Typhis ferus* Claus says that it is clear Milne-Edwards only knew the male of a species probably belonging to the genus *Hemityphis*, Claus. *Typhis rapax*, Claus considers to belong to a different genus, perhaps that which he calls *Schizoscelus* in his family *Seelidæ*. As "espèces douteuses" Milne-Edwards places under this genus, *Typhis oroides*, Risso ; *Gammarus monoculoides* ? Montagu ; *Cancer ampulla* ? Phipps ; and *Gammarus gibbosus* ?? Fabreius.
 11. *Oxycephalus*, n. g., thus described :—"Ces Amphipodes s'éloignent de la plupart des Hypériques par la forme grêle et allongée de leur corps, par leur tête aplatie et laniéolée, etc. Les antennes sont semblables à celles des *Typhis* ; les pattes des deux premières paires sont terminées par une main didactyle bien formée ; les autres sont grêles, cylindriques et non préhensiles ; celles de la septième paire sont très-courtes. La disposition de l'abdomen et de ses appendices est assez semblable à ce qui existe chez les Hypériques," with the type species *Oxycephalus piscatoris*, n. s., a name afterwards changed to *Oxycephalus piscator*.
- Among genera *incertæ sedis* he mentions *Hiella*, Straus, as no doubt belonging to *Hyperia*, *Lepidactylis*, Say, as seeming to come among the *Hyperina*, *Pterygocera*, Latreille, *Sperchius* and *Leplurus*, Raffinesque, on which he ventures no opinion, *Apseudes*, as probably near to *Tanais*, in the Order of the Isopoda, Family Idoteidæ, and lastly *Ione*, *Anceus* and *Praniza* as certainly belonging not to the Amphipoda but to the Isopoda.

In the Hist. nat. des Crustacés, Milne-Edwards gives a description of his "*Amphitoe Prevostii*," differing very little from his account of *Amphitoe pontica*, as he calls the *Hyale pontica* of Rathke. Rathke in his Norwegian Fauna, p. 81, names a species, "*Amphithoë Prevostii*, M. Edwards?," which he thought had no telson, and was thereby distinguished from his own Crimean species *Hyale pontica*. But the want of a telson in such an Amphipod is obviously only an accidental defect. Rathke subsequently, p. 264c, without giving any reasons, makes his Norwegian specimen a separate species as "*Amphithoë Nilssonii*." This species Spence Bate in the British Museum Catalogue, p. 38, accepts under the name "*Allorchestes Nilssonii*," with references to Rathke, while *Amphithoë Prevostii*, Milne-Edwards, is made a synonym of *Nicea prevostii* at p. 53. Milne-Edwards' species will stand as *Hyale prevostii* whether *Hyale nilssonii* be a synonym of it or not. *Hyale pontica* is a distinct species.

1831. LATREILLE, P. A.

Cours d'Entomologie, ou de l'histoire naturelle des crustacés, des arachnides, des myriapodes et des insectes. Ouvrage accompagné d'un atlas. A Paris, 1831.

The class of Crustacea is discussed from p. 311 to p. 469. The *Lamellipoda* are here the third order, without alteration within the order itself. The genus *Nempredia*, Latreille, evidently founded on an imperfect specimen of a *Proto*, is still retained.

The Amphipoda are here the fourth order. "Envisagés sous la considération des habitudes," he says, "les amphipodes peuvent être partagés en trois sections, les sauteurs, les marcheurs et les parasites. Les premiers composeront la famille des crevettines, les seconds celle des podocérides, et la dernière celle des hypérines de M. Milne-Edwards. Les deux premières, composées d'amphipodes errans ou vagabonds, se distinguent de celle-ci par les caractères suivants: pieds-mâchoires (ceux de la première paire, et présentant l'apparence d'une lèvre inférieure recouvrant les autres parties de la bouche) pluriarticulés, et réunis seulement à leur naissance; deux paires de lobes triangulaires, et dont les deux supérieurs plus grands, mais n'atteignant pas l'extremité de ces organes dans leur entredéux, et annexés à leur côté interne."

In the first family, CREVETTINES (GAMMARINÆ), while waiting for the new distribution by Milne-Edwards, Latreille forms two sections, one containing LEUCOTHOË (*leucothoe*) Leach; the other containing CREVETTE (*gammarus*); PHÉRUSE (*phcrusa*), Leach, (including in this latter genus "plusieurs autres de ce naturaliste, tels que ceux d'*ampithoe*, de *mæra*, *melita* et *dexamine*"); TALITRE (*talitrus*), and ORCHESTIE (*orchestia*).

In the second family, PODOCÉRIDES (PODOCERIDES), he mentions *Corophium*, with M. d'Orbigny's account of its habits, *Podocerus*, *Jassa*, *Cerapus*, *Atylus*.

In his account of the third family, HYPÉRINES (HYPERINÆ), he alludes to the genera "*lestrigon* et *daira* de M. Edwards." He also says, "Le genre DACTYLOCÈRE (*dactylocera*, LATR.; *vibiliæ*, EDW.) se distingue de tous les suivants par plusieurs caractères. La tête est de grosseur ordinaire ou moyenne. Au-devant de la fausse lèvre inférieure, à l'origine de ses lobes latéraux, est de chaque côté un petit corps palpiforme; les antennes supérieures sont très courtes et terminées par un grand article lamelliforme. M. Edwards exposera les autres caractères de ce genre dans sa *Monographie des amphipodes*: j'y rapporterai la *phrosine en croissant* de MM. Risso et Desmarest." He then gives an account of *Typhis*, *Phronima*, *Themisto*, in regard to the latter explaining the origin of his term *decempèdes*. The first four feet being small and closely applied to the mouth, he regarded them rather as mouth-organs than as legs in *Themisto*, in his own genus *Hyperia*, and in that which in the new edition of Cuvier's *Règne animal*, he had called *Phrosine*, with *phrosine gros-œil* of

Risso for the type species. With this last he considers that Straus' *Hiella* is identical, and this he notes has been identified with *Hyperia* by Milne-Edwards. He commends Straus' exact description of *Hiella d'Orbignii*, except for the attribution of seven instead of six segments to the pleon.

1832. COCCO, ANASTASIO.

Su di alcuni nuovi crustacei de' mari di Messina Lettera del dott. ANASTASIO COCCO al celebre dott. WILLIAM ELFORD LEACH uno de' conservatori del Museo britannico in Londra. Effemeridi scientifiche e letterarie per la Sicilia. T. II. N. 6. Giugno 1832. pp. 205-209.

In the letter he makes mention of *Ischyrocheles Leachi*, *Chiropristis litorea*, *Charybdis zanclea*, and various other Crustacea. He gives a long description of a Decapod which he names *Arctes arachnopus*, and then continues as follows:—

“Agli schiropodi criofthalmi, ed a que' soprattutto, che a cagione del loro capo sprovvveduto di antenne direi gimocefali, spetta un nuovo genere di crustacei, che vo appellare dal nome del primo fondatore di Messina Orione.

“ORIO . . . Capite fornicato. Pedibus maxillaribus exterioribus longissimis, capillaribus, replicatis, capite obtectis. Binis pedum anticorum paribus chelatis, brevissimis, reliquis simplicibus; binis posterioribus basi squamâ instructis. Caudâ stiliferâ.

“O. Becco d'uccello. O. Ornithorhamphus fig. 2.

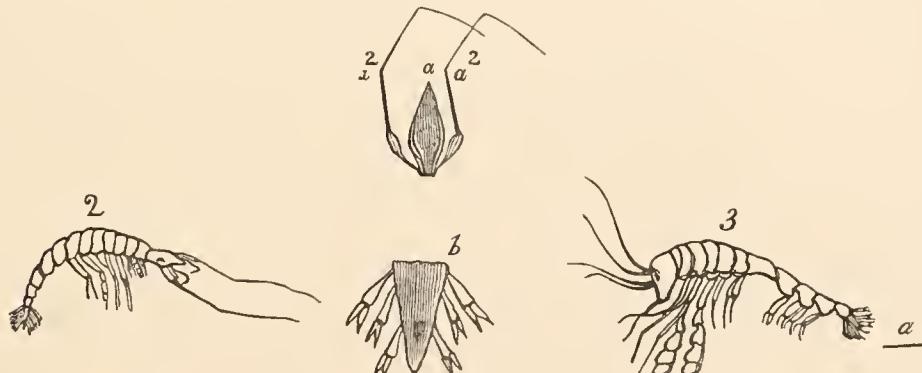

Fig. 22.

“Il corpo di questo crustaceo è cristallino, molle, lungo nove lince, largo una, composto di sette segmenti toracici uguali, e di cinque addominali più grandi, che impiccoliscono in verso la coda: quest'ultimi terminano co' loro margini postico-inferiori appuntati. Il capo è ovoidale, reticolato, inferiormente tagliato in forma di becco di penna da scrivere, e questo agguaglia intorno il terzo della lunghezza del capo.—Gli occhi sono piccioli, rotondati, di color marrone. I piedi mascellari esteriori pressochè della lunghezza del corpo son composti di quattro lunghi articolati, de' quali il basilare è allargato all' apice.. I piedi-mani sono cortissimi, gli altri quattro sono sottili, terminati da una piccola unghia acutissima, e le ultime due paga hanno alla base una squama ovale.—La coda ha la squama intermedia ovale-oblunga, e sostiene da ogni lato tre steli bifidi, decrescenti in grandezza dalla base all' apice di essa.

“Trovasi in sulle spiagge di Messina balzato dalle onde in marzo, di unita alle fronde, alle frosine, al mio *Chiropristis*, ed alla mia *Charybdis Zanclea*. Ho voluto cambiare quest'

ultimo genere in quello *di Orio*; perciocchè mi sono accorto, avere il ch. Raphinesque appellato Cariddi uno dei crustacei macrogasteri podoftalmi.—Terrà ella adunque l'*Orio Zanclus* come sinomino della *Charybdis Zanclæa*, il quale differisce assai dall' *Orio ornithoramus* per aver quello il capo corto, ottuso, gli occhi grandi, semilunati, il corpo conico, ed il colorito cinereo puenteggiato di fosco. Diverso è ancora l'ornitoramfo da un altro orione, che il mio discepolo Niccolò Prestandrea descriverà, appellandolo *O. Oxyrhinus*; conciosiacchè sia questo più piccolo, alquanto compresso, di color roseo, ed abbia il capo assai sottilmente allungato.

“Vado finalmente a descrivere un piccolo crustaceo alla stessa sezione pertinente, che per avere il capo fornito di antenne, potrebbe con molti altri costituire la divisione de' *Cheratocefali*, e piacemi appellarlo.

“*BIVONIA . . Corpore linearis, molli, compresso. Pedibus decem, tertio pari validiore, manibus cheliformibus, altero digito mobili instructo. Capite verticali. Antennis quatuor capillaribus. Caudâ styliferâ.*

“B. Zanzara. B. Culicina Fig. 3.

“Il corpo di questo piccolo crustaceo è cristallino, molle, sparso di pochi e minuti punti ranci, lungo cinque linee, largo una. Ha il capo turgido superiormente a' lati, reticolato, proboscideo; la fronte piena; gli occhi sessili, rotondi, ranci, con due punti laterali dello stesso colore. Le antenne superiori poste tramezzo agli occhi sono capillari, lunghe tre linee sostenute da peduncoli grossi, lunghi una linea e mezza, composti di due articoli: il basilare piccolo, rotondato, e l'estremo ciliudrico, tre volte più lungo. Le antenne inferiori parimenti capillari, quasi eguali alle superiori, compresi i peduncoli di queste, sono sostenute da corti peduncoli tri-articolati. Il corsaletto si compone di sei segmenti, l'anteriore de' quali strettissimo; l'addome di cinque è più larghi. Il primo e secondo pajo de' piedi sono lunghi, assai sottili, e tini in verso l'apice di rancio. Il terzo pajo è più forte, ed ha una mano più o meno rigonfiata col dito anteriore corto, semplice, immobile, ed il posteriore graude, incurvo, acuto, mobile. La mano inoltre è sparsa di minutissimi punti ranci, visibili col soccorso della lente, ed ha, come il carpo e l'avambraccio, il margine anteriore dentellato; il braccio poi, ch'è dilatato all' apice, ha nella parte anteriore di esso una piccola punta. Le due paja di piedi posteriori sono semplici con alla base una squama ovale-oblunga. La coda si termina con una piccola squama ottusa, punteggiata di rancio, e porta da ogni lato tre stili bifidi.

“Questo crustaceo, che come i precedenti viene in marzo balzato dalle onde in sulla spiaggia, a dirle il vero, mi fe'restare gran pezza in forse se dovessi farne di esso un nuovo genere, ovvero una delle fronime riputarlo. Grandemente diffatti le si assomiglia; ma il numero delle antenne, e la loro costruttura me lo fanno bastantemente distinguer. Ho voluto poi intitolarlo al mio compatriota barone A. Bivona Bernardi, com' ella sa, delle cose naturali della Sicilia illustratore amplissimo.”

In the “Spiegazione della Tavola,” he gives:—

“Fig. 2. *Orione becco d'uccello.* (a) *Capo di esso ingrandito che presenta la parte di sotto.*
(a² a²) *Pievi muscellari esteriori.* (b) *Coda con gli steli indrandita [ingrandita].*

“Fig. 3. *Bivonia zanzara.* (a) *Sua lunghezza naturale.*

Cocco's genus *Orio* is evidently synonymous in part with *Oxycephalus*, Milne-Edwards, 1830; while his *Orio zanclus* coincides generically with *Eupronoë*, Claus, 1879; and his genus *Bivonia* clearly belongs to the Phronimidae, which will be discussed later on in this Report. Milne-Edwards, Hist. des Crust., vol. iii. p. 98, supposes that Cocco's *Orio* may be the same as Risso's *Typhis*, an opinion rejected by de Natale. See note on that writer, 1850.

1832. GUÉRIN, F. E.

Expédition scientifique de Morée. Section des sciences physiques. Tome III.
—1^{re} Partie. Zoologie. Deuxième Section.—Des animaux articulés. Par M. Brullé, membre de la commission scientifique de Morée; Les Crustacés par M. Guérin. Paris, 1832.

The general introduction to this part says, "Aucune classe d'articulés ne prouve mieux que celle des Crustacés combien la Morée est quelquefois pauvre en objets nouveaux." On pages 44–46 Guérin gives the Amphipoda numbered as follows:—"47 TALITRUS SALTATOR, Miln.-Edw.," "48 ORCHESTIA FISCHERI, Miln.-Edw."

"49 TALITRUS PLATYCHELES Guér.—Corporesso compresso, glaberrimo; pedibus pare primo secundoque aequalibus.—Long. 2 centim.—(Voyez notre Pl. XXVII.)

"Cette espèce remarquable pourrait à la rigueur constituer un nouveau genre, qu'on devrait placer entre les Talitres et les Orchesties, si on prenait pour caractères génériques l'organisation des deux premières paires de pattes; en effet, chez les deux genres que nous citons, les quatre premiers pieds sont terminés par un ongle crochu et pointu, tandis que dans notre espèce les seconds pieds n'ont plus d'ougles à l'extrémité; ils sont d'une consistance membraueuse, très-plats, transparents, et dépourvus des épines qu'on observe aux autres pieds; nous n'avons cependant pas cru devoir faire un nouveau genre pour ce petit amphipode, nous le plaçons parmi les Talitres, et nous établirions pour lui une petite division, à l'exemple de M. Milne-Edwards (Ann. des sc. nat., t. 20, p. 364.), ce qui apportera une légère modification dans le tableau que ce naturaliste donne des espèces du genre Talitre; voici ce tableau modifié:

"A. Pattes de la première paire beaucoup plus grandes que celles de la seconde. *T. locusta* (Voyez notre Pl. XXVII. fig. 4e.), *Baucoulraii*.

"B. Pattes des première et seconde paires égales entre elles. *T. platycheles*.

"C. Pattes de la première paire beaucoup moins grandes que celles de la seconde paire. *T. Cloquetii*. (Voyez notre Pl. XXVII. fig. 4f.).

"Ou voit par ce tableau que notre Talitre est très-facile à distinguer des autres espèces connues; ses antennes sont plus courtes, proportion gardée, que celles du *T. locuste*; ses premières pattes sont fortes, à articles cylindriques, et terminées par un crochet simple, qui ne peut se replier en dessous. Les secondes sont de la même longueur, membraneuses et transparentes, avec leurs deux derniers articles presque égaux, aplatis, de forme ovalaire allongée; le dernier ne nous a pas offert de crochet terminal, quoique nous l'ayons placé sous une très-forte loupe. Les pattes de la troisième paire sont de forme ordinaire, plus longues de moitié que celles qui précédent. Celles de la quatrième paire ont à peu près la longueur des deux premières. Les suivantes sont encore plus courtes, robustes, garnies d'épines; enfin les deux dernières paires sont les plus longues et dépassent notablement celles de la troisième paire.

"Hab. Cette espèce a été trouvée à Modon; nous l'avons aussi reçue du golfe de Gênes, et des mers de la Corse.

"50 GAMMARUS PELOPONNESIUS Guérin.—Anteunis inaequalibus, posticis cupulis instructis; pedibus quatuor anticus subaequalibus, subcheliformibus, cæteris longioribus, aequalibus.—Long. 13–16 millim."

"51 GAMMARUS LOCUSTA Leach." This is followed by the Læmodipodes, represented by "52 CAPRELLA LOBATA—*Squilla lobata*, Müller."

In the account of *Gammarus peloponnesius*, he criticises Milne-Edwards' division of the genus *Gammarus*, "car la Crevette des ruisseaux (*G. fluviatilis*), qu'il place dans la division où

le cinquième anneau de l'abdomen doit être lisse, a cependant ce segment garni d'un faisceau d'épines ou de poils raides, comme sa Crevette ornée et comme notre Crevette de Morée ; en sorte que ces espèces doivent être placées, de moins quant à ce caractère, dans la même division." He then proceeds to call attention to the appendages of the antennæ since called calceoli, which his species has in common with *Gammarus ornatus*. The characters by which he distinguishes the new species are in fact only the comparative shortness of its upper antennæ and magnitude of its first gnathopods.

In the Brit. Mus. Catal., Spence Bate comments on the fact that Guériu has figured the mandible of *Talitrus platycheles*, with a very minute appendage (see Note on Atlas to this work, under date 1835). "This is a feature," Sp. Bate says, "that is absent not only from the genus, but from the whole tribe of SALTATORIA." It will be remembered, however, that Savigny has likewise figured such an appendage for the mandible of *Orchestia montagui*. In the Iconographie des Crustacés Guérin appears to have used Savigny's figure of this mandible, and therefore his testimony is perhaps not independent.

1832. SCHLOTHEIM.

Merkwürdige Versteinerungen aus der Petrefactensammlung des verstorbenen wirklichen Geh. Raths Freiherrn v. Schlotheim. Mit 66 Kupfertafeln. Gotha, 1832.

In this reprint at page 22 is mentioned in the description of Tab. xxii., "Fig. 8. a. b. Trilobites problematicus. Aus den jüngern Schichten des zur Kupferschieferformation gehörigen Kalksteins bei Glücksbrunn." The original figures are reproduced on the plate named.

1832. ZENKER, JONATHAN CARL.

De Gammari Pulicis, *Fabr. historia naturali atque sanguinis circuitu commen-*
tatio. Accedit Tabula Aenea. Jenae, 1832.

Zenker believes that Degeer "(quem vulgo De Geer falso scribunt)", Gruithuisen, Mayer, Wagner (*Isis*, 1832, iii), had observed the circulation of the blood in *Gammarus pulex* before him.

His section prior on the natural history of *G. pulex*, *Fabr.*, begins with a "Conspectus generum præcipuum familiæ Squillarum, cui Gammarus noster a numerandus est." Thus:—

"A. Antennæ quatuor

"a) antennæ inferiores haud in pedis modum effectæ, plures articulatæ.

"aa) antennæ superiores inferiores subæquales.

" 1. Pollices manuum sic dictarum anteriorum 2-articulati :

Cerapus et Leucothoë.

" 2. Pollices manuum anteriorum 1-articulati :

Melita, Eridithus, Squilla, Phasmatocarcinus, Amphithoë, Dexamine, Gammarus et Pherusa.

" bb) antennæ superiores inferioribus breviores ;

Orchestia, Talitrus et Atylus.

" b) antennæ inferiores magnæ pedum instar efformatæ (pedatae), vix 4-articulatæ :

Corophium, Podocerus et Jassa.

"B. Antennæ duæ ; *Phronima.*"

He observes that many of the little animals belonging to this family are phosphorescent, as the *Phasmatoecarini* and perhaps the *Amblyrhyncoti*, *Erythrocephali*, *Acanthocephali*, &c.

Under the heading *Systematica, Synonymica et Diagnostica* he gives:—

“1. *Classis*: Insecta L.; Crustacea Cuv.; Polymeria Goldf.

“2. *Ordo*: Aptera L.; Agonata Fabr.; Decapoda Goldf.; Insecta imparifeta Zenk.

“3. *Familia*: Amphipoda Cuv.; Anthocephala Dumeril; Squillares Goldf.; Gammarinæ (Cervettines) Latreille; Squillæ Zenk.”

For the synouyma he refers to *Gronov. Zooph.*, no. 990. *Schwenckfeldt* ther. Siles. p. 557. *Onomast. list. nat.* vi. 706. *Baster* (An *Gammarus marinus*?). *Raj. ins.* p. 44. *Frisch*, *Geoffroy*, *Klein*, *Roesel*, *Degeer*, *Linné Syst. nat.*, ed. xii. T. v. p. 2992, n. 81. *Scopoli*, &c. *Herbst*. *Linn. Faun. Suec.* 2. 241. *Hüll. zool. dan. prodr.* n. 2366. *Blumenbach*. *Fabric. syst. entom.* 1775. *Oken*, *Cuvier le règne anim.*; übers v. *Sehinz* iii, 68. *Nat. f. Sch.*, p. 725. *Dict. des sciences chez Levrault* xi., 408, and *Leach* (*Gammarus aquaticus*) *Edinb. Encycl.* vii.

He quotes the *diagnosis generis Gammari* of *Fabricius*, 1778, *Leach* (*Linu. Transact.* xi. 2, 1815), *Oken* (*Naturg. f. Sehuleu*, p. 725), *Cuvier le règne anim.*; trans. by *Schinzi*, and his own “Antennæ quatuor, auticæ (inferiores) breviores, posticæ (superiores) longiores cum ramo parvo accessorio, utræque articulatae. Zenk.” in which it will be observed that, like *Fabrieius*, he applies the terms *anticæ* and *posticæ* to the lower and upper antennæ respectively (see Note on *J. C. Fabrieius*, 1798). He criticizes with some justice the earlier diagnoses, and gives a brief account of the distinctions between those genera in his *Conspectus* which he considers to come nearest to *Gammarus*. He then gives the diagnosis of the species “*G. Pulex Fabr.*” by *Linné*, *Scopoli*, *Fabricius*, *Oken*, *Cuvier*, *Leach*, winding up with his own, in which he distinguishes two varieties, α) *longicaudatus*, β) *brevicaudatus*. In the description he applies the term *femur* (in preference to *cora*) to the first joint of the leg. Of the six free joints he calls the first *tibia*, the second *tarsus*, the three following *metatarsus*, the last of these being terminated by an *unus*.

The second section is on the *Sanguinis circuitus*, as to which his conclusions are not entirely in agreement with modern investigation. He sums up the results of his paper as follows:—

1. For the numerical law in all the external parts of *Gammarus Pulex*, the *ternary* arrangement is found to be the predominant, the *quinary* the subordinate. [See p. 13. *Totius corporis annuli* 3. $5 = 15$. α) *caput eum collo* 3. β) *peetus* 3. γ) *abdomen superius* 3. δ) *abdomen inferius* 3. ϵ) *cauda* 3. &c. &c.] 2. The creature has three species of parasites, two internal, in the blood, orange-coloured, surprisingly large in proportion to their host, and one external, louse-like, almost microscopic. 3. The dorsal vessel is rather to be compared with the swim-bladder of fishes than with a heart. 4. There are no special blood-vessels, but the blood flows freely round all the organs in the cavity of the trunk. 5. The globules of the blood are not animated (and therefore are not to be compared with mounds). The last statement is in opposition to *Mayer*, *Suppl. zur Lehre vom Kreislaufe*, 1827, some of whose statements he quotes with derision.

1833. BOUCHARD-CHANTEREAUX.

Catalogue des Crustacés observés jusqu'à ce jour à l'état vivant dans le Boulonnais. (Soc. d'Agric., du Comm., et des Arts, de Boulogne-sur-mer, années 1831 et 1832. Boulogne, 1833.)

“Il existe les 5 espèces suivantes : *Talitrus locusta* Lmk. *Orchestia littorea* Desm. *Melita palmata* Desm. *Gammarus pulex* Lin. *Proton pedatum* Desm.” (M. Edouard Chevreux *in litt.*)

1833. Cocco, ANASTASIO.

Descrizione di alcuni Crustacei di Messina per ANASTASIO Cocco, Giornale di Scienze Lettere e Arti per la Sicilia. T. XLIV. Anno XI. Ottobre Novembre e Dicembre. Palermo, 1833.

At page 113 he says, “È da grandissimo tempo che mi è noto un Orione, e già appellailo *orio zanclus* (Effem. n. VI pag. 207) iudicandone insin d'allora i principali caratteri, chè dagli altri il distinguesscro: ed ora vò qui completamente descriverlo.

“*Orione Zanclus Orio Zanclus—Corpore conico subrotundato cinereo-rufescente, punctulis fuscis vir conspicuis adsperso—Capite obtuso oculis maximis semilunatis nigrescentibus.*

“Perviene questo Orione infuò alla lunghezza di otto linee, ed alla larghezza di tre: ha il corpo conico quasi rotondato cincriccio-carnicino sparso in tutto di minutissimi punti bruni. Il capo agguaglia la quarta parte o poco più dell' intiera lunghezza: è alquanto compresso, declive, ed ottuso. Gli occhi son grandissimi, bruni, semilunati, colla convessità volta in avanti. Il torace è costrutto di sette segmenti de' quali i due anteriori sono più ristretti: son tutti forniti nel margine inferiore d'un appendice quadrilatera cui appicansi gli arti. L'addome ne ha cinque più larghi de' primi: di questi gli ultimi due sono più ristretti: i margini inferiori sono rotondati, e gli angoli postico-inferiori ottusi, l'ultimo segmento è scavato sul dorso, e questo incavo prolungasi infino all'apice della squama codale—I piedi mascellari son poco meno, o tanto lunghi che il corpo, e compongansi di quattro articoli quasi uguali—I piedi-mani son cortissimi, i quattro segmenti assai dilieati, le tre ultime paia hanno le cosce aderenti ad una squama: l'ultima è delle altre più piccola, ed in essa il piede è eziandio cortissimo: le uerne in ciascun piede sono acutissime. I piedi natatori terminano con un appendice bi-partita. La squama codale terminale ha forma triangolare coll' apice assai acuto, e sorpassa appena la lunghezza delle tre appendici styliformi bi-partite, che stanno in ogni lato della coda: quelle delle due prime paia sono ristrette ed acutissime, e l'altre dell' ultimo paio per alquanto rotondate terminano pure acutamente.

“Quest' Orione abondevolissimamente vien dalle onde gittato in sulla spiaggia, assieme al mio *Orio Ornithoramus* ed all' *O: Oxyrhingus* (Prestandrea) (1) i quali però son men communi. [(I)¹ I caratteri specifici premessi dal Prestandrea alla descrizione di questo *Orione* non possono nè punto nè poco convenirgli; conciossiachè sieno quelli stessi per me assegnati al mio genere *Orio* e tali quali leggonsi nel nom. VI. dell' *Effemeridi scientifiche, e letterarie per la Sicilia*—A far meglio adunque dovrebbero così venire indicati—*Corpore compresso—Roseo—Capite in rostrum acutissimum producto—Oculis magnis, semilunatis, nigrescentibus. N.]*

“Un esame diligente dc' tre orioni mi fecc accorto, che i caratteri per me a questo genere assegnati, era forza si riformassero; poichè i piedi *squamigeri* non al numero di due paia, ma si di tre costantemente in quelli si rinvengono—Un buon carattere generico è pur quello della forma del primo articolo de' piedi mascellari; perchè questo mio genere vò abbia i caratteri seguenti: *Orio—Capite fornicato, Pedibus maxillaribus longissimis capillaribus, replicatis, capite obtectis, quatriarticulatis, articulo basilari apice dilatato compresso. Binis pedum articorum paribus, chelatis, brevissimis, tribus posticis basi squamâ instructis. Caudâ stylifera. Effem. scient. e lett. per la Sic. Tom. VI. pag. 11.*”

“Fig. 3^a, a Orio Zanclus alla grandezza naturale.”

1833. GRIFFITH, EDWARD, and PIDGEON, EDWARD.

The Animal Kingdom arranged in conformity with its organization, by the Baron Cuvier. With supplementary additions to each order, by Edward Griffith. Volume the thirteenth. London, MDCCCXXXIII. The Classes Annelida, Crustacea, and Arachnida, arranged by the Baron Cuvier, with supplementary additions to each order, by Edward Griffith, F.L.S., A.S., &c., and Edward Pidgeon Esq. London, MDCCCXXXIII.

The Third Order of Crustacea, Amphipoda, and the Fourth Order, Læmodipoda, pages 204–215, are described “from the text of Latreille.” The supplement deals with these Orders on pages 315–318, but supplies no new or original information.

1833. JOHNSTON, GEORGE.

Illustrations in British Zoology. The Magazine of Natural History. London. Vol. VI. 1833. London, 1833. pp. 40–43.

He here figures and describes *Caprella acuminifera*, from Berwick. He remarks, “I do not know to whom the discovery of the animal just described is due; it is probably to Montagu.” In the eighth volume of this Magazine, page 670, under *Caprella acanthifera*, Leach, he gives as a synonym “Cap. acuminifera Desm., Crust., 277; Johnston, in Mag. Nat. Hist., vi. 40. fig. 7. a.” But though the *Caprella acuminifera* of Desmarest is the same as *Caprella acanthifera*, Leach, the species which Johnston names at first *acuminifera* and then *acanthifera* is, Mayer says, indubitably *Protella phasma*, Montagu.

1833. PRESTANDREA, NICOLÒ.

Su di alcuni nuovi crustacei dei mari di Messina. Memoria di NICOLÒ PRESTANDREA chimico-farmacista messincense. Effemeridi scientifiche e letterarie per la Sicilia. N. 16. Aprile 1833. Tomo VI. Anno secondo Aprile Maggio e Giugno. Palermo, 1833.

In this paper, pages 10–12, the following notices occur:—

“ANFIPODI. *Scinà . . . Corpore trigono caricato, marginibus rilevatis; segmentis sex anterioribus latioribus, quatuor posterioribus angustioribus.*—*Pedibus quatuor decim simplicibus, punto articulo quinto paris omnium longioris ultra articulationem prolongato.*—*Capite truncato inclinato. Caula stilifera.*

“4.—*Scinà ensicorne.*—Corpo trigono col piano inferiore più largo de’ laterali, lungo cinque linee, carenato sul dorso: margini laterali rilevati, il colorito del corpo è rosso arancio intenso, sebbene nel mezzo presenta uno o due semmenti biancastri. Capo troncato, inclinato, con due linee rilevate divergenti, che partendo dal principio della carina, ove formano un angolo acuto, terminano alla base delle antenne superiori.—Antenne superiori ensiformi, triangolari sino alla metà della loro lunghezza, col l’angolo inferiore dentillato alla base, lunghe tre linee, e mezzo, color di carne con due linee di punti rosso arancio: sono sostenute da un corto peduncolo cilindrico. Antenne inferiori capillari, bianche molto più lunghe de’ superiori, formate da sei articoli, il primo de’ quali è molto più lungo degli altri. Occhi picciolissimi, rotondi, rosso-arancio posti sul lato esterno alla base delle antenne superiori.

—Torace di setti semmenti, che crescono gradatamente in larghezza sino al quinto: il sesto, e settimo sono più stretti.—Addome di quattro anelli più stretti, ma più lunghi di quelli del torace, in ginsacchè l'insieme dell' animale si vede come diviso in due pezzi, cioè; il mezzo anteriore più largo, il posteriore abbrantamente ristretto.—Sette paja di piedi propriamente detti, semplici, gracili, che conservano nella loro lunghezza l'ordine de' semmenti del torace: il quinto pajo più lungo di tutti è dentillato nel lato esterno per tutta la lunghezza del secondo articolo, che nel lato interno si prolunga oltre l'articolazione in una punta acuta.—La coda porta sei stili molto sottili; quattro inserti sulla stessa linea, e le altre due laterali alquanto più sotto, e sono più lunghi di quelli.

“Di questi bellissimo *crustaceo*, che viene dalle onde in febbrajo balzato in sulla spiaggia insieme ad altri individui appartenenti a' generi *Phrosina Phronima Tiphis Phillosoma* ho creduto farne un nuovo genere, perciocchè la conformità del capo, il corpo trigono, le antenne esteriori forti, triangolari, ed i piedi del quinto pajo lo fanno da qualunque altro genere degli *anfipodi* abbastanza differire.

“Ho voluto dedicarlo al dottissimo abate Cav. Domenico Scinà, qual celebre conoscitore delle scienze naturali.

“Anfipodi. *Orio* (1) *Oeyahingus*—*Capite fornicato—Pedibus macillaribus exterioribus, longissimis, capillaribus, replicatis, capite obtectis—Binis pedum anticorum paribus didactylis, brevissimis, reliquis simplicibus; binis posterioribus basi squama instructis—Cauda stilifera.* [(1)¹] Questo nuovo genere di fresco stabilito per il sig. Cocco, e che nel fascicolo sesto delle Effemeridi Scientifiche, e Letterarie per la Sicilia dell'anno 1832 trovasi posto, credo per errore tipografico, nell' ordine de' *Schizzopodi Eriofthalmi*, devevi noverare nell' ordine degli Anfipodi, come ne conviene l'istesso Autore.]

“Corpo lungo sei linee, e largo meno di una, alquanto compresso, eostantemente color di rosa, molle, composto di sette semmenti toracici, e cinque addominali più grandi, che impiccoliscono inverso la coda. Quest' ultimi terminano co' loro margini postico-inferiori appuntati. Capo ovoido, inferiormente tagliato in forma di becco da penna da scrivere molto sottilmente allungato, e questo aggnaglia la lunghezza del capo.—Gli occhi sono grandi semilunati nerastri. I piedi mascellari esteriori della lunghezza del corpo sono composti di quattro lunghi articoli de' quali il basilare è allargato all' apice.—I piedi-mani sono cortissimi, gli altri quattro sono sottili, terminati da una picciola maglia acutissima, e le ultime due paja hanno alla base una squama ovale.—La squama intermedia ovale-oblunga sostiene da ogni lato tre stili bifidi decrescenti in grandezza dalla base all' apice di essa.

“Trovasi in sulle spiagge di Messina balzato dalle onde in marzo.

“Differisce dall' *Orio Ornithiramplus* (Cocco) per avere il corpo più piccolo, alquanto compresso, di color constantemente roseo, il capo assai sottilmente allungato, gli occhi grandi, semilunati, e li stili della coda proporzionalmente più grandi.”

In the above account *Oeyahingus* is apparently a misprint for *Oeyrhingus*, see note on Cocco, 1832. *Oeyrhingus* itself, we may suppose, is a malformation for *oxyrrhynchus*. The genera and species mentioned in this paper belong to the Hyperina, to be discussed in the later portion of this Report. The *Orio oeyrhingus* clearly belongs to the Oxycephalidae.

1834. DEWHURST.

The natural history of the order Cetacea and the oceanic inhabitants of the Arctic regions. 1834.

Lütken, 1873, quotes a passage from page 199 of this work alluding to *Oniscus ceti*, L., the *Cyamus mysticeti*, Lütken, parasitic on *Balaena mysticetus*, being no doubt intended. From page

¹ Footnote.

259 he quotes the observation that "the narwal is liable to the annoyance of a similar but smaller animal," but remarks that Dewhurst must certainly be wrong in the opinion which he expresses on the same page 259, that all species of whales are tormented by whale-lice.

1834. MILNE-EDWARDS, HENRI.

Histoire naturelle des Crustacés, comprenant l'anatomie, la physiologie et la classification de ces animaux. Tome premier. Ouvrage accompagné de planches. Paris, 1834.

The Introduction, pages i.-xxxv. is chiefly occupied with an interesting sketch of the literature of Carcinology down to the date of the work then in hand. The First Part, pages 1-200, in the first chapter, discusses the position of Crustacea in the animal kingdom, the character and various adaptations of the Crustacean integument, and its exuviation; in the second chapter, nutrition, respiration, circulation, and secretions; in the third chapter, the organs of sense, the nervous system and the muscles; in the fourth, the apparatus of reproduction and the process of development. In the Second Part, the first chapter, pages 201-236, describes the different systems and methods employed up to that date in the classification of Crustacea, concluding with that preferred by Milne-Edwards himself.

Milne-Edwards considers the normal number of segments of the Crustacean body to be twenty-one, the same segment never carrying more than one pair of limbs. Each segment he composes theoretically of two arcs, an upper one constructed out of two tergal pieces with an epimere or side-plate on either side, and a lower one constructed of two sternal pieces with an episternum on either side. He says that M. Audouin has arrived at this general principle, "*que ce n'est que de l'accroissement semblable ou dissemblable des segmens, de la réunion ou de la division des pièces qui les composent, du maximum de développement des uns, de l'état rudimentaire des autres, que dépendent toutes les différences qui se remarquent dans la série des animaux articulés.*" After discussing the number of distinct segments in various groups of Edriophthalma, he concludes by saying, p. 22, "*Enfin nous ajouterons que dans certaines espèces d'Amphipodes les deux moitiés latérales du septième anneau abdominal ne se réunissent pas sur la ligne médiane comme dans les autres segmens du corps, et qu'il prends alors la forme de deux petites lames cornées ou de deux appendices styliformes, disposition très-curieuse en ce qu'elle offre un exemple frappant de la division d'un anneau en deux moitiés symétriques et latérales,*" with the following note, "*Cela se voit dans la Crevette d'Othon E., la Crevette locuste L, etc.; mais, dans la plupart des Amphipodes, ces rudimens des septièmes segmens abdominaux manquent complètement. (Voy. Pl. 1, fig. 5.),*" as though he thought that the presence of a telson in the Amphipoda was the exception, whereas in the limits of this order which he accepted there is no instance of its absence which can be regarded as certain.

The appendages when fully developed, he says, present three distinct parts; the main portion, la tige, the stem which carries the other two and is almost always composed of several joints placed end to end; the second, or palp, is an appendage of the stem, on the outer side of which it almost always takes its origin, generally from the basal joint, but sometimes at the extremity of the second or third joint; the third portion, le fouet or flagellum, also arises from the stem, separating from it always above and on the outer side of the palp, p. 45. "In the natural group of the Amphipoda, the thoracic limbs almost always present in the females the maximum of composition above-mentioned; the stem serves for locomotion; the flagellum becomes membranous and serves for respiration; lastly, the palp takes

the form of the flagellum of the maxillipeds of the crabs, and serves to retain the eggs in the thorax of the mother," p. 49.

The Crustacean mouth-opening is described, p. 61, as bounded in front by a small horny or bony plate called the labrum or upper lip, and behind by a plate, generally bifid, called the tongue, *langouette*, but which "might better be called the lower lip." The sides of the mouth are occupied by the mandibles, "which often carry an articulated appendage, that has been called the mandibular palp, but which appears to be the continuation of the stem of the limb, and not the analogue of the part above-called the palp." After treating of the maxillæ and maxillipeds, he comes to the *Canal digestif*, which runs from the mouth to the anus, which is always in the terminal segment. This canal is composed of three parts, the oesophagus, stomach and intestine. In the Edriophtalma he observes that the stomach is constructed on essentially the same lines as in the Podophtalma. He notes, p. 72, that in *Orchestia* "there exist in the anterior part of the stomach, near its oesophageal opening, two little ciliated teeth." These are the structures for which in this Report the expression *triturating organs* has been adopted. On page 80 he remarks that "in the Amphipoda and Læmodipoda it is the flagella (*les fouets*) of the thoracic limbs that appear specially assigned to the exercise of the respiratory functions; these organs, from eight to twelve in number, take the form of large membranous vesicles suspended below the thorax between the ambulatory feet, and a current of water set in motion by the natatory feet of the abdomen continually bathes them."

In describing the antennæ of Crustacea, p. 111, he says that the *tige* or stem is composed in general of a stouter part called the peduncle, with one, two, or three joints, and a more or less elongate terminal portion, many-jointed, which he calls "*tige terminale*." The "palp" takes the form either of a second terminal multiarticulate lash, fixed at the extremity of the peduncle, or of a large horny plate inserted at the base of the antenna, while the remaining accessory portion, when present, also constitutes a terminal lash (*un filet terminal*).

He notices, p. 113, that the Crustacea known under "le nom de *Talitres* ou de *Puces de mer*" must have the sense of smell, as they gather round decaying food after it has been buried. On p. 116 he gives the following account of the eyes as examined in "*Amphitoe Prevostii*" and a few other Edriophtalma; "chez ces animaux on trouve d'abord pour chaque œil composé une cornée lisse sans division; mais immédiatement derrière cette lame tégumentaire il existe une seconde tunique, de même nature et également transparente, qui y adhère intimement, et qui est divisée en une multitude de facettes hexagonales; derrière chacune de ces facettes ou cornéoles est situé, comme d'ordinaire, un cristallin dont la face antérieure est convexe et dont la face postérieure, qui se prolonge en un cône à sommet obtus, est contiguë à un petit cylindre gélatineux, avec lequel le filet correspondant du nerf optique se confond." On p. 121 he says that in *Cyamus* there are two smooth eyes and two compound faceted eyes, as to which see Note on Savigny, 1816. He repeats the account of the nerve-system of *Talitrus* from a paper by Audouin and himself read in 1828, and at page 147 he says that, combining Rathke's observations with theirs, "on peut conclure que le système nerveux des Crustacés se compose toujours de noyaux médullaires dont le nombre normal est égal à celui des membres, et que toutes les modifications qu'on y rencontre, soit à diverses époques de l'incubation, soit dans différentes espèces de la série, dépendent principalement des rapprochemens plus ou moins complets de ces noyaux, aggrégation qui s'opère des côtés vers la ligne médiane, en même temps que dans la direction longitudinale; mais peuvent tenir aussi en partie à un arrêt de développement dans un certain nombre de ces noyaux."

In the chapter on development it is remarked, page 199, that among the Edriophtalma the head is much larger [proportionally] in the young than in the adults, that the abdomen often shows analogous differences, and that when in the adult one of the pairs of feet exhibits some peculiarity of structure, the anomaly is either not found, or is little apparent, in the

young. It should be remembered that throughout this portion of the work the Crustacea in general are dealt with, and that therefore, when the Edriophthalma are not being described in especial, many of the observations made are calculated to throw light upon their structure.

In the chapter on classification, after noticing earlier systems, Milne-Edwards explains his own. He prefers the zoological method which is not daunted by great differences of structure from grouping animals of high organization with others in which it may be far less complex, yet of the same general type and recalling "les états transitoires par lesquels les êtres les plus parfaits de la série ont passé pendant la durée de leur vie embryonnaire." He gives the definition of the class as follows:—

"Crustacés. Animaux ayant le corps divisé en anneaux, en général très-distincts, mobiles et d'une consistance assez grande (cornés ou calcaires), sans squetette intérieur proprement dit, et portant une double série de membres, presque toujours bien distinctement articulés, et constituant des antennes, des mâchoires, etc., et des pates dont le nombre est, le plus ordinairement, de cinq ou de sept paires; le système nerveux, en général bien distinct, ganglionnaire et longitudinal; la respiration en général aquatique, et se faisant toujours à l'aide de branchies ou de la peau; la circulation, en général bien distincte; presque toujours un cœur aortique et des vaisseaux sanguins propres; les sexes séparés." p. 231.

He makes three subclasses, namely the Crustacés maxillés, Crustacés suceurs, and Crustacés xiphosuriens. The first of these he subdivides into various legions, the first of which, les Podophthalmiens, contains two orders, the Decapods and Stomapods, while the second, les Edriophthalmes, contains three orders, the Amphipods, Isopods, and Læmipods.

It is in treating of the Decapods, p. 243, that he mentions the designations which he says are often applied to the six joints into which the ambulatory foot is commonly divided. These terms are 1. hanche, 2. trochanter, 3. cuisse or bras, 4. jambe or carpe, 5. metatarsé, 6. tarse or doigts. The last two of these sometimes, "disposés en manière de pince," form a hand (main).

The Atlas, plate xi. fig. 1, repeats the diagram of the nervous system of *Talitrus* given in the earlier work.

1834. ROUSSEL DE VAUZÈME, AUGUSTUS.

MÉMOIRE sur le *Cyamus ceti* (Latr.) de la classe des Crustacés. Annales des Sciences Naturelles. Rédigées pour la Zoologie par MM. Audouin et Milne-Edwards. Seconde Série. Tome premier.—Zoologie. Paris, 1834. pp. 239–255. 257–265. Pls. 8. 9. Fig. 19.

The author explains that he was able to study these parasites from a great number of whales harpooned under his own eyes in the Atlantic, in the neighbourhood of Tristan da Cunha, and off the Falkland Islands. He distinguishes three species, which he thinks had been hitherto confounded by authors under the same name. Lütken points out that all the three species are distinct from the northern *Cyamus mysticeti*, with which Roussel de Vauzème supposes his *Cyamus ovalis* to be identical. Of this species the anatomy is very fully described. The mistakes of Savigny and Treviranus are pointed out. Among other details of his own investigations, he says, "Des perquisitions inutiles pour trouver les glandes salivaires, m'ont fait remarquer souvent dans les tuniques de l'estomac des matières blanches, friables, de forme variée, dont je n'ai pu déterminer la nature, à moins qu'elles ne soient analogues aux pièces calcaires qu'on présume servir à la réparation du test chez les crustacés." He remarks that there is "parmi les viscères une membrane diaphane, parsemée de points

noirs en relief, interposée entre le vaisseau dorsal et le tube digestif." He notices the different authors who have written about *Cyamus*, and the various names and systematic positions which have been assigned to it. He himself considers that it comes nearest to the Isopoda, though it ought not to be united with them. He objects to the term Læmodipoda, because the anterior feet are affixed to a special segment, not to the head or neck, as that epithet would imply. After a definition of the genus *Cyamus*, he defines his three species; 1. *Cyamus ovalis*, of which he says, "cette espèce vit agglomérée sur les éminences cornées de la tête des Baleines franches (*Balaena mysticetus*)," herein, Lütken says, going astray; 2. *Cyamus erraticus*, of which he says, "il vit errant, on le trouve sur la peau lisse, à la base des tubercles cornés, sur les nageoires, principalement aux aisselles et dans les plis des parties génitales et anales;" 3. *Cyamus gracilis*, of which he remarks, "il demeure avec les Cyames ovales sur les protubérances de la tête." In a chapter on their "manners and customs," he speaks of the prodigious quantity of the *Cyamus ovalis* and *Cyamus gracilis* which can be seen a good way off at sea whitening the head of a whale, when it comes up to breathe. He had reason to think that they must cause the whale no little irritation with their sharp claws. Some care is needed in their capture, since these claws penetrate the human finger like a needle, causing a sharp pain. Cutting the branchiæ did not seem to affect these animals, but when their large antennæ were cut, they would sway uneasily about, as if they were drunk. He never found any in the stomach of the Albatrosses or other sea-birds, which are sometimes supposed to help the whales to get rid of the parasites, but he believed that the winter storms might be highly useful in this respect. He decisively rejects the suggestion of MM. Audouin and Milne-Edwards that the *Cyamus gracilis* might only be the young of the other species.

1835. GERVAIS.

Note sur deux espèces de Crevettes qui vivent aux environs de Paris. Annales des Sciences naturelles. Seconde Série. Tome quatrième.—Zoologie. Paris, 1835. pp. 127–128.

The Crevettes d'eau-douce, he says, have been confounded under the names *Gammarus pulex*, *aquaticus* or *fluvialis*, as forming but a single species, whereas they really form two species, differing not only by zoological characters, but also by their habits. "Jamais elles ne s'accouplent ensemble, et l'une a sur le dessus des anneaux de l'abdomen des épines que l'autre ne présente pas." Roesel and Geoffroy have described and figured the one, Desmarest and Zenker have figured the other. The former he proposes to call *Gammarus Roeselii*, because the names *fluvialis* and *aquaticus* are inappropriate, since there is another river Gammarus, and all the Gammari are aquatic. His definitions are "GAMMARUS PULEX, Fabr. *Oculis reniformibus, antennis subæqualibus; lingulo quoque abdomis [cingulo quoque abdominalis] leví, id est non spinigero," and "*Gammarus roeselii* Nobis. *Oculis ac antennis gammari pulicis, sed abdominalis cingulo quoque aculeato, id est supernè et posticè unispinigero. Astacus fluvialis* Roësel. Insecten belistegungen III, pl. 52. *Crevette des ruisseaux* Geoffroy. Hist. des Insectes pl. 21, fig. 6." I do not for my own part consider Gervais justified by the reason he gives in altering Rösel's name. What he states as to the two species never mating is guarded in a note by the remark that such a thing might happen, without disproving the distinctness of the species.*

Gervais concludes as follows:—"On trouve aussi dans les environs de Paris, mais seulement dans l'eau de puits, une troisième sorte de Crevette, remarquable par la petitesse de sa taille, qui ne dépasse pas en effet trois ou quatre millimètres. Cette Crevette, que nous considérons comme une simple variété de séjour est constamment étiolée, et ses yeux, au lieu d'être

noirs, comme chez les précédentes, sont tout-à-fait sans pigmentum et non apparens. Nous la nommerons *Gammarus pulex minutus*, parce que c'est en effet à l'espèce sans épines qu'elle appartient." As to this see note on Koch, 1835.

1835. GUÉRIN-MÉNEVILLE.

Expédition scientifique de Moree. Atlas, 1831-1835. Paris, 1835.

On page 3, in the description of Pl. XXVII., what relates to the Amphipoda is thus given :—

"Fig. 4. *Talitrus platicheles*, Guérin; voy. p. 44. Grossi; *a* dernier segm. de l'abdom. plus grossi; *b* mandibule très-grossie; *c* une patte de la seconde paire très-grossie; *d* patte antérieure du *Thalitrus locusta* grossie; *e* celle du *Thalitrus Cloquetii* également grossie. —Fig. 5. *Gammarus peloponnesiacus*, Guérin voy. p. 45. Grossi; *a* partie d'une antenne externe très-grossie." On Pl. XXVII. itself, which has the inscription "E. Guérin pinxit," there is no figure 4. d. Figures 4. e. and 4. f. represent not single feet but the whole anterior portion, head, antennæ, gnathopods, etc., of two Orchestidae, the former copied from Desmarest's copy of Montagu's *Gammarus saltator*, the latter from Savigny's figure of *Talitrus cloquetii* (Audouin). In figure 5, the two last peræopods are represented without side-plates, and attached to the fifth and sixth peræon-segments, while the pleopods are attached respectively to the seventh peræon- and the first and second pleon-segments. The telson appears to spring from the fourth pleon-segment.

1835. JOHNSTON, GEORGE.

Illustrations in British Zoology. The Magazine of Natural History. London. vol. viii. 1835. London, 1835. pp. 668-675.

Under "Class CRUSTACEA. Subclass C. mandibulata," Johnston gives a definition, first of the "Legion EDRIOPHTHALMA," then of the "Order LÆMODIPODA Latreille, in Cuv. Règ. Anim., iv. 126," which he divides into

"(1.) Branchial lamellæ 2 pairs, attached to the second and third segments, which are apodal CAPRÉLLA.

"(2.) Branchial lamellæ 3 pairs, attached to the base of the second, third, and fourth pairs of legs, which are all monodactyle PRÔTO."

To *Caprella* he assigns "1. *C. Phasma*"; "2. *C. acanthifera*," with "? var., Leach's *Cap. linearis*, "in Edin. Encycl., vii. 404," and a reference to Fleming's opinion that it is probably only "a variety of *C. Phasma*"; "3. *C. Pennantii*"; "4. *C. linearis*."

To *Proto* he assigns two varieties of *Proto pedatus*, which he figures and describes. After the fuller description of the species he distinguishes

"Variety 1.—Hands oval with a single denticle at the base: head rounded in front: branchial lamellæ larger and elliptical. Obs. To this variety the figures of Müller and Montagu belong.

"Variety 2.—Anterior hands triangular, somewhat lobed at the base; the wrist deeply sinuate; posterior hands oval, with two teeth at the base, and serrulate on the inner aspect: head very obtuse in front: branchial lamellæ smaller and cylindrical. Obs. All the specimens I have seen belong to this variety."

"Latreille (Cuvier, Règne Animal, tom. iv. p. 127) and Desmarest assert that the figures of Müller and Montagu refer to distinct animals, which do not even pertain to the same genus. There is some error in this; for the figures are in reality more closely alike than could have

been anticipated, when it is remembered that they are both original, and taken by different draughtsmen ; and they unquestionably represent the same species."

Mayer decides, in regard to the species here given by Johnston, that his *Caprella phasma* and *Caprella acanthifera* are alike *Protella phasma*, Montagu, his *Caprella pennantii* is *Caprella acutifrons*, Latreille, his *Caprella linearis* is rightly named, while his two varieties of *Proto pedatus* both belong to *Proto ventricosa*, O. F. M., the hands in variety 2. having become wrinkled after death. Johnston's figure of this variety, it may be observed, shows the marsupial plates of a female specimen.

1835—Koch, CARL LUDWIG, died 1857 (Hagen).

1841.

1847. Deutschlands Crustaceen, Myriapoden u. Arachniden. Ein Beitrag zur deutschen Fauna. Herausgeg. von Herrich-Schäffer. Regensburg 1835—1841. Heft 36.

Zusammenstellung der in Koch's "Deutschlands Crustaceen, Myriapoden und Arachniden," daneben so in "Deutschlands Insecten von Dr Panzer und Herrich-Schäffer," vorkommenden Crustaceen, 1847.

Of these works I have only seen portions, and therefore quote the titles and dates as given in Boeck's list. Apparently with a special view to the confusion of Bibliographers, Koch's work was issued in loose leaves. For each species there is a separate plate measuring about five inches in breadth by four in depth, and a separate leaf of description, six and a quarter inches broad by four in depth. A series of these in a loose paper cover forms a *Heft*. On the outside of this cover is the table of contents and the date. The date of the 162d Heft is "Den 1. Oktober 1838." The number of the Heft is repeated on each leaf, and the synonymy invariably gives a reference to "Koch Dtschl. Crust. Myr. u. Arachn.", with a different numbering; thus in Heft 138, the references are to h. 5; in 162, to h. 22; in 180 to h. 34; in 186 to h. 36. Mr. G. K. Fortescue of the British Museum tells me, on the authority of Hinrichs, that Heft 36 was published in 1841. Hagen, Bibl. Ent. ii. 27, states that Georg Wolfgang Franz Panzer (born 1755, died 1829), began his "Faunæ Insectorum Germaniae initia" in 1793; that Heft 109, the last by Panzer, appeared before 1813; that after a long interval Heft 110 was published by Maler Geyer at Augsburg, and that the continuation was by Gtli. Aug. Wilh. Herrich-Schaeffer (born 1799), the title of his work being "Die Fortsetzung von Panzer Faunæ insectorum Germaniae initia Regensburg, (Manz), 1829—1844. 8. Heft. 111—190. à 24 tab. col."

Mr. Edward Saunders, the well-known entomologist, informs me that Engelmann, Bibl. Hist. Nat. 1846, quotes the titles thus:—

"Koch, C. L. Deutschlands Crustaceen, Myriapoden, u. Arachniden. Ein Beitrag zur deutschen Fauna, Herausgeg. von (G. A. W.) Herrich Schäffer. 1—40 Heft (Jedes mit 24 lith. u. illum. Abbildgn. u. à 24 Bl. Text) qu. 16. Regensburg, 1835—1841 (Manz)."

"Panzer, G. W. F. dan. Fortsetz. von G. A. W. Herrich Schäffer. 111—190. Hft. Jedes mit 24 illum. Kpfrn (u. zusamm. 1592 Bl. Text) 16. Regensburg, 1829—1844 (Manz)."

From the latter work Mr. Saunders sends me the following synonymy:—

"*Gammarus fossarum* Koch

Panz. Faun. Germ. (H. Schiff.) 138. 1.

Koch. Deutsch. Crust. Myr. u. Arach. 5. 1.

"*Gammarus putcanus* Koch

Panz. Faun. Germ. (H. Schiff.) 138. 2.

Koch. Deutsch. Crust. Myr. u. Arach. 5. 2.

"*Gammarus Pulex*. Fab.

Panz. Faun. Germ. (H. Schff.) 186. 21.
Koch. Deutsch. Crust. Myr. u. Arach. 36. 21.

"*Gammarus puteanus* Koch

Panz. Faun. Germ. (H. Schff.) 186. 22.
Koch. Deutsch. Crust. Myr. u. Arach. 36. 22."

The following descriptions are quoted from the former work. There can be little doubt that the same plates have been used for both works, although, as Mr. Saunders observes, Engelmann applies the term "lith." to those in Koch, and "Kupfrn" to those in Herrich-Schäffer's continuation of Panzer. The two works would seem to be practically identical. It seems convenient to bring Koch's four descriptions together, but it must be remembered that in all probability the two numbered respectively 138.1, and 138.2, belong to 1835, while the numbers 186.21, and 186.22, belong to 1841.

"138. 1. *GAMMARUS fossarum* Koch.

"*G. testaceus*, vitta utrinque laterali fusca, testis caudæ iuermibus.

"*Squilla Pulex* Degeer Abh. VII. p. 193. t. 33. f. 1. 2.

"Frisch. ins. 7. t. 13.

"Koch Dtschl. Crust. Myr. u. Arachn. h. 5. n. 1.

"Etwas schlanker und kleiner als *Gamm. pulex*; die Schwanzringe oben unbewaffnet, und ohne vorstehende stachelartige Spitzen. Das vorletzte Glied der vier Vorderbeine etwas schmal eiförmig.

"Bräunlich gelb, mit einem dunkelbraunen, bis fast zur Schwanzspitze ziehenden, zuweilen schwächer oder stärker ausgedrückten Seitenstreif, und mit rothen Randstreifchen an den Hüften und an den Seiten der drei vordern Schwanzringe; zuweilen auch ein solches Fleckchen der Länge nach an den Seiten der zwei Endringe.

"Das dunkeler gefärbte Weibchen hat kürzere Schwanzspitzen; auch scheint der Eiersack an den vier vordern Seitenschilden schwärzlich durch.

"In Gräben mit fliessendem Wasser. Bei Regensburg in dem Königswieser Graben und in dem kleinen Bach bei der Weichselmühle in grosser Anzahl."

"138. 2. *GAMMARUS puteanus* Koch.

"*G. diaphano-albus*, lateribus subochraceis, testis caudæ iuermibus; articulo penultimo pedum 4 anteriorum quadrato.

"Koch Dtschl. Crust. Myr. u. Arachn. h. 5. n. 2.

"Die Gestalt von *Gamm. pulex*, aber von diesem durch die fehlenden stachelartigen Spitzen auf den Schwanzringen leicht zu unterscheiden. Von *Gamm. foss.* unterscheidet ihn das vorletzte Glied der vier Vorderbeine; dieses ist sehr gross, breiter als lang, fast quadratförmig, blattartig breitgedrückt.

"Körper, Fühler, Taster, Beine und Schwanzspitzen etwas glas-artig weiss; in den Seiten bis zum letzten Schwanzring mit ochergelbem Anstrich, und mit einem violettblauen Streif in den Seiten der Leibringe. Die Augen sind gelb.

"In Schöpf- und Ziehbrunnen. Bei Regensburg nicht selten."

"186. 21. *GAMMARUS Pulex*.

"*G. cæsius*, dorso fusco testaceus, segmentis posterioribus postice medio in dentem acutum productis.

"Koch Dtschl. Crust. Myr. u. Arachn. h. 36. n. 21.

"Fabr. syst. ent. II. p. 516. n. 7.

"Latr. gen. crust. et ins. I. p. 58. n. 1.

"Cancer Pulex Linn. syst. nat. I. II. p. 1055. n. 81.

"Roes. III. p. 351. t. 62. f. 1-7.

"Grösser als *Gamm. fossarum*, 6 bis 7 Linien lang, von derselben Gestalt, doch an den scharfen

zahnartigen Spitzen des achten, neunten und zehnten Körperringes leicht zu erkennen, es ist nemlich der Hinterrand dieser Ringe in ein scharfes stachelartiges Zähnchen verlängert.

“ Durchaus graubräunlich, platzweise gelblich durchscheinend, daher mit olivengrünen Anstriche; in den Seiten ein von innen durchscheinender Längstreif braun oder röthlich, auf dem Rücken vor der Spitze des 8, 9 und 10ten Ringes ein scharlachrothes Fleckchen, dergleichen rothe Querfleckchen in den Seiten der Ringe und kleinere an den Hüften der Beine.

“ In grossen Wassergräben, auch in Weihern, gewöhnlich in grosser Anzahl.”

“ 186. 22. GAMMARUS puteanus.

“ Koch Dtschl. Crust. Myr. u. Arachn. h. 36. n. 22.

“ In den Brunnen der Stadt Zweibrücken fand ich diese Species ziemlich häufig, ganz mit der im 138sten Hefte abgebildeten übereinstimmend, alle aber waren durchsichtig weiss, und nur der Darmgang ein wenig auf's Bräunliche ziehend; das vorletzte Glied der vier Vorderbeine schien weniger breit zu seyn. Wahrscheinlich ist das Abbleichen der Farbe zufällig und vielleicht Folge des Wassers, worin sie leben.”

Boeck, who spells Koch's name as Kock, gives the following accounts of his works;—“ Kock omtaler i 1844 i Deutschl. Crust. Myriapod. und Arach., H. XXXVI. *Gammarus putaneus*, som nu henføres til Slægten *Niphargus*.” Here the date 1844 is inconsistent with that which he gives with the title. The specific name is also misprinted. The second account says;—“ Kock sammenstiller i 1847 i ‘Deutschlands Crustaceen, Myriapoden und Arachniden’ de der fundne Amphipoder, nemlig: *Gammarus fossarum*, *G. pulex*, *G. puteanus* og desuden de nye Arter *G. medius* og *G. pilicornis*, hvilke han afbilder paa Pl. VII. Fig. 92–93.” I regret that I have not been able to find out anything further about these last two species, or about the plate on which they are supposed to be figured, or indeed about the work in which they are reported to occur.

Leydig, 1878, points out that as the account of *Gammarus pulex minutus* by Gervais appeared in the same year (1835) with Koch's account of *Gammarus puteanus*, the honour of having first made known the well-shrimp must belong to Gervais and Koch in common. Koch's *Gammarus fossarum* is identified by Bate and Westwood with *Gammarus pulex*, Linn.; his *Gammarus pulex* appears to be Rösel's tooth-backed species, *Gammarus fluviatilis*.

1835. MILNE-EDWARDS, H.

Observations sur les changemens de forme que divers Crustacés éprouvent dans le jeune âge. (Lues à l'Académie des Sciences, le 27 mai 1833). Annales des sciences naturelles. Seconde Série. Tome troisième.—Zoologie. Paris, 1835. pp. 321–334.

After discussing the subject in regard to the Isopoda, from *Cymothoa* and *Anilocra* Milne-Edwards passes on to make the following remarks on the Amphipoda:—“ Les CYAMES ou poux de baleines présentent aussi des différences considérables dans la forme de leur tronc et de leurs membres, suivant l'âge auquel on les examine, et ces différences rentrent encore dans la même catégorie que celles dont les Cymothoés nous ont fourni les premiers exemples.

“ En effet, ce qui contribue le plus à donner aux Cyames adultes l'aspect si particulier qui les distingue, et les éloigner du type normal des Læmipodes, est l'aplatissement et la largeur considérable des segmens de leur thorax, la forme bizarre de leurs pattes et le grand

développement des vésieules fixées à la base des rudimens des membres thoraciques de la troisième et quatrième paires (Pl. 14, fig. 13). Les jeunes Cyames ont au contraire une forme svelte et élancée. Tous les segmens de leur thorax se ressemblent parfaitement entre eux, et représentent des tronçons d'un cylindre ; leurs pattes sont grèles, cylindriques, et parfaitement extensibles ; enfin les vésicules respiratoires ne sont pas plus développées que chez les Protons, les Chevrolles et les Amphipodes. (Voyez pl. 14, fig. 14).

“Il en résulte que les Cyames, lorsqu’ils viennent de naître, diffèrent bien moins des autres Crustacés du même groupe naturel que lorsqu’ils sont déjà parvenus à l’âge adulte. [Ces observations ont été faites sur de très jeunes Cyames ovales (Roussel de Vauzème) extraits au moment même de la poche ovifère de leur mère ; les différences ne peuvent donc être attribués à ce que les petits auraient appartenu à une espèce distincte comme quelques naturalistes à qui j’ai communiqué mes recherches semblent le penser].

“J’ai eu également l’occasion d’examiner quelques jeunes PHRONIMES. Les adultes, comme on le sait, se font remarquer par la grosseur démesurée de leur tête, par la forme presque couique de leur thorax, par le renflement de l’article basilaire des six premières fausses pattes abdominales, et surtout par le développement considérable des pattes thoraciques de la cinquième paire et par la grosse main didactyle qui termine ces membres, disposition dont les Amphipodes n’offrent pas un second exemple. (Voyez pl. 14, fig. 9). Dans les jeunes Phronimes, ces anomalies n’existent pas encore. La tête est de la grosseur ordinaire. Le thorax est presque aussi large en avant qu’en arrière, et se renfle par le milieu ; l’article basilaire des fausses pattes abdominales est grêle et cylindrique ; enfin les pattes thoraciques de la cinquième paire ne sont pas plus longues que les pattes voisines, et ne sont pas didactyles ; on y remarque seulement un peu d’élargissement dans le pénultième article, sur le bord inférieur duquel le doigt mobile s’infléchit comme cela a lieu pour les pattes subchéliformes de toutes les Crevettines. (Voyez pl. 14, fig. 10).”

In his own “AMPHITOÉ DE PREVOST,” he notes the enlargement of the hand of the secoud gnathopod in the adult. In the young, the head is more voluminous than in the adult, and the lower antennæ, instead of being twice as long as the upper, are but little longer ; “enfin les pattes mâchoires extérieures sont beaucoup moins élargies.”

1835. ROSS, JAMES CLARK.

OWEN, Sir RICHARD, born 1804 (Hagen).

Appendix to the narrative of a second voyage in search of a North-West Passage, and of a residence in the Arctic regions during the years 1829, 1830, 1831, 1832, 1833. By Sir John Ross, C.B., &c., &c. Including the Reports of Commander, now Captain, James Clark Ross, R.N., &c., and the discovery of the Northern Magnetic Pole. London, 1835. (Amphipoda, pp. lxxxvi-xcii, partly by Owen.)

Guérin’s *Themisto gaudichaudii*, from the Falkland Islands, is here rerecorded as occurring of greater size near the west coast of the Peninsula of Boothia, but it is, Boeck says, the *Gammarus (Themisto) libellula* of Mandt that is intended. The *Gammarus nugax* next mentioned is referred by Boeck to *Anonyx (Socarnes) valili*, Kröyer. Among other already known species, *Talitrus edwardsii*, Sabine, is renamed *Amphithoe edwardsi*, being in fact *Oniscus aculeatus*, Lepechin, now called *Rhachotropis aculeatus*.

The new genus *Acanthonotus* (Owen, MS.), is thus defined :—“Antennæ subæquales, 4-articulatae, articulo ultimo e plurimis segmentis efformato, articulo tertio superiorum brevissimo. Pedes 4-antici, monodactyli, filiformes, articulo ultimo primi paris serrato. Rostrum pro-

¹ Footnote.

ductum acutum, incurvatum. Oculi parvi." The type species, *Acanthonotus cristatus*, is described and figured. The generic name being preoccupied, is changed by Boeck to *Acanthonotozoma*.

The new genus *Acanthosoma* (Owen, MS.), is thus defined:—Antennæ inaequales, superiores dimidio breviores, articulo ultimo e plurimis segmentis efformato, articulis tertis et secundis superiorum æqualibus. Pedes 4-antici, monodactyli, filiformes, articulo ultimo primi paris unguiculato. Rostrum productum acutum, undulatum. Oculi parvi."

This generic definition was sharply criticised by Krøyer, who transferred the type species, *Acanthosoma hystrix*, to *Amphithoë*. Bruzelius made it a species of his genus *Paramphithoë*. Boeck regards it as identical with *Oniscus cuspidatus*, Lepechin, and as Owen's generic name was preoccupied, he calls it *Acanthozone cuspidata*. E. J. Miers would retain it as a distinct species, *Acanthozone hystrix*, Owen. The *Acanthozone hystrix* of Buchholz is, I think, clearly a distinct species, as Miers points out, and may receive the name *Acanthozone buchholzi* in honour of its describer. Owen, in speaking of the rostrum of his species, says, "this part is white, curved over the head, and directed forwards." The description by Spence Bate, Brit. Mus. Catal., p. 147, corrects this statement, saying, "Cephalon furnished with a minute rostrum. First segment of the pereion having a large central dorsal tooth projecting upwards and forwards on the anterior margin." Buchholz supposes that Krøyer, Bruzelius, and Boeck, have only had young examples to examine, and would so account for the differences between their specimens and his, but Owen says expressly "Plate B, fig. 4, represents a large-sized specimen of the *Acanthosoma Hystrix*," so that to him, at least, Buchholz's argument will not apply.

1829-GUÉRIN-MÉNEVILLE, F. E.

1844.

Iconographie du Règne Animal de G. Cuvier, ou représentation d'après nature de l'une des espèces les plus remarquables et souvent non encore figurées, de chaque genre d'animaux. Avec un texte descriptif mis au courant de la science. Ouvrage pouvant servir d'Atlas à tous les traités de zoologie. Par M. F. E. Guérin-Méneville. Tome II. Planches des Animaux invertébrés. Tome III. Texte explicatif. A Paris, 1829-1844.

[This work was published in *livraisons* between 1829 and 1844. The Plates containing Amphipoda probably all belong to the early part of 1836. An advertisement in the "Quarante-cinquième livraison. Crustacés. Pl. 35.", says, "La 46^e et dernière livraison se composera du Texte descriptif de l'Iconographie et paraîtra fin mars 1838," but the promise was not, it appears, fulfilled till the end of 1843. The specific names, however, being given on the Plates, will carry the date 1836.]

In the third order of Crustacea, les Amphipodes "genre CREVETTE (GAMMARUS. Fab.)" stands alone, with various sub-genera. In the description of Pl. 25, fig. 4 is referred to *Phronima atlantica*, Guérin, 1836. Branchial vesicles are shown as attached to the third, fourth and fifth pereopods. The observation follows, "Nous avons une autre espèce, pris dans l'Océan qui baigne les côtes de l'Amérique, assez loin de l'embouchure de la Plata. Elle ressemble à la précédente, mais la main de la cinquième paire de pattes est beaucoup plus longue et plus grêle, peu renflée vers l'extrémité, avec la griffe simple, mais fortement renflée au milieu et une forte dent au côté interne de la pointe opposée de cette griffe. Cette troisième espèce a, comme on le voit, beaucoup de ressemblance avec la *Phr. sedentaria*, mais elle s'en distingue facilement par l'absence de dent au milieu interne du doigt mobile. Nous lui avons donné le nom de *Phronima solitaria*."

- Fig. 5. is referred to "*Hyperia Latreillii*. Edw.", with the note that Straus described it under the generic name of *Hiella* (Mém. du Mus., t. xviii. pl. iv.).
- Fig. 6. *Hyperia pedestris*, Guér., is thus described, "Très-distincte par la longueur de ses pattes et de son corps. Antennes inférieures un peu moins longues que les supérieures : celles-ci, moins longues que la tête. Pattes de longueurs très-inégales, grêles avec le premier article ou la hanche aussi mince que les articles suivants.—Hab. les côtes du Chili."
- Fig. 7. is of "*Themisto Gaudichaudii* Gnér.", the mandible of which is drawn with a four-jointed palp. Guérin adds a "Nota. M. Kroyer (Groenland amphipoder, p. 63, etc.,) a fait connaître deux autres espèces de ce genre curieux."
- On Pl. 26, fig. 3 represents "*Orchestia Fischerii*, Edw." Fig. 4 is described by the words "Mandibules de l'*Orchestia gamarella*." The figure is very like Savigny's figure of the mandible of *Orchestia montagui*, and, like that, shows a rudimentary three-jointed palp. Fig. 5. is of *Talitrus platycheles*, Guér.; Fig. 6. of "*Atylus carinatus*. Leach."; Fig. 7. of "*Gammarus locusta*. Latr.", with the "Nota. Voir la description de plusieurs Gammarus d'Angleterre par M. Johnston (Zool. Journ., 1827, t. iii. p. 175)." Fig. 8 represents "*Leucothoe furina*, Savigny.;" Fig. 9. "*Amphiöe filosa*. Savigny."
- On Pl. 27, fig. 1 represents "*Corophium longiorne*. Fab. Latr. (mâle)"; Fig. 2, "*Corophium longicorne*, F. (femelle)."; Fig. 3. "*Jassa pellucida*. Leach."; Fig. 4. "*Cerapus tubularis*. Say.;" Fig. 5, "*Pterygocera arenaria*. Latr. Hab. les mers d'Europe (copie de Slabber)." Fig. 8. "*Typhis ferus*. Edw.;" Fig. 9. "Le même, jeune."
- Figures 1 and 2 Pl. 26, are of "*Ione thoracica*, Montagu," male and female.
- Figures 6, 7, and 10 on Pl. 27, represent respectively "*Apseudes talpa*. Leach." "*Anceus forficularis*. Rissö."; "*Praniza maculata*. Westw."
- In the fourth order, Les Læmodipodes, "Genre CYAME (CYAMUS. Latr.)" stands alone with three subgenera. On Pl. 28, fig. 1 represents "*Caprella tuberculata*. Guér.", "Hab. l'île de France."; the explanation of the figure being followed by the "Nota. Cette espèce est voisine des *Caprella acuminifera* et *scaura*; mais elle est bien distincte par sa tête courte, cornue, par ses antennes supérieures très-petit plus longues que les inférieures, et par les segments de son corps portant chacun un assez grand nombre de tubercules." Fig. 1a. "Sa queue vue en dessous," shows a pleon very clearly triarticulate, the terminal joint bearing a pair of wart-like limbs. These figures evidently represent the male sex, and are very different from the figure of "*Caprella tuberculata*, ♂," in Bate and Westwood, ii, 68, although to some extent resembling the figure they give for the female of that species, but still more resembling, except in regard to the frontal horn, the figure on page 63, which they name "*Caprella hystrix*," Kröyer. Fig. 2 is named "*Caprella lobata*. Latr. (*C. linearis*? Lin. Edw.), with the "Nota. M. Templeton (Trans. Ent. soc., vol. 1, p. 191) a décrir et figuré plusieurs espèces de ce genre provenant de l'île Maurice." Fig. 3. is named "*Leptomera pedata*, Mull.;" Fig. 4. is of "*Cyamus oralis*. Roussel de Vauzème." Numerous details are given, with the acknowledgment, "(figures empruntées au travail de M. Roussel de Vauzème)" It would save some trouble if authors of systematic or general works on a subject would always acknowledge the sources from which their figures are borrowed. Fig. 5. is thus described:—*Cyamus Delphinii*, Guér. 5a. Le même vu en dessous. 5b. Appendice respiratoire et lame ovigère de la femelle.—Hab. Trouvé sur les parties génitales d'un Dauphin, sur les côtes des Autilles.
- "Nota. Cette espèce est bien distincte de celles que M. Edwards mentionne, tant par ses formes que par son habitat. Elle est en ovale allongé; ses segments thoraciques se touchent sur presque toute leur étendue, à l'exception des derniers qui sont un peu séparés sur les côtés. La grosse pince des secondes pattes porte au côté interne une forte dent saillante. Les filets branchiaux sont très-courts, inégaux et beaucoup moins longs que les pattes. Les premières articulations des pattes postérieures sont fortement dentées et de formes très-diverses."

1836. GUÉRIN, F. E.

Description de quelques genres nouveaux de Crustacés appartenant à la famille des Hypérines. Magasin de Zoologie VI. 1836. Classe VII. Pl. 17, 18. 10 pages. (avril 1836). Classe VII. Pl. 19. 2 pages. (Mars 1836.)

After briefly reviewing the classification of the Hyperina in the various works of Latreille and Milne-Edwards, Guérin proceeds to define his new genus, *Primno*, as follows:—

“Corps longé, de quatorze segmens, non compris la tête. Tête ovale, très bombée, perpendiculaire et terminée en pointe. Deux antenues plus longues que la tête, subulées, composées de deux articles, dont le premier court et le second effilé vers le bout, et n'étant pas articulé. Pieds de la première paire, les plus courts de tous, à article cylindrique, dépassant la tête de presque toute sa hauteur, et terminés par un petit ongle pointu. Secouds pieds un peu plus longs, avec le premier article large et aplati : les deuxième et troisième très courts, les quatrième et cinquième plus longs et égaux entre eux, et le cinquième terminé par un petit ongle pointu : troisième et quatrième pieds encore plus longs, simples, à articles cylindriques ; cinquièmes pieds de plus du double plus grands que les précédens ; le premier article grand, un peu aplati, presque aussi long que les pieds qui précédent ; le second court, armé d'une épine en arrière ; le troisième également court, très étroit à la base, renflé en demi lune, et aigu à ses extrémités ; quatrième article presque aussi grand que le premier, large et aplati, armé de fortes épines à son côté antérieur ; cinquième, grêle, plus long que le quatrième, cylindrique, et un peu courbé, terminé par un ongle assez long, très aigu et un peu courbé ; sixièmes pieds beaucoup plus courts, à premier article large et plat ; deuxième court, inerme ; troisième deux fois plus long ; quatrième aussi long que le premier, étroit et armé d'épines en avant ; cinquième aussi long que le précédent et terminé par un ongle aigu ; septières pattes eucore plus courtes ; à premier article large et aplati, ayant les autres articles cylindriques et grêles, et la griffe du dernier renflée et arrondie, au lieu d'être aiguë comme aux autres pattes. Trois premiers segmens de l'abdomen grands et arrondis en arrière, portant chacun une paire de pattes natatoires conformées comme dans les Phronèmes ; les suivants courts, plus étroits, et donnant attache à des laines natatoires simples, larges, un peu lobées au bout, mais n'étaut point terminées par deux petits appendices comme dans les Phonimes.

“Comme on le voit par ces caractères, ce genre est très voisin des Phronimes, et doit être placé immédiatement après ces Crustacés.”

The type species, *Primno macropa* is figured. The derivation of the oddly formed specific name is indicated by the French name “*P. à grands pieds*.”

The new genus *Hieraconyx* is next described:—“Corps court et ramassé, composé de treize segmens non compris la tête. Tête ovale, très grosse, perpendiculaire, occupée en entier par les yeux ; quatre antenues inégales ; les supérieures de la longueur de la tête, cachées dans une fossette ; les inférieures un peu plus longues ; ces quatre antennes composées d'un support plus épais, court, et d'une tige multiarticulée. Premier et second segments du thorax réunis, et portant les deux premières paires de pattes ; les deux segments qui suivent égaux entre eux et plus étroits que le premier ou les deux premiers, soudés ; cinquième segment plus large et dilaté en arrière et en bas ; les deux derniers étroits, cachés en bas par la dilatation du cinquième ; pieds des deux premières paires assez courts, simples, égaux entre eux, à articles peu aplatis, troisièmes et quatrièmes terminés par une petite main imparfairement didactyle, ayant le doigt mobile formée du cinquième article et de l'ongle aigu qui le termine ; cinquièmes pieds les plus grands de tous, ayant le premier article très large et aplati, les deux suivants courts et transversaux ; le quatrième grand, épais, denté au côté antérieur ; le cinquième de la longueur du précédent, cylindrique et terminé par un ongle

assez grand, aigu et un peu courbé ; sixièmes pieds plus courts, à premier article aplati, les deux suivants petits, le quatrième renflé, inerme ; pieds de la septième paire encore plus courts, ayant le premier article grand, plat, et les suivants cylindriques, moins longs ensemble que le premier, recourbés et cachés sous celui-ci dans le repos ; les trois premiers segments de l'abdomen grands, diminuant de grandeur, portant chacun une paire d'appendices natatoires, semblable à ceux des autres genres de la même famille ; les trois segments suivants courts, portant chacun une paire de lames plates, ovales, un peu échancrees au bout, mais d'une seule pièce, comme dans le genre précédent." Guérin considers that this genus comes very near his other genus *Themisto*. He figures the type species *Hieraconyx abbreviatus*, which Spence Bate gives as *Anchylomera abbreviata*, regarding the genus *Hieraconyx* as representing the male form of Milne-Edwards' *Anchylomera*.

The new genus *Pronoë* is thus described :—Corps allongé, étroit, composé de quatorze segments, en n'y comprenant pas la tête. Tête grande, occupée par les yeux, arrondie, avancée, ayant le front très bossu, creusé devant pour recevoir les antennes supérieures, avec le tubercule buccal peu saillant. Antennes plus courtes que la tête, plates, paraissant composées de trois articles, dont les deux premiers très courts. Antennes inférieures insérées près de la bouche grêles, cylindriques, sétacées et formées de cinq articles se repliant l'un sur l'autre. Pattes simples et monodactyles, allant en augmentant de longueur depuis les premières jusqu'aux cinquièmes ; les quatre premières paires ayant tous leurs articles cylindriques ; premier article des trois dernières paires large, aplati et arrondi ; sixième paire beaucoup plus courte ; septième, composée seulement du premier article et d'un petit tubercule qui semble le rudiment des autres. Les trois premiers segments abdominaux grands, arrondis et portant chacun une paire d'appendices natatoires, conformés comme dans les autres genres. Les trois segments suivants ayant des appendices étroits, plats, allongés et terminés par deux petites lames arrondies au bout ; le dernier segment court et triangulaire."

Guérin at first thought that his *Pronoë* was the young of *Typhlos*, to which it comes very near, especially in regard to the antennæ, but he found that it differed markedly in regard to the gnathopods. He figures the type species, *Pronoë capito*. He also figures and describes in detail his *Phronima atlantica*, which Claus considers to be the immature female form of *Phronima sedentaria*, but which Streets upholds as a distinct species. He figures and describes as a new species *Oxycephalus oceanicus*, though somewhat doubtfully separating it from "*Oxycephalus piscatorius*," Milne-Edwards, of which species Claus decides that it is the young male.

The new genus *Phlias* is thus described :—"Corps court, eomprimé latéralement, composé de quatorze segments, non compris la tête ; tête petite, en grande partie cachée dans le premier segment. Yeux saillants. Antennes supérieures grandes, ayant un péduncule renflé et composé de trois articles (la tige est détruite, et il n'en reste que la base. On voit qu'il n'y avait pas de petit filet supérieur comme dans les crevettes). Antennes inférieures très petites, insérées sous les précédentes, composées de deux articles égaux et d'une courte tige multi-articulée. Quatorze paires de pattes filiformes ; simples, monodactyles ; les quatre premières égales entre elles, plus courtes que les trois dernières, qui sont aussi égales entre elles. Appendices natatoires des trois premiers segments de l'abdomen de forme ordinaire ; ceux du quatrième un peu plus petits, mais encore semblables, c'est à dire terminés par deux lames plus longues que la tige qui les supporte, ciliées ; ceux du quatrième [cinquième] sont composés d'une tige plate, terminée par deux petites lames ovalaires et plus courtes, enfin ceux de l'avant-dernier segment ont leur tige plus courte, large et arrondie, et terminée par deux petites lames ovales et un peu pointues. Dernier segment abdominal très court, transversal et un peu arrondi." Of the type species *Phlias serratus*, which is figured, pl. 19, figs. 1–4, he gives the following account, "ce petit Crustacé est long de cinq à six millimètres ; tous les segments de son corps ont leur tranche supérieure très saillante, ce

qui le rend fortement dentclé quand on le voit de profil; il est d'un jaune brun opaque. M. Gaudichaud a trouvé cette jolie petite espèce pendant la traversée des îles Malouines au Port Jakson." Guérin's figures should be compared with those of *Ieridium* by Grube, and of *Pereionotus* by Bate and Westwood.

1836. TEMPLETON, ROBERT.

Catalogue of Irish Crustacea Myriapoda, and Arachnida, selected from the Papers of the late John Templeton, Esq. By Robert Templeton, Esq. The Magazine of Natural History, and Journal of Zoology, Botany, Geology, and Mineralogy. Conducted by J. C. Loudon. Vol. IX. London, 1836. Art. III. p. 12.

Under Malacostraca is included the following notice:—"EDRIOPHTHALMA, *Gammáridæ*. *Tálitrus Latr.*, *Locústa Latr.* Inhabits all our sandy shores.—*Orchéstia Leach* littorea *Mont.* Inhabits all our sandy shores, living under stones and *Fuci*, and, when disturbed, leaping to a considerable distance.—*Gámmarus Latr.* *Púlx Linn.* *aquáticus Leach*. Inhabiting our rivers and springs.—*G. Locusta Mont.* Inhabits the sea along our coasts, never voluntarily leaving the water.—*Corophium Latr.* *gróssipes Linn.*, *longicorne Latr.* Leach. Inhabits Belfast Lough. In the little pools of salt water at the point fields Belfast." The remaining Edriophthalma mentioned are Isopods.

1836. TEMPLETON, ROBERT.

Descriptions of some undescribed exotic Crustacea. (Read 1st June, 1835.) The Transactions of the Entomological Society of London. Vol. I. London, 1836. Part III. pp. 185–194.

The *Crustacea* in question were "picked up either at Mauritius or on the way thither." He first describes:—

"ANISOPUS DUBIUS. Pl. XX. fig. 1. Greenish, dotted over with reddish-brown specks. Head large, subquadangular, carrying 4 antennæ, the superior nearly as long as the body, and exceeding in length by about one-fifth part the inferior; the 1st joint is minute, the 2nd large and thick, the 3rd elongate, nearly cylindric, and wanting the little process which characterizes the true *Gammari*; 4th joint multiarticulate, tapering. The inferior antenna has the 2nd and 3rd joints, subequal, much longer than any of those of the superior, and the remaining similar, but of smaller dimensions. Both antennæ are spiny or hairy. The thoracic rings are narrow, and extend inferiorly into plates concealing the upper part of the 5 anterior pairs of legs. Those of the abdomen are much larger and end in a 4-articulated tail, with a jointed stylet on each side proceeding from the inferior posterior angle of the ultimate and penultimate articulations. The first pair of legs is extremely minute and terminates in a simple claw, the 2nd much longer, as are the 3 succeeding pairs, and terminates in joints slightly dilated, the last carrying a tolerably strong curved claw. The 3rd pair has the last joint very much dilated, subtriangular, not toothed, but bearing a very strong curved claw; the posterior edge is waved and hairy. The 2 succeeding pairs of legs resemble the 1st pair except in their greater size; but the 6th and 7th pairs, of nearly equal dimensions, exceed all the anterior legs in being both much longer and much more robust, and besides differ in having the coxae very much dilated, and the last joint of each

leg clavated, surmounted by two blunt teeth, and a large dentated curved claw directed forwards. Immediately behind these legs arises, from the inferior part of each joint, the bifurcate articulated appendages which are called fin-feet; so that all the rings of the body have either true or fin feet or styles articulated to them, in this respect differing from all hitherto noticed genera.

"This species swius with considerable rapidity and has all the habits of our common European marine *Gammarus*. Its size is about $\frac{1}{6}$ th of an inch, and its colour subject to but little variety, being of a greenish tint more or less brownish in the specimens I have examined. In its generic characters the great and disproportionate length of the 2 last pairs of feet, the fin-feet arising from the succeeding joints, and the appearance presented by the antennæ, which are much longer than in the contiguous genera, at once distinguish it. The claws also offer distinctions."

In the above description, Templeton speaks of a minute first joint to the upper antennæ, which he very properly does not figure. He speaks of the lower antennæ having joints *much* longer than any of those of the superior, and again his figure contradicts his description. By the extremely minute "first pair of legs" he evidently means the maxillipeds, what he calls the second and third pairs being the two pairs of gnathopods. The third pereiopods are missing both from the figure and the description. It is curious that Templeton should have thought his genus distinguished by having appendages to all the rings of the body, since few genera of Amphipods are without this characteristic, unless the telson be counted as one of the rings. Milne-Edwards introduced the genus between *Isaea* and *Amphithoe*, adopting Templeton's error as to the gnathopods, and not noticing his other mistakes, unless obliquely in the words, "l'abdomen ne paraît offrir rien de particulier." Spence Bate, in the Brit. Mus. Catal., p. 245 (*Anisopus dubius*, p. 145, by error in the index), describes Templeton's species as *Amphithoe dubia*, adding that "this description is taken from Templeton's figure, which is not well drawn," and that "if the telson (which is neither figured nor described) should be found to be formed into a hook, then it belongs to *Sunamphithoe*." As a matter of fact, fig. 7, on Plate XLII, of the Catalogue does not fairly represent Templeton's figure, and since the generic distinction which separates *Sunamphithoe* from *Amphithoe* is no longer the hooked telson, but the distal widening of the fifth joint in the hinder pereiopods, which Templeton expressly describes and very clearly figures, the name *Anisopus* would have priority over *Sunamphithoe*, had it not been preoccupied among the Decapod Crustacea by de Haan, and also among Coleoptera, in 1835. The species itself is probably the same as *Sunamphithoe hamulus*, Sp. Bate, 1856, but I do not think that for such a negation of a name as *dubius*, any alteration should be made in the commonly received nomenclature. In the figure the last uropods show the terminal hooks which are characteristic of the Amphithoinæ.

The next species is described as follows:—

"THAUMALEA DEPILIS. Plate XX. fig. 2. *Erythrocephalus melanophthalmus?* Tilesius, Neue Ann. Wetterausch. i. p. 6. pl. xxi. a. fig. 5.

"Body hyaline, with a few dark specks, especially along the edges of the abdominal plates or rings. The head is quadrangular, not large; the eyes deeply imbedded in it; front retracted inferiorly, from about its middle arise the superior antennæ, which are short and tumid; 1st joints short, forming together a truncated cone on which rests the elongate spindle-shaped 4th joint. The inferior antennæ arise from the inferior part of the frontal surface; they are much smaller than the superior, composed of 4 joints, of which the 1st is small and oboconic, the remainder in length subequal, the last conic. The body swells out to about the 5th ring, when it again becomes gradually reduced in size and ends in a bifurcate articulated tail. There are only 6 legs apparent, the 2 first pairs being very short and apparently without claws, the 4 posterior pairs of about equal length, tapering, and with

slender slightly curved claws. From the abdominal joints proceed bifurcate articulated appendages, but, as well as the whole animal, apparently devoid of hairs.

"This minute species swims but badly, having none of the celerity of motion so conspicuous among the *Gammari*, to which it bears resemblance in its form. It differs from every genus I am acquainted with, in the antennæ, in the relative dimensions of the legs, the elongate and undilated form of the tarsal joints, and in the claws. I confess my inability to allot it to its proper place among the minute *Crustacea*, the differences being in fact more conspicuous than qualities by which its affinities to any one genus can be traced. It was found off Port Natal, in the summer of 1835, in lat. 37° S. and 21° E., while I was searching for *Zoæ* in the sea-water. It is about $\frac{1}{8}$ th of an inch in length."

In 1838 Milne-Edwards suggested that this species might belong to his genus *Vibiliæ*. In the *Hist. des Crust.*, 1840, he leaves it unnoticed. Spence Bate, *Brit. Mus. Catal.*, p. 304, calls it *Vibiliæ depilis*, remarking that he has little doubt that Templeton's "figure is an imperfect representation of *Vibiliæ*, and probably the young of some known species."

The next Amphipod described is:—

"*CERAPUS (Say) ABDITUS*. Plate XX. fig. 5."

Templeton does not happen to include in the description and figures any of the distinctive marks on which S. I. Smith has founded his subfamily Cerapinæ with its single genus *Cerapus*, Say. In extracting his specimen from its tube, he seems to have left three pairs of the peræopods in the tube, and to have forced back one pair to an apparent attachment with the second segment of the pleon. There is, however, no reason for withdrawing the species from the genus *Cerapus*, Say, in which Templeton has placed it, its transfer to *Cerapodina* by Milne-Edwards having been based on obvious errors in the original description, and an undue importance attached to the number of articulations in the antennary flagella. Templeton's remarks appended to his description of the animal are worth quoting. "The entire animal is about $\frac{1}{8}$ th of an inch long, exclusive of the antennæ, and it presents some peculiarities, with one exception, unique in this family. It has formed for itself or seized upon a little membranous tube, nearly $\frac{1}{5}$ th of an inch long, which does not resemble the case of *Tubularia*, but seems composed of a series of rings, and resembles in texture the papyritious covering of the pendulous wasps' nests. It is perfectly cylindrical, of a brown colour, and opaque. When disturbed, the little animal retires within this tube, the tips of the antennæ alone appearing, with which it continues to investigate its neighbourhood; and whenever the feeling of perfect security prevails, it comes out as far as the second or third ring from the head, the antennæ being perpetually in motion, extended to the right or left, or as if lashing the objects about it. When it wishes to change its place it seizes with its claws the little fragments of sea-weed about it, and dragging, urges itself forward. I have never seen it dash itself through the water by any mode similar to that of the *Gammari*; and I should infer that the tube was its natural place of residence from the want of legs or fin-feet at the middle rings, in which it differs from *C. tubularis* of Say, that author figuring a regular succession of both. I have observed the tail slightly protruded, and the members which are sketched as attached to adjoining rings used as feelers. While watching it, which I did for some hours, I was exceedingly surprised and amused to find it disappearing from one end of the tube, and reappearing like magic at the other, having doubled itself up towards its belly in the passage, but with such quickness, considering the narrow calibre of its mansion, that I could hardly credit my eyes but that it had two heads, and indeed, a gentleman who was in the pavilion with me at the time could not be persuaded to the contrary. The animal, however, scarcely remained a second at this extremity, but shot back to the one it had formerly occupied; and during the time I watched it I never saw it remain permanently at it, or rather I should say for a longer period than a second, or a second and a half at furthest. The maxillæ resemble those of *Scolopendra*, but are very

minute, and I believe the smaller palpi arise from them or a very closely adjoining part, but vision is so indistinct in so small an object as to make me hesitate in affirming this. The circulation of the blood was distinctly visible in the antennæ, and the globules, unlike those I had hitherto examined, were rotund, and of comparatively large dimensions. From the upper part of the head a spine, with a very dilated base, extends forwards to between the roots of the superior antennæ. The eyes were black, with a pale encircling ring. The head brown, dotted with white, especially behind; and the antennæ pale, annulated imperfectly with reddish brown."

Templeton further describes "CAPRELLA (Lam.) SCAURA. Plate XX. fig. 6." and "CAPRELLA (Lam.) NODOSA. Plate XXI. fig. 7."

Caprella scaura, from Mauritius, in Mayer's opinion perhaps includes *Caprella attenuata*, Dana, and undoubtedly includes *Caprella nodosa*, also from Mauritius, *Caprella attenuata* being the male, *Caprella nodosa* the form of the female and young. Spence Bate, Brit. Mus. Catal., pp. 355, 357, gives the length of both forms as half an inch, whereas the original from which he is quoting gives for the length of *Caprella scaura*, "from the tips of the antennæ to the claw of the hind leg," about one inch, and states that *Caprella nodosa* "is about $\frac{1}{8}$ th of an inch long."

1837. BENNETT, FREDERICK DEBELL.

On the Natural History of the Spermaceti *Whale*. Proceedings of the Zoological Society of London. Part V. 1837.

The account of this paper says, p. 42, "it appears that the sperm *Whale* is not like the *Balaenoptera mysticetus*, constantly found with *Barnacles* and other parasites adhering to its skin, a circumstance accounted for by Mr Bennett from the former species inhabiting deep water, while the latter frequents soundings, and is also much more sluggish in its movements. One species of *Barnacle*, the *Otion Cuvieri*, is sometimes found attached in a single cluster to the lips or lower jaw of the *Cachalot*, and a few small *Onisci* occasionally adhere to the skin; in its blubber also numerous cysts of a species of *Cysticercus* are met with." Lütken considers that the *Onisci* here mentioned are probably *Cyamis*.

1837. BURMEISTER, HERMANN.

Handbuch der Naturgeschichte. Zum Gebrauch bei Vorlesungen entworfen von Hermann Burmeister. Zweite Abtheilung. Zoologie. Berlin, 1837.

Burmeister's first principal group in the Animal Kingdom contains the Gastrozoa with four Classes. The second group consists of the Arthrozoa, beginning with Class five, Vermes. Class six, the Crustacea, is divided into the following orders, Pseudocephala, Asidostraca, Thoracostraca, Arthrostraca. The Arthrostraca, comprising the Amphipoda and Isopoda, are thus defined, p. 567:—

"Vierte Ordnung. Arthrostraca. Malacostraca edriophthalma, Leach. Der Kopf ist frei abgesondert, trägt 2 Paar Fühler, die äusseren ohne Schuppe am Grunde, 1 Paar umgestielter zusammengesetzter Augen mit fazettirter Hornhaut, seltener 2-4 einfache Augen, 1 Paar Kiefer und 3 Paare accessoirischer Mundtheile. Brustkasten gegliedert, 4-7 ringelig, jeder Ring mit 1 Paar einfacher, selten scheerenförmiger Füsse. Hinterleib 1-, 3-6 gliedrig, oder fehlt ganz, im letzteren Falle ohne, gewöhnlich mit Flossen am Ende und Flossenfüssen an seiner Unterfläche. Die Jungen haben die Form der Alten, doch öfters fehlt ihnen das

letzte Fusspaar, welches sich jedoch bald entwickelt; die Weibchen tragen die Eier an der Brust unter Schuppen, bis die Jnngen ausgekrochen sind, ja selbst diese bestehen darin ihre Ausbildung, bis das letzte Fusspaar fertig ist."

In defining the "Flohkrebs. *Amphipoda*," he says "die Kiefer gewöhnlich mit einem 3gliedrigen Taster." He makes of them two divisions:—"A. Mit grossem 6gliedrigem Hinterleibe, woran die aus den letzten Flossenfüßen gebildete 5lappige Schwanzflosse," containing the two families *Gammarina* and *Hyperina*, and "B. Mit verkümmerten Hinterleibe und einfachen Augen," containing the two families, *Læmodipoda* and *Pycnogonidae*. Kröyer finds much fault with him for including the second subdivision in the *Amphipoda*, but with regard to the *Læmodipoda* Burmeister's view has prevailed. His name *Arthrostraea* has been adopted by authors of eminence for the group to which he applied it. His arrangement of the first two families is as follows:—

- "Fam. *Gammarina*. Das letzte Paar der accessorischen Muudtheile bedeckt die vorhergehenden völlig und schiesst den Mund; der Kopf ist klein, aber die Fühler sind lang. Alle schwimmen behende, vorzüglich durch Schlagen des Hinterleibes und seiner Flossen.
- "a. *Saltatoria*. Leib stark seitlich zusammen gedrückt; die vier ersten Fusspaare stehen nach vorn, und werden von einer Platte ihrer Ringe am Grunde bedeckt; Hinterleib gebogen. Alle haben 4 Fühler.
 - "a. Kiefer ohne Taster, innere Fühler kürzer als die äusseren.
- "Gatt. : *Talitrus*, *Orchestiu* (2tes Fusspaar gross zum Rauben geschickt. *O. littoralis*, Nordsee).
- "β. Kiefer mit Taster, iunere Fühler länger als die äusseren.
 - "aa. 2 Vorderfüsse ohne Auszeichnung.
- "Gatt. : *Lysianassa*, *Dexamine*.
 - "ββ. 2 Vorderste Fusspaare sind Raubfüsse.
- "Gatt. : *Gammarus* (2 Geissel am inneren Fühler. *G. pulex*, in allen Gräben). *Amphithoe* (nur 1 Geissel ebenda).
 - "γγ. 2 vorderste Füsse scheerenförmig. Gatt. : *Leucothea*.
- "b. *Ambulatoria*. Leib flachrund, die 4 ersten Brustringe ohne Seitenplatten, daher die Füsse bis zum Grunde frei sind. Hinterleib grade. Augen klein, oft kaum zu bemerken.
 - "a. Untere oder äussere Fühler lang, fadenförmig.
- "Gatt. : *Erichthonius* (2tes Fusspaar Scheeren). *Atylus*.
 - "β. Dieselben Fühler sind fuss-förmig und haben statt der Geissel ein einfaches Glied.
 - "aa. Zwei Geissel an den oberen inneren Fühlern.
- "Gatt. : *Unciola*.
 - "ββ. Eine Geissel am obereu Fühlerpaar.
- "Gatt. : *Cerapus*, *Podocerus* (mit Raubfüßen am 2ten Paar), *Corophium* (ohne Raubfüsse).
- "Fam. *Hyperina*. Das letzte Paar der accessorischen Mundtheile bedeckt die vorhergehenden nur wenig und lässt den Mund frei. Kopf gross, dick, mit kleinen Fühlern aber sehr grossen Augen. Keine Seitenschilder an den ersteu Brustringen. Sie sind grösstentheils Schmarotzer an Fischen.
 - "a. Alle vier Fühler an der Stirn eingelenkt.
 - "a. Die 3 letzten Fusspaare gleichförmig, zum Rudern geschickt.
 - "Die Gatt. *Vibilia*, *Hyperia* (*Hiella* Strauss), *Phorcus*, *Lestrigonus* haben 2 Paar Fühler; die Gatt. *Daira* nur ein. Bei allen 5 sind die Füsse des 3ten und 4ten Paars von gewöhnlicher Bildung, aber bei *Themisto* sind sie Raubfüsse.
 - "β. Manche der 3 letzten Fusspaare sind Scheeren.
 - "Die Gatt. *Dactylocera* und *Anchylomera* haben schildförmige Grundglieder an den 3 hinteren Fusspaaren, und die erste am sechsten eine Scheere; die Gatt. *Phronima* hat am 5ten eine Scheere, keinc unteren Fühler und keine schildförmigen Grundglieder.
 - "b. Das untere Fühler paar sitzt an der hinteren Seite des Kopfes und ist geknickt.

- “ Mit langem glattem Kopf : Gatt. *Oxycephalus*; mit kurzem dickem : *Typhis* (erstes Glied des 5ten und 6ten Fusspaars gross, schildförmig, nach vorn gerichtet).”
 In defining the Læmodipoda, he assigned them “ 2 einfachen Augen,” “ Kiefer ohne Taster,” and says “ Hinterleib fehlt, oder 1gliedrig.” He briefly arranges them thus :—
 “ a. Leib flach gedrückt, mit grossen Krallenfüßen, wovon das 3te und 4te Paar in wurstförmige Kiemenblasen verändert sind.
 “ Gatt. *Cyamus* (*C. ceti*, Walfischlans. Ann. des scienc. natur. sec. sér. T. 1. p. 239 seq.).
 “ b. Leib lang gestreckt, linienförmig ; Beine schlank, dünn, gleichförmig ; obere Fühler mit Geissel.
 “ Gatt. : *Caprella*, *Proton*, *Leptomera*. ”
 The Pycnogonidæ follow, with *Nymphon grossipes* and *Pycnogonum balænarum*.

1837. RATHKE, MARTIN HEINRICH, born 1793, died 1860 (Hagen).

Zur Morphologie, Reisebemerkungen aus Taurien. Riga u. Leipzig, 1837.
 5 pl. Dritte Abhandlung. Zur Entwicklungsgeschichte der Crustaceen.

This includes references to *Amphithioë* and *Gammarus* (Faxou).

1837. RATHKE, M. H.

Beitrag zur Fauna der Krym. Mémoires présentés à l'Académie Impériale des Sciences de St Petersbourg par divers Savans. Tom. iii. 1837. pp. 371–380. Pl. V.

Rathke here describes and partially figures a species under the name of *Orchestia littorea*, which Spence Bate identifies with *Orchestia mediterranea*, Costa, but Rathke himself in a note refers to pl. 11, fig. 7 of Savigny's Descript. de l'Egypte, as giving a capital representation of his species. But this *Orchestia montagui* is identified by Spence Bate with *Orchestia littorea*, Montagu. A comparison of Rathke's figure with Savigny's makes it tolerably clear that Rathke did not commit an error in his Note, and since Savigny's species cannot be *Orchestia mediterranea* and by its long sloping palm and the comparatively short final joint to the shaft of the lower antennæ is possibly quite distinct from *Orchestia littorea*, it will be best to retain *Orchestia montagui*, Savigny, and refer Rathke's *Orchestia littorea* to it. His *Gammarus gracilis* is identified by Spence Bate and Boeck with *Gammarus marinus*, Leach. The name of his new genus *Amathia* being pre-occupied was altered by Bate and Westwood to *Amathilla*. He thus defines it :—“ Thorax subcylindraceus, abdomen eompressum. Antennæ quatuor inaequales; superiores inferioribus paulo breviores, earum quævis ex articulis tribus atque flagello composita; superiores cum ramo parvo accessorio juxta flagelli basin. Oculi magni, reniformes. Pedes quatuordecim; duo eorum paria antica chelis monodactylis eomplanatiioribus, subaequalibus. Stylorum abdominalium paria tria. Abdominis appendicula terminalis simplex, erecta, lamelliformis.”

His new species *Amathia carinata*, Bate and Westwood say, “ from his description and figure, agrees so closely with *A. Sabinii* of Leach, that we should certainly have considered them as identical had not Rathke (1843) stated that they were distinct.” An author's statement, however, in defence of his own species need not be taken as invariably conclusive.

The new genus *Hyalr* is defined as follows :—“ Corpus elongatum compressum. Antennæ inferiores superioribus aliquantulum longiores; earum qualibet e tribus articulis atque

flagello composita. Oculi disciformes. Pedes quatuordecim: duo eorum paria antica chelis monodactylis complanatis, secundi paris multo majoribus. Stylorum abdominalium paria tria. Abdominis appendicula terminalis simplex, erecta verruciformis."

On this genus Spence Bate, B. M. Catal., p. 87, remarks, "Dana has arranged this genus in his subfamily Lysianassinae. Not having seen a specimen, I adopt the same arrangement; but judging from the figure of the author, I should be inclined to classify it near to *Nicea* of Nicolet, from which the female appears to differ only in the posterior pair of pleopoda having two branches—a feature that the author has not alluded to in the description of the animal, although exhibited in the figure. It is this character, together with the absence of any mention whether the mandibles are furnished with an appendage or not, that has precluded my placing it among the Orchestidae."

Axel Boeck in 1870 united *Allorchestes*, Dana, and *Nicea*, Nicolet, as synonyms to *Hyale*, Rathke. In this identification I myself (1876) and Wrześniowski (1879) have agreed with him. Faxon, Crustacea of the Lake Titicaca, 1876, takes a different view, which, to make the subject intelligible, must be given in full. The genus *Allorchestes*, he says, "differs from *Nicea*, Nicolet (as limited by Bate and Heller) in having the telson single instead of double or cleft. The fourth segment of the palpus of the maxillipeds is well developed, as in *Nicea* and *Gammarus*, and, as in these genera, is commonly unguiculiferous. Neither Dana, in describing *Allorchestes*, nor Nicolet, in his description of *Nicea* (published in the same year), mentioned the form of the telson. The two names were therefore synonyms. Bate, in a list of British *Amphipoda*, published in 1856 in the Report of the British Association for the Advancement of Science, indicates, without describing, two genera, *Allorchestes*, Dana, and *Galanthis*, gen. nov., which, as appears from his subsequent description, were based upon the trivial character of a different length of the first and second antennæ, and a differently formed telson, Dana's name, *Allorchestes*, being restricted to those species in which the first antennæ are (at least) as long as the peduncle of the second antennæ and the telson entire, and his own name *Galanthis* including the species with the two pairs of antennæ subequal and short, and the telson cleft or double. In 1861 he suppressed the name *Galanthis* in favor of Nicolet's *Nicea*. The proportion of the antennæ and the form of the telson brought together by Bate in his generic diagnoses are not in reality always concomitant, and Heller for the first time properly distinguished the two genera by the character of the telson alone. Grube (1866) adopts the relative length of the two pairs of antennæ (at most a specific character) as the generic distinction. All his species of *Allorchestes* have a double telson, and should be transferred to *Nicea*.

"Boeck (1872) apparently misled by the fact that Bate carelessly describes *Nicea Nilssonii* with an entire telson, and places it under *Allorchestes* §, would unite the two genera, giving as a generic character '*appendix caudalis brevis, crassa et fissa*.' He furthermore considers both *Allorchestes* and *Nicea* synonymous with Rathke's older *Hyale*, the type of which, *H. pontica*, was carefully described and figured with the posterior caudal stylets two-branched. Boeck has not had access to Rathke's type, as far as I can learn; but in a specimen from the Mediterranean 'which is doubtless Rathke's species,' he finds the last pair of saltatory appendages one-branched. This assumption of identity, it seems to me, cannot outweigh the careful description and illustration of the founder of the genus, unless confirmed by examination of the type of *Hyale Pontica*.

"In 1874 Professor S. I. Smith described a new amphipodous genus, *Hyalella*, from the fresh waters of the United States, differing from '*Hyale*' in having a styliform fifth segment to the palpus of the maxillipeds and an entire telson. The so-called fifth segment may perhaps be more correctly regarded as a movable spine, like those seen both lateral and terminal on the caudal stylets, or like the *unguis* which tips the dactylopodite of the thoracic legs. However this may be, it is quite as well developed in several species of

'*Hyale*' (*Nicea*), and is not therefore a generic character. *Hyalella* is then a synonyme of *Allorchestes*."

To the second paragraph of this quotation is appended this note: "§ Doubtless a large number of the species placed under *Allorchestes* by Bate in his Catalogue of the *Amphipoda* in the British Museum have in reality a divided telson. In fact, it would seem that the telson is cleft in *most* of the marine forms, and such probably formed the bulk of Dana's original genus *Allorchestes*. The only types of Dana's species that I can discover are two specimens of *A. media* in the Museum of Comparative Zoölogy. In these the telson is cleft to the base. This, however, will not affect the synonymy as given above."

There are, however, some considerations which Mr. Faxon does not appear to have taken into account. He says that *Hyale pontica* was carefully described and figured with the posterior caudal stylets two-branched (zur Fauna der Krym, p. 87, pl. v. figs. 20-28, 1836), but no allusion to this feature is made in the generic character by Rathke (though Spence Bate introduces it in his Catalogue), and in the description of the species Rathke's words are:—"die Sprungbeine sind nur kurz und schwach; das erste Paar ist am längsten, jedoch kürzer als das hinterste Paar der Afterbeine, das zweite ist noch kürzer, und das letzte am kleinsten: an den beiden ersten Paaren sind die Aeste ungefähr so lang, als die Wurzelglieder, an den letzten aber bilden die Aeste nur zwei sehr kleine warzenförmige Vorsprünge des Wurzelgliedes." Here we find that in the first and second uropods the rami are about as long as the peduncles (not much shorter as the B. M. Catalogue makes out), but on the last pair the rami form only two very small wart-like processes of the peduncle. Possibly this means *only two to each peduncle*, but I think that it more probably means *only two* for the pair of peduncles. It is true that on Pl. v., Fig. 21, representing "das hinterste Sprungbein," shows two rami to one peduncle, but this plate is signed "W. Pape del," not as on other plates in the same memoir, "Rathke del." This takes something from the force of Mr. Faxon's expression, "the careful description and illustration of the founder of the genus." Nevertheless with only these facts in view I should accept Mr. Faxon's ruling. But in his later work, B. z. Fauna Norwegens, pp. 81-83, Rathke describes, under the name "*Amphithoë Prevostii*, M. Edwards?", a species of which he says "the pleopoda of the sixth pair are very small, and do not end with two rami, but each consists only of two joiuts, tolerably thick in proportion to their length, of which the terminal joint is smaller than the basal, and bears at the end some small spines. The back is quite smooth throughout." He further says, "this animal is very nearly related to an Amphipod which I found in the Black Sea and described under the name *Hyale Pontica*, but is distinguished from it chiefly by the want of a telson." At the end of his book, p. 264c, he has made up his mind that the species is new and names it *Amphithoë nilssonii*. He thought it a question (p. 83) whether this species and *Hyale pontica* ought not to form a new genus, on the ground that the second gnathopods were so different from those of the *Amphithoë* species as then accepted. His ascribing to *Amphithoë nilssonii* the want of a telson was of course due only to an oversight or an accidental defect in his specimen, but he says nothing of distinguishing it from *Hyale pontica* by the difference of the last uropods. *Amphithoë nilssonii* is transferred by Spence Bate to the genus *Allorchestes*, while *Amphithoë Prevostii* of Milne-Edwards he assigns to *Nicea*, although when he saw the type specimen he considered it "synonymous with *Nilssonii* of Rathke, but unfortunately omitted to observe the character of the telson," B. M. C., p. 53. Now if *Hyale pontica* really has two rami to the peduncle in the last uropods, that one little extra wart will cut it off from the family of the *Orchestidae*, in which the last uropods are uni-branched. Yet there is nothing else to distinguish it from that family. Its antennæ, its gnathopods in both sexes, its general shape both of the body at large and the pleon in particular, will identify it with the *Orchestidae*. Its habitat among stones and mussels on the beach, its colouring, clear bottle-green shading into brown, its

size, 3·6 lines, all coincide with the position in the system which Boeck has assigned to it. My own drawings of *Hyale (Nicea) lubbockiana*, Ann. and Mag. Nat. Hist. for May 1876, made years before I was acquainted with Rathke's work are in close agreement with those by W. Pape on Rathke's plate v. As in the Annals for November 1879, I identified *Allorchestes imbricatus*, Sp. Bate, with *Nicea lubbockiana* of the same author, so now, after seeing the strongly imbricated figure in Rathke's work, I am inclined to identify both with Rathke's *Hyale pontica*.

From Mr. Faxon's own observations, that in the type of *Allorchestes media*, Dana, the telson is cleft to the base, and that in fact the telson is probably cleft in most of the marine forms, which would be the bulk of Dana's genus, I think it is unreasonable to give the name *Allorchestes* to species with an entire telson. But *Nicea*, which has been assigned to the species with a double or cleft telson, cannot claim priority over *Allorchestes*. They are in fact both synonyms of *Hyale*. For the species with an entire telson there will then be left the name *Hyalella*, originated by S. I. Smith in 1874. See also Note on Brandt, 1851.

One other new Amphipod is described by Rathke from the Crimea under the name *Amphithoë picta*. Of this Spence Bate remarks, "I can detect no specific distinction between this species and *A. littoralis* of our own shores." Nevertheless he retains the species, giving the description of it from Milne-Edwards instead of from Rathke. But Milne-Edwards describes the first and second gnathopods as "presque égales, mais assez larges," whereas Rathke himself says, "Das erste und zweite Beinpaar sind gleich lang und haben auch ziemlich gleich grosse, in Verhältniss zum ganzen Körper aber nur kleine Hände," and in his Latin description, "pedum duobus paribus anticus subæqualibus, chelis eorum minimis. In the British species or variety, "*Amphithoë littoralis*, Spence Bate," the size of the gnathopods is very variable, so that Milne-Edwards' account may perhaps be unintentionally accurate. Rathke found his specimens "in the bay of Balaklava, where it habitually lodges under stones, and resembles Gammarus in its mode of life."

1838. MILNE-EDWARDS, H.

Histoire naturelle des Animaux sans vertèbres par J. B. P. A. de Lamarck. Deuxième Édition. Revue et augmentée de notes présentant les faits nouveaux dont la science s'est enrichie jusqu'à ce jour; Par MM. G. P. Deshayes et H. Milne-Edwards. Tome cinquième. Araehnoides, crustacés, annélides, cirrhipèdes. Paris, 1838.

The history of the Crustacea, the Eighth Class, occupies from page 154 to page 498 of this volume. Of the sub-class, Crustacés maxillés, the second legion, Edriophthalmes, contains the three Orders, Amphipodes, Loemipodes, Isopodes. At p. 256 the editor remarks that most authors have wrongly assigned as a character to the Isopoda, the absence of a palpiform appendage from the mandibles; he divides the Isopoda into three families, Cloportidiens, Cymothiodiens, Idotidiens, in the second of which he places *Typhis*. However, at p. 285, a note signed "E" states that "les Typhis appartiennent à l'ordre des Amphipodes, et à la famille des Hypéridiens," and refers to the "article Typhis du Dictionnaire classique d'histoire naturelle, t. 16, p. 449." "Espèce. 1. Typhis ovoide. *Typhis ovoides*. Risso. Hist. nat. des crust. p. 122. pl. 2. fig. 9," is followed by references to Desmarest and Latreille and to "le *typhis ferus*" and "le *typhis rapax*" [rapax], both of Milne-Edwards, but so given as to appear more like synonyms of *ovoides*, than separate species for which they are no doubt intended.

On les Caprellines, pages 293–299, an editorial note says, "Cette division correspond à l'ordre

des Læmipodes et se distingue facilement des autres Edriophthalmes par l'état rudimentaire de l'abdomen qui est réduit à un simple tubercule. Elle se subdivise en deux petites familles naturelles : les Caprelloidiens ou Læmipodes filiformes et les Cyamoidiens ou Læmipodes ovalaires." In the first of these subdivisions, *Leptomera*, with the species *rubra* and *pedata*, still holds the place which belongs to *Proto ventricosa*, O. F. M., *Proton pedatum* being added from Desmarest to the synonymy of *Leptomera pedata*. *Caprella* has the species *scolopendroides* of Pallas, and *plasina* of Montagu, with references to additional species described by Latreille, Leach, Desmarest and Templeton. Under *Cyamus*, with the "Espèce. Cyame de la baleine. *Cyamus ceti*," *Cyamus oralis*, Roussel de Vauzème is also given, seemingly as a synonym. Latreille's unpublished East Indian species is mentioned, and the observation made that, "suivant M. Roussel de Vauzème, on aurait confondu sous le nom de *Cyamus ceti*, trois espèces de Cyames qui vivent toutes sur la baleine ; mais ce naturaliste ne paraît pas avoir fait assez d'attention aux changemens de forme que l'âge amène chez ces animaux. (Voyez Ann. des Se. nat. 2^e série. I. 2.)"

On the Amphipods, pages 299–317, a note points out that there are six pairs of abdominal feet, instead of five as stated in the text, and where Lanarck says of the Amphipods, "c'est toujours sur le côté qu'ils se posent," a note observes that "plusieurs amphipodes qui ne lui étaient pas connus, n'ont pas le corps comprimé et nagent dans la position ordinaire," The editor observes that the Amphipods form two natural families :—

"1^o Les CRÉVETTINIENS qui ont le corps grêle et allongé ; la tête petite et les pattes-mâchoires recouvrant toute la bouche et formant une espèce de lèvre inférieure terminée par quatre grandes lames cornées et deux longues tiges palpiformes et qui ne sont pas parasites.

"Genres Crevette, Talitre, Corophie, etc.

"2^o Les HYPERINIENS qui sont plus ou moins parasites et ont eu général le corps gros et bombé ; la tête forte et les pattes-mâchoires très-petites, recouvrant seulement la base des autres appendices buccaux, terminées par trois lames cornées et dépourvues de tiges palpiformes ou n'en présentent que des vestiges.

"Genres Hypérée, Phronime, Tiphis (p. 285), etc."

On the species of *Phronima*, he remarks that they have seven thoracic rings, each with a pair of feet, the fifth of which ends in a didactyle hand ; that they have also seven abdominal rings, the fifth and sixth more or less coalescent, and the seventh laminar. He thinks that *Phronima atlantica*, Guérin, may be only the young of *Phronima sedentaria*. *Hyperia*, Latreille, is given with three species, *latreillii*, *cyanex* and *pelagica*. The last of these he identifies with Say's *Lanceola pelagica*, the first with *Hiella orbignyi*, Straus, and also with "*Oniscus medusarum*?" Othon Fabricius," and "*Marflue*, Strom, Sondmor," both which he subsequently transferred to *Metocetus Medusarum*, Kröyer. "*Hyperia Suerii*" is likewise here a synonym of *Latreillii*, but later on under the name *Lesueurii*, Milne-Edwards speaks of it as a distinct species. "*Phorcus Reynaudi*," M.-Edw.; "*Lestrigon Fabrei*," M.-Edw.; *Daira Gabertii*, M.-Edw.; *Themisto Gaudichaudii*, Guérin; *Dactylocera*, Latreille, and the species *Dactylocera Nicæensis*, M.-Edw.; *Hieraconyx abbreviatus*, Guérin; *Primno macroura*, Guérin; *Anelylomera Blossevillii*, M.-Edw.; *Anelylomera Hunteri*, M.-Edw.; *Pronoe capito*, Guérin; *Oxycephalus piscatorius*, M.-Edw.; *Oxycephalus oceanicus*, Guérin; and *Vibilia Peronii*, M.-Edw.; have met with remark in earlier notes. On *Dactylocera* the observation is made that *Phrosina semilunata*, Risso, "paraît appartenir aussi à ce genre, comme l'a très bien remarqué Latreille (Règne anim. t. 4. p. 117)." On *Vibilia* the remark is made that Templeton's *Thaumalea depilis* "paraît devoir appartenir à ce genre."

To the account of the genus *Gammarus* is added the note, "les Crevettes forment le type d'une tribu particulière de la famille des Crevettiniens que nous avons désignés sous le nom des *Crevettiniens sauteurs*, et que l'on reconnaît facilement au mode d'organisation de la partie postérieure de l'abdomen. Ce groupe renferme aussi les Talitres et quelques genres

nouveaux." In the species of *Gammarus* from the earlier edition, number 6, the *Pherusa fucicola* of Leach, is given as "Crevette fucicole. *Gammarus pherusa*," the last word probably by a slip. We are told to add a great number of species described or figured by various authors. The notes remark that in all these crustacea the upper antennæ have a peduncle of three joints with a multiarticulate lash, and that the peduncle of the lower antennæ has four joints. *Dexamine*, Leach, is referred with hesitation to the "division des Amphitoës." Of *Leucothoë* the only species well known is said to be the *Lycesta furina* of Savigny, but the *Gammarus articulosus* of Montagu "paraît être aussi un Leucothoë." Leach's genera *Melita* and *Moera* [Mæra] are rejected. "Les Phéruses doivent être réunies aux Amphitoës dont elles ne diffèrent que par un peu moins d'élargissement dans les mains." *Amphitoë*, Leach, distinguished from *Gammarus* by the absence from the upper antennæ of an accessory flagellum, is accepted.

In the text of this oddly arranged work the following remarks occur as if part of the original edition, though the references show that they are not so:—"Nous avons donné le nom générique d'*ISEA* à des Amphipodes qui sont très voisins des Crevettes, mais qui ont toutes les pattes subchéliformes (voyez Ann. des Sc. nat. t. 20. pag. 380, et Hist. des Crust. pl. 29, fig. 11).

"Dans notre genre *LYSIONASSE* il n'est au contraire aucune patte qui ait ce mode d'organisation (voyez le *Lysionassa costæ*. Edwards, Ann. des Sc. nat. t. 20, pl. 10, fig. 17).

' Le genre *PHLIAS* de M. Guérin ne diffère du précédent que par l'absence du filet multiarticulé accessoire des antennes supérieures. (Esp. le *Phlias serratus*, Guérin, Mag. de zool. cl. vii, pl. 19)."

To *Talitrus* Lamarck had assigned "bouche comme dans les Crevettes." A note here says "excepté que les mandibules ne portent que des vestiges d'une tige palpiforme." This statement probably rests not on original observation but on Savigny's figure of the mandible of *Orchestia montagui*, or on Guérin's figure of the mandible of *Talitrus platychelis*, 1835, since in 1840 Milne-Edwards says of *Talitrus*, "les mandibules (fig. 3) ne présentent que des vestiges d'un appendice palpiforme, ou en manquent même complètement. His figure shows no trace of a palp. Nevertheless it may be true that in some of the Orchestidae there is a rudiment of it. Such at least I fancy that I have discerned in *Hyalella inermis*, S. I. Smith. *Talitrus* in Lamarck has three species, *locusta*, *gammarellus*, *carinatus*. A note to the second points out the difference of *Orchestia* from *Talitrus*, and that to *Orchestia* should be referred Savigny's figures 7 and 8 on Plate 11 of his great work, "*Orchestia Fischerii*, M.-Edw." etc. A note on the third, which is Fabricius' species, referred by Leach to *Atylus*, says, "le genre *Atyle* doit prendre place dans la tribu des Corophioïdes ou Crevettiniens marcheurs et se distingue par ses antennes non pédiformes, et ses mains de la seconde paire très petites et à griffes simples."

Corophium is regarded as type of a tribe called here *Crevettiniens-marcheurs*, distinguished from the *sauveteurs* by slender body, small epimera, tail not formed for leaping, and distinguished from other genera of the same division by pediform lower antennæ, upper antennæ without accessory flagellum, second gnathopods neither didactyle nor prehensile.

Jussa and *Podocerus* of Leach are distinguished from *Corophium* "en ce que leurs quatre pattes antérieures sont terminées par une grosse main subchéliforme," but it is rightly observed that they are distinguished from one another only by trifling characters. "Le genre *UNCIATA* de Say," the editor remarks, "doit prendre place auprès des genres précédens, mais s'en distingue par l'existence de deux tigelles multiarticulées à l'extrémité des antennes supérieures." Say's *Unciola* is of course intended. Say's *Cerapus* is mentioned with the type species *tubularis* and Templeton's *ablitus*. It is then observed in conclusion:—"Enfin, notre genre *ERICHTHONIE* établit le passage entre ces Crustacés et les Leucothoés; la conformation générale du corps est la même que chez les précédens, mais les antennes ne

sont pas péiformes et les pattes de la seconde paire sont terminées par une longue main imparfaitement didactyle dont la griffe est biarticulée. (Voyez Ann. des Sc. nat. t. 20, p. 382, et Hist. nat. des Crust. pl. 29. fig. 12.)"

1838? COSTA, ORONZIO GABRIEL, and COSTA, ACHILLE.

Fauna del Regno di Napoli. Crostacei.

Preface, pp. 1–4, dated May 15, 1838, briefly notices what had been already done for Italian Crustacea, and proposes to follow Latreille's last classification of the Crustacea in his *Familles Naturelles du R. Anim.*

Animali articolati. Classe I. Crostacei (Crustacea) pp. 1–4.

In this paper Latreille's classification is given.

1838. KRØYER, HENRIK NIKOL, born 1799, died 1870 (G. O. Sars).

Grönlands Amfipoder beskrevne af Henrik Krøyer. (Som Tillæg; Beskrivelse af nogle andre grönlandske Kræbsdyr, og Optælling af Kræbsdyrklassens hidtil bekjendte grönlandske Arter, i Forbindelse med nogle zoologisk-geografiske Bemærkninger over de boreale Krustaceer). *Vid. Sel. naturvid. og mathem. Afh. VII Deel.* [1838]. pp. 229–326. Tab. I–IV.

The introductory observations note that Latreille and Milne-Edwards agreed in making twenty-four genera of Amphipods, but of this number had only thirteen in common. Burmeister's inclusion of the Læmodipoda and Pyenogonidae in the order of Amphipoda is disapproved, and Milne-Edwards' definition and division of that order held to be the most satisfactory in the then existing knowledge of the subject.

The first species described is called "*Lysianassa Vahlii Rhrdt*," with the remark emphasized in regard to the second gnathopods, that the sixth joint or finger is altogether wanting, a statement which, nevertheless, requires corroboration. Krøyer assigns the species to Reinhardt, whose manuscript name for it he adopts, but it had, in fact, been previously described by Owen under the preoccupied name *Gammarus nugax*; Krøyer presently changed the name to *Anonyx vahlii*; Boeck in 1870 made it *Socernes vahlii*, but, as his *Socernes* cannot fairly be distinguished from *Ephippiphora*, White, the name will be *Ephippiphora vahlii*, Krøyer (sp.). The next two species, figured and described respectively as "*Lysianassa Lagena Rhrdt*" and "*Lysianassa appendiculosa Kr.*," are now regarded as the female and male of *Cancer nugax*, Phipps, in the genus *Anonyx*, and will therefore stand under the name *Anonyx nugax*, Phipps (sp.). In describing *Lysianassa appendiculosa*, Krøyer calls attention to "small appendages, with which the flagella are furnished: the flagellum of the upper antennæ along its lower edge, that of the lower antennæ along its upper edge. I know," he says, "no other hitherto described Amphipod, in which anything of the kind is found, except in the *Gammarus ornatus* described by Milne-Edwards." These are the appendages since called calceoli. He also here observes that the number of joints in the antennæ increases with age, thus early giving a warning against the separation of species simply on the ground of differences in the length of the antennary flagellum. He then proceeds to remark that the three species just described were referred to *Lysianassa* as the only one among existing genera capable of receiving them, but that even that would require re-defining to include them with propriety. The monstrous size

of the peduncle of the upper antennæ, and the want of a finger and other peculiarities in the second gnathopods, were peculiarities so marked in the three species that he proposes a new genus for them, thus defined:—"Anonyx: *pedunculus antennarum superiorum crassissimus, ovalis; inferiorum multo gracilior, cylindricus; (oculi magni*); pedes primi paris breviores, parvulo instructi ungve; pedes secundi paris sat elongati, gracillimi, ungve carentes (quinquearticulati), ejusque vice ad finem articuli quinti multis validisque præditi setis.*" To this generic character, he says, may also be added, that the head in all the species is tolerably small, and partially concealed by the first side-plates, a rostrum projects in the middle in a little blunt point, formed by the small lateral excavations for the insertion of the anteunæ, while the trunk is pretty strongly compressed, though dorsally rounded. Though not considering the mouth-organs of use for generic characters, he mentions that the mandibles are strong, furnished along the inner edge with three dental tubercles (Tandknnder), meaning, to judge by the figure, a divided tooth at the tip of the cutting edge and a small molar tubercle; the upper rim shows near the outer angle a tolerably deep incision; the palps are tolerably short. The second maxillæ have the lower lobe (inner plate) very small, furnished at the extremity with some long, plumose setæ. The maxillipeds have the palps long, the inner terminal plates narrow, linear. A footnote to the words "oculi magni" explains that a species otherwise in agreement with the genus need not be excluded merely on account of its having small eyes.

He next describes "*Gammarus Sabini* Leach," commonly known now as *Amathilla sabini*, but in my view having a claim to the title *Amathilla homari*, J. C. Fabr. He expresses surprise that it should have escaped the notice of [Otto] Fabricius, and calls attention to the very considerable differences between the young and adults, and the necessity for naturalists to take such variations into account if they would avoid the groundless multiplication of species. The next species described and figured, *Gammarus loricatus* Sab., has by Spence Bate been named *Gammaracanthus loricatus*, Sabine. The new species figured and described as *Gammarus pinguis* is now called *Amathilla pinguis*. "*Gammarus Locusta*, Montagu," is judged to be the commonest of all the Greenland Amphipods, and to be undoubtedly identical with O. "Fabricius's Oniscus pplex (n. 231 pag. 254)." The suggestion is offered that it may be identical with *Cancer nugax* and *Gammarus nugax* in the English travels, dating "from Phipp's time." "*Amphithoe carinata* Rhrdt. (Tab. II, fig. 6)," is next described. This, which is the *Gammarus carinatus* of Fabricius, now bears the name *Atylus carinatus* given it by Leach. "*Amphithoe Hystrix*. (*Acanthosoma Hystrix* Owen). Tab. II, fig. 6 [7].," next described, has been identified by Boeck with Lepechin's species, under the name *Acanthozone cuspidata*, but the distribution of the species, according to the accounts of Lepechin, Kröyer and Boeck, makes the identification doubtful. In describing the flagellum of the upper antennæ, Kröyer remarks that, with exception of the four first joints, which are all furnished with hairs at the end of the lower edge, of the remainder, as a rule, only every alternate one exhibits hairs. Consequently, he says, those joints without hairs easily escape observation and cause discrepancies in counting the total number of joints. From the alternation just mentioned and from the considerable length of individual flagellum-joints in young individuals, he argues that the increased number of these joints in the adults results, not from the budding forth of new joints, but from the subdivision of the old ones. His description of the species in brief is:—"Amphithoe Hystrix: fronte non rostrata; antennis superioribus dimidiata inferiorum partem non æquantibus; oculis orbicularibus, convexis; corpore parum compresso; annulis thoracis, tribusque abdominalis anterioribus series aculeorum quinque præbentibus; primo thoracis annulo præ ceteris aculeato, cornu gerente procumbens et a caput prominens; epimeris femori solito minus appressis, plerumque in aculeos productis; manibus linearibus, ungula præditis minuta; appendice caudali unica, postice

aliquantulum emarginata." This is followed by a sharp criticism of the generic character given by Owen for *Acanthosoma*. "*Amphithoe Serra* Kr. (Oniseus serratus, Fabr. Fn. gr. n. 237), (Tab. II, fig. 8)," is now *Acanthonotosoma serratum*. Krøyer changed *serratus* to *serra* to avoid displacing *Amphithoe serrata*, Say. "*Amphithoe panopha* Kr. (Tab. II, fig. 9)," has since been called *Pleustes panophus*. "*Amphithoe bicuspis* Rhrdt (Tab. II, fig. 10)," has been referred successively to *Paramphithoe*, *Amphillopis*, *Pherusa*, and *Pleustes*, and is restored by G. O. Sars in 1882 to *Paramphithoe*. "*Amphilhoe inermis* Rhrdt. (Tab. III, fig. 11) (Oniseus Cieada Fabr. Fn. gr. n. 233 ?),," together with "*Amphilhoe crenulata* Rhrdt (Tab. III, fig. 12). (Oniseus abyssinus Fabr. Fn. gr. n. 236 ?),," has been already mentioned in the note on Otto Fabrieus, 1780, as now bearing the name *Pontogeneia inermis*, Krøyer. "*Amphilhoe læviuscula* Kr. (Tab. III, fig. 13),," is now called *Culliopus læviusculus*. "*Ischyrocerus angripes* Kr. (Tab. III, fig. 14),," is now known as *Podocerus angripes*, Krøyer, though not without the admission that it may be identical with the earlier *Podocerus cylindricus*, Say.

The new genus *Ischyrocerus* is thus defined:—"Mandibulæ magnis instructæ palpis qvorum ultimus articulus obovatus, fere truncatus; antennæ pediformes; pedunculus (o: pars basalis) antennarum multo longior flagello (o: parte terminali), qvod per paucis modo gaudet articulis; antennæ superiores flagello appendiculati brevi, unarticulato ornatae; pedes primi paris minutæ sed validi, manuqve gerentes; pedes secundi paris maximi, manu portentosæ in adultis magnitudinis armati; reliqui pedes solito ferme more conformati; pedes spurii quarti, quinti & sexti paris saltatorii; articulus basalis sexti paris articulus terminalibus triplo vel quadruplo longior; annuli abdominales tres anteriores annulis thoracis breviores; epimeri mediocris magnitudinis." The name *Ischyrocerus* is a synonym of the earlier *Podocerus*.

"*Metoecus Medusarum* Kr. (Tab. III, fig. 15). (Oniscus Medusarum Fabr. Fn. gr. n. 232),," was transferred by Boeck to Dana's genus *Tauria*, the name *Meloecus* being pre-occupied. Bovallius, however, argues that the species cannot properly be separated from *Hyperia*, and the specific name *medusarum* being pre-occupied in that genus, he calls the present species "*Hyperia Kroeyeri*." But if G. O. Sars, 1882, be right in identifying *Tauria abyssorum*, Boeck, with the so-called *Tauria medusarum*, the species will by the law of priority become *Hyperia abyssorum*. The genus *Metoecus* is thus defined by Krøyer:—"Pedes primi et secundi paris reliquis permulto breviores, sed validi, manuqve armati e heliformi. Articulus horum pedum quartus qui forma prædictus est triangulari, manum efficit, a cuius margine inferiori producunt pollex biarticularis anterior et digitus posterior. Primus pollicis articulus (v. quintus pedis) magnus, conicus; secundus unguis est pusillus. Digitus conicus, pollice aliquantillum brevior. Margo utriusque pollicis articuli posterior, margoqre digiti anterior per lotam longitudinem serrati. Cetera cum genere *Hyperia* ferme convenienti."

"*Themisto arctica* Kr. (*Themisto Gaudichaudii* Ross.). (Tab. IV, fig. 16),," and "*Themisto crassicornis* Kr. (Tab. IV, fig. 17),," are by Boeck both made synonyms of *Themisto libellula*, Mandt. Krøyer himself felt he had grounds for believing that his *Themisto arctica* was not identical with "*Themisto Gaudichaudii* Guérin," but that it might well be so with "Ross's *Themisto Gaudichaudii*."

"*Lestrigonus exulans* Kr. (Tab. IV, fig. 18),," is considered by Boeck and others to be the male of *Hyperia medusarum*, O. F. Müller. F. H. Streets would keep the genus *Lestrigonus* distinct from *Hyperia*. "*Hyperia obliqua* Kr. (Tab. IV, fig. 19),," is also held to be a synonym of *Hyperia medusarum*, O. F. M.

The second part of this work is concerned with Crustacea outside the order of Amphipoda. In the third part Krøyer reviews the Greenland Crustacea in general, naming, among the fifty-eight species which, he says, had come under his own observation, the Amphipods already discussed, which are numbered from 11 to 31 in the series. Under number 38 he

says, “*Caprella septentrionalis* (*Squilla lobata* Fabr. Fn. gr. n. 225) not only differs very considerably from the *Caprella quadriloba* (*Capr. linearis* Latr.) which occurs with us, in the form of the second pair of hands, etc., but, so far as I can judge, is also distinct from all known European species. It seems frequent in the Greenland Sea, but is not mentioned by Sabine and Ross.” He subsequently figures and describes *Caprella septentrionalis*, Kr., in the Nat. Tidsskr., pp. 590–596, Tab. VIII. fig. 10–19, without reference to *Squilla lobata* of O. Fabricius. Under number 39 he says, “*Cyamus Ceti* (*Oniscus Ceti* Fabr. Fn. gr. n. 230), is sent both from northern and southern districts.”

Of the species recorded by O. Fabricius, of which Krøyer personally knew nothing, he thinks that “*Oniscus arenarius* (Fn. gr. n. 234)” may be a *Gammarus* or *Amphithoe*, and “*Oniscus stroemianus* (Fn. gr. n. 235)” an *Orchestia*, as supposed by Milne-Edwards. He then mentions from English authors “*Amphithoe Edwardsii* (*Talitrus Edwardsii* Sab. tab. 2. fig. 1–4),” “*Amphithoe cristata* (*Acanthonotus cristatus*, Owen. App. to the Voy. of Ross. tab. B. fig. 8–12),” which he says seems to stand pretty near to *Amphithoe Serra*, and “*Hyperia Cyaneæ* (*Talitrus Cyaneæ* Sab. tab. 1, Fig. 12–18),” all which have been already discussed. In a note he expresses disappointment that Owen should have left *Cancer boreus*, *Cancer ampulla* and *Cancer nugax* of Phipps without elucidation.

In the ten orders of Crustacea, which Krøyer here admits, he reckons that the Arctic species number 68, or, taking the number of all then known Crustacea to be 1500, the Arctic species furnish a proportion of about 1 to 22. In these 68, 26, he says, are Amphipods, giving the large proportion of 26 out of a total of 99 then known from the world at large. The total is arrived at by the combination of his own list with that furnished by Milne-Edwards. It should be observed that two species of Læmipoda are here not included in the number of the Amphipoda.

Lastly, Krøyer calls attention to the tendency in the genera *Gammarus* and *Amphithoe*, as he accepted them, to develop sharp and angular forms, with horn-like processes and spines, the more conspicuously the higher the latitude. As examples he adduces “*Gammarus loricatus*, *Gammarus Sabini*, *Amphithoe Edwardsii*, *Amphithoe Hystrix*, *Amphithoe cristata*, which all extend very far within the Polar zone.”

1838. KRØYER, H. N.

Conspectus Crustaceorum Groenlandiae. Naturhistorisk Tidsskrift. S. I. B. II. pp. 249–261. 1838.

This is stated by the author to be chiefly an epitome of his previous work on the Amphipoda of Greenland with very few alterations. For the three species assigned in that work to *Lysianassa*, he now gives the name *Anonyx*. After the description of *Amphithoe serra*, Kr., the epitome breaks off with the notice, “continuabitur.”

1839. ANDRZEIOWSKI, ANT.

Catalogue des objets qui se conservent dans le cabinet zoologique de l'université impériale de St Vladimir à Kiéf. I^{re} Partie : Mammifères, oiseaux, reptiles, poissons et crustacées. Par A. Andrzeiowski. 1838. Bulletin de la Société Impériale des Naturalistes de Moscou. Année 1839. No. 1. Moscou, 1839.

In the “État de la Collection en 1833,” the “Crustacées” comprise only one Amphipod, “Gammarns Pulex.” For “Année 1838,” under the same heading the following Amphipods

are named; "Orchestia littorea Leach. Gammarus Pulex Fabr. ind. Gammarus marinus Leach. Odessa. Gammarus stagnalis Nob. K." "ind" signifies "indigène de ces Gouvernemens," "K" stands for "Kief." To *Gammarus stagnalis*, a note is given as follows:—Celui-ci diffère du précédent par ses yeux elliptiques réniformes, bien plus grands en raison de la tête que ceux du *G. Pulex*, malgré que l'animal lui-même ne le surpasse pas par sa taille. Les appendices de la queue surpassent en longueur les deux derniers articles de la queue, tandis qu'ils sont plus courts dans le *G. Pulex*. On peut les définir ainsi; *G. Pulex oculis oblongis exiguis, appendicibus caudalibus duobus articulis ultimis caudæ brevioribus. G. stagnalis oculis reniformibus magnis, appendicibus duos ultimos articulos caudæ superantibus.*" The characters given are insufficient for specific distinction. It is therefore of little importance that the name *Gammarus stagnalis* is preoccupied as a synonym for a non-Amphipod Crustacean, *Branchipus stagnalis*.

1839. PHILIPPI, RUDOLPH AMANDUS, born September 14, 1808 (Hagen).

Einige zoologische Notizen von Dr. A. Philippi. 5. *Chelura terebrans* ein neues Amphipoden-Genus. Fig. 5. Archiv für Naturgeschichte. Wiegmann. Fünfter Jahrgang. Erster Band. Berlin 1839. pp. 120–121.

The earliest known description of this singular, mischievous, common, and, since Philippi's paper, often-described Amphipod is as follows:—"Das Thier ist, einschliesslich Fühler und Schwanzanhäuge $4\frac{1}{2}$ " lang und ohne dieselben $2\frac{3}{4}$ " lang, und gegen $\frac{3}{4}$ " breit. Der Kopf ist am schmalsten und so lang als die zwei folgenden Segmente, der Körper wird vom Kopf an allmählig breiter ohue sich jedoch bedeutend von der lincalischen Form zu entfernen. Die Augen sind klein und ruud; die obern Fühler von mässiger Länge, borstenförmig, siebengliedrig. Die untern Fühler sind anderthalb mal so lang und bestehn aus 6 Gliedern; die beiden ersten Glieder sind sehr kurz, die übrigen nehmen allmählig an Länge zu, werden platter und die letzten sind dicht gewimpert, so dass sic eher ein Organ zum Schwimmen als zum Tasten zu sein scheinen. Die Brustsegmente sind gleich lang und haben ihre Seitentheile nur sehr wenig entwickelt. Der Schwanz oder Abdomen ist fünfgliedrig; die beiden ersten Glieder sind den Brustsegmenten ähnlich, das dritte Glied trägt auf der Mitte des Rückens ein langes gekrümmtes Horn, welches ganz dem der Sphinx-raupen gleicht, und jederseits noch 2 kleine Spitzen. Das vierte Glied ist anderthalbmal so lang als breit, unten ziemlich flach, oben couav mit kleinen Höckerchen besetzt, an den Seitenrändern gewimpert. Zwei kleine Höckerchen in der Mitte des hintern Randes zeichnen sich besonders aus. Dieses Glied trägt jederseits zwei Paar sonderbare Anhängsel, die an seinem Grunde eingelenkt sind. Die obern Anhängsel sind senkrecht aufgerichtet und bestehn aus 3 länglichen abgerundeten Lappen, die alle mit langen Haaren dicht gewimpert sind, und von denen der vorderste der grösste, der hinterste der kleinste ist. Das seitliche Paar Anhängsel entspricht volkommen einem der Schwanzanhängsel der Gammarinen und besteht aus einem Stiel, der zwei kleine spitze Blättchen trägt. Das fünfte Glied ist sehr kurz, zeigt unten in einer Spalte den After oben in der Mitte und an seinem Grunde (oder am hintern Rande des 4ten Gliedes) eingelenkt ein ovales Blättchen und an seinem Eude eine ungeheure Zange, die beinahe anderthalbmal so lang als die beiden letzten Schwanzglieder ist. Ihre beiden Blätter sind flach gedrückt, etwas divergirend, gegen das Eude verschmälert und hakenförmig gebogen, und haben gezähnelte Ränder. Die 14 Füsse nehmen von vorn nach hinten an Länge zu, jedoch nicht bedeutend. Die beiden ersten tragen am Ende eine umgebogene Klaue und der Tarsus ist breit mit einem divergirenden Zahn. Das erste Fusspaar ist weit breiter als

das zweite. Die folgenden Füsse enden mit einer langen graden nur an der Spitze schwach hakenförmig gebogenen Klaue, die drei hintern haben nur ein kleines blattartiges Hüftglied. Die *Kiemen* an ihrem Grunde habe ich nicht gesehen, desto deutlicher die 3 Paar falscher *Abdominalfüsse*, die aus einem beiförmigen, lamellenartigen Grundglied und zwei gegliederten und gewimperten Borsten bestehn; so dass über die Ordnung der Crustaceen, zu welcher das Thierchen gehört, kein Zweifel sein kann. Die *Kauwerkzeuge* schienen mir aus einer ausgerandeten Oberlippe, einem Paar mit 2gliedrigen Palpen versehenen Mandibeln, drei (?) oder vier (?) Paar lamellenartiger Maxillen, und 2 sechsgliedrigen Kaufüssen zu bestehn."

1839. RATHKE, HEINRICH.

Beobachtungen und Betrachtungen über die Entwicklung der *Mysis vulgaris*. Archiv für Naturgeschichte. Wiegmann. Fünfter Jahrgang. Erster Band. Berlin 1839.

This paper on the development of *Mysis vulgaris* is illustrated throughout by reference to corresponding facts in regard to the Isopoda and Amphipoda.

1839. WIEGMANN, AREND FRIEDRICH AUGUST, born 1802, died 1841 (Hagen).

Abweichende Form der Blutkörperchen und Blutlauf bei Lämopoden. Vom Herausgeber. Archiv für Naturgeschichte. In Verbindung mit mehreren Gelehrten herausgegeben von Dr. Ar. F. Aug. Wiegmann. Fünfter Jahrgang. Erster Band. Berlin 1839. pp. 111–112.

"In a little *Leptomena* from the Skagerak," Wiegmann observed that the blood corpuscles were not round or roundish, but "elongate, thin at either end, fusiform." In the gnathopods and other limbs he observed "two active currents, the one arterial, descending, on the hinder side of the legs, the other aseending, on their front side. Each passes through the whole extent of the limb, till at the end of the foot the descending bends round into the ascending."

1840. BENNETT, F. D.

Narrative of a Whaling Voyage round the Globe. Vol. II. pp. 169. 234. 237.

To this work Lütken refers for mention of Whale-lice (*Larunda ceti*) on the Cæhalot, p. 169, a Cetacean on which Roussel was unable to find any *Cyamus*. On a Dolphin, larger than the common Dolphin (*Delphinus delphis*), and which in the spaces between the teeth in both jaws had cavities to receive the teeth from the opposite jaw, "some *Onisci* adhered to the body," p. 237. In reference to "the Blackfish of South-Sea Whalers," he says, "a few whale-lice (*Larunda ceti*) adhere to the skin of this Cetacean," p. 234. See Lütken, 1873, p. 14 (242).

1840. COSTA, O. G. and COSTA, A.

Catalogo de' Crostacei del Regno di Napoli. pp. 1-7.

Here, as Order III. of the Malacostraci, stand the Amfipodi, including "Phronima sedentaria. Phronima custos. Phrosine semilunata. Orio zanclus. Coe. *Sicilia*. Orio oxyrhinchus. Prest. *ivi*. Orio ornithoramphus. Scinà ensicornis, Prest. *Sicilia*. Cleistotoma Gemmellari, id. Orchestia littorea. Talytrus locusta. Lisanassa Costæ, Edw. Gammarus pulex. Gammarus marinus? Dexamine spinosa. Leucothoe articulosa. Amphithoe annulata, n. Sannazaria pallida, n. Callisoma punctata, n. Typhis ovoides. Anceus forficularius. Praniza cœruleata." As Order IV. stand the Lemodipodi, including "Caprella phasma. Caprella linearis. Caprella acutifrons. Cyamus acutifrons, n. *Sicilia*." No descriptions, and in most cases no authorities.

Costa's figure of *Phrosina semilunata*, Risso, "Fn. Nap. tav. IV, fig. 1-5," cannot be of later date than 1840, as Milne-Edwards refers to it, Hist. nat. des Crust., iii., p. 91, with the following observation, "la *Phrosina semilunaire*, à en juger par la figure très-détaillée qu'en a donnée M. Costa, diffère de l'espèce précédente par l'absence d'une grosse dent à l'angle antéro-inférieur du pénultième article des pattes antérieures, par la forme plus acuminée des lames natatoires que représentent les trois dernières paires de fausses pattes, et par quelques autres caractères." The preceding species referred to by Milne-Edwards is his own *Phrosina Nicetensis*. Costa himself in 1857 gives the following references, which are probably all of later date than 1840:—"Orchestia deshayesii, Aud., Edw., A. Cost. Faun. Nap. tav. VIII bis, fig. 3"; "Talitrus platycheles, Guer.—A. Cost. Fn. Nap. tav. VIII bis, f. 2"; "Lysianassa Costæ, Edw.—A. Cost. Fn. Nap."; "Callisoma punctatum, Cost. Fn. Nap. Tav. VIII, fig. 4-7"; "Callisoma Hopei, A. Cost. Fn. Nap. Tav. VIII bis, fig. 1." *Leucothoe denticulata*, A. Cost., "Fn. Nap. Tav. IX., fig. 3. (senza testo)." *Vibilia speciosa*, A. Cost. "Fn. Nap. tav. IX, fig. 1 (senza testo).", and the *Phrosina* already mentioned.

1840. LUCAS, HIPPOLYTE.

Histoire Naturelle des Crustacés, des Arachnides et des Myriapodes. Paris,
M DCCC XL.

In the account of the orders Læmodipodes and Amphipodes, pages 219 to 240, no original information appears to be given. There is a full account of *Cyamus*, taken from Roussel de Vauzème. Of the Læmodipodes filiformes the genera mentioned are *Leptomera*, *Naupredia*, *Caprella*. In the definition of *Leptomera*, the legs "ne paraissent pas tous pourvus d'appendices en forme de sac vésiculeux à leur base, ou même n'en ayant pas du tout." Of the species, *Leptomera ventricosa*, he says, "Cette espèce présente un appendice en forme de lobe à tous les pieds, les deux premiers exceptés. M. Latreille lui rapporte aussi l'espèce représentée par Slabber, *Micros.*, tab. 10, fig. 2, et le *Cancer Pedatus*, Montagu. *Transact. Linn.*, t. xi, pl. 2, fig. 6, qui en a tous les pieds pourvus, moins ceux de la première et des trois dernières paires." *Proto ventricosa*, O. F. M., has in fact only three pairs of branchia, though Slabber figures it with six pairs. *Naupredia* is here as usual without a species.

In the account of the Amphipodes the first mentioned is *Orchestia littoralis*, with references to Leach in the Edinb. Encycl. and the Linnaean Transactions, in both of which he remarks that his *Talitrus littoralis* is the female of *Talitrus locusta*. Of *Orchestia littoralis* he makes no mention. The name *Gammarus fluviatilis*, M.-Edw., is used for the *Squilla pulex*

of Degéer, while *Gammarus roeselii*, Gervais, is entered without reference to Roesel. The genera assigned to the first family, Crévettines, are *Orechestia*, *Talitrus*, *Lysianassa*, *Gammarus Amphithoe*, *Phlias*, "Isœa," *Leucothoe*. To the second family, Podocérides, are assigned *Erichtonius*, *Atylus*, *Unciola*, *Cerapus*, *Podocerus*, *Corophium*. On "Corophia longicornue" d'Orbigny's observations are as usual quoted. To the third family, Hypérines, are assigned the genera, "Vibilia, Hyperia, Phorcus, Lestrigon, Daira, Themisto, Hieraconyx, Dactylocerus, Anchylomera, Phronima, Primno, Tiphis, Pronoe, Oxycephalus." The descriptions of Gnérin's genera are given with great fulness. To each of the species "Vibilia Peronii," M.-Edw., "Phorcus Reynaudi," M.-Edw., "Lestrigon Fabrei," M.-Edw., "Daira Gaberti," M.-Edw., the remark is attached, "Cette espèce est encore inédite," as though the species were still undescribed, but it is obvious that, when a new genus is established for a single species, the characters of the genus are for the time those of the species also. Part of Plate 17 and the whole of Plate 18 are devoted to figures of Amphipoda, but the figures are not original. The names of *Cerapus tubularis* and *Corophium longicornue* are interchanged on Plate 18.

1840. MILNE-EDWARDS, HENRI.

Histoire naturelle des Crustacés, comprenant l'anatomie, la physiologie et la classification de ces animaux. Tome troisième. Ouvrage accompagné de planches. Paris, 1840.

This volume opens with the Édriophthalmes of Leach as second legion of the subclass "Crustacés maxillés." To mark them off from other Crustacea, Milne-Edwards points out that they have the body divided into three very distinct parts, head, thorax, and abdomen, the rings of the two latter being almost always distinct and free to move; they have no earapace, no movable peduncle to the eyes, although like the Podophthalma they have the mouth armed with mandibles and maxillæ, and the thoracic limbs all or almost all in the form of ambulatory feet. They do not, however, breathe by branchiae properly so called but by the help of a portion of the locomotive limbs, wholly or in part modified for the purpose; "tantôt c'est l'appendice phalliforme des pates thoraciques qui affecte la forme d'une grande vésicule membrancuse à texture délicate, et qui devient ainsi propre à servir d'instrument à la respiration." In the small number of species in which the inner structure is known, "le foie est remplacé par trois paires de canaux biliaires, le cœur a la forme d'un vaisseau dorsal situé tantôt dans le thorax, tantôt dans l'abdomen, et les organes génitaux se rapprochent, par leur structure, de ce qui se voit chez les Insectes." They form, he says, three natural classes thus distinguished:—

Edriophthalmes ayant,	l'abdomen bien développé et pourvu de cinq ou six païres de membres.	Des vésicules branchiales sous le thorax. Membres abdominaux des cinq premières païres hétéromorphes et servant à la locomotion.	Amphipodes.
		Presque jamais de vésicules branchiales sous le thorax. Membres abdominaux des cinq premières païres à peu près de même forme, impropre à la locomotion, et paraissant remplir les fonctions de branchies.	Isopodes.
	l'abdomen rudimentaire dont la forme est celle d'un petit tubercle sans appendices bien distincts. Des vésicules branchiales suspendues au thorax,		Læmodipodes.

In his general description of the Amphipod structure, Milne-Edwards notes that the mandibles are "pourvues, en général, d'une tige palpiforme," that the dorsal arch in the thoracic segments is generally "composé de trois pièces bien distinctes, savoir : un tergum et deux épimères," that at the base of most of the thoracic limbs there is on the inner side "une grande vésicule membraneuse qui semble être le représentant de la branche externe des pates-mâchoires et des pates ordinaires chez certains Podophthalmes, et qui présente ici tous les caractères d'un organe de respiration." The females, he continues, carry their eggs under the thorax, and often have flabelliform appendages fixed to the base of the feet to serve this purpose, but at other times their functions are discharged by the respiratory vesicles. He does not, however, here specify any instances to justify the last observation, but subsequently he applies it to the genus *Hyperia* and the genus *Plironima*, asserting that in the latter genus there are five pairs of branchial vesicles, not three pairs only as commonly supposed. He says that the Amphipoda are all aquatic—a statement, which, in the light of later discoveries, requires some modification. He divides the order into two groups or families in the following manner :—

"Pates-mâchoires très grandes recouvrant toute la bouche et formant une espèce de lèvre sternale impaire terminée par quatre grandes lames cornées et deux tiges palpiformes très-longues. . . . Famille des Crevettines.

"Pates-mâchoires ne recouvrant que la base des appendices précédents, et formant une espèce de lèvre sternale impaire terminée par trois lames cornées, et dépourvue de tiges palpiformes ou n'en ayant que des vestiges, Famille des Hypérines."

The Crevettines he divides into the Tribu des Sauteurs with twelve genera, and the Tribu des Marcheurs with seven genera. The first Tribe contains two groups, the first of which, comprising only *Talitrus* and *Orchestia*, "essentiellement arénicoles, ne présentent au plus que des vestiges d'une tige palpiforme aux mandibules." The remaining ten genera form the second group, which live habitually in the water and have a very long mandibular palp.

In the description of genera and species under *Talitrus*, Latr., he gives the species, 1. *saltator*, named from the *Squilla saltatrix* of Klein rather than from *Oniscus locusta* of Pallas, or *Cancer locusta*, Linné; 2. *Beauforti*, M.-Edw.; 3. *brevicornis*, n. s., from New Zealand; 4. *platycheles*, Guérin; 5. "*Cloquetii*," (Audouin), Savigny."

Under *Orchestia*, Leach, "§ 1. Espèces dont les pattes de la sixième paire sont à peu près de même grandeur que celles de la septième, ou un peu plus petites," he includes the species, 1. *littorea*, Leach, with references to Baster, Herbst, Montagu, &c., and the observation that *Oniscus gammarellus* of Pallas and *Oniscus stroemianus* of Otto Fabreius and *Talitrus gryllus* of Bosc, all seem to belong to this division of the genus *Orchestia*; 2. "*Montagui*," Audouin; 3. "*Bottae*," n. s., "espèce très voisine de l'*Orchestia sauteuse*, mais dont les pattes de la septième paire sont étroites et de même forme que celles de la paire précédente. Habite la mer Rouge," where as Sp. Bate suggests, he has probably written *sauteuse* by mistake for *littorella* or *littorea*. 4. "*Deshayesii*," Audouin; 5. *longicornis*, Say's *Talitrus longicornis*; 6. "*Chilensis*," n. s., which Dana and Spence Bate call *Chilensis*; 7. "*Quoyana*," M.-Edw., called *Talorchestia Quoyana* by Dana and Spence Bate.

"§ 2. Espèces dont les pattes de la sixième paire sont beaucoup plus grandes que celles de la septième paire" has the species 8. "*Fischerii*," M.-Edw., figured pl. 29. fig. 4.

In the genus *LYSIANASSA* he places the species, 1. "*Costæ*," M.-Edw.; 2. *lagena*, answering to "*Lysianassa lagena* vel *Anonyx lagena*, Kröyer;" 3. "*Vahlii*," Kröyer's *Anonyx Vahlii*;

4. *appendiculata*, answering to “*Lysianassa appendiculata vel Anonyx appendiculatus*, Kröyer;” 5. *atlantica*, for his own *Gammarus atlanticus*; with the concluding observation that *Cancer ampulla*, Phipps, and the imperfectly known *Cancer nugax*, Phipps, appear also to belong to this genus.

He forms the new genus *Alibrotus* with the one species “*Chauseicus*,” to receive *Lysianassa chauseica*, Milne-Edwards, and defines it thus:—“Les Alibrotes, que nous avions d’abord réunies aux Lysianasses, s’en distinguent par la longueur considérable des antennes et la forme grêle de celles de la première paire, qui ressemblent tout-à-fait à celles des Crevettes, et par la conformation des pates des deux premières paires qui sont grandes, fortes et propres à la marche et à fourir; elles ont à peu près la même forme et se terminent par un grand article plat et allongé, dont le sommet est arqué d’un ongle gros, conique, et à peine flexible. Du reste, ces animaux ne diffèrent pas notablement des Crevettes.” To this genus Spence Bate in the Brit. Mus. Catal., p. 86, adds “*Anonyx littoralis*, Kröyer, Voy. en Scand. pl. 13. f. 1.,” but without reference to Kröyer’s own account of it, Nat. Tidssk. 2. R. 1. B. 1844, pp. 621–629, which describes the first joint of the upper antennæ as of the thickness usual in the genus *Anonyx*, and the second gnathopod as nearly filiform. Boeck includes *Anonyx littoralis*, Kröyer, and two other species in a new genus *Onesimus*, to which he appends *Alibrotus* as a doubtful synonym.

Milne-Edwards next gives *Pilius*, Guérin, with its one species, *serratus*, Guérin. *Acanthonotus*, “Owen et J. C. Ross,” receives the species (1) *cristatus*, Owen; (2) *Nordmannii*, n. s., thus described:—“Front dépourvu de rostre, mais formant au-dessus de la base des antennes inférieures, une grande protubérance qui loge les yeux, et qui porte à son extrémité les antennes supérieures (à peu près comme chez les Ischyrocères). Antennes très-grêles et assez longues; le pédoncule de celles de la paire [supérieure] très-court, et le filet terminal long, mais ne dépassant que de peu le pédoncule des antennes inférieures. Thorax et abdomen arrondis et sans dents ni épines en dessous. Pièces épimériennes des quatre premiers anneaux extrêmement grandes. Pates de la première paire ayant leur pénultième article élargi en dessous, près de sa base, et la griffe assez longue, de façon à ressembler à une petite main très-imparfaite. Pates de la seconde paire filiformes et sans trace d’une main préhensile. Pates de la troisième et de la quatrième paire ayant leur troisième article très-grand, et élargi, les deux suivants très-petits et le dernier très-long, mais grêle et styliforme. Pates des trois dernières paires courtes, mais ayant leur premier article très-grand et presque aussi large que long. Fausses pates de la dernière paire beaucoup plus saillantes que celles des deux paires précédentes, et pourvues de deux lames lancéolées de même longueur. Abdomen terminé par deux lames sublancéolées dont le bord interne est droit. Longueur environ 5 lignes. Habite les côtes de la Crimée.” This species appears to be still unidentified. It does not appear among the Mediterranean species in the recent work by Victor Carus. In the Brit. Mus. Catal., Spence Bate re-names it *Protomediea nordmannii*. Kröyer, Nat. Tidssk., 4 Bd. 1842, p. 161. n., had already expressed his belief that the species could not be retained in the genus *Acanthonotus*, but without proposing to place it in the genus *Protomediea*, which he had just instituted, loc. cit., p. 154, and since to that genus he assigns “Epimera sat brevia,” while to *Acanthonotus nordmannii* Milne-Edwards assigns “Pièces épimériennes des quatre premiers anneaux extrêmement grandes,” the union of this species to that genus is hardly likely to stand. The difficulty of such union is augmented by the statement in Boeck, De Skand. og Arkt. Amph. p. 576, that “Pedes secundi paris parvi, manu non instructi subcheliformi” in Kröyer’s generic definition is a slip of the pen for “Pedes primi paris.” Milne-Edwards considers rightly that *Amphitoe serra*, Kröyer, ought to be placed in the genus *Acanthonotus*, and wrongly that *Oniscus cicada* of Otho Fabricius is probably the same species; he thinks further that *Gammarus spinosus*, Montagu, the type of Leach’s

genus *Dexamine*, may well also be an *Acanthonotus*, but that further information is needed about it.

After describing the genus *Isxa* with its type species, *Isxa montagui*, Milne-Edwards, which is figured pl. 29, fig. 11, he passes to *Anisopus*, with its single species *dubius*, Templeton, for which see Note on Templeton, 1836.

Accepting the distinction of *Amphitoë* from *Gammarus* as convenient and in general use, though depending only on the absence of the accessory flagellum from the upper antennæ of the former, Milne-Edwards unites under this name the "Amphitoë," *Pherusa* and *Dexamine* of Leach. On the other hand he divides and subdivides his own *Amphitoë* as follows:—

"§ 1. Espèces dont le dos est arrondi et dépourvu de grandes dents médianes.

"A. Thorax et abdomen dépourvus d'épines.

"a. Antennes supérieures au moins aussi longues que les antennes inférieures," with the species 1. *Jurinii*, M.-Edw.; figured pl. 1. fig. 2.; 2. *leviuseula*, Kröyer; 3. *Pausilipi*, M.-Edw.; 4. *indica*, M.-Edw.; 5. *picta*, Rathke; 6. *Gaudichaudii*, n. s., from Brazil, in which he emphasizes the peculiarity "Handle des pates de la troisième et quatrième paire ovalaire (au lieu d'être presque linéaire comme d'ordinaire);"; 7. *Filosa*, Savigny, from which he thinks that "l'Amphitoë de Ramond, and l'Amphitoë des varecs," as he names *Pherusa fueicola*, Leach, scarcely differ. He gives notes on *Gammarus obtusatus*, Montagu, for which he had already proposed the name *Amphitoë obtusata*; on l'Amphitoë rouge, that is, the *Gammarus rubricatus* of Montagn, or *Amphitoë rubricata* of Leach; and lastly on l'Amphitoë dentelé, Say's fresh-water *Amphitoë dentata*.

"aa. Antennes supérieures moins longues que les inférieures.

"aa*. Mains des deux premières paires à peu près de même grandeur," with the species, "8. *Crenulata*," Kröyer; 9. *inermis*, Kröyer, to which he appends a note, "Oniscus cicada? Oth. Fabricius, Fauna Groenl. p. 258,"; 10. "Armoriea," M.-Edw.; 11. "Reynaudii," M.-Edw.; 12. "Swammerdamii," M.-Edw.; 13. *punctata*, Say.

"aa**. Mains des pates de la seconde paire plus de deux fois aussi grosses que celles des pates antérieures," with the species 14. "Prevostii," M.-Edw.; 15. *pelagica*, M.-Edw.; 16. "Gaimardii," n. s., which Dana transferred to *Allorchestes Gaimardii?*, and for which Spence Bate adopts the name *Allorchestes Gaimardii*, making *Allorchestes compressa*, Dana, a synonym of it; 17. *pontica*, with *Hyale pontica*, Rathke, for a synonym.

"AA. Côtés du thorax ou le dessus de l'abdomen, garnis d'épines ou de petites dents.

"AA*. Des épines sur les flans."

18. *eancella*, the *Oniscus eaneellus* of Pallas.

"AA**. Flans dépourvus d'épines."

19. *bicuspidis*, Kröyer; 20. *podura*, Müller's *Gammarus podurus*; 21. "Fresnelii, Audouin."

"§ 2. Espèces dont le dos est plus ou moins caréné en dessus et armé vers sa partie postérieure de grandes dents médianes comprimées et dirigées en arrière.

"B. Front dépourvu de rostre."

22. *costata*. M.-Edw.; 23. *lystrix*, the *Acanthosoma lystrix* of Owen; 24. *Marionis*, M.-Edw.; 25. "Panopla," Kröyer; 26. "Carinata," Kröyer, followed by the concluding observation that Say's *Amphitoë serrata* "a le dos dentelé comme les espèces précédentes, mais paraît s'en distinguer par l'existence de trois épingles saillantes situées à égale distance l'une de l'autre sur le bord inférieur de chacune des mains."

CREVETTE. *Gammarus*, Fabricius, is thus subdivided:—

"§ 1. Espèces dont les yeux sont ovalaires, réniformes ou linéaires.

"A. Bord postérieur des trois premiers segments de l'abdomen droit et ne se prolongeant pas de manière à former une grosse épine ou dent médiane.

"a. Des épines sur la portion dorsale du quatrième et du cinquième anneaux abdominaux," with the species, 1. *locusta*, referred to *Oniscus puler?* O. Fabr., *Caneer Gammarus locusta*,

Montagu, etc.; 2. *fluvialis*, Roesel, which does not agree with the character "A"; 3. *fasciatus* Say, with which he identifies Say's *Gammarus minus* giving the specific name as *minimus*; 4. *marinus*, Leach; 5. *Olivii*, M.-Edw.; 6. *affinis*, a new species, which "ressemble presqu'en tout à la Crevette d'Olivii, mais s'en distingue parce que les mains de la première paire, au lieu d'être un peu plus petites que celles de la seconde paire, sont beaucoup plus grosses," and which Spence Bate unites along with *Gammarus olivii* to *Gammarus marinus*, Leach; 7. *pungens*, n. s. from "les eaux thermales du mont Cassini en Italie"; 8. *Ornatus*, M.-Edw.; 9. *Peloponesius*, Guérin; 10. *campylops*, Leach.

"au. Point d'épines sur la portion postérieure de l'abdomen." 11. *pulex*, Geoffroy (text, not figure), etc., a species, as Bate and Westwood point out, not agreeing with the character "aa," any more than *fluvialis* agrees with the character "A"; 12. "*Ermanni*," n.s., figured in the Brit. Mus. Catal., pl. xxxii. fig. 7, as "*Crangonyx Ermanni*"; 13. "*Impostii*," M.-Edw.; 14. "*Othonis*," M.-Edw.; 15. *pinguis*, Kröyer.

"AA. Bord postérieur du troisième anneau de l'abdomen, et en général celui des deux anneaux précédents se prolongeant en arrière de manière à former sur la ligne médiane une grosse dent."

This section includes the species "16. *Sabinii*," Leach; 17. *mucronatus*, Say; 18. *appendiculatus*, Say.

"§ 2. Espèces dont les yeux sont circulaires.

"B. Griffe des secondes pates s'infléchissant sur le bord de la main et non sur sa face interne," with the species;—

19. *loricatus*, Sabine; 20. "*Savii*," M.-Edw., with the notice appended in regard to *Gammarus mutilus*, Müller, Zool. Dan., vol. 3. p. 60. tab. 116, figs. 1-11, that "La CREVETTE TRONQUÉE de Müller ressemble assez à l'espèce précédente, mais s'en éloigne par la grandeur du filet accessoire des antennes supérieures qui paraît être aussi long que leur péduncule, par le peu de largeur du premier article des pates postérieures, et par la grandeur des lames terminales des appendices abdominaux de la sixième paire.;" 21. *podager*, M.-Edw.; 22. *brevicaudatus*, M.-Edw.; followed by the remark that "si le *Gammarus grossimanus* de Montagn était pourvu d'un appendice sétacé accessoire aux antennes supérieures, c'est près de notre Crevette brevicandale qu'il devait prendre place; mais, dans le cas contraire, il rentrerait dans le genre *Amphitoë*."

"B.B. Griffe des secondes pates s'infléchissant sur la face interne de la main," containing only the species, 23. "*Dugesii*," M.-Edw., with the note, "cette espèce présente tous les caractères assignés par M. Leach à son genre *MELITE*," and followed by the well-grounded suspicion that *Gammarus palmatus*, Montagu, may be the same species.

Ischyrocerus, Kröyer, has the one species, *anguipes*, Kröyer.

Leucothoe, Leach, has only the species *furius*, Savigny, but the description of this is followed by the observation that "le *Gammarus articulosus* de Montagu, d'après lequel Leach a établi le genre Lencotheoé ressemble beaucoup à l'espèce précédente, mais est trop mal connu pour que nous puissions y assigner des caractères; Leach dit à la vérité que les antennes ne sont formées que de trois articles, ce qui le ferait distinguer facilement, mais il me paraît peu probable que cette observation soit exacte."

In the "Tribu des Crevettines marcheuses," with slender, semi-cylindrical bodies, not laterally compressed, with narrow side-plates, lower antennæ generally pediform, the palps of the maxillipeds little developed, and the pleon not formed for leaping, he places *Eriethonius*, M.-Edw., with the one species *diformis*, M.-Edw., and the remark that, "le *Gammarus spinicarpus* de Müller se rapproche beaucoup des Eriethonies, mais devra probablement constituer un genre particulier."; *Cerapus*, Say, with the species 1. *tubularis*, Say; 2. *pelagicus*, Leach, to comprise *Cancer falcatus*, Montagu, and *Jassa pelagica*, Leach. The new genus *Ceropodina* is thus explained;—"Nons rangerons sous ce nom générique

un petit Crustacé qui a été décrit dernièrement par M. Templeton, et qui ressemble beaucoup aux Cérapodes, tant par son organisation que par ses moëns, mais qui s'en distingue par la conformation des antennes, dont les deux paires se terminent par un filet multi-articulé. Il est aussi à noter que la tête est ici confondue avec le premier anneau du thorax, et que les quatrième, cinquième et sixième anneaux paraissent être dépourvus de pates." The single species is *Cerapodina abilita*, the *Cerapus abditus* of Templeton, which must retain its name, the new genuis being only founded on obvious errors in Templeton's description.

The next genus given is *Podocerus*, Leach, with the species, 1. *variegatus*, Leach; 2. *pulchellus*, Leach; followed by an observation on the *Podocerus cylindricus* of Say. The genus *Corophium*, Latreille, receives the species, 1. *longicornis*, with the usual synonymy; 2. " *Bonnelli*," M.-Edw. *Atylus*, Leach, has the one species *carinatus*, for the *Gammarus carinatus* of Fabricius. *Unciola*, Say, has the single species, *irrorata*, Say.

The Famille des Hypérines is divided into three tribes. The first, the Tribu des Hypérines gammaroides "characterised by the smallness of the head and the compressed form of the body," includes a single genns, *Vibilia*, M.-Edw., with *Dactylocère*, Latreille, for a synonym, and with one species, *Peronii*, M.-Edw., Pl. 30, fig. 1.

In the second division, the Tribu des Hypérines ordinaires, "le corps est large et renflé; la tête est très-grosse; les antennes de la première paire sont subnlées et pointues; enfin celles de la seconde paire sont styliformes et ne peuvent pas se replier sur elles-mêmes comme chez les Typhis, etc." The genera and speeies included are as follows:—*Hyperia*, Latreille, identified with *Cancer*? Montagu, *Lanceola*, Say, *Hiella*, Straus, and containing the species, 1. " *Latreillii*," M.-Edw., pl. 30, fig. 16; 2. *oblivia*, Kröyer; 3. *Gaudichaudii*, n. s., from Chili, redescribed in the Brit. Mus. Catal., p. 289, and figured as " *Lestrigonus Gaudichaudii*," with the remark that "it closely resembles *L. exulans*, but may be at once recognized by the distinct armature on the propoda of the gnathopoda." After the numbered species of *Hyperia*, Milne-Edwards observes that " *Hyperia Lesueurii*," Latr., seems to differ from the two preceding species by having two little triangular horizontal plates, instead of the single plate at the distal end of the abdomen; that Say's *Lanceola pelagica* agrees essentially with *Hyperia*, but is distinguished from the other species by having the sixth pair of legs much longer than the rest; and lastly, that *Gammarus galba* of Montagu probably belongs to this genus. *Metoecus*, Kröyer, has the one species, " *Medusarum*," O. Fabr., followed by the remarks on *Talitrus cyaneæ*, Sabine, already qnoted in note on Sabine, 1821. *Phoreus*, M.-Edw., has its one species, formerly spelled *Reynaudii*, but here *Raynaudii*, M.-Edw.

Tyro is a new genus instituted to receive *Hyperia cornigera*, M.-Edw., and is thus explained:—"Dans cette petite division générique, la forme générale du corps est la même que chez les Hypéries si ce n'est que la tête est tronquée antérieurement. Les antennes inférieures sont extrêmement petites comme dans les genres précédens, mais celles de la première paire sont plus longues que le corps, et composées de deux articles dont un basilaire très-court, et l'autre terminal styliforme, gros et excessivement long. Aucune des pates n'est préhensile, mais leur longueur est très-inégale; celles de la cinquième paire sont beaucoup plus longues que les autres, et quoique assez fortes, ont leurs deux derniers articles filiformes; les pates de la septième paire sont très-petites et si grêles qu'elles ne paraissent pas être propres à la locomotion. Quant à l'abdomen, sa conformation est semblable à celle des Hypéries, si ce n'est que les fausses pates des trois dernières paires sont très-grêles, et ne présentent pas à leur extrémité deux lames distinctes." It has been pointed out by Bovallins, 1886, that this genus anticipates *Clydonia*, Dana.

Primno, Gnérin, is given with the species *macropa*, Guérin. *Lestrigonus*, M.-Edw., has the species " *Fabreii*," M.-Edw., figured pl. 30, fig. 18., the description being followed by the remark that *Lestrigonus exulans* of Kröyer seems to be intermediate between the preceding

species and the Hyperiæ. *Daira*, M.-Edw., has the species “*Gabertii*,” M.-Edw. *Themisto*, Guérin, has the species, 1. “*Gaudichaudi*,” Guériu; 2. *arctica*, Kröyer, including *Themisto Gaudichaudii* of Ross and Owen, both being synonyms of *libellula*, Mandt; 3. *crassicornis*, Kröyer, another synonym of *libellula*. *Anchylomera*, M.-Edw., has the species, 1. “*Blossevillei*,” 2. “*Hunterii*,” M.-Edw., figured pl. 30. fig. 4, the description being followed by the remark that *Hieraconyx* of Guérin “ne nous paraît pas différer notablement de nos Anchylomères,” &c., a view accepted by Spence Bate, who gives Guérin’s species as *Anchylomera abbreviata*.

Phrosina of Risso, not Latreille, with *Dactylocera*, Latreille, for a synonym, is next described.

A note says, “dans l’espèce que j’ai examinée il n’existe aucun vestige d’appendice palpi-forme inséré aux mandibules; mais dans la figure que M. Costa a donnée de ce genre, on voit de chaque côté de la bouche un petit appendice sétacé qui paraîtrait être un palpe mandibulaire, et qui est considéré par ce naturaliste comme une seconde paire d’antennes; il serait possible que ces appendices ne fussent autre chose que les pièces terminales des pâtes-mâchoires devenues plus saillantes que d’ordinaire.” To this genus is assigned the species “*Plrosina Nicetensis*,” M.-Edw., previously called *Dactylocera Nicetensis*, the description being followed by the remark that “La PHROSINE SEMI-LUNAIRE, à en juger par la figure très-détaillée qu’en a donnée M. Costa, diffère de l’espèce précédente par l’absence d’une grosse dent à l’angle antéro-inférieur du penultième article des pates antérieures, par la forme plus acuminée des lames natatoires que représentent les trois dernières paires de fausses pates, et par quelques autres caractères.” In the synonymy of the species he gives “*Pisitoë bispinosa*? Raffinesque,—*Phrosine semilunata*? Risso,—Desmarest, Consid. p. 259.—Costa, Fauna, Crust. pl. iv. fig. 1–5.

To *Phronima*, Latreille, he assigns the species, 1. *sedentaria*, Forskal; 2. “*Atlantica*, Guérin, and adds, in regard to *Phronima custos*, Risso, that it is probably the same, although in the figure, given by Risso and copied by Desmarest, the third segment of the abdomen, probably by error of the draughtsman, is without false feet. He thinks that if Rafinesque’s *Sperchius* were better known, it would perhaps come near to *Phronima*.

The Tribu des Hypérines anormales is characterized by “un mode de conformation des antennes inférieures qui est très-remarquable; ces organes, au lieu d’avoir la forme d’une tige cylindracée ou d’un stylet peu flexible, et de faire saillie au-devant de la tête, s’insèrent à la face inférieure de celle-ci, sur les côtés de la bouche, et se replient trois ou quatre fois sur eux-mêmes en zigzag.” “Voyez Pl. 30, fig. 10.”

To this tribe he assigns the following genera and species:—

Typhis, Risso, with the species, 1. *ferus*, M.-Edw.; 2. *rapax*, M.-Edw.; 3. *ovoides*, Risso. He also says “le genre ORIONE de M. Cocco ne paraît pas différer de celui dont nous faisons ici l’histoire; mais les figures qu’il en a données sont trop grossières pour que nous puissions assigner des caractères aux espèces dont il fait mention.” He thinks further that the *Cancer gammarus monoculoides* of Montagu ought probably to be referred to *Typhis*, but this is now known to be an erroneous supposition.

Pronoe, Guérin, has the single species, *capito*, Guérin.

Oxycephalus, M.-Edw., has the species, 1. *piscator*, M.-Edw., figured Pl. 30. fig. 10; 2. *oceanicus*, Guérin; 3. *armatus*, n. s., “Tête aussi longue que tout le reste du corps, terminée par un rostre styliforme très-long, renflée au milieu dans le point occupé par les yeux, puis rétrécie dans une étendue assez considérable, et renflée de nouveau à son extrémité postérieure, où se trouve la bouche. Antennes de la première-paire très-petites et terminées par une lamelle ovalaire; celles de la seconde paire extrêmement longues et grêles. Pates des deux premières paires extrêmement petites; le premier article de celles des cinquième et sixième paires étroit et semblable à celui des pates précédentes. Les pates de la septième paire paraissent manquer complètement, mais il existe, au point où elles devraient s’insérer, une

lamelle membraneuse semblable à celle fixée près de la base des pates précédentes. Portion postérieure de l'abdomen très-étroite ; le sixième segment, cylindrique, et terminé par un stylet impair aussi long que le corps. Les fausses pates des trois dernières paires très-grêles, très-longues, et terminées chacune par deux stylets. Longueur, environ 1 pouce." This under the name *Rhablosoma armatum* became the type of the new genus *Rhablosoma*, Adams and White, 1848.

The Ordre des Lœmodipodes or Lœmipodes is still described as being without mandibular palp. It is divided as usual into two families. The Famille des Caprelliens, or Lœmodipodes filiformes, contains the following genera and species :—*Caprella*, Lamarck, with the species, 1. *linearis*, answering to " *Cancer linearis?* Lin. Syst. nat." etc.; 2. *acuminifera*, Leach, pl. 33, fig. 1, including *Puce de mer arpenteuse*, Queronic; 3. *saura*, Templeton; 4. *nodosa*, Templeton; 5. *acutifrons*, for which inaccurately Desmarest is given as the authority, and *Caprella atomos*, Leach, as a synonym; 6. *phasma*, Montagu; the description of which is followed by the remarks that *Caprella tuberculata*, Guérin, Iconogr. Crust. Pl. 28, fig. 1, resembles the preceding species by the existence of a cephalic horn, but is distinguished by having a great number of blunt tubercles all along the back, and by the form of the legs of the three last pairs, of which the penultimate joint is widened and armed with a large tooth on its inner edge; " *Caprella mantis*, Latreille, Nouv. Dict. d'Hist. nat." he says, is very imperfectly known; *Cancer filiformis*, Linn., Amoen. Acad. t. 6, p. 415, et syst. nat. t. 1, pars 5, p. 2993, probably, he thinks, belongs to this genus.

" *Naupridia*," Latreille, with no described species.

Leptomera, Latreille, with the species, 1. *pedata*, Müller, and 2. *ventricosa*, Müller, which are, as Milne-Edwards suspected, the male and female of the same species properly called *Proto ventricosa*. That *Proto*, Leach, is the same as *Leptomera* is recognised by Milne-Edwards, though he does not give *Proto* its rightful precedence.

In the Famille des Lœmodipodes ovalaires ou Cyamiens he places the single genus *Cyamus*, giving Lamarck, instead of Latreille, as the earliest authority for the name. The species he recognises are, 1. *erraticus*, Roussel de Vauzème, in the synonymy of which he erroneously groups together the various names applied to species of *Cyamus* in writings earlier than R. de Vauzème's treatise; 2. *ovalis*, R. de V.; 3. *gracilis*, R. de V., with the concluding observation that " le *Cyamus Delphini* de M. Guérin (Iconographie, Crust. Pl. 28, fig. 5) paraît différer des espèces précédentes par la brièveté des appendices branchiaux, et par la manière dont les divers anneaux du thorax se touchent latéralement."

184.—MILNE-EDWARDS (Editor).

Les Crustacés. Le Règne Animal distribué d'après son organisation, pour servir de base à l'histoire naturelle des animaux, et d'introduction à l'anatomie comparée par Georges Cuvier. *Edition* accompagnée de planches gravées, . . . par une réunion de disciples de Cuvier. Paris, Fortin, Masson et C°, Libraires, successeurs de Croehard. (No date is given in the work itself; I understand from Mr. G. K. Fortescue of the British Museum that it appeared in *livraisons* between 1836 and 1849; it is sometimes called the Croehard Edition, or the Illustrated Edition.)

Pages 165–188 refer to the Amphipoda.

The Amphipoda, pls. 58 to 61, include under "des Crevettes (*Gammarus*, Fab.)," *Phronima*, Latr.; *Hyperia*, Latr.; *Phrosine*, Risso; *Dactylocera*, Latr.; *Ione*, ("mais uniquement d'après une figure de Montagu, *Oniscus thoracicus*, Trans. linn. soc. ix. iii., 3, 4"); *Orchestia*,

Leach; *Talitrus*, Latr.; *Atylus*, Leach; *Gammarus*, Latr.; *Melita*, Leach; *Mara*, Leach; *Ampithoe*, Leach; *Pherusa*, Leach; *Dexamine*, Leach; *Leucothoe*, Leach; *Cerapus*, Say; *Podocerus*, Leach; *Jassa*, Leach; *Corophium*, Latr.; *Pterygocera*, Latr.; *Apseudes*, Leach, (*Eupheus*, Risso); *Typhis*, Risso; *Anceus*, Risso, (*Gnathia*, Leach); *Praniza*, Leach. These form the third order. The fourth order, Læmodipoda, pl. 63, includes under "De Cyame (*Cyamus*, Latr.)" *Leptomera*, Latr. (*Proto*, Leach); *Naupredia*, Latr.; *Caprella*, Lamck.; and for "des cyames proprement dits," *Cyamus*, Latr., (*Larunda*, Leach).

The only part of this work which is of any independent value as regards the Amphipoda is the group of fine plates.

As to "*Dactylocera Nicaxnis*, Edw.," pl. 58, fig. 2, the editor says, "Cette espèce ne me paraît pas différer de celle désignée par M. Risso sous le nom de *Phrosina semilunata*, et citée par M. Latreille comme type de son genre Dactylocère; cependant elle ne présente pas les caractères assignés par notre auteur à ce même genre."

On "*Jone thoracicus*, Latr." pl. 59, fig. 1, he says, "il suffit de comparer ces figures d'une part avec celles des Talitres et des autres Amphipodes proprement dites, et de l'autre part avec celles des Cymothoés, etc. (Pl. 65), pour se convaincre que ce n'est pas ici la place naturelle du genre *Jone*; dans la classification adoptée dans mon Histoire Naturelle des Crustacés, ces parasites sont rangés dans une division particulière de l'ordre des Isopodes à la suite des Cymothoadiens."

Bate and Westwood, i. p. 19. n., consider that the representation of *Talitrus saltator*, Edw., pl. 59, fig. 2.a., has in reality been taken from *Talitrus Beaucoudraii*, Edw.

The mandible of *Orchestia littorea*, pl. 59, fig. 2.d., seems to show a rudiment of a palp, but unjointed.

"*Orchestia Quoyiana*," Edw., pl. 59, fig. 4, is clearly depicted.

"*Gammarus Dugesii*," Edw., pl. 60, fig. 3, has the remark, "Cette espèce offre un exemple de la forme des mains de la deuxième paire, qui est caractéristique du genre *Melita* de Leach. Genre qui ne paraît pas devoir être adopté." It is in fact a synonym of *Melita palmata*, Montagu, the type-species of Leach's genus.

"Pl. 60. Fig. 4. *Gammarus brevicaudatus*, Edw. Individu mâle. Ici la main de la deuxième paire offre les particularités de forme propres au genre *Mara* de Leach. "Fig. 4. a. Patte de la seconde paire chez la femelle, conformée de la même manière que chez les Crevettes ordinaires." These are the two sexes of *Gammarella brevicaudata*. Ou fig. 5. *Melita palmata*, Leach, he says, "Ce genre, comme nous venons de le dire, ne paraît pas être admissible." Fig. 6. "*Amphithoe Marionis*," Edw., is identified by Spence Bate with *Dexamine spinosa*, Montagu.

Pl. 61. fig. 4, "*Podocerus variegatus*, Leach," "d'après l'individu décrit par Leach et conservé dans le Muséum Britannique," has the last peræon-segment and the first of the pleon dorsally produced backwards in a very marked tooth-like process.

Pl. 62 bis, is devoted to *Typhis ovoides*, Risso, and *Typhis ferus*, Edw.; pl. 63 to *Caprella linearis*, *Leptomera ventricosa*, and to *Cyamus ovalis*, Roussel de Vauzème.

1841. DELLE CHIAJE.

Deserizione e notomia degli animali invertebrati della Sicilia citeriore. Napoli, 1841. 5 vols. folio.

Bate and Westwood, ii. p. 27, refer to plate xxiii. of this work as containing a figure of *Doliolum papillosum*, Delle Chiaje, with *Pluronima sedentaria* inside it. Claus, 1862, makes a similar reference. Bate and Westwood, *loc. cit.*, also refer to Otto, "Nova Acta," xi. p. 313, and Otto is referred to by Claus likewise.

1841. EICHWALD, EDUARD VON, born July 4, 1795 (Hagen).

Fauna Caspio- caucasia nonnullis observationibus novis illustravit Eduardus Eichwald. Cum Tabul. lithograph. XL. Petropoli, MDCCCXLI.

At page 225, under "Crustata," he says, "Inter caspii maris et nigri incolas e *Crustatorum* classe similis quoque ac inter Pisces intercedit differentia; in hoc scilicet propter maris communionem eum mediterraneo alia deprehenduntur genera aliæque prorsus species, quam in illo; sic ad Ponti incolas pertinent inter alia complura *Pagurus Diogenes Riss.*, *Pisidia longicornis Leach.*, *Xantho rivulosus Riss.*, . . . aliique; porro *Orchestia littorea Leach*, *Gammarus locusta Leach*. aliique, *Anthiae* dein et *Hyalæ*, duo Amphipodum genera nova, *Amphithoæ*, *Ilothex* . . . multaque alia, a cel. Rathke fusius descripta et a caspio mari plane aliena; alia denique in utroque mari offenduntur, quibus potissimum *Astaci* pertinent." For the "duo Amphipodum genera nova," he refers to Rathke, *zur Fauna der Krym*, 1837, so that for *Anthiae* we should probably read *Amathia*. His own descriptions of Amphipoda are as follows:—

"GAMMARUS CASPIUS PALL. Reise durch Russland I. Petersb. 1801, pag. 477.

"Seguenta eaudalia in dorso mueronata, postrema duo stylo dorsali mutico notata et appendice utrinque cylindracea bifurea, interjecto insuper medio foliolo linearis, primi paris pedibus minutis, secundo et tertio cheliferis, reliquis retrorsum versis.

"Hab. in caspio mari, ad ostium Rhymni una cum *Gammaro pulice Fabr.*, ad insequentem fortasse speciem referendo.

"GAMMARUS HÆMOBAPHE M. Tab. xxxvii. Fig. 7. a. b. c.

"E fusco- viridis, segmentorum singulorum postero margine extreuo lateraliter purpureo- sanguineo.

"Hab. in mari nigro; in caspio adesse quoque videtur.

"Corpus vix 4 lin. longum; antennæ ac pedibus omnibus et appendicibus caudalibus ciliatis.

"Inter antennas capiti parvo infixas mucro compressus nullus, quo itaque recedit a *Gam. cancello* Pall., (Spieleg. Zoolog. Fase. IX. Berol. 1772 Tab. III. fig. 18.) cui in ceteris quoad antennas simillimus; priores tres articuli (pedunculus) superiorum antennarum *G. hæmobaphis* breves, articuli vero flagelli multo minores, minimi, numerosissimi; priores dein articuli duo inferiorum antennarum multo longiores, saltem duplo longiores illis superiorum, at minus numerosi articuli flagelli inferiorum ideoque haec multo breviores superioribus, licet paullulum crassiores iis, non ut in *Gam. locusta* Pall. antennæ superiores multo breviores inferioribus. *Gammarus locusta*, a eel. Rathke descriptus (l. c. 373) fortasse ad hanc pertinet speciem, exceptis tamen antennis, quas superiores parum tantum longiores dicit inferioribus.

"Oculi viridi-nigri, semilunares.

"Squamæ segmentorum pectoralium laterales sive laminæ ab his segmentis dirempæ pedesque contegentes volumine conspicuo notabiles; quarta lamina omnium reliquarum latissima, maxima, post eam tres aliae minimæ, quasi rudimentariae; numerus carum in universum illi pedum respondet, ut itaque septem segmenta pectoralia laminas ibidem laterales adæuctas et a media parte disjunetas monstrant; reliqua abdominalia segmenta genuina simplicia.

"Canda sensim latitudine increscens, postrema duo segmenta exigua aculeis in dorso prædicta ultimumque suum conversa spina apicali. Sub hac caudæ extremæ parte subtus inflexi spurii pedes breviores, apice bifidi versusque anteriora elongati alii.

"Pedes pectorales 7, antici duo tarsis latioribus instructi, tarso secundi pedum paris (l. c. b.) latiore, longiore, quam ille prioris (l. c. a.) subtusque hispido- aculeato; primi quoque paris pedum tarsus hispidus, at minus aculeatus, reliquorum instar; omnesque reliqui tertii instar (l. c. c.) pedes hispiduli; in *Gammarus locusta* duo pedes antici tarsis subæqualiter latis longisque instructi; tales quoque in nostro balthico.

"Carnivorus cancellus retia corredit et forsitan fulgorem maris pontici (an quoque caspii?) nocturnum efficit; constat enim observationibus, *Gammarum locustam* nocturna luce splendere in germanico mari. (v. Desmarest considerations générales sur la classe des Crustacés, Paris 1825 pag. 267)."

Boeck thinks that this *Gammarus hæmobaphes* is much the same as *Gammarus locusta*. Spence Bate does not notice it in the Brit. Mus. Catalogue.

1841. GOULD, AUGUSTUS ADDISON, born April 23, 1805, died Sept. 18, 1866 (Encycl. Brit., 9th Edition).

Report on the invertebrata of Massachusetts, comprising the Mollusca, Crustacea, Annelida, and Radiata. Published agreeably to an order of the Legislature, by the Commissioners on the zoological and botanical survey of the State. Cambridge, 1841.

The Crustacea occupy pages 321–341. At page 333 the account of the "Amphipoda" begins, followed by that of the "Locipoda." The following notes are given:—

"Genus ORCHÉSTIA, Leach. O. LONGICÓRNIS. Tálitrus longicórnis, Say; *Journ. Acad. Nat. Sc.*, i. 384. This appears to be the same as *Cancer gámmarus saltator* of Montagu (*Trans. Lin. Soc.*, ix. 94, tab. 4, f. 3,) which is given as synonymous with *Tálitrus locústa* of Lamarck, Pennant, and others. But it is not *Gámmarus locústa* of Montagu.

"O. GRYLLUS. Tálitrus gryllus, Bosc; *Hist. Nat. des Crust.*, ii. 104. Say; *Journ. Acad. Nat. Sc.*, i. 386. The following seem to be synonyms, viz. Tálitrus gamaréllus, Latr. and Lam. Orchéstia littoræa, Leach; *Trans. Lin. Soc.*, xi. 356. Desm.; *Consid.*, &c., 261, pl. 45, f. 3.

"Genus GAMMARUS. G. LOCÚSTA, Montagn; *Lin. Trans.*, ix. pl. 4, f. 1. Milne-Edw.; *Ann. des Sc. Nat.*, xx. 367. This is not *G. locústa* of Pennant, Gmelin, Pallas and Fabricius, which is a *Tálitrus*.

"G. MINUS, Say; *Journ. Acad. Nat. Sc.*, i. 576. Found in ditches and sluggish fresh water, adhering to sticks.

"Two or three other species of ORCHÉSTIA, and one of AMPHÍTHÖE, remain undetermined.

"Genus HYPÉRIA, Latr. H. GALBA. Gámmarus Galba, Montagn; *Lin. Trans.*, xi. pl. 2, f. 2. The following are doubtless synonyms: *Oniscus medusarum*, O. Fabr.; *Fauna Grænl.*, 275. Hypèria Sueurii, Latr. Hypèria Latréillii, Milne-Edw.; *Ann. des Sc. Nat.*, xx. 388, pl. 11, f. 1–7. This curious animal is found in the ponches of the Medusæ or Sun-fish as they are commonly called. Whether they make this their home, or whether they become entrapped there or not, it would be difficult to determine. They seem, however, to be quite at their ease in this situation.

"Another animal with long, many-jointed antennæ, was found in company with the above, which belongs either to the same genus, or to the genus HIERACONYX.

"LOEMÍPODA. Genus CYAMUS, Latr. C. CETI, Latr.; Gen., i. 60. Desm.; *Consid.*, 280, pl. 46, f. 4. Edwards; *Ann. des Sc. Nat.*, 2d Series, iii. 328, pl. 64, f. 13, 14. Oniscus ceti, Lin.; Mull. Larúnda ceti, Leach. The whale-louse may be properly enumerated among our Crustacea, as it is found on the whales which are occasionally caught on our coast. It varies in form, according to its degree of development.

"Genus CAPRÉLLA, Lam. I have observed two species of this curious genus, neither of which can I refer to any described species. One of them is very delicate, about half an inch long, with no spines upon any part, that I can discover, and having its back thickly dotted with dark green.

"The other is an inch in length, entirely crimson except its black eyes. The head is blunt, the lower antennæ ciliated and extending to the second segment, and the upper ones to the third segment; first two segments nearly as long as the three next, and about one-third of the whole length; on the middle of the first is a spine; two last segments short and heart-shaped. Hands having a long curved finger; an imperfect thumb on the second pair of legs; a tubercle at the base of the ovate carpus, and a small spine at the middle. This might be called *C. sanguinea*, from its colour, which it retains in spirit.

"These curious animals are found among clusters of zoophytes and delicate sea-weeds. Their mode of walking is like that of some caterpillars, who bring the tail forward to the head and then thrust the body forward its whole length to prepare for another step."

Mayer, 1882, considers that the descriptions of *Caprella sanguinea* given by Gould and Stimpson leave the species indeterminate.

1841. KOCH, C. L. See Note on Koch, 1835.

1842. GOODSR, HARRY D. S., lost in Sir J. Franklin's Expedition of 1845.

On a New Genus, and on Six New Species of Crustacea, with Observations on the development of the Egg, and on the Metamorphoses of Caligus, Careinus and Pagurus. The Edinburgh New Philosophical Journal. Vol. XXXIII. Edinburgh, 1842. pp. 174-192. Pl. 3.

The pages 363-368 of this volume by the same author, though mentioned in Boeck's list, do not refer to the Amphipoda. Under the title above given, Section IV. is "On the Structure and Habits of the Caprellæ; with descriptions of some new Species."

Goodsir gives a short account of the circulation of the blood in the *Caprellæ*, describes the ovaries, and in regard to the process of exuviation says that the skin "bursts behind the head in a transverse direction, and also down the mesial line of the abdominal surface." He speaks of their being little known, owing "firstly, to their pelagic habitats," and further on says, "they are in general local in their habitats, frequenting coralines which are found in deep water." As a matter of fact, the Caprellidæ have a very extensive distribution, and may be found in great profusion between tide-marks. The species which he describes and figures are:—

Caprella spinosa, of which he says, "this species differs from the *Caprella Plasma* of Colonel Montagu in having five spines on the first thoracic segment, and from the segments being considerably longer. The third joint of the superior antennæ is very much longer, and the first pair of feet are also minute and slender, differing in so far from those of *Plasma*, which are strong and powerful. The inferior edge of the last joint of the second pair of feet is also armed with two strong spines, whereas in *Plasma* there is only one strong spine." It is nevertheless identified by Mayer with *Protella plasma* without hesitation, in accordance with the opinions of Bate and Westwood, and of Boeck.

Caprella tuberculata, the full description of which is followed by the remark, "This species is apt to be confounded with the *Caprella acanthifera* of Leach, but may be distinguished from it by the double fringe of spines on the lower edge of the inferior antennæ; the superior antennæ are also much shorter than those of the *acanthifera*."

Caprella lœvis, of which he says, "this species may be distinguished from *Caprella linearis*, with which it is most apt to be confounded, by its greater comparative size, the structure of the antennæ; by the shortness of the post-occipital segment; the situation of the swelling on the first thoracic segment, which is at the posterior edge, whereas in the *linearis* it is at the

anterior; the femoral joint of the second pair of legs is not clavate in the *linearis*, and is also quite straight."

Caprella linearis, after describing which he says, "this appears to be the *Caprella linearis* of authors; there are some marks of difference, but they are trivial, and not sufficient to authorize any new specific distinctions."

Of these last three species, Mayer remarks, "Goodsir's species *C. laevis* and *C. tuberculata*, were referred by Boeck to *C. linearis* and *C. septentrionalis*, the second was referred by Bate to *C. acanthifera*; I refer them both to *C. linearis*, that is, to *C. lobata*, Kröyer, var. α and var. γ , leaving it on the other hand undecided, whether Goodsir's *C. linearis* has anything in common with the Linnaean species." In a note Mayer observes that Goodsir rightly distinguished his *Caprella tuberculata* from *Caprella acanthifera*, Leach, by the double fringe of spines on the lower edge of the inferior antennae. The name *Caprella tuberculata* was preoccupied by Guérin, whose species is most probably distinct from Goodsir's.

1842. WHITE, ADAM, born April 29, 1817, died 1879. DOUBLEDAY, EDWARD, born Oct. 9, 1810, died Dec. 14, 1849 (Hagen).

GRAY, JOHN EDWARD, (*Editor*), born 1800, died March 7, 1875 (Eneyel. Brit., 9th Edition).

Fauna of New Zealand.

List of the Annulose Animals hitherto recorded as found in New Zealand, with the Descriptions of some New Species by Messrs. Adam White and Edward Double-day, Assistants in the Zoological Department of the British Museum.

In the "Class Crustacea" only 29 species are here included, with only 2 Amphipods, "*Talitrus brevicornis*, M. Edw. Hist. Nat. des Crust. iii. p. 15," and "*Orchestia Quoyana*, M. Edw. iii. p. 19."

1842. GUÉRIN-MÉNEVILLE, F. E.

Description d'un Crustacé amphipode formant un genre nouveau dans la famille des Hypérines. Revue zoologique, par la Société Cuvierienne; association universelle pour l'avancement de la zoologie, de l'anatomie comparée et de la paléontologie; Journal mensuel. Paris, 1842. Juillet, 1842. pp. 214-216.

The giant Amphipod here described is closely allied to one which was among the first prizes of the Challenger dredgings, and which, owing to the comparatively scanty supply of literature available on board, was considered to be of a new genus, receiving the title *Thaumops pellucida*. Guérin says:—

"La famille des Hypérines se compose aujourd'hui de 15 genres, tous formés avec des Crustacés de petite taille. En voici un que l'on peut regarder comme un géant dans sa famille, car il est cinq ou six fois plus grand que les plus grandes espèces connues. Ce genre devra être placé entre nos *Themisto* et les *Daira* de M. Edwards, dans le groupe formé avec les Hypérines qui n'ont qu'une paire d'antennes; voici ses caractères essentiels:

"Genre *CYSTISOMA*.—Deux antennes seulement, composées de trois articles. Pattes des première et seconde paires terminées par une petite pince à doigt mobile un peu plus long que le doigt immobile, terminé par un petit ongle articulé à son extrémité. Les autres pattes allongées, grêles, aplatis; les troisième et quatrième augmentant graduellement de longueur. Pattes des quatrième cinquième et sixième paires munies à leur base d'une large

plaqué respiratoire arrondie et aplatie. Les trois premiers segments de la queue ayant chacun eu dessous une paire de fausses pattes assez grandes, formées d'une tige terminée par deux lames. Quatrième et cinquième segments plus petits, munis chacun, en arrière, d'une paire de fausses pattes allongée, portant au côté externe une petite lame articulée et formant une large nageoire postérieure. Corps très globuleux, vide en dedans comme une vessie, allant ensuite en diminuant jusqu'à l'extrémité postérieure, tête fort grosse et presque entièrement occupée par les yeux."

"Comme on peut le voir par l'exposé de ces caractères, ce genre se distingue des *Daura*, dont il est voisin, par les pattes très-inégales, et des *Themisto* par l'absence des antennes inférieures. On ne peut non plus le confondre avec les *Primno*, car ceux-ci n'ont pas les pattes antérieures terminées en pince.

"*Cystisoma Neptunus*. (Voy. notre pl. I, fig. 1.) Tête et corps vides, gonflés comme une vessie. Tête plus large que le Thorax, ayant de chaque côté et un peu inférieurement une rangée d'épines partant de l'insertion des antennes en avant, et se terminant au bord postérieur près de la bouche : une seconde rangée très courte, formée de petites épines, de chaque côté de la bouche en dessous. Thorax formé de six segments apparents ; le premier et le second réunis, portant les deux premières paires de pattes : segments du thorax offrant au milieu, en dessus, une carène assez aiguë avec deux petites épines, et présentant de chaque côté au premier segment, et au bord postérieur seulement aux autres, une ligne transversale de petits tubercles. Segments abdominaux également carénés au milieu. Pattes armées de petites dents sur leur tranche interne.—Long. 9 cent. (3 pouces 4 lignes), Larg. de la tête, 2 cent. 1/2.—Hab. le grand océan Indien. Ce précieux Crustacé nous a été donné par M. Petit de la Saussaie."

Guérin's species is called *Thaumatops Neptunus* by Bovallius, 1886, but it should in my opinion be named *Cystisoma spinosum*, J. C. Fabr. See Notes on Fabricius, 1775, and Bovallius, 1886.

1842. KRØYER, H. N.

Nye nordiske Slægter og Arter af Amfipodernes Orden, henhørende til Familien *Gammarina*. (Foreløbigt Uddrag af et storre Arbejde). Naturhistorisk Tidsskrift. 4de Binds 2det Hæfte. (Med to Tavler). Kjøbenhavn. 1842. pp. 141–166.

Krøyer, who had himself visited Spitzbergen and the north of Norway, and likewise for a time resided within the tropics, here brings forward arguments against the application to the Amphipoda of the supposed law in zoological geography, that animal life is more vigorously developed progressively from the Poles to the equator. He finds it inapplicable to these Crustacea and some other inhabitants of the sea, whether we regard variety of forms, numbers of individuals, the size they attain, or the brilliance of their colouring. He says, "on a glass bottle, with a little Amphipod, not an inch long, which was sent to the Royal Museum, the sender has written, 'with this Crustacean Godthaab Bay was filled to such an extent on the 11th of July 1841, that in several places it was impossible to see through the water.' The small creatures, which are known to fishermen under the name of *Tanglopper*, and which likewise belong to the Amphipoda, are so numerous off Greenland, that in a single night they can consume the largest seal, so that nothing but the skeleton remains." He then gives Hollboll's often-quoted experience of hauling up masses of this abundant and voracious species of *Anonyx*, by means of bait in an open basket. The Crustacean from Godthaab Bay he names *Themisto arctica*, Kr. Where species are common to Spitzbergen, Greenland and the coast of Norway, he finds that they diminish in size the further south they are found. *Caprella septentrionalis*, he

says, is the largest species of its genus. He further illustrates his point by reference to the considerable size of the northern Amphipods, "Anonyx lagena, Amphitoe Edwardsii, Gammarus Sabini, Gammarus Locusta and above all Gammarus loricatus, of which," he says, "I possess an individual from Spitzbergen, of a length of more than two inches." On the whole, he concludes that the colder seas may be regarded as the true and proper home of the Amphipoda.

He proceeds to define several new genera as follows:—

1. *Opis*:—"Pedes primi paris chelis armati portentosae magnitudinis. Reliqua cum genere *Anonyx* conveniunt." The type species is given as *Opis Eschrichtii* Holbl. The generic name being preoccupied has been changed to *Opisa* by Boeck.
2. *Stegocephalus*:—"Epimera iusignis magnitudinis, loricaem efficiens, sub qua latent membra. Caput maximum, quasi proboscideum, epimeris omnino fere tectum, oculis, ut videtur, destitutum. Antennæ breves (capitis altitudine non longiores); superiores pedunculo crassissimo, flagello appendiculare minimo, uniarticulato; inferiores subpediformes. Mandibulae palpo instructæ brevissimo, crasso, uniarticulato, dentato, parum mobili; pedes maxillares quasi pedunculati; labrum maximum. Pedes primi et secundi paris manibus subheliformibus destituti. Pedes quinti paris pedibus tertii quartique paris structura et directione similes." Spence Bate corrected the error of attributing a palp to the mandibles, as indeed Krøyer had himself done tacitly in the figures of *Stegocephalus inflatus*, in the Voyage en Scandinavie, &c. The type species, *Stegocephalus inflatus*, as also pointed out by Spence Bate, is the same as *Cancer ampulla*, Phipps.
3. *Phoxus*:—"Caput permagnum (quintam ferme longitudinis animalis partem efficiens), triangulare, depresso, antice productum et acuminatum. Antennæ superficie capitis inferiori adfixæ, alterum par anterius, alterum posterius, ntrumque validum, pedunculo crassissimo. Antennæ anteriores perbreves (capite breviores), flagello appendiculari insolite magnitudinis ornatae; pedunculus flagellis longior. Antennæ posteriores parum anterioribus longiores. Mandibulae sat magna, palpo longissimo. Pedes primi et secundi paris manu subheliformi armati valida; pedes tertii quartique paris manu quoque quasi inuniti subheliformi, cuius palmam præbent articulus tertius quartusque juncti, ungues quintus sextusque; sextum pedum par eeteris multo longius. Flagellum pedum fere filiforme. Epimera permagna, margine inferiori setis sat longis instructa. Appendix caudalis laminis constans duabus." For this genus Krøyer says Captain Holbøll had proposed the unsuitable name *Spinifer*, distinguishing two species, *Spinifer spinosissimus* and *Spinifer flagelliformis*, which Krøyer unites in his type species *Phoxus holbølli*. The other new species, given as "*Phoxus plumosus* Holbl," Krøyer afterwards thought should form a new genus, an opinion acted on by Boeck, who, ever ready to make new genera, instituted the genus *Harpina*, a preoccupied name, which he changed into *Harpinia*. J. Sp. Schneider, 1884, calls attention to the fact that in Boeck, 1876, fig. 1 on pl. viii., does not represent *Harpinia plumosa*, though it is so named.
4. *Pontoporeia*:—"Antennæ valide, subpediformes, pedunculo crasso, elongato. Flagellum appendiculare antennarum superiorum perpusillum. Instrumenta cibaria brevia sed lata. Pedes primi et secundi paris perbreves, robusti, illi manu lata instruendi, ungues vero breviore; hi manu carentes, unguesque prædicti rudimentario. Pedes tertii quartique paris longiores, validi, subheliformes, articulo quarto dilatato palmam efficiente, ungues armati conico, aculeato. Pedes quinti et sexti paris recurvi, articulo primo parum modum dilatato, ungues armati pusillo. Pedes septimi paris recurvi, articulo primo permagno, elyptiformi; articulo sexto vel ungues fere rudimentari. Epimera magna, margine inferiore plurimis instructo setis plumosis (epimero excepto septimo). Pedes natatorii sat breves, ceteroquin forma vulgari; pedes saltatorii multis armati aculeis." The type species is *Pontoporeia femorata*, Kr.

5. *Pardalisca* :—“Caput crassiusculum, subtumidum. Epimera exiguae magnitudinis. Antennae pertenues, superiores flagello instructae appendiculari; pedunculus antennarum inferiorum pedunculo superiorum duplo ferme longior. Mandibula apice dilatata, quadridentata, palpo triarticulato. Palpus maxillarum posterioris paris articulo terminali valde dilatato, cordiformi. Pedes maxillares unico instructi laminarum terminalium pari, palpoque quadriarticulato. Pedes primi secundique paris ea sunt conformatioe, ut quartus corum articulus manu efficere videatur, quintus sextusque juncti ungve quodammodo præstent; ita tamen, ut sextus formam monstret ovalem, multisque armatus sit aculeis marginalibus. Pedes tertii quartique paris ungve sublaminari, postice subtiliter serrulato. Pedes reliqui elongati, sat debiles, femoribus subangustis. Pedes spurii priui, secundi et tertii paris natatorii, reliqui saltatorii.” The type species is *Pardalisca cuspidata*, Kr.
6. *Protomedieia* :—“Annuli thoracici latiores quam altiores, dorso subdepresso. Antennae superiores pedunculo elongato (flagello parum breviori) instructæ, flagelloque appendiculari multiarticulato. Antennæ inferiores pediforues, pedunculo longissime-, flagellum ter ad minus longitudine superante. Pedes secundi paris parvi, manu non instructi subcheliformi. Pedes tertii quartique paris sat magni; articulus corum quintus sextusque quasi in ungve longissimum sunt coaliti, qui cum articulo tertio quartoque manum quodammodo efficere videtur prehensilem. Epimera sat brevia. Pedes spurii quarti, quinti et sexti paris saltatorii.” In this description Boeck notices that the expression, “pedes secundi paris parvi, manu non instructi subcheliformi,” is a slip of the pen for “pedes primi paris etc,” which has led subsequent authors astray. The type species is *Protomedieia fasciata*, Kr.
7. *Ampelisca* :—“Pedes primi secundique paris nulla instructi manu subcheliformi; pedes tertii quartique paris forma peculiari, manu quodammodo muniti, eius quasi palmam efficit articulus tertius, digitum vero quartus, quintus et sextus juncti; sextus articulus sive ungvis longissimus gracillimusque; pedes quinti sextique paris articulis modo compositi quinque, quorum ultimus ad fiuem marginis posterioris ungve armatus est rudimentari, recurvo, immobili (vel parum mobili). Septimum pedum par ungve laminari, lato, natatorio (?). Antennæ graciles, pedunculus iucundiorum pedunculo superiorum multo longior. Oculi simplices (?). Pedes maxillares palpo sat brevi. Epimera magna, paria quatuor anteriora multis ornata marginis inferioris setis. Sextum pedum abdominalium par uatatorium. Reliqua ferme ut in genere Amphithoe.” The type species is “*Ampelisca Eschrichtii*,” Kroyer.
8. *Photis* :—“Corpus sat altum, compressum. Antennæ subpediformes (o: elongatae, sat validæ, pedunculo flagellis pauciarticulatis multo longiori), flagello appendiculari destitutæ. Pedes primi et secundi paris sat breves, validi, manu subcheliformi armati robusta. Pes quinti paris recurvatus, inversus, ungve rudimentari. Epimera permagna; quinque paria anteriora ad marginem inferiorem setis sat longis instructa; quintum eadem est ac quartum altitudine, postice profundius excisum. Lamina terminalis interior pedis saltatorii tertii paris rudimentaris.” Boeck points out that this genus is omitted from the British Museum Catalogue. The type species is “*Photis Reinhardi*, Kr.”
9. *Oediceros* :—“Frons in rostrum producta plus minus acutum obtusumve, semper vero nodo pellucente, ovali, flavo rubescente turgidum. Oculi nulli? Pedunculi antennarum longi, superiorum flagelli longitudinem æquantes vel superantes; antennæ superiores flagello appendiculari destitutæ. Pedes primi et secundi paris manu armati subcheliformi permagna. Pedes tertii quartique paris validi, ungve instructi lato, laminari; quod quoque usu venit quinto sextoque pari, quorum coxa vel articulus primus dilatatus non est. Pedes septimi paris longissimi, tenues, fere filiformes (coxa vel primo articulo excepto). Epimera mediocreis magnitudinis multis longisque armata setis marginis inferioris simplicibus; margo posterior quarti paris integra (non sinuato-excisa).” The type species is *Oediceros saginatus*, Kr.
10. *Lafystius* :—“Caput depresso, latius quam longius, rostratum. Antennæ sat breves,

subulatæ, validæ (superiores validissimæ), eadem ferme pedunculi et flagelli longitudine, subrostro in eodem plano positæ, alterum par anterius alterum posterius. Oculi in superficie capitis dorsali siti. Mandibulae angustiores, acuminatæ, palpo instructæ; lamina maxillaæ prioris exterior nullis divisa articulis; pedes maxillares palpo biarticulato. Thorax latus, depresso. Pes primi paris gracillimus, manu linearis, ungue elongato; pes secundi paris brevis, validus, manu quadrata, ungue sublaminari apice setoso. Reliqui deceun pedes validi, subcheliformes, eadem ferme longitudine. Epimera mediocris magitudinis, quartum par in acumen inferne productum. Pedes natatorii elongati, pedes saltatorii debiles." The type species is "*Lafystius Sturionis*, Kr.," at the time the species was constituted the only one of the Gammarina known to be parasitic.

Under the heading "new species of known genera," Krøyer here alters Milne-Edwards' definition of *Leucothoë*, Leach, to embrace two new species which he describes, *Leucothoë clypeata*, Kr., from Greenland, and *Leucothoë glaeialis*, Kr., from Spitzbergen. These, he thinks, if refused admission to *Leucothoë*, would require, not simply one, but two new genera for their reception. He rightly observes that every genus founded on a single species must be liable to modification in its form to include subsequent discoveries. His own two species are now included in Boeck's genus *Metopa*, of which *Leucothoë clypeata* is the type. He describes *Gammarus dentatus*, n. s., by Sp. Bate named *Megamorra dentata*, and by Boeck transferred to *Melita dentata*. He reluctantly admits the separation of *Aeanthonotus*, Owen, from *Amphithoë*, excluding from it *Aeanthonotus nordmannii*, Milne-Edwards, which Spence Bate gives as *Protomediea nordmannii*. Krøyer adds a new species *Acanthonotus inflatus*, very near to *Oniscus serratus*, O. Fabr., but "with back rounded, not dentato." These two by Boeck are named *Acanthonotozoma inflatum* and *Acanthonotozoma serratum* respectively, Owen's generic name and White's alternative for it, *Vertumnus*, being both pre-occupied. Krøyer next re-describes *Isehyrocerus angripes*, adding a new species *Ischyrocerus latipes*, both of which belong to the older *Podocerus* of Leach, and *Ischyrocerus angripes* in Bate's opinion certainly, in Boeck's doubtfully, being a synonym of *Podocerus cylindricus*, Say. The new species "*Podocerus Leachii*" here described was afterwards called "*Cerapus Leachii*" by Spence Bate, and *Cerapus difformis* by Boeck. To this last S. I. Smith restores its original name *Erichthonius difformis*, Milne-Edwards. Krøyer notices that the male of his species is an *Erichthonius*, for which reason he makes that genus yield as a synonym to *Podocerus*. In the genus *Anonyx* he notes that his *Anonyx appendiculatus* is only the male of *Anonyx lagena*. He has also discovered, he says, that in this genus the males are distinguished from the females in that the antennæ, besides being considerably longer in the lower pair, are furnished with a number of small appendages, which seem to act as suckers (Sugeskaaler), by which probably the male holds the female fast. These had been already noticed by Milne-Edwards in 1830 on his *Gammarus ornatus*. They have since, at Stimpson's suggestion, been called *calceoli*; it is now known that they are not in all species confined to the male sex, or to the lower antennæ, and as they are sometimes found in both sexes, Krøyer's explanation of their use is thought untenable. He finds a similar distinction between the sexes in his new genera *Opis*, *Phoxus* and *Ampelisca*, considers that *Amphithoë crenulata* and *Amphithoë inermis* should on this ground be considered male and female of the same species. These are united by Boeck under the name *Pontogeneia inermis*. He attributes his discovery indirectly to Captain Holboell, his suspicions being aroused by the great number of the species to which Holboell gave names. Of these Krøyer paired "*An. seeletator*" with its female "*An. Krøyeri*," "*An. velatus*" with "*An. ornatus*," "*An. Eschrichtii*" with "*An. bona spec.*," names of undescribed species which do not re-appear. In a note he expresses a regret that Milne-Edwards did not retain *Alibrotus chauseicus* in the genus *Lysianassa* and transfer *Lysianassa costæ* to the genus *Anonyx*.

The second portion of the paper deals with the genus *Tanaïs*, Milne-Edwards, describing the new species *Tanaïs savignyi*, *Tanaïs edwardsii*, *Tanaïs dubius*, *Tanaïs gracilis*, *Tanaïs tomentosus*, *Tanaïs örstedii*, *Tanaïs curculio*.

1843. KRØYER, H. N.

Om *Cyamus Ceti* (med et Par Bemærkninger, betræffende den mulige Anvendelse af de paa Hvalerne levende Smaadyr ved Hvalarternes Adskillelse). Naturhistorisk Tidsskrift. Ser. 1. B. IV. pp. 474–489.

Krøyer says that both Roussel de Vauzème and Milne-Edwards took it for granted that the “*Pediculus Ceti*” of Martens, and the “*Oniscus Ceti*” of Linnaeus, must be the same as one of the three species brought home by the former of these two authors. R. de Vauzème thought that his *Cyamus ovalis*, as being the commonest, must be identical with *Cyamus ceti*. But the differences are, in fact, so striking that Milne-Edwards chose *Cyamus erraticus*, R. de V., for identification with *Cyamus ceti*. Krøyer therefore gives full accounts of “*Cyamus Ceti* Linn. (Tab. V. Fig. 63–70)” and “*Cyamus erraticus* (Tab. V. Fig. 71–76),” to show how distinct they really are. He thinks it probable that the distinctions between species of *Cyamus* may be of use in distinguishing the species of whales which they infest, different species of whales having one or more different species of *Cyamus* or some other peculiar parasite upon them. Lütken expresses his surprise that Krøyer, while correcting the errors of others, and offering the ingenious suggestion just mentioned, should have himself made the mistake of supposing that there was only one northern species of whale-louse, and not have recognised that the forms described by Martens and Abildgaard were different species from that which Otto Fabricius had before him. Lütken cannot understand how Krøyer came to ignore the article on *Cyamus* in the “Zoologia Danica,” and points out his error in attributing the habitat of Marten’s whale-louse to the long-armed Fin-whale, *Balaenoptera longimana* (Krepokaken), while affirming that no *Cyamus* has been found on “*Balaena Mysticetus*,” the northern *Slætbag*, *Rethval*, or *Right-Whale*, to which, in fact, the *Cyamus ceti* described by Krøyer, the *Cyamus mysticeti* of Lütken, undoubtedly belongs.

1843. KRØYER, H. N.

Beskrivelse af nogle Arter og Slægter af Caprellina; med indledende Bemærkninger om *Læmodipoda* og deres Plads i Systemet. Naturhistorisk Tidsskrift. Ser. 1. Bd. IV. pp. 490–518. 585–616. Pl. VI. VII. VIII. 1843.

After remarking on various mistakes and improvements made by his predecessors in the classification of the Læmodipoda, Krøyer gives his own opinion that they ought not to constitute a separate order, but to be united with the Amphipoda, as a family of that order. This had been already done by Burmeister, but as he at the same time united the Pycnogonida to the Amphipoda, Krøyer thinks that his systematic arrangement was not well grounded. Krøyer points out that the Læmodipoda no less than the Amphipoda have seven segments to the peræon (Brystringe), the first being always distinguished from the head by a more or less obvious line of demarcation; the mandibles, though sometimes without a palp, in some species have a large, three-jointed one; the eyes are not, as Burmeister states, simple, but “consist, as in the Amphipoda, of a number of small pyriform lenses, ensheathed in pigment and covered by a common cornea;” the want

of side-plates (epimera) only carries a little further the reduction observed in some Amphipoda, especially *Gammarina gressoria*. Where the action of the pleon keeps up a fresh supply of water to the branchiæ, Krøyer thinks that the side-plates covering the branchiæ may attain their fullest development without interfering with respiration, but that in the Læmodipoda, there being no pleon to fulfil this office, the branchiæ have to be left free. The absence of a pleon he connects with their mode of life, which leads them to cling and climb, and only very rarely to swim. Important as this mark of difference is, Krøyer urges that its weight is much diminished by the discovery of two new genera of Læmodipoda, in one of which the pleon, though small, has five segments, in the other only two, but in both is furnished with two pairs of jointed limbs. Thus, he considers, a transition is established to those Amphipoda, such as *Corophium*, in which the pleon is less strongly developed. He mentions that the genus *Cerapodina* wants feet on some of the segments of the peræon in common with the Læmodipoda, but that argument only rests on the faulty description of *Cerapodina*. He considers that the Læmodipoda, as a family or division of the Amphipoda, come nearest the *Gammarina gressoria*, referring to the pediform antennæ among other marks of resemblance. He characterizes the family as follows:—"Pleon rudimentary or only little developed. No Epimera. The first of the seven peræon-segments united with the head along an oblique line, its pair of feet projecting under the maxillipeds. Feet generally wanting on the third and fourth peræon-segments. All the feet are in general claspers, that is to say, furnished with hand and movable finger. Only two or three pairs of branchial vesicles (on the second and third [3rd and 4th], or on the second, third and fourth peræon-segments). Antennæ more or less pediform, the upper always larger and stronger than the lower. Eyes very small, circular." Of the family he makes two subdivisions:—"Caprellina. Form generally very elongate, thin, cylindrical. Branchial-plates bladder-like. The lower antennæ of moderate size, and the feet of moderate strength. Often a palp on the mandibles. "Cyamea. Form generally very flat and broad. Branchial-plates very large, sword- or sabre-shaped, sometimes bipartite, in the males furnished with special appendages at the base. The lower antennæ rudimentary. Feet extraordinarily developed. Mandibles without palp."

The general form, he says, has ceased to be a striking distinction between the two subdivisions, since the discovery of a thin *Cyamus* in *Cyamus gracilis*, and a stout *Caprella* in *Caprella dilatata*. To the *Caprellina* he assigns four genera, 1. *Leptomera*, Latr., 2. *Cercops*, Kr., 3. *Ægina*, Kr., 4. *Caprella*, Lam. All these he defines; the two new ones as follows:—*Cercops*. "Quinque pedum paria, omnia manu armata subcheliformi. Mandibula palpo instructa triarticulato. Flagellum antennarum inferiorum biarticulatum, articulo ultimo primum ferme longitudine æquante. Tria vesicularum branchialium paria (annuli thoracici secundi, tertii & quarti). Abdomen distinctum, quinquearticulatum, appendicibus quatuor elongatis, biarticulatis." *Ægina*. "Quinque pedum paria, omnia manu armata subcheliformi. Mandibula palpo instruncta triarticulato. Flagellum antennarum inferiorum biarticulatum, articulo ultimo fere rudimentari. Duo vesicularum branchialium paria (annuli thoracici tertii et quarti). Abdomen minutissimum, sed sat distinctum, biarticulatum, appendicibus quatuor elongatis, duabus anterioribus biarticulatis, posterioribus uniarticulatis."

Latreille's *Naupredia* (*Naupridia* in Milne-Edwards) is dismissed by Krøyer as founded on a misconception, and the identity of *Proto*, Leach, with *Leptomera*, Latreille, being pointed out, the claim of *Proto* to priority is vindicated. Why Krøyer himself does not adopt it is not explained.

"*Caprella Januarii* Kr. (Tab. VI. fig. 14-20)" from Rio-Janeiro, is described with much detail. This species is identified by Spence Bate with the earlier *Caprella aequilibra*, Say. Mayer agrees with Spence Bate, and points out that Krøyer, usually so exact, does

not mention the ventral median spine on the second peraeon-segment of the male. Kröyer calls attention to the great difference between the adult males and females, especially shown in this, but existing also in other species of *Caprella*.

“*Cercops Holbölli* Kr. (Tab. VI. fig. 1–13),” from South Greenland, is described in detail. It is still the only known species of the genus. In regard to the quinque-articulate pleon, in a note Kröyer says, “it is possible, as in itself not improbable, that the pleon consists of six rings, in that the ring which I have treated as the fifth, is perhaps composed of two pretty closely united.”

“*Aegina longicornis* Kr. (Tab. VII. Fig. 1–12),” also from Greenland, is next described.

At page 585 begins the description of “*Caprella dilatata* Kr. (Tab. VIII. fig. 1–9),” from Rio Janeiro. Mayer identifies it with the earlier *Caprella arutifrons*, Latreille. “*Caprella septentrionalis* Kr. (Tab. VIII. fig. 10–19),” already alluded to in previous papers, is here fully described, without the reference to “*Squilla lobata* Fabr. Fn. Gr. n. 225,” given in Grönl. Amph. It is said to be the commonest of the *Caprellina* in Greenland.

For “*Caprella lobata* Müll. (Tab. VII. fig. 24–28)” Kröyer gives the references

“Müller, Zool. dan. Prodri. n. 2359: *Squilla lobata*.

“— Zoologia danica, fasc. II^{us}, pag. 21: *Squilla quadrilobata*.

“— — — fasc. III^{us}, pag. 58: *Gammarus quadrilobatus*.

“Linné, Systema naturæ, edit. XII^{ma}, pag. 1056: *Cancer linearis*?

“Pallas, Spicil. zool. IX. 78: *Oniscus scolopendroides*?

“Zool. danica tab. 56 fig. 4–5 ♂ og tab. 114 fig. 11–12 ♀.”

These are followed by a full description, winding up with the discrimination of three varieties as follows: “var. α . superficies dorsalis annuli thoracici quinti, sexti, septimiqve aculeis destituta. var. β . superficies dorsalis annuli thoracici quinti, sexti septimiqve aculeis destituta; laminæ branchiales suborbicularies. var. γ . caput annulusque thoracis secundus, tertius quartusqve aculeis nodisve minutissimis praedita.” Mayer assigns the species, with varieties α and γ , to the name *Caprella linearis* (Linn.) Bate. var. β ., he thinks may belong to Kröyer's *Caprella septentrionalis*, though that itself, he supposes, may be but a variety of *Caprella linearis*.

“*Caprella Hystrix* Kr. (Tab. VIII. fig. 20–26),” of which the largest specimen was only about 3" long, is regarded by Mayer as, with little doubt, a young form of *Caprella acanthifera*, Leach, and quite distinct from the *Caprella hystrix* of Bate and Westwood.

“*Leptomera pedata* Abildg. (Tab. VII. fig. 13–23),” receives a full description, preceded by the following references and synonyms:—

“Müller's Prodromus, n. 2360: *Squilla ventricosa* (Hunnen).

“— Zool. dan. Fasc. II^{us}, pag. 20: *Sq. ventricosa* (Hunnen).

“Abildgaard, Zool. dan. Fasc. III^{us}, pag. 33: *Gammarus pedatus* (Hannen).

“Desmarest, Consid. s. les Crustacés pag. 276: *Leptomera ventricosa* (♀).

“— — — — — Proton pedatum (♂ & ♀).

“Latreille i Curiers Règne an. II^{eme} ed. IV, pag. 128: *Naupredia*?

“Zool. dan. tab. 56 fig. 1–3 (♀) og tab. 101 fig. 1–2 (♂).”

Kröyer notices the incorrectness of the view propounded by Eschscholtz, 1830, that *Leptomera rubra*, Lam., might be regarded as a synonym of *Caprella scolopendroides*, Lam. He recognises the priority of the name *ventricosa*, but rejects it for the insufficient reason that its meaning is only suitable to the female. Mayer reinstates it, in the title *Proto ventricosa*, O. F. Müller.

1843. RATHKE, M. H.

Beiträge zur Fauna Norwegens. Mit 12 Kupfertafeln. Besonderer Abdruck aus den Verhandlungen der kaiserl. Leopoldinisch-Caroliischen Akademie der Naturforscher. Band XX. Abth. I. Breslau. 1843. (Amphipoda. pp. 63–98. Pl. III. IV.)

On pages 60–63, Rathke describes *Liriope pygmaea* as type of a new Amphipod genus. The name *Liriope* had been already used for a genus of Medusæ by Lesson, and Dana recognised that the creatures described by Rathke were not Amphipods. A full account is given in the British Sessile Eyed Crustaceans, vol. ii. pp. 257, etc., of what is known of these strange animals, and of the nomenclature, under the genus *Cryptothiria*, among the Bopyridæ.

Of the genuine Amphipods, Rathke's *Gammarus anomalus* n. sp. (Tab. IV. Fig. 7.) is by Spence Bate and Boeck named *Microdeutopus anomalus*. *Gammarus sundevallii* n. sp. (Tab. III. Fig. 2.) was redescribed by Bate and Westwood as "Liljeborgia Shetlandica," by myself as "Liljeborgia Normanni," and by Hoek as *Cheirocratus brevicornis*, its name finally being *Cheirocratus sundevallii*. *Gammarus pacilurus* n. sp. (Tab. IV. Fig. 2.) and *Gammarus kröyeri* n. sp. (Tab. IV. Fig. 1.) are alike identified with *Gammarus marinus*, Leach, both by Sp. Bate and Boeck. Of *Gammarus sabini*, Leach, Rathke gives a new description in order to distinguish it from his own nearly-related species, *Amathia carinata*, from the Crimea, and *Gammarus angulosus*, n. sp. (Tab. III. Fig. 3.) from Norway. Nevertheless, it is not an absolutely untenable opinion that these three species are in reality identical. That his *Gammarus angulosus* is not the young of *Gammarus sabini*, Rathke thinks is proved by two circumstances, first, that he had seen several specimens of it with eggs, and secondly, that the young of *Gammarus sabini* of the same size (4 to 4½ lines) have already the same shape as the old. But the female may be very much smaller than the male, as in *Melita palmata* and other species, and Rathke's observation as to the young of *Gammarus sabini* does not agree with the experience of some other observers. Bate and Westwood unite *Gammarus angulosus* with *Amathilla sabini*, and would do the same to *Amathia carinata*, but for the (insufficient) reason that Rathke himself says that it is different.

Rathke's *Gammarus zebra* n. sp. (Tab. III. Fig. 4.) is identified by Spence Bate with the female of *Podocerus cylindricus*, Say, which Boeck accepts as a synonym only with a ?, placing the species under *Podocerus (Ischyrocerus) anguipes* of Kröyer. *Amphithoë tenuicornis*, n. sp. (Tab. IV. Fig. 3.), is named *Dexamine tenuicornis* by Spence Bate, who notices the improbability of Rathke's statement that the species has no telson, and observes that "certainly Rathke's *tenuicornis* is very closely allied to, if not identical with Montagu's *spinosa*." Of the latter species Boeck makes it a synonym. *Amphithoë podoceroides*, n. sp. (Tab. IV. Fig. 4.) which Sp. Bate transferred to his genus *Sunamphithoë*, is retransferred by Boeck to *Amphithoë* and made to supersede *Amphithoë littorina*, Sp. Bate. In my opinion *Cancer Gammarus rubricatus*, Montagu, is the same as *Amphithoë littorina*, in which case the name will stand as *Amphithoë rubricata*. *Amphithoë prevostii*, M. Edwards? (Tab. IV. Fig. 5), is said to have no telson. At p. 264c it is established as a distinct species, with the name, "*Amphithoë Nilssonii*"; it has already been discussed in the note on Rathke's earlier work, 1837. *Amphithoë norvegica*, n. sp. (Tab. IV. Fig. 6.), is now placed in the genus *Calliopus* (see Sp. Bate and A. Boeck). Of the new genus *Iphimedia*, the following definition is given:— "Antennæ superiores inferioribus breviores: illarum pedunculus e tribus, harum e quatuor articulis ecompositus: omnium flagellum tenui, multiarticulatum. Pedes secundi parisi manibus simplicibus, primi parisi, illis minores, chelis instructi, quarum pollex ex uno tantum articulo constat: reliqui pedes iis Gammarorum similes. Pedes spurii in duos ramos plus minusve complanatos divisi." Spence Bate objects to this definition that the hands of the

second gnathopods are not simple, but subchelate, as Rathke's figure represents them. This is only a question of terminology, as may be seen from Rathke's specific description, "An dem zweiten Beinpaare (*K*) kommen nur Andeutungen von Händen vor, indem das letzte Glied derselben kaum etwas breiter, als das vorletzte, übrigens aber ziemlich lang, tafelartig dünne und mit seinem hinteren unteren Wiinkel so hervorspringend ist, dass es hier einen platten, breiten und abgerundeten Fortsatz bildet, der ungefähr halb so lang erscheint, als die dieht vor ihm eingelenkte Klaue." The type species, to which this description applies, is named *Iphimedia obesa* (Tab. III. Fig. 1.). Kröyer afterwards described the same species as *Microcheles armata*, and Dana, altering the definition, included in the genus species which have nothing to do with it.

Podocerus capillatus, n. sp. (Tab. IV. Fig. 8) is said by Rathke to come near *Podocerus variegatus*, Leach, but to be adequately distinguished from it. In this view Bate and Westwood agree with him. Bruzelius named it *Jassa capillata*. Boeck considers it the same as *Podocerus variegatus*, which was the type of Leach's genus *Podocerus*, but he rejects Leach's genus *Jassa* as synonymous with his *Podocerus*. *Jassa* of Bruzelius he alters into *Janassa*, because after Leach's time *Jassa* was used for a fish. He then enters *Podocerus capillatus*, Rathke, as a synonym of *Janassa variegata*, Leach. But surely, when a genus is retained, the type species must continue to belong to it, and if *Janassa variegata* really differs generically from the other species of *Podocerus*, *Janassa* must be called *Podocerus*, and the other species by some other name. The muddle that will ensue may best be avoided by re-uniting *Janassa* to *Podocerus*, from which it is separated only by fine-drawn distinctions. *Podocerus calcaratus*, n. sp. (Tab. IV. Fig. 94) Boeck unites to *Podocerus falcatus*, Moutagu. The *Caprella phasma*, Lamarek, *Caprella acuminifera*, Leach? and *Caprella scolopendroides*, Lam. (*C. linearis*, Latr.) all belong to *Caprella linearis*. *Leptomera pedata*, Lam. (*Proton pedatum*, Desmar.) corresponds to *Proto ventricosa*, O. F. M.

1843. KRAUS, FERDINAND.

Die Südafrikanischen Crustaceen. Eine Zusammenstellung aller bekannten Malacostraca, Bemerkungen über deren Lebensweise und geographische Verbreitung, nebst Beschreibung und Abbildung mehrerer neuen Arten. Mit IV lithographirten Tafeln. Stuttgart. 1843.

The only Amphipods noticed are *Orchestia bottae*, Milne-Edwards, *Gammarus pulex*, Fabr., *Cyamus erraticus*, Roussel de Vauzème, and *Cyamus ovalis* of the same author. Lütken notices that the identification by Kraus of *Cyamus erraticus* with *Cyamus ceti*, Desmarest, is erroneous.

1844. COSTA, ORONZIO GABRIELE.

Catalogo de' Crostacei raccolti nel Golfo di Taranto Nella primavera del 1830. Atti della R. Accademia delle Scienze, sezione della società reale borbonica. Vol. V. (pte. 2) Napoli. Nella Stamperia Reale, 1844. pp. 67-74. (Apparently read in 1830, though published so long after; the Royal Society Catalogue of Printed Papers gives the date as 1843 [1830].)

In the second Legion, Edriofthalmi, Order 3, Anfipodi, are given *Orchestia littorea*, and *Gammarus fasciatus*, a new species which is figured Tav. i. f. 3, but not described, except in so far as two

varieties are thus mentioned. "Var. *a*, *corallinus*. Var. *b*, *violaceus*." In Order 4, Lemodipodi, are given *Caprella phasma*, *Caprella linearis*, *Caprella acutifrons*. *Anceus forficularius* and *Praniza coeruleata* are now placed in the 5th Order, Isopodi.

To judge by the figure Costa's *Gammarus fasciatus* must belong to the *Mæra* and *Melita* group. It is not mentioned in the Brit. Mus. Catalogue, and is quite distinct from the earlier *Gammarus fasciatus*, Say, which is there described and figured. The three last segments

Fig. 23.

of the pereon and the three first of the pleon are dorsally produced backwards into small teeth, the fourth and fifth of the pleon into large ones. The side-plates of the pereon are represented as low and all nearly alike. The lower hinder angle in the first three segments of the pleon is produced sharply backwards. The upper antennæ have a long peduncle, the first joint long, the second still longer, the third not

very short. No secondary appendage is shown. The second gnathopod has a large hand, with bidentate palm. The fourth pereopod is rather longer than the fifth. The first joints are but slightly dilated. The branches of the third uropods extend far beyond those of the second and third. In spite of some differences it seems tolerably clear that this is the *Ceradocus orchesiipes* of Achille Costa, said by him to have been "found by Prof. O. G. Costa in the Gulf of Tarentum," though he gives no reference to *Gammarus fasciatus*. Since the name *Gammarus fasciatus* lapses as pre-occupied by Say, and since *Ceradocus* is recognised by Heller as identical with *Mæra*, O. G. Costa's species will become a synonym of *Mæra orchesiipes*, A. Costa.

1844. DE KAY, JAMES E.

Zoology of New-York, or the New-York Fauna; comprising detailed descriptions of all the animals hitherto observed within the state of New-York, with brief notices of those occasionally found near its borders, and accompanied by appropriate illustrations. Part VI. Crustacea. Albany, 1844.

The Crustacea belonging to "Order III. Amphipoda," and "Order IV. Lœmipoda," are described on pages 35 to 41. In the preliminary list of works consulted, no mention is made of Rafinesque, on whose lucubrations, had he seen them, this author might have thrown much light. De Kay includes in his definition of the Amphipoda the old statement not universally applicable, that the mandibles are furnished with a palpus. Of the species which he figures his descriptions are probably independent, though only one of the species is new. For *Orchestia longicornis*, Say, "Pl. IX. fig. 28 & 28a. Female," he says:—"Eyes oval. Lower antennæ longer than the body; the third joint, under the lens, armed with series of short spines, the fourth joint, with about thirty articulations, minutely spinous beneath. Second pair of feet with the hands dilated, oval, smooth, with two obtuse spines on the anterior margin; one at the lower angle, and the other more elevated in the middle; the thumb much curved, acute at its tip, which rests on the interval between the two tubercles (see fig. 28, a.). The two posterior pairs of feet longest. Upper pair of antennæ short, not extending beyond the second joint of the lower pair. Length, 0·5-1·0. These small crustaceans are well-known under the name of Sand-flea or Beach-flea, occurring along the shores of Long island, digging holes in the sand in which they conceal themselves, and living upon dead animal substances. They furnish an abundant supply of food to the numerous birds along that coast."

Of *Orchestia gryllus*, Bosc, pl. vii. fig. 19, he says:—"Lower antennæ much shorter than the body, slightly hairy, but not rugose upon the third peduncular joint; last article with about twenty-five articulations. Anterior pair of feet with a prominent obtuse tubercle on the antepenultimate joint; penultimate joint dilated into an obtuse tubercle at the inner tip to receive the thumb. Palm convex so as to receive the thumb without an interval, as long as the lower edge of the hand. Length, 0·5–0·6. Habit of the preceding, and abundant along the sandy beaches above the influence of the tide."

Of *Talitrus quadrifidus*, pl. ix. fig. 27, he gives the following description:—"Head compressed, eyes obliquely oval. Lower antennæ shorter than the body, and only reaching as far back as the fourth segment, slightly hairy and somewhat rugose on the third joint. Upper antennæ very short, scarcely exceeding the second joint of the lower ones. Body compressed. Tail with three appendices terminating in four spines, each furnished with a series of rigid setæ. All the feet armed with a slender acute claw. Color, dark brown; eyes blackish brown. Length, 0·3–0·5. This species also passes under the name of *Bear-flea*, and is frequently found concealed under stones and sea-weed."

Of *Gammarus minus*, Say, pl. ix. fig. 29, he says:—"Body incurved, subcompressed. Upper antennæ longest, with the setæ short, attaining the tip of the second articulation of the terminal joint, which has about twelve articulations. Eyes reniform. Color. Body whitish, with a few pale fulvous spots on the sides. In dried specimens, the color becomes reddish, and the lateral spots, more particularly towards the tail, are bright red. Length, 0·15–0·3. This species is common in most of our fresh-water streams, and may often be detected under stones and pieces of wood. It is extremely active, and is popularly known under the name of *Fresh-water Shrimp*."

As "extra-limital" species, he gives brief accounts of *Gammarus mucronatus*, Say; *Gammarus fasciatus*, Say; *Gammarus locusta*, Montagu; *Gammarus appendiculatus*, Say; *Amphithoe serrata*, Say, *Amphithoe dentata*, Say, *Amphithoe punctata*, Say. His account of *Cerapus* is as follows:—"Genus CERAPUS, Say. Antennæ very large and robust, nearly equal; the upper of four joints, the lower or lateral ones of five. Anterior pair of feet small, monodactyle; the second pair with a broad palm and a two-jointed thumb. Head distinct, ending in a small rostrum. "C. tubularis. (Id. [Say, Journ. Acad. Nat. Sc.], p. 49. *C. abditus*, TEMPLETON, Tr. Ent. Soc. Lond. Vol. i, pl. 20, fig. 5. See Pl. 10, fig. 43 of this work.) Head with a mucronate carina before, hand and first joint of the thumb with one or two obtuse teeth; eyes oval, black. Color. Body above blackish, with irregular paler spots; antennæ and feet white; joints tipped with blackish; two hind pair of feet and tail white. Inhabiting a membranous tube open at both ends. Length, 0·25. *Seabeach, Egg Harbor, New Jersey.*" This is followed by an account of Say's *Lepidactylis dytiscus*, of Say's *Unciola irrorata*, and of *Hyperia*, Latreille, to which he assigns "*Hyperia latreilli*. (Edw. An. Sc. Nat. Vol. 20, p. 388. SAY, *Lanceola pelagica*, Ac. Sc. Vol. 1, p. 318. GOULD? loc. cit. p. 335.) Anterior pair of feet shortest; third, fourth, and seventh equal; fifth longer; sixth longer than the thorax. This species is probably the same noticed by Dr. Gould under the name of *H. galba*, Mont., as occurring in the pouches of *Medusa* —, on the coast of Massachusetts. Mr. Say's specimen was obtained from the Gulf stream." Lastly he describes Say's *Podocerus cylindricus*. Under Læmipoda he figures, plate vi. fig. 14, and describes *Cyamus ceti*, which, he says, "is usually found attached to the bodies of whales along our coast, and occasionally on tunnies and other large marine animals. It varies much in form according to its degree of development, and this has given rise to several nominal species, which have not yet been sufficiently examined." In the description he speaks of the second and third pairs of feet as "replaced by slender appendices, at the bases of which are the branchial vesicles." As "extra-limital" he notices *Cyamus abbreviatus*, Say. In the genus *Caprella* he describes Say's species, *Caprella geometrica*, and as "extra-limital," notices the two species mentioned by Gould in 1841, and *Caprella equilibra*, Say.

1844. MILNE-EDWARDS.

Crustacés. Dictionnaire universel d'histoire naturelle. Dirigé par M. Charles d'Orbigny. Tome quatrième. Paris, 1844. pp. 378–412.

The two orders, Amphipodes and Læmodipodes, are defined at page 382. The tribes, families and genera pertaining to them are named, and to *Cyane* is subjoined the remark, “Je suis porté à croire qu'il faudrait rapprocher de ce groupe les Pyenogonides.”

1844. TELLKAMPF, THEODOR G.

Beschreibung einiger neuer in der Mammuth-Höhle in Kentucky aufgefunder Gattungen von Gliederthieren. Archiv für Naturgeschichte. Gegruendet von A. F. A. Wiegmann. Herausgegeben von Dr. W. F. Eichhorn. Zehnter Jahrgang. Erster Band. Berlin, 1844.

On pages 321, 322, is given the description of “*Triura eavernicola*. (Fig. 18.) *Crustacea. Malacostraca*,” with “Charaeter. 10 Fusspaare, von denen die vorderen 2 Paare in Palpen verwandelt sind. Drei Schwanzspitzen.” Without the remainder of the desription, the copy of Tellkampf's fig. 18 will suffice to show that this creature cannot belong to the

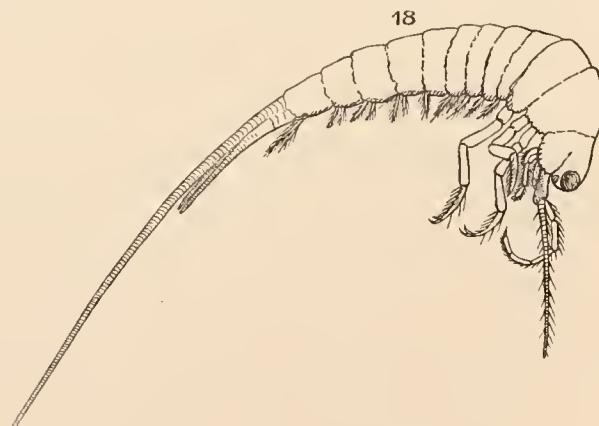

Fig. 24.

Amphipoda, as suggested by Schiödte, and afterwards by Boeck. Dana, Choristopoda, p. 306, says in a note, “Genus *Triura*, Tellkampf, Rhœæ forsau affinis.” It is mentioned, but not described in the Archiv für Anatomie, Physiologie und wissenschaftliche Medizin, herausgegeben von Dr. Johannes Müller, Berlin, 1844, p. 383.

1844. THOMPSON, WILLIAM, died Feb. 17, 1852 (Hagen).

Additions to the Fauna of Ireland. The Annals and Magazine of Natural History. Vol. XIII. London, 1844. pp. 430–440.

In the list of Crustacea, p. 435, he mentions “*Proto pedatum*, Müll. (sp.), Zool. Dan.; *Leptomera pedata*, Edw., Hist. Crust. vol. iii. p. 109. Among *Algæ* dredged at Bangor,

County Down, 1834, Mr. Hyndman and W. T." There is nothing else about Amphipoda. On " *Pychnogonum balænarum*, Fabr." he observes, " *Pyc. balænarum* must on our coast be content with a smaller victim than a whale, and condescends to suck the juices of an *Actinia*."

1844. ZADDACH, ERNST GUSTAV, died June 5, 1881 (Friedländer, *Naturae novitates*).

Synopseos crustaceorum Prussicorum prodromus. Regiomonti, 1844.

Under the heading "Crustacea, adhuc in provincia nostra Borussia reperta," Zaddach enumerates seven Amphipods. These he names 1. *Talitrus saltator*, M.-Edw., which is better called *Talitrus locusta*; 2. *Gammarus locusta*, Fabr. (?), his doubt being occasioned by differences which he found in his specimens from the description by Milne-Edwards; 3. *Gammarus fluviatilis*, M.-Edw., which is *Gammarus puder*, De Geer; 4. " *Gammarus Dugesii*," M.-Edw., which has been identified with *Melita palmata*; 5. " *Amphithoe Rathkii*, nov. specie," which, in Zaddach's opinion, "maxime affinis est *Amphithoe norwegicae*," Rathke, and by Boeck is identified with the neighbouring species *Calliopus læviusculus*, Kröyer; 6. *Leptocheirus pilosus*, n. g. et sp.; and 7. *Corophium longicorne*, Latr.

The new genus Leptocheirus is thus defined:—

"Inter Amphipoda, quæ in maris baltiei littoribus habitant animalia reperta sunt, quæ, concesso genero Amphipodum notis a Milne Edwards constitutis discernenda esse, nulli generi adhuc descripto adnumerari possunt, sed in novum genus, quod Leptocheirum nuncupari propono, colligenda sunt. Genus enim Amphithoe secundum illum scriptorem pedibus dorsum primorum parium cheliferis, ceterorum non prehensilibus, et antennis superioribus inferiorum trunco longioribus simplici flagello instructis insigne est. Illa autem animalia, quæ nunc describam, eum genere Amphithoe antennarum quidem structura eeterorumque partium formis omnino convenientia, pedum autem secundi paris constructione ab his differunt et generi Talitro similiora sunt. Hi enim chelis vacui nec ad comprehendendas [comprehendendas] res apti nec ad gradientur sunt habiles, sed debiles conpressaque a lateribus et contraet eeterisque pedibus occulti reperiuntur. Ne autem fines hujus novi generis augustiores fiant, hac singulari pedum constructione non respecta, quæque Amphipoda saltatoria pedibus primi tantum paris cheliferis, eeteris non prehensilibus et antennis superioribus flagello auxiliario vacuis inter se congruant, generi Leptocheiro adnumeranda esse' puto."

In the description of the type species, Zaddach very plainly says, "Maudihularum palpi et tribus articulis constant, artieulis paene inter se æqualibus, ultimo piloso," so that Boeck, De Skand. og. arkt. Amph., p. 548, seems under some misapprehension when he says, "Müller viste i 1848 (Arch. f. Naturgesch. xiv. p. 62), at Zaddach havde overset, at Kindhakkerne ere forsynede med en Palpe, ligesom han ikke havde bemærket, at de øvre Følere have en Bisvøbe." That the upper antennæ have a minute accessory flagellum is in fact remarked by Müller. Boeck retains the name *Leptocheirus*, though affirming that it is pre-occupied for an insect, but the earlier name alluded to is spelled *Leptochirus* if Scudder may be trusted on the point.

1845. GOODSR, HARRY D. S.

Description of some Animals found amongst the Gulf-Weed. The Annals and Magazine of Natural History. No. 96. February 1845. Vol. XV. London, 1845.

At p. 75 he describes " *Amphitoe pelagica*. Pl. VII. fig. 4. A. with peduncle of superior antennæ about half the length of the inferior antennæ, being almost the same length as the first three

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

XXX 27

joints of the peduncle of the lower antennæ. First pair of legs small, second pair with "the wrist very much enlarged, and the claw sickle-shaped and moveable, inferior edge having a small tooth with a slight notch on either side of it near the distal extremity; claw as long as the wrist, and tapering very gradually to a point." The figure shows that by "wrist" in the above description the large ovate hand of the second gnathopod is intended. The antennæ are slender, the lower only about half the length of the upper. The right number of legs are shown, but there are distinctly nine peræon-segments figured. The uropods and telson are small. The Brit. Mus. Catalogue certifies that Goodsir's species is identical with *Amphithoe pelagica*, Milne Edwards.

1845. KRØYER, HENRIK.

Karcinologiske Bidrag. Naturhistorisk Tidsskrift. Ny Række. Første Bind. Kjøbenhavn, 1845. pp. 283–345, Pl. I.–III. and pp. 403, 453–638, Pl. VI. VII.

After a detailed account of the new species, *Podalirius typicus*, the new genus *Podalirius* is thus described:—

"Quatuor pedum paria (annuli thoraciei primi, secundi, sexti et septimi); pedes annuli thoraeici quinti prorsus rudimentarii, ungue earentes, biarticulati, natatorii (?). Mandibula palpo destituta. Flagellum antennarum inferiorum biarticulatum; articulo secundo dimidiata primi longitudinem aequante vel superante. Duo vesicularum branialis paria distincta (annuli thoracici tertii et quarti). Abdomen minutissimum, biarticulatum.

"*Pod. typicus*: fuscus, pilosus, capite thoraceque inermibus. Long. 2". Hab. in Asteraeanthio rubente."

"Fig. prima tab. IIIæ exhibet annulum thoracicum quintum cum pede rudimentario et vesicula branchiali (?) rudimentaria."

P. Mayer vindicates Krøyer's accuracy in the above account against various succeeding writers. The rudimentary branchia (?) is, however, he says, as Krøyer himself suspected, only a sexual appendage (die weiblichen Geschlechtsklappen) of the female. Mayer adds that the lower antennæ are without "Ruderhaare," and that in *Podalirius krøyeri*, Haller, there are traces of the first and second peræopods.

Krøyer next describes *Orchestia grandicornis*, n. s., from Valparaiso, figured Tab. 1, fig. 2. a–n, and accidentally misnamed *Orchestia longicornis* on the plate. This species is omitted from the Brit. Mus. Catal. It evidently belongs to *Hyale*. The next species, *Orchestia nidrosiensis*, n. s., is identified by Boeck with *Hyale nilssonii*, Rathke, Krøyer himself having suspected that this and the preceding species were separated from *Orchestia* by their longer upper antennæ, and the unguis of the maxillipeds. *Orchestia platensis*, n. s., tab. ii, fig. 2, a–i, from Monte Video, though retained by Spence Bate as a separate species, has in his opinion nothing but locality to distinguish it from *Orchestia gryllus*, Bosc, a North American species. *Talitrus tripudians*, n. s. ♀, tab. iü. fig. 2, a–e, is identified by Boeck as the female of *Orchestia gammarellus*. It is omitted from the Brit. Mus. Catal. *Gammarus anisochir*, n. s., tab. ii. fig. 1, a–p, from Rio Jaueiro, was transferred to *Mæra* by Dana, who thought it very near *Mæra setipes*; by Spence Bate it was referred to *Melita*. Krøyer himself was inclined to make it the type of a new genus, *Anisochir*, but he was restrained by finding that the female was a true *Gammarus*, and the male only distinguished from that genus by having the second gnathopod on the left side strongly chelate. He considered it very near to, though clearly distinct from, *Gammarus appendiculatus*, Say. Krøyer here takes the opportunity of criticising Milne-Edwards' division of the *Gammari* by the shape of the eyes as very artificial and perhaps untrustworthy. The absence of the accessory flagellum on the upper antennæ, which separates *Amphithoe* from *Gammarus*, he considers a comparatively

trivial character. The want of a second ramus on the third uropods, or its quite rudimentary condition, he thinks may be of considerable importance, considering the relation of these uropods to the frequent springing movements of the *Gammari*, and that on this account not only his species *anisochir*, but *podager*, Milne-Edwards, *dentatus*, Kröyer, *brevicaudatus*, Milne-Edwards, might form a separate genus. The first three have since been transferred to *Melita*, the last to *Gammarella*.

Kroyer next describes *Aora typica*, n. s., tab. iii., fig. 3, a-l, the new genus *Aora* being described as follows:—

“Antennæ superiores flagello instruetæ graeillino, flagelloque appendiculari; antennæ inferiores subpediformes. Labium inferius profunde bifidum; laciniae ternis armatae hamis maximis marginis anterioris appendiceaque magna subpalpiformi ad basin marginis exterioris. Pedes maxillares palpo brevi. Pedes primi et secundi paris thoraciei manu instructi subheliformi. Pes primus maris maximus, articulo tertio postice in apieem longissimum producto, manu angusta, ungve fere lamellari. Pedes tertii et quarti paris articulo quarto ovali, manum præbente, ejus ungvvis efficit articulo quinto et sexto. Quintum pedum par brevissimum, robustum; sextum par septimumque quinto multo longiora sed graeiliora. Epimura sat parva, setis instrueta marginis inferioris. Pedes abdominales quarti, quinti et sexti paris saltatori; par sextum, ut quartum et quintum, binis armatum stylis saltatoriis, qui vero setis apicalibus (non aculeis) prædicti sunt. Appendix caudalis duabus formata laminis hamatis.”

There seems no doubt that Kröyer was misled by a lateral view of the telson into supposing it bifid; his description of the “hand” in the first and second pereiopods is rightly rejected by Boeck; Kerguelen specimens of an *Aora*, very closely allied to Kröyer's species, exhibit the characters of the lower lip which he describes, but the marginal hooks are not so large as those which he figures, and the appendages which Schiødt has designated “mandibular processes,” though more than usually produced, scarcely suggest the epithet subpalpiform.

As largest of the South American Amphipods he had met with, Kröyer describes from Valparaiso, *Amphithoe femorata*, n. s. (Tab. iii. fig. 4, a-i), $9\frac{1}{2}$ " long, the antennae not included, intermediate between *Amphithoe* and *Photis*, and suited, Kröyer thinks, to be the type of a new genus, when the Amphipoda come to be thoroughly revised. It agrees, he observes, with all that Milne-Edwards says of his “*Amphithoe Gaulichaulii*” from the Brazils, except in the eoneal rami of the third uropods assigned to that species. But one of Kröyer's own figures shows that also in *Amphithoe femorata*, from a certain point of view, these rami may appear to be eoneal. Kröyer thus defines the species:—“Forma robusta, dorso rotundato, fronte, thorace et abdome inermibus. Antennæ superiores dimidiatae animalis longitudinem superantes, pedunculo valido, flagello setiformi; secundus pedunculi articulus primo parum modo brevior, multo vero graeilius; tertius articulus eum articulis flagelli et longitudine et crassitudine fere conveniens. Oculi suborbicularis, minuti. Antennæ inferiores subpediformes, superioribus tercia ferme parte breviores, flagello dimidiata pedunculi longitudinem aequante, nltimumque ejus articulum longitudine superante (quinta parte). Pedes thoracici primi et secundi paris feminæ manu ferme rectangulari, ejus margo inferior sat profunda sed angustissima prædictus est incisura ad unguem excipiendum. Pes primus maris ut feminæ; secundi vero pedis manus aenminata, incisura earens. Pedes tertii et quarti paris articulo primo maximo, valde dilatato, laminari; ungve parum mobili. Quintum par robustissimum, femore (o: articulo primo) latiori quam longo; ungve prehensili (ut et sextum par septimumque). Epimera magna, margine inferiori piloso; epimerum quintum postice profunde et angulariter excisum ad femur quiuti pedis excipiendum, quum supra dorsum protendatur. Pes abdominalis sexti paris robustissimus, stylis brevissimis; exteriori sublongiori, subeouieo, inferius bihamato et spinosissimo; interiori suborbiculari. Appendix caudalis unica constat lamina triangulari, setis marginis posterioris quatuor.”

This species is omitted from the Brit. Mus. Catal., 1862.

At p. 403 (see Index and p. 476) a new species, as Krøyer supposed, is introduced under the name *Caprella longispina*, which he soon after transferred to the genus *Ægina*. *Ampelisca rotundata* (for which see Note on Liljeborg, 1852) is also according to the Index, mentioned on p. 403; *Amphithoe albomaculata* is said to be mentioned on the same page, and the genus *Ægina* on p. 402, but these two pages I have not seen.

In the Continuation, the description of Amphipoda begins at p. 476 with *Ægina longispina*, Kr.; this he found necessary to remove from *Caprella*, in which he had previously placed it, by reason of the mandibles having palps. He doubted whether it ought not to become the type of a new genus, since he found rudimentary branchiae on the fifth peraeon-segment, and the pleon tri-articulate, without any trace of limbs or appendage. Mayer considers that the supposed branchiae were the external sexual organs of a female specimen, and agrees with Spence Bate in identifying this species with *Protella phasma*, Montagu.

The new genus " *Siphonoecetes*, novum Amphipodum genus, ad *Gammarina gressoria* referendum," is thus described :—

" *Antennæ superiores* inferioribus multo breviores, subpediformes, flagello brevi, pauciarticulato; *anteunæ inferiores* pediformes. *Oculi* haud conspicui. *Mandibula* angulo antico-interiori profunde bifurcata, tuberculo molari denticulato, palpo brevi uniarticulato. *Labium superius* profunde bifidum vel duabus compositum laminis ovalibus; *labium inferius* bifidum, lateraliter productum et acuminatum. *Maxillæ* bilaminares, forma vulgari. *Pedes maxillares* palpo brevi quadriarticulato. *Pedes thoracici* primi et secundi paris validissimi, manu instructi subcheliformi. *Pedes tertii et quarti paris* articulo primo latissimo, laminari; articulo quarto obcordato, laminari, manum præbente, ejus ungvis efficitur articulo quinto subconico articuloque sexto aciculari. *Pedes quinti sextique* paris minutissimi sed robusti, recurvati, articulo primo clavato, ungve furcato. *Pedes septimi* paris graciles, recurvati, articulo primo laminari, ungve miuitissimo, furcato. *Pedes abdominales* primi, secundi et tertii paris natatorii, breves, validissimi, parte basali latissima, rhomboidali; pedes quarti quintique paris saltatorii; pes abdominalis sexti paris natatorius, unica instructus lamina terminali."

" Animal tubum iuhabitat, e lapillis fragmentisque concharum formatum."

The type-species is described under the name of *Siphonoecetes typicus*, Tab. vii. fig. 4, a-f. Boeck thinks that Krøyer has been led to describe the upper lip erroneously, by confusing it with the lower lip. Boeck also says that Krøyer's figure of the last uropods is incorrect, as he draws them with two small rami, though in fact there is but one, the prolongation of the peduncle on the inner side giving the appearance of a second. In the present work the last uropod is not figured, Boeck must therefore be referring to the Voy. en Scand., pl. xx. fig. 1., in forgetfulness that Krøyer has here described the uropod in question just as Boeck himself does, but with the additional observation that, " Den fremspringende Vinkel er iøvrigt ved en skraastrøbe afsat fra den øvrige Roddeel, og kunde maaskee saaledes antyde den ikke fuldt sondrede indre swommeplade." It is this appearance, not a second ramus, that is shown in the Voy. en Scand., pl. xx. fig. 1 u. Krøyer places the genus nearer to *Corophium* than to *Cerapus*, and is followed in this view by Dana and Boeck.

He next describes *Glauconome leucopis*, n. s., Tab. vii. fig. 2, a-c, as type of a new genus, *Glauconome*, which he considers near to *Ischyrocerus*, these two genera in his opinion uniting the *Gammarina saltatoria* and *Gammarina gressoria*. He thus defines *Glauconome* :—

" *Antennæ subpediformes*; *superiores* flagello ornatae appendiculari perparvo. *Oculi* minnti, parum distincti. *Mandibulae* apex in duos fissus ramos, qui dentibus sunt armati conicis; tuberculus molaris dentibus confertissimis instructus. *Labium superius* breve, depresso, latissimum, margine anteriori medio inciso; *labium inferius* quatuor compositum laminis setosis. *Laminæ maxillares* pedum maxillarium dentibus armatae validis; ungvis palpi apice

setosus. Pes primi paris robustissimus, manu subcheliformi; pes secundi paris gracilior, manu carens subcheliformi; pedes tertii quartique paris pergraciles; pedes quinti, sexti septimique paris graciles, femoribus parum dilatatis. Pedes abdominales primi, secundi et tertii paris natatorii, breves sed robustissimi; pedes abdominales quarti quintique paris *saltatorii*, validi; pedes sexti paris fere rudimentares, natatorii. Epimera minima, fere evanescentia."

In the description of the species *Glaucome leucopis*, Krøyer says, "Sjette Par Bugfødder meget smaa og plumpe; Røddelen omrent to Gange saa lang som den ydre Endeplade, meget bred, i Enden skraat afskaaren i Retningen indad og bagtil; den ydre Endeplade regelmæssigt oval, væbnet i Enden med fem eller sex temmelig lange Børster; den indre Endeplade er endel mindre end den ydre, stump konisk, ligeledes forsynet med et Par Børster." Boeck does not notice this detailed description, but refers to the figure in the Voy. en Scand., as erroneously giving these uropods with two branches, instead of a single branch and a produced peduncle. S. I. Smith, 1880, on the ground that Boeck had access to Krøyer's types, accepts his correction of Krøyer, and identifies *Glaucome leucopis* with *Unciola irrorata*, Say. It should, however, be observed that Krøyer's description is extremely precise, and that the figure, Voy. en Scand., pl. 19, fig. 1u, which agrees with it, was not drawn by Krøyer himself, if we may trust the signature "C. Thoruam del." at the foot of the plate. In any case, as S. I. Smith observes, the name *Glaucome* is preoccupied, but whether it should be identified with *Unciola* may still perhaps remain a little doubtful. *Eusirus cuspidatus*, n. s., figured pl. vii. fig. 1, a-d., is next described as type of a new genus near to *Gammarus* and *Amphithoë*, and with some approach to *Leucothoë*. The genus *Eusirus* is described as follows:—

"Antennæ superiores flagello appendiculari rudimentari, tertioque pedunculi articulo minutissimo, fere rudimentari. Antennæ inferiores pedunculo flagelli longitudinem superante. *Marilla prioris* paris palpo elongato, acuminato, setoso, ejus articulus primus dimidiam secundi articuli longitudinem superat. *Mandibula parva*, apice bifurco, dentato, flabello setarum marginis interioris, tuberculo molari transverso-elliptico dentibus minutissimis confertis formato; palpus triarticulatus duplam fere æquat mandibulæ longitudinem. Pedes maxillares laminis maxillaribus minutis, dentatis; palpo maximo, robustissimo. Pedes thoracici primi et secundi paris eadem ferme invicem forma et magnitudine, manu armati subcheliformi maxima, laminari, ungve maximo sed gracillimo; articulo antepenultimo prælongo, gracili, postice calcarato, antice ad medium marginem manus anteriorem proteuto. Pedes thoracici tertii quartique paris pergraciles sed forma vulgari. Sex branchiarum paria (annuli thoracici 2di-7mi). Quatuor laminarum in feminis paria thoracicarum (annuli 2di-5ti). Reliqua ferme ut in genere Gammaro vel Amphithoe."

This genus is placed by Boeck in his subfamily Leucothoinæ.

Dulichia spinosissima, u. s., Tab. vi., fig. 1, a-k, is described as type of a new genus intermediate between the *Gammarina* and *Caprellina*. The genus is thus defined:—

"Corpus valde elongatum, gracile. Antennæ longissimæ (imprimis superiores), subpediformes; superiores flagello instructæ appendiculari. Oculi prominentissimi, acuminati. Pedes maxillares forma valde dilatata. Pedes thoracici primi paris compressi, manu (articulo quarto) magna, ungueque biarticulato instructi (qui ungvis articulo quiuto sextoque junctis efficitur). Pedes secundi paris manu instructi subcheliformi (quæ apud marcs maxima est). Pedes tertii quartique paris minimi, fere filiformes, invicem ejusdem [eadem] ferme longitudine et forma. Pedes quinti, sexti septimique paris elongati, lineares (femore non dilatato), prehensiles. Sextus thoracis annulus cum septimo coalitus, ut difficilius distingvatur. Epimera nulla vel prorsus rudimentaria. Abdomen quinque modo compositum annulis et quinque præditum pedum paribus, quorum tria anteriora natatoria, duo posteriora saltatoria sunt."

To receive this genus Dana instituted the family Dulichiidae, in 1849. *Stegocephalus inflatus*, Kröyer, is next described in detail. This is now known as *Stegocephalus ampulla*, Phipps, 1774.

Pontoporeia femorata, Kröyer, is here next described in detail, but without any reference to the curious dorsal process which is represented in the Voy. en Scand. pl. 23, figs. 2a, 2y., on the observation of which Bruzelius established a new species, *Pontoporeia furcigera*, which, according to G. O. Sars, is not distinct from *Pontoporeia femorata*.

Descriptions are next given of *Leucothoe glacialis*, Kröyer, Tab. vi. fig. 2, a-f, *Leucothoe clypeata*, Kröyer, Tab. vi. fig. 3, a-g, "Phoxus Holbølli Kr." and *Phoxus plumosus*, Kr., now known respectively as *Metopa glacialis*, *Metopa clypeata*, *Phoxus holbølli* and *Harpinia plumosa*. Kröyer himself was inclined to regard the two latter as generically distinct. Of both species he notes that he has never found the maxillipeds united to the head, but always to the first pereon-segment.

Pages 578-637 are devoted to the genus *Anonyx*. Kröyer first discusses and describes at great length what he calls "*Anonyx Ampulla*, Phipps," combining with it "*Cancer nugax*, Phipps??" his own "*Anonyx Lagenaria* (Hunnen)," *Anonyx appendiculatus* (Haunen), and other synonyms. The species which he here describes, which he figures in the Voy. en Scand., pl. 13, fig. 2, a-z, and which does in fact include the species of *Anonyx* just mentioned, is now known as *Anonyx nugax*, Phipps, while the *Cancer ampulla* of Phipps, figured here pl. vii. fig. 3, a-g, and in the Voy. en Scand., pl. 20, fig. 2, a-t., as *Stegocephalus inflatus*, Kr., is now known as *Stegocephalus ampulla*, Phipps.

A full description is next given of "*Anonyx Vahlii* Kr." which Milne-Edwards had transferred to *Lysianassa*, and which Boeck calls *Socarnes calli*.

Anonyx gulosus, n. s., is described, with a note that "Fabricius's *Oniscus Cicada* seems in many, if not in all, respects to come very near to it, and is obviously in any case an *Anonyx*."

Anonyx litoralis, n. s., is next described. This was made by Boeck type of a new genus *Onesimus*, which he thinks possibly a synonym of Milne-Edwards' *Alibrotus*, to which Spence Bate had previously referred the *Anonyx litoralis* of Kröyer.

A species, to the young and sexes of which Captain Holbøll had given three separate manuscript names, *velatus*, *ornatus*, and *brevipes*, is next described as *Anonyx plautus*, n. s. This also is placed by Boeck in his genus *Onesimus*. Figures of the various species above mentioned are given in the Voy. en Scand.

1845. MILNE-EDWARDS, and LUCAS.

D'Orbigny, Alcide, Voyage dans l'Amerique méridionale exécuté dans le cours des années 1826, 1827, 1828, 1829, 1830, 1831, 1832, et 1833. Vol. VI. Animaux articulés. Crustacés par MM. Milne-Edwards et H. Lucas.

No Amphipoda are mentioned in this report, so far as I can perceive. It was perhaps included in Boeck's list under some misapprehension.

1846. DANA, JAMES DWIGHT, born February 12, 1813 (S. I. Smith).

Notice of some Genera of Cyclopacea. Silliman's American Journal. March, 1846. Also Annals of Natural History. Vol. XVIII. 1846. pp. 181-185.

This article is prefaced by the following classification of Crustacea:—

CRUSTACEA.

Sublassis I.	Sublassis II.	Sublassis III.
PODOPHTHALMIA.	EDRIOPHTHALMIA.	MANDYATA.
Ordo 1. DECAPODA.	Ordo 1. CHORISTOPODA.	
Tribus	Tribus	
1. Brahyura.	1. Isopoda.	
2. Anomoura.	2. Læmipoda.	
3. Maeroura.	3. Amphipoda.

		1. Cirripeda, or Balanacea.

1846. KROYER, HENRIK.

Karcinologiske Bidrag. Fortsættelse. Naturhistorisk Tidsskrift. Ny Række.
II. Kjøbenhavn, 1846. pp. 1-88, 115-123.

In this continuation Krøyer first describes "*Anonyx Edwardsii*," n. s. ♀. This is transferred by Boeck to *Onesimus*, and distinguished from the species called "*Anonyx Edwardsii*, Kr." in the Brit. Mus. Catal., p. 73.

"*Anonyx Holbølli*," n. s., next described, is made by Boeck the type of a new genus, *Hippomedon*.

The next species, *Anonyx tumidus*, n. s., is made by Boeck the type of another new genus, *Aristias*.

Anonyx minutus, n. s., is transferred by Boeck to his genus *Orchomene*.

Anonyx nanus, n. s., is made by Boeck the type of a new genus, *Tryphosa*.

Figures are given of these five species in the Voy. en Seand.

From the species of *Anonyx*, Krøyer passes on to the nearly related form *Opis*, since called *Opisa*, and now describes in detail under the name "*Opis typica*, Kr.," what he had previously described in brief as "*Opis Eschrichtii* Holbl." He explains that Holbøll had given the name "*Anonyx Eschrichtii*" and three other names to what were only varieties, sexual or otherwise, of a single species; Krøyer himself therefore thought proper to unite them under the name *Opis typica*. But the name "*Opis Eschrichtii*" already published

must take precedence. The Brit. Mus. Catal. gives them as two separate species, though Krøyer's descriptions are identical, so far as the shorter one extends.

Remarks on the habits of animals belonging to the genera *Anonyx* and *Opis* are quoted from Holbøll. These are followed by an account of *Microcheles armata*, supposed to be a new species and type of a new genus *Microcheles*, thus defined:—

“ Primum secundumque *pclum thoracicorum* par exilia, linearia, *chelis* armata minutissimis. *Mandibula* parva, apice bifurcato, non vero dentato; palpo triarticulato; tuberculo molari proprio nullo, ante palpum vero corpore instructa claviformi, dentato. *Labium inferius* quatuor constans laminis fere æqualibus, cornibusque lateralibus sat magnis. *Pedes maxillares* laminis maxillaribus magnis, palpo brevi, *triarticulato* (ungue destituto). *Epimera magna*; paria quatuor anteriora inferius in angulum acutum producta. *Pedes abdominis saltatorii* elongati, gracilesque. *Antennæ* forma ferme vulgari, superiores flagello appendiculari destitutæ.”

The species, *Microcheles armata*, is figured in the Voy. en Scand., pl. 11 B, fig. 2, *a–v*. It was subsequently identified by Liljeborg with the earlier *Iphimedia obesa* of Rathke, so that both the generic and specific names used by Krøyer take rank as synonyms.

Amphithoe albomaculata, here described as new, is by Boeck identified with *Amphithoe poloceroides*, Rathke, and is therefore probably not more than a colour variety of *Amphithoe rubricata*, Montagu.

Next, “*Amphithoe Edwardsii*” is described, under the name which Owen gave to the “*Talitrus Edwardsii*” of Sabine, which is identical with *Oniscus aculeatus*, Lepechin. See Note on Lepechin, 1780.

Lastly, *Acanthonotus tricuspidis*, n. s., is described, pages 115–123. This species was afterwards by Boeck made the type of his genus *Cleippides*. The species included in this continuation are all figured in the Voy. en Scand. For the benefit of any one unacquainted with the alphabetical order used in the Scandinavian languages, it may be pointed out that in the Indices to Krøyer's papers, the diphthong æ and the symbol ö or ø follow the letter z.

1846? KRØYER, HENRIK.

Voyages de la commission scientifique du Nord; en Seandinavie, en Laponie, au Spitzberg et aux Ferö, pendant les années 1838–1840, sur la corvette la Recherche, commandée par M. Fabvre. Publiéés par ordre du Roi sous la direction de M. Paul Gaimard. 17 vols. Paris, 1842–1848. 8°. Atlas, fol. undated.

The reputed date of publication is 1846, for the Atlas of Crustacés. It consists of plates for which no text was ever published, and is attributed by repute to Krøyer. W. Thomson, in 1847, refers to the plates as Krøyer's. Brandt, in 1851, compliments Krøyer on figures of *Anonyx* in this Atlas, “Livr. 37–41 auf. Pl. 13–18 meisterhaft von ihm dargestellt.” The beautiful figures agree with the elaborate descriptions which Krøyer gave from time to time in his *Naturhistorisk Tidsskrift*, but the plates which appeared occasionally in that magazine have none of the artistic pretensions of those in the Voyages. As Krøyer's own name nowhere appears in the present work, it may be presumed that he was not the draughtsman, but the editor, who supplied the dissections and supervised the delineations. The Amphipoda figured are named as follows:—Pl. 10. *Amphithoe edwardsii*, Sab.; *Amphithoe pulchella*, Kr. sp. n. Pl. 11. *Amphithoe curinata*, Kr.; *Amphithoe panopla*, Kr. Pl. 11 B. *Amphithoe albomaculata*, Kr. nov. sp.; *Microcheles armata*, Kr. nov. gen. et sp. Pl. 13. *Anonyx littoralis*, Kr. Nov. sp.; *Anonyx ampulla*, Phipps. Pl. 14. *Anonyx valhii*, Kr. ♂ et ♀.; *Anonyx gulosus*, Kr. nov. sp. Pl. 15. *Anonyx holbollii*, Kr. nov. sp.; *Anonyx plautus*, Kr. nov. sp. Pl. 16. *Anonyx edwardsii*, Kr. nov. sp.; *Anonyx tumidus*, Kr. nov. sp. Pl. 17. *Opis typica*, Kr.; *Anonyx nanus*, Kr. nov. sp. Pl. 18. *Acanthonotus tricuspidis*, Kr. nov. sp.; *Anonyx minutus*,

Kr. nov. sp. Pl. 19. *Glauconome leucopis*, Kr. nov. sp.; *Eusirus cuspidatus*, Kr. nov. gen. sp.; *Egina (?) longispina*, Kr. nov. sp. Pl. 20. *Siphonocetes typicus*, Kr. nov. gen. et sp.; *Stegocephalus inflatus*, Kr. Pl. 22. *Dulichia spinosissima*, Kröyer; *Leucothoe clypeata*, Kr.; *Leucothoe glacialis*, Kr. Pl. 23. *Ampelisia [Ampelisca] gaimardii*, Kr. nov. sp.; *Pontoporeia femorata*, Kr. Pl. 24. *Caprella hystrix*, Kr.; *Cercops holbölli*, Kr.; *Egina tenuicornis*, Kr. Pl. 25. *Podalirius typicus*, Kr.; *Caprella septentrionalis*, Kr.; *Caprella lobata [lobata]*, Müll. ♂, ♀ et Var. All these are described in the Naturh. Tidsskr. except *Amphithoe pulchella* (which Bruzelius assigned to *Paramphithoe*, and Boeck transferred to *Pleustes*, Sp. Bate), and "*Ampelisca Gaimardii*" (which Boeck in 1870 transferred to a separate genus, as *Byblis gaimardi*).

Plates 10, 11, 11 B, 18, are inscribed "C. L. Petersen del.", the others "C. Thorsam del." except pl. 23, of which the draughtsman is not mentioned.

1846. MÜLLER, FRIEDRICH.

Ueber *Gammarus ambulans*, Archiv f. Naturg. 12 Jahrg. 1846, pp. 296–300.
T. x. Fig. A–C.

This species Axel Boeck (De Skand. og Arkt. Amph. p. 52) proposed to refer to the genus *Crangonyx*, Sp. Bate, but Aug. Wrześniowski, after detailed comparison of Müller's description of *Gammarus ambulans* with his own species, decides that Müller's species must stand as *Goplana ambulans* in the new genus along with *Goplana polonica*. The points which distinguish *Goplana polonica* from *Goplana ambulans* are perhaps due rather to age than to difference of species. Müller gives the following diagnosis of his species:—"Gammarus ambulans, fronte inermi, oculis subrotundis, antennis superioribus inferiores excedentibus, flagello auxiliari minimo biarticulato instructis, dorso lœvi, pedibus spuris paris sexti simplicibus, conicis, perexiguis, appendiceibus eaudæ duabus, brevibus, cylindricis, apice spinulosis. Long. 2", antennar. sup. 0·8""."

1847. ALLMAN, GEORGE J.

Biological Contributions. No. II. On *Chelura tercibrans*, *Philippi*, an *Amphipodous Crustacean destructive to submarine timber-works*. The Annals and Magazine of Natural History. No. 128. June 1847. Vol. XIX. London, 1847, pp. 361–370. Plates XIII. XIV.

The characters of the genus, of which Philippi gave no detached summary, are thus drawn out:—"CHELURA, Phil. GEN. CHAR. Body not compressed. Head distinct. Superior antennæ shorter and more slender than the inferior, and consisting of a peduncular portion which supports two unequally developed rami; inferior antennæ large, not divisible into a distinct peduncle and ramus. Mandibles strong, palpigerous, furnished with a molar tubercle with transverse ridges. First pair of maxillæ strong, pyramidal, palpigerous; second pair lamelliform. Maxillary feet large, bearing a palp-like stem, and united at their origin so as to constitute a great opercular lip covering all the other organs of the mouth. Thorax composed of seven distinct segments with the epimere distinct and moderately developed. First two pairs of thoracic feet didactyle, five remaining pairs terminated by a small unopposable claw. First three segments of abdomen each bearing a pair of biramous natatory feet, remainder of abdomen consisting of one very large trunk supporting anteriorly a pair of large foliaceous lobed appendages and a pair of cylindrical false feet, and terminated

posteriorly by two lamellar leaping organs and an intermediate leaf-like lobe." Reference is made in a note to the researches of Erichson (*Entomographia*) which would displace the use of the terms thorax and abdomen as applied by carcinological writers. In the specific description, he says that the superior antennæ "consist of a peduncular portion which is composed of three hirsute articulations, the last of which supports two rami of very unequal development," remarking in a note that "this condition of the superior antennæ is not described by Philippi." He mentions the name *destructor*, which he had given to his Irish specimens, before becoming acquainted with Philippi's account, in case after-investigation should show the Irish form to be in fact distinct from the Adriatic species. In describing the appendages of the terminal segment of the abdomen, he says "the appendages of the third pair constitute a sort of tail, by which the body is prolonged backwards; they are borne upon the posterior extremity of the segment, and consist each of a very large leaf-like lamina supported on a short basal joint;" adding in a note that, "it is these basal joints of the two caudal appendages which Philippi seems to have mistaken for a fifth abdominal segment, with the anus in a fissure on the back."

He considers that "the families of the Amphipodous Crustacea may be analytically arranged as follows:—

Family.

"Fourth and fifth abdominal segments confluent. Abdominal appendages of the fourth and fifth pair very different in form (heteromorphous). CHELURIDÆ.

"Fourth and fifth abdominal segments distinct. Abdominal appendages of the fourth and fifth pair nearly similar in form (isomorphous). { Mouth concealed by the maxillary feet. . . GAMMARIDÆ.
Mouth not concealed by the maxillary feet. . . HYPERIDÆ."

1847. BRANDT, JOHANN FRIEDRICH, born 1802 (Hagen).

Ueber den gleichzeitig mit der Ausrottung der Pflegemutter bewerkstelligten geschiehtlich naehweisbaren Untergang einer kleinen parasitischen Krebsart (*Cyamus*? oder richtiger vielleicht *Sirenoeyamus*? *Rhytinæ*) und eines Eingeweidewurmes der Jetzwelt, von J. F. Brandt. (Lu le 20 mars 1846). Bulletin de la classe physico-mathématique de l'Aeadémie impériale des sciences de St.-Pétersbourg. Tome cinquième. St.-Pétersbourg, 1847.

This paper, though earlier published, was originally read after the more full account published in the Mém. de l'Ac. imp. de St. Petersbourg, 1849. See note under that date. Brandt thinks that the want of the breathing appendages, which could scarcely have escaped so accurate an observer as Steller, had they been as strikingly developed as in *Cyamus*, points to an affinity between "*Sirenoeyamus?*" and *Leptomera*.

1847. FREY, HEINRICH, and LEUCKART, RUDOLPH.

Beiträge zur Kenntniss wirbelloser Thiere mit besonderer Berücksichtigung der Fauna des norddeutschen Meeres. Von Dr. Heinrich Frey and Dr. Rudolph Leuckart. Mit zwei Kupfertafeln. Braunschweig, 1847.

Pages 100–109 are "Ueber den Bau der Caprellen." The authors object to Kröyer's proposal to make the order of Læmodipoda a family among the Amphipoda. They refer to Natürh.

Tidsskr. iv. p. 141, but their reference should have been to p. 492. For their own investigations they used "Caprella linearis Müll. and Podalirius typicus Kröy," especially young specimens, for the sake of their transparency. The error of their opinion that *Caprella* never swim is pointed out by Dohrn, 1866. Their statement that "das Ganglion des zweiten Ringes, des Mesothorax, übertrifft an Mäeltigkeit alle übrigen, wie das diesem angehörende Greiffusspaar die stärkste Extremität des ganzen Körper ist," is approved by Mayer on the general principle that the size of the ganglia depends, as might be expected, on the extent of the regions they have to provide for. In regard to the heart they say, "an ihm bemerkt man seitlich fünf paarige, mit Klappen versehene Spaltöffnungen. Das erste Paar liegt ganz am Anfang des Herzens, also noch im Kopfsegmente, das letzte Paar ganz an seinem Ende, also im sechsten Ringe. Die drei übrigen Paare sind so vertheilt, dass die eine Spaltöffnung am hinteren Theile des zweiten, die andere in der Mitte des vierten Ringes liegt, und endlich noch ein Paar Spaltöffnungen gerade am Uebergange des vierten in das fünfte Segment, also unterhalb der Conjunetiva beider Ringer, befindlich ist." For the correction of this view, see note on Delage, 1881. Delage attributes to these authors, among some errors and defects, "le fondement de ce que nous savons aujourd'hui sur la circulation des Caprelles."

To the Amphipoda they attribute seven instead of five pairs of lateral slits in the heart, although three would have been sufficient for the Caprellæ as well as the (other) Amphipoda. They consider that the so-called branchiae in the Caprellæ are not sufficient to discharge the whole function of respiration, and that probably the legs and antennæ take a share in it.

Pages 136–168, "Verzeichniss der zur Fauna Helgoland's gehörenden wirbellosen Seethiere," are due to Dr. Leuckart alone. Among the Arthropoda, Crustacea *Malacostraca*, he enumerates the following Amphipoda:—"Talitrus saltator (Montag.) Milne Edw.—Orchestia littorea Leach.—O. sp. dub.—Gammarus loensta Fabr.—G. elongatus n. sp.—G. Sabini Leach.—G. angulosus Rathke.—Melita palmata (Mont.) Leach.—Iphimedia obesa Rathke [Kölliker.]—Amphitoe podoceroides Rathke.—A. gibba n. sp.—Podocerus capillatus Rathke.—P. calearatus Rathke.—Metoeus medusarum Kröy."—"Caprella linearis (Lin.) Latr.—Podalirius typicus Kröy."

The doubtful *Orchestia*, which he thinks may be "Orchestia Bottae," Milne-Edwards, is obviously, as Boeck observes, only a young *Orchestia (littorea) gammarellus*. The *Gammarus elongatus*, n. sp., not mentioned in the Brit. Mus. Catal., is a little doubtfully united by Boeck with *Mæru longimana* (Leach) Thompson. In describing *Melita palmata*, Leuckart suggests that *Gammarus dugesii*, Milne-Edwards, is the same species, a view adopted by subsequent authors. He says that *Amphitoe gibba*, n. sp., "is distinguished from the nearly related A. norvegiae Rathke and A. Rathkii Zadd., by the fact that the second, third and fourth segments of the postabdomen in the front half are narrowed, while projecting (buckelförmig) in a hump in the hinder half, giving the part of the body in question a peculiar appearance." None the less, or one might say, all the more, Boeck identifies it with *Calliopius larvusculus*, Kröyer. Leuckart recognises that *Podocerus* has a minute accessory appendage on the upper antennæ. He agrees with Kröyer in supposing that the fifth pereon-segment of *Podalirius typicus* has a (third) pair of branchiae, misled, Mayer says, by "die weiblichen Geschlechtsklappen."

Among works consulted, Leuckart mentions "Kölliker (Beiträge zur Kenntniß der Samenflüssigkeit wirbelloser Thiere. Berlin 1841)." In this treatise perhaps would be found a reason for the addition of Kölliker's name to Rathke's as an authority for *Iphimedia obesa*.

1847. NARDO, GIOVANNI DOMENICO, died 1877 (E. v. MARTENS).

Sinonimia moderna delle specie registrate nell' opera intitolata : Descrizione de' Crostacei, de' Testacei e de' Pesci che abitano le lagune e golfo veneto rappresentati in figure, a chiaro-seuro ed a colori *Dall' Abate Stefano Chiereghini Ven. Clodiense applicata per commissione governativa dal Dr. Gio. Domenico Nardo. Venezia, 1847.*

Nardo says that Chiereghini's work occupies twelve volumes, nine of plates, and three of text.

The index to the Crustacea is in the first volume, and the figures of them are in the second. The portion applying to the Amphipoda, with Nardo's synonymy, is given as follows :—

- “ Sp. 58, f. 74. Can. [Cancer] locusta, *L.* volg. *Saleotto de' Fosso.* *Orchestia littorea,* *L.*
- “ Sp. 59, f. 75. Can. *Salectus, Ch.* volg. *Saleotto de Mar.* *Orchestia?*
- “ *Macrourus, articularis, testa perpendiculariter subtruncata, fronte mucronato; pedibus*
deem absque manibus.
- “ Trovato ne' fondi fangosi del mare.
- “ Sp. 60, f. 76–79. Can. *Algensis, Ch.* *Lusyta algensis,* *Ch.*, Nardo.
an. n. g. *Mss.*
- “ *Maerourus, thorace rostrata, manibus duabus adactylis, pedibus decem, extremitate*
caudae trifida.
- “ Trovato copiosamente in laguna, nidulato sulle foglie della zosteria alla maniera delle
Friganee.
- “ Sp. 61, f. 80. Can. *linearis, L.* *Caprella, n. sp.?*
- “ Sp. 81 [61], f. 81–82. Can. *Varietas linearis, Ch.* *Caprella, n. sp.?"*

For a little additional light on these species, see Note on Nardo, 1869.

1847. SCHIØDTE, JØRGEN CHRISTIAN, born April 20, 1815, died April 21, 1884 (R. Bergh).

Undersøgelser over Huledyrene i Krain og Istrien. Oversigt over det Kgl. danske Vidensk. Selskabs Forhandlinger for 1847, Kiøbenhavn. pp. 75–81.

Boeck says that in this paper, page 81, Schiødte gives a short diagnosis of *Gammarus stygius* [? *stygius*], which later became type of the genus *Niphargus*.

1847. THOMPSON, WILLIAM.

Note on the Teredo norvegiae (T. navalis, Turton, not Linn.), Xylophaga dorsalis, Limnoria terebrans and Chelura terebrans, combined in destroying the submerged wood-work at the harbour of Ardrossan on the coast of Ayrshire. The Annals and Magazine of Natural History. No. 132. Sept. 1847. Vol. XX. London, 1847. pp. 157–164.

He observes that *Chelura terebrans*, Philippi, was known to Leach, who had labelled specimens as *Nemertes nesæoides*, a name adopted by White in his “List,” etc., 1847. Both *Nemertes* and *Chelura*, he observes, are preoccupied as generic names. The habits of the species are discussed, and its powers of surviving out of sea-water. Seudder only gives two uses of *Chelura*, viz., “*Chelura Phil. Crnst. 1839. A.*” and “*Chelura Hope. Lep. 1840. A.*”

1847. THOMPSON, WILLIAM.

Additions to the Fauna of Ireland. The Annals and Magazine of Natural History. Number cxxxiii. pp. 237–250. Vol. XX. London, 1847.

In the order Amphipoda he mentions the following:—“6. *Orechestia*, (sp.), Bangor, Co. Down, 1835, W. T.; distinct from *O. littorea*.” “7. *Amphithoë fueieola*, Leach (sp.),” with a reference to *Pherusa fucicola*, Leach. “8. *Amphithoë rubricata*, Mont. (sp.).” “9. *Amphithoë*, sp. Bangor, Co. Down, 1835, W. T.; distinct from the preceding and *A. obtusata*, on comparison with the specimens in the British Museum.” “10. *Gammarus marinus*, Leach.” “11. *Gammarus campylops*, Leach.” “12. *Gammarus longimanus*, Leach (sp.). *Mara longimana*, Leach MSS.” “13. *Gammarus punctatus*, Johust. Zool. Journ. vol. iii. pp. 177, 490. I found in a case formed by itself among the branches of *Corallina officinalis* growing in pools between tide-marks at Springvale, Co. Down, in July 1846. The species was determined by comparison of mine with those from Berwick presented by Dr. Johnston to the British Museum.” “14. *Opis typica*, Kroyer.” “15. *Anonyx* (Kroyer) sp.” It is distinct, he says, from the species described by Krøyer, and “although a proper description cannot (on account of the state of my eyes) be drawn up, some idea may be given of this *Anonyx*—(which is well worthy of the name of *elegans*)—by the following note:—length of body 6 lines; of upper antennæ 1 line; of lower antennæ 4 lines; general colour yellowish pink; eyes red; lateral or abdominal plates adorned with scarlet stellate markings, of which there are five or six on those nearest the head; they become gradually fewer on those towards the tail, so that not more than one appears on the hinder plates. These markings render it very beautiful. My *Anonyx* is distinct from a British species (locality unknown) in the collection of the British Museum.” “16. *Anonyx*, genus?, or rather a form between it and *Stegocephalus*, Kroyer, was dredged from a depth of twenty-three fathoms (shelly sand) in Belfast Bay in Oct. 1846 by Mr. Hyndman.” “17. *Cerapnus falcatus*, Mont. (sp.), Linn. Trans. vol. ix. t. 5. f. 2. *Jassa pelagica*, Leach.” “18. *Hyperia galba*, Mont. (sp.).” “19. *Hyperia Latreillii*, Edw.” “20. *Lestrigonus*, sp.”

In the “Order Læmodipoda” he mentions “21. ‘*Caprella lobata*, Müll.’ Krøyer, Voy. Seand. et Lapon. Crust. pl. 25. f. 3a†, dredged Oct. 1839.” The note † says, “3b presents a very different form, but is considered a variety only.” “22. *Caprella tuberculata*, Goodsir, Edin. New Phil. Journ. vol. xxxiii. p. 188, pl. 3. f. 6. specimens taken with the last. Guérin in his Iconographie, &c. pl. 28. f. 1. represents a species which he calls by this name; it is from the Manritius (Texte Descrip. Crust. p. 24).” “23. *Caprella acuminifera*, Leach.” “24. *Aegina?* *longispina*, Kroyer, Voy. Seand. &c. Crust. pl. 19. f. 3. (described in Krøyer’s ‘Naturhist. Tidssk.’ 1st binde, 5th hæfte, 1845, p. 476). A single individual of this very fine, large and spinous form was taken with the two first-noticed *Caprella*. My specimen differs only from that represented by Krøyer in having one or two more spines retrally on the body; it is wholly red like his, and has retained this colour in spirits to the present time. Goodsir’s *Caprella spinosa* (Edin. New Phil. Journ. vol. xxxiii. p. 187. pl. 3. f. 1) approaches very near to this species, if it be not the same; it is described as ‘having the whole body of a pale white colour.’”

1847. WHITE, ADAM.

List of the Specimens of Crustacea in the Collection of the British Museum. Printed by Order of the Trustees. London, 1847.

The book is anonymous, but the introduction, pp. iii.–viii., signed John Edward Gray, says “Great care has been taken by Mr. Adam White in the determination of the species, the

verification of the synonyms, and in arranging them into generic groups, in accordance with the present state of the science." Since, then, the work is due to Mr. Adam White, it is difficult to appreciate the fairness of omitting his name from the title-page. He divides the Malacostraca Edriophthalmata into two orders, Amphipoda and Læmodipoda, the former containing the two families, the Gammaridæ and Hyperiadæ; the latter the two families, the Caprellidae and Cyamidæ. In the Gammaridæ, after *Talitrus locusta* and *Orchestia littorea*, come the following entries.

- "*Orchestia Montagni*, *Audouin, Expl. Pl. Egypte* t. 11, f. 7. *Edwards, Crust.* iii. 17. *Oreh. littorea*, *Rathke, Faun. Crim.* t. 5, f. 1-6 (*not Montagu*). *Orch. trigouochirus*, *Leach, MSS.* a. Sicily. b. Malta.
- "*Orchestia longieornis*, *Edw. Ann. Sc. Nat.* xx. 361. *Crust.* iii. 18. *Talitrus long.*, *Say, Journ. Acad. Sc. Phil.* i. 384. *Scamballa long.*, *each [Leach]*, *MSS.* a-c. U. States (New Jersey). Presented by Thomas Say, Esq.
- "*Orchestia Deshayesii*, *Audouin, Ex. Pl. Egypte*, t. 11, f. 8. *Edw. Crust.* iii. 18. *Scamballa Knhliana*, *each [Leach]*, *MSS.* a. British Coast.
- "*Orchestia gryllus*. *Talitrus gryll.*, *Bosc. Crust.* ii. t. 15, f. 1-2. *Say, Journ. Acad. Sc. Phil.* i. 386. *Scamballa Sayana*, *each [Leach]*, *MSS.* a-d. U. States (sandy beaches). Presented by Thomas Say, Esq.
- "*Orchestia Tristensis*. *Scamballa Trist.*, *Leach, MSS.* a-d. I. of Tristan d'Acunha. Presented by Capt. Caruichael."
- "*Orchestia megalophthalmus*. *Scamballa meg.*, *Leach, MSS.* a, b—?
- "*Orchestia Quoyana*, *Edw. Crust.* iii. 19. *Cuv. R. A. (Coch.)* t. 59, f. 4. a, b. Male and female. New Zealand. Presented by W. W. Saunders, Esq."

In the Brit. Mus. Catal., 1862, *Orchestia trigonocheirns*, *Leach MS. B.M.*, is figured and described as a new species; *Orchestia tristensis* is identified with *Orchestia platensis*, Kröyer, 1845, from Monte Video; *Orchestia megalophthalma* is figured and described; and *Orchestia quoyana* is transferred, in agreement with Dana, to *Talorchestia*.

The list continues with *Lysianassa Costæ*; *Dexamine spinosa*; "Dexamine? carino-spinosa. *Cancer earino-spin.*, *Turton, Mont. Linn. Trans.* xi. 4. ? a. Isle of Wight," for which see Note on Turton, 1802. Seven species are assigned to *Amphithoe*, namely *A. rubricata*; *A. fueicola*, with *Pherusa fucic.*, *Leach*, for a synonym; *A. obtusata*, *Melita obtusata*, *Leach*; "Amphithoe viridis. *Elamis viridis*, *Leach, MSS.* a. Sieily." "Amphithoe punctata, *Say, Journ. Acad. Sc. Phil.* i. 383. a. U. States (Great Egg Harbour). Presented by Thomas Say, Esq.;" "Amphithoe truncatipes, *Spinola*. a-e. Italy. Presented by M. Spinola," afterwards figured and described by Spence Bate in the Brit. Mus. Catal. as *Mæra truncatipes*, with the remark, "this species may be *Gammarus crassimanus* of Viviani, 'Phosphor. Maris,' etc. p. 10. t. 2. figs. 7 and 8; but not having seen that work I hesitate to do more than suggest the possibility;" and lastly, *Amphithoe Edwardsi*, *Ross*, Sabine's *Talitrus Edwardsii*, from Spitzbergen, for which see Note on *Oniscus aculeatus*, Lepechin, 1780.

To *Gammarus* White's list refers 1. *G. locusta*, Fabr.; 2. " *Gammarus fluviatilis*, *Edw. Crust.* iii. 45. *Astacus fluv.*, *Ressel, Ins. Bel.* iii. t. 52. *Geogr. Hist. Ins.* t. 21, f. 6. *Squilla pulex*, *De Geer, Mem.* vii. t. 33. *Gamm. Roeselli*, *Gervais, Ann. Sc. Nat. 2nd series*, iv. 128. *Gamm. aquaticus*, *Leach, Enc. Brit. Suppl.* i. 425. a-g. Duddingston. From the collection of Dr. Leach;" 3. *G. fasciatus*, *Say*, presented by *Say*; 4. " *Gammarus minimus*, *Say, Journ. Acad. Sc. Phil.* i. 376. *Gam. fasciatus?* *Edw. Crust.* iii. 46. a-f. United States. Presented by Thomas Say, Esq.;" in naming which White followed Milne-Edwards in tacitly assuming that *minimus* was the form which *Say* intended for the specific designation, not the incorrect *minus* which in fact he printed, and which Spence Bate restores in the Brit. Mus. Catal. p. 221; 5. *G. marinus*, *Leach*; 6. *G. campylops*, *Leach*; 7. " *Gammurus pulex*,

Fabr. Ent. Syst. ii. 516. *Latr. Hist. Nat. Crust.* vi. 316. *Mont. Linn. Trans.* ix. t. 4. f. 2. *Desm. Cons.* 267, t. 45, f. 8. *Cancer p., Linn. Syst. Nat. Geöff. Ins. Par.* ii. 667. a-c. Ireland. Presented by J. Thompson, Esq.;” 8. *G. Sabinii*, Leach; 9 “*Gammarus Boreus, Sabine*, App. to Parry's First Voy. 229. Ross's Second Voy. Suppl. 88. *Gammarus arcticus*, Leach, MSS. a. b. Adult. Baffin's Bay. c-e. Young. Baffin's Bay. f-g. Spitzbergen. Presented by the Admiralty,” a species which Boeck unites with *Gammarus tocosta*. 10. “*Gammarus ornatus*, Edwards, Ann. Sc. Nat. xx. 372, t. 10, f. 9-10. Crust. iii. 47. *Gamm Redmanni*, Leach, MSS. a-c. North America. From the collection of Lieut. Redman;” 11. “*Gammarus glacialis*, Leach, MSS. a, b. Spitzbergen;” 12. “*Gammarus acanthonotus*, Leach, MSS. a—;” 13. “*Gammarus Zete*, n. s. a, b—;” 14. *G. mueronatus*, Say, presented by Say, for which see Note on Say, 1818; 15. “*Gammarus glaber*, Spinola, MSS. a, b. Mediterranean. Presented by M. Spinola,” a species identified by Sp. Bate with *Lysianassa costae*, Edw.; 16. *G. grossimanus*, Mont. and 17. *G. longimanus*. For the last two, “Mæra grossim., Leach,” and “Mæra, longi., Leach, MSS.” which White gives as synonyms, are now preferred as the established names, but each with the termination -manus rather than -mana. By Spence Bate *Gammarus Boreus*, Sabine, is accepted as a distinct species, with *G. glacialis*, Leach, and *G. Arcticus*, Leach, as synonyms, the remark being made that “this species closely resembles *Gammarus ornatus*, from which it appears to differ only in some minute details of the gnathopoda.” The Brit. Mus. Catalogue likewise gives as a distinct species, “*Gammarus Redmanni*, Leach, MS. B.M.” with the synonym “*Gammarus ornatus*, White, Cat. Crust. B.M. 1847 (not Edwards),” and the remark, “This species resembles *Gammarus ornatus*, but microscopic examination of the gnathopoda exhibits a distinction.”

“After the Gammari the list gives “*Vertumnus*, Leach. *Vertumnus Cranchii*, Leach, MSS. a-d. Falmouth. From the collection of Dr. Leach,” since identified by Boeck with *Epimeria cornigera*, Fabricius, 1779. After *Leucothoe articularosa*, Montagu's Devonshire species, “*Leucothoe* — a, b. Mediterranean (Genoa),” is given. Then come *Cerapus pelagicus*, Edw., identified with *Jassa pel.*, Leach; and *Cerapus fulcatus*, as a name for “*Cancer (Gammarus) falcatus*, Mont.,” and “*Cerapus pelagicus* p., Edw. Crust. iii. 61. (not *Jassa pel.*, Leach).” These are followed by *Podocerus variegatus*, Leach, and *Podocerus pulchellus* (= *Jassa pulchella*, Leach), all the last four in White's list being now recognised as forms of a single species. *Corophium longicorne*, Latr., is given with various authorities, and the synonyms “*Gammarus long.*, Fabr. Ent. Syst. ii. 516. Roemer. Gen. Ins. t. 33. f. 6. *Astacus linearis*, Pennant, Brit. Zool. iv. 17, t. 16, f. 31. *Oniscus volutator*, Pallas, Spie. Zool. ix. 59 t. 4, f. 9.” Next is “*Nemertes*, Leach. *Nemertes nesaeoides*, Leach. a-d. Britain. From the collection of Dr. Leach,” identified by W. Thomson, 1847, with *Chelura terebrans*, Philippi, 1839. *Atylus carinatus*, Fabr., and *Unciola irrorata*, Say, presented by Say, conclude the Gammaridæ.

The Hyperiadæ are represented by “*Hyperia Latreillii*,” Edw., with “*Hiella Orbignii*, Strauss,” for a synonym; by *Hyperia galba*, with the synonyms “*Cancer (Gammarus) galba*, Mont.,” and “*Callianira*, g. Leach, m. n.;” by *Metoecus cyanex*, Edw., with the synonyms “*Talitrus Cy.*, Sabine” and “*Hyperia Cy.* Edw.,” the whole of which group is united into a single species by Boeck as *Hyperia Medusarum*, O. F. Müller, 1776. Before *Metoecus cyanex*, the list gives *Metoecus medusarum*, Krøyer, with the synonym *Oniscus Met.* O. Fabr., for which see Note on Kroyer, 1838. The next species is thus entered, “*Primno*, Guerin. *Primno Guerinii*. a. Atlantic Ocean (S. Lat. 8° E. Long. 46°). Congo Expedition.” No notice is taken of this species in the Brit. Mus. Catalogue, where Guérin's type-species, *Primno macropa*, is figured and described. The list next gives *Phronima sedentaria*, Forsk., and *Phronima attantica*, Guerin; concluding the Hyperiadæ with “*Typhis monoculoides*. *Cancer (Gammarus) mon.*, Montagu, Linn. Trans. ii. [xi.] t. 2. f. 3. a. South east of Devon.

From the collection of Col. Montagu," and "Typhis—*a-c.* Norfolk (Cromer)." Since the *Typhis monoculoides* is in point of fact the Gammarid, *Stenothoë monoculoides*, the *Typhis* from Cromer has but a doubtful claim to that generic title.

The Caprellidae contain 1. *Caprella linearis*, Latr. *Hist. Crust.* vi. 324, with many other references, the localities assigned for the specimens being "a. British Coast. From the collection of Dr. Leach. b-d. Firth of Forth. Presented by H. Goodsir, Esq., Surg. R.N." ; 2. *Caprella lœvis*, Goodsir; 3. *Caprella aruminifera*, Leach, *Desm. Cons.* 277. *Edw. Crust.* iii. 107. t. 33, f. 1. *Queronic*, *Mem. Sar. etr.* iii. 329, f. A. B.; 4. *Caprella acutifrons*, Desm., with *C. atomos*, Leach, for a synonym; 5. *Caprella phasma*, Montagn's species; 6. *Caprella tuberculata*, Goodsir, with the synonym "C. tuberculata, Guerin, *Icon.* t. 28. f. 1?" ; 7. *Caprella geometrica*, Say; 8. *Caprella equilibra*, Say; the two last presented by Say. These are followed by "Proto, *Linn.* Proto pedatum, *Leach. Linn. Trans.* xi. 362," with "Gammarus ped., *Müller*," and "Leptomera ped. *Guer.*" for synonyms; on which it should be noticed that the genus *Proto* was instituted by Leach, while the species is properly *Proto ventricosa*, O. F. Müller.

To the family Cyamidæ are assigned five species of *Cyami*, 1. *Cyamus erraticus*, Rouss. with the synonyms *Oniscus ceti*, L.; *Squilla c.*, Degeer; *Cyamus c.* Latr.; *Panope c.*, Leach; *Larunda c.*, Leach; 2. *Cyamus ovalis*, Rouss.; 3. *Cyamus gracilis*, Rouss., all these three being said to come from British Seas. No. 4 is mysteriously represented by "Cyamus—a—." No. 5 is *Cyamus abbreviatus*, Say, from North America. Presented by Say.

On p. 130, among the additional species are given, "Ephippiphora, White. Ephippiphora Kroyeri, n. s. *Zool. Ereb. and Terr. t. f. a.* Tasmania," and "Rhabdosoma, Adams and White. Rhabdosoma armatum. Oxycephalus arm. *Edw. Crust.* iii. 101. a. Indian Ocean. Presented by Capt. Sir Edw. Belcher, C.B., R.N."

1847. WHITE, ADAM.

Descriptions of new or little known Crustacea in the Collection at the British Museum. Proceedings of the Zoological Society of London, July 27, 1847. Part XV. 1847. Also in the Annals and Magazine of Natural History. Vol. I. Second Series. Number III. pp. 221–228. London, 1848.

In the "Order Amphipoda, Family Gammaridæ," White thus describes his genus *Ephippiphora*:

"Head rather large; antennæ distant from each other, the upper pair with the basal joints very thick and corneous, inserted in a deep notch in front of head; two setæ at the end of each, the outer the thicker. Lower pair of the antennæ with the basal joint somewhat elongated and furnished with hairs.

"Body much compressed, the lateral appendages on the first eight joints very large, and nearly concealing the legs; the appendage of the fourth joint much dilated behind at the end; eighth to eleventh joints slightly keeled on the back; appendages of the three last joints of abdomen longish, with short spines on the edge behind.

"A genus allied to *Orchestia* and *Talitrus*."

"*EPHIPPIPHORA KROYERI*, White, List. p. 130.

"The body is very highly polished, the edges of the segments behind somewhat tinged with yellow; the legs and caudal appendages slightly brownish.

"*Hab.* Van Diemen's Land.

"Named as a small compliment to the very eminent Danish naturalist, whose researches among the less studied orders of Crustacea are so well developed in his published but not easily accessible works. I regret that, excepting a few foliated plates of the large 'Voyage en

Islanda,' &c., I had not seen any part of them when I prepared the 'List of Crustacea in the British Museum.'"

The account of the upper antennæ shows that White is wrong in allying his new genus to the Orchestidæ; in Boeck's opinion his own *Socarnes* may possibly be a synonym of White's *Ephippiphora*.

1848. ADAMS, ARTHUR, and WHITE, ADAM.

The Zoology of the Voyage of H.M.S. "Samarang"; under the command of Captain Sir Edward Belcher, C.B., F.R.A.S., F.G.S., during the years 1843–1846. Crustacea by Arthur Adams, F.L.S., and Adam White, F.L.S. London, 1848.

On page 63 is given "RHABDOSOMA, *Adams & White*. *Oxycephalus*, M.-Edwards. We regret that the state of the only specimen in the British Museum is such that we cannot give the generic character with that detail which we should wish. It is founded on the third species of Professor Milne-Edwards, indeed Mr. White has the authority of that eminent Crustaceologist that it is his very species; it is so different from the *Oxycephalus piscator*, M. Edwards (Crust. III. p. 100 t. 30. f. 10), that we have traced the figure of *Oxycephalus piscator*, and added it below that of the *Oxycephalus armatus* to show the difference. Someday it may be proved to be a sexual character, when of course our name will sink, but *as yet* we know of no such discrepancies in the sexes of these Crustacea.

"The head is as long as the rest of the body, and ends in a very long beak; from the state of our specimen we cannot describe this, but indicate it on the plate from a drawing made at the time of capture. The immense length of the body and beak would sufficiently mark this generic form. The first two pairs of legs are shown in the figure, which must serve till we can procure further specimens, when we hope to give ample details of this very singular crustacean, and to analyse its characters at length. It forms a singularly interesting link between the *Amphipoda* and *Læmodipoda*, uniting, as it were, the two; we should like to have this form examined particularly by Prof. M. Edwards or Dr. Kroyer.

"RHABDOSOMA ARMATUM, *Adams and White*. (Tab. XIII. Fig. 7.) *Oxycephalus armatus*, M.-Edw. Crust. III. p. 101. pl. 30. f. 10, copied. (Tab. XIII. Fig. 8.)

"The specimen described by Professor Milne Edwards was found by MM. Quoy and Gaimard in the Ocean between Amboina and Van Dieman's Land, and is now in the Paris Museum. Ours was taken during a calm, floating on the surface of the South Atlantic Ocean."

1848. LEYDIG, FRANZ.

In his Treatise "Ueber Amphipoden und Isopoden," 1878, page 229, note 2, Leydig says that he had already in 1848 described and figured the segmentation-process of *Gammarus*; but he does not say that the account was published, though this would seem to be implied by the context.

1848. MILNE-EDWARDS, H.

Note sur un crustacé amphipode, remarquable par sa grande taille. Annales des sciences naturelles. Troisième Série. Zoologie. Tome neuvième. Paris, 1848.

This note, at page 398, records the finding of an amphipod, with a body 9 cm. long and 3 cm. high, by M. d'Orbigny, who took it from the stomach of a fish caught off Cape Horn. Supposing it to be new, Milne-Edwards names it "*Lysianassa Magellanica*".

It has since been identified with Mandt's *Gammarus gryllus*, and named *Eurythenes gryllus*.

1848. MÜLLER, FRIEDRICH.

Orchestia Euchore und Gryphus, neue Arten aus der Ostsee, beschrieben von Dr. Friedrich Müller. (Hierzu Taf. IV.) Archiv für Naturgeschichte. Vierzehnter Jahrgang. Erster Band. Berlin, 1848.

Müller notices that the genera *Talitrus* and *Orchestia* belong to the warmer seas, and seem to be wanting in the arctic waters, the proper home of the typical Gammarina. From this point of view he thinks the discovery of two new species from the Baltic not without interest. He does not consider the presence of the large second hands in *Orchestia* sufficient for a generic distinction from *Talitrus*, while in the two new species, as in *Orchestia platensis*, Kröyer, the males belong to *Orchestia*, the females to *Talitrus*. *Orchestia euchore* is fully described and figured, but it is, as Boeck says, not to be distinguished from *Orchestia gammarellus*. Müller says that the mandibles are without any trace of a palp, as if he had given special attention to that point. He recognizes the great likeness between *Orchestia gryphus* and *Orchestia deshayesii*, Audouin. In conclusion he says, “*Orchestia platensis*, *Euchore* et *Gryphus* inter se convenient:

“*Antennis sup. capitii longitudinem haud aut vix superautibus; mandibulis palpi ne vestigio quidem gaudentibus: maxillarum paris I lamina interna angusta setis pinnatis curvatis duabus instructa; palpi pedum maxillarium articulo ultimo brevi lato rotundato; pedibus II paris in ♂ manu valida instructis, in ♀ debilibus, ungue exiguo articuli Vⁱ foliaceo-dilatati, cuius margini anteriori inseritur, apicem haud superante preditis; branchiis Iⁱ paris angustis elongatis flexuosis; pedibus saltatoriis paris ultimi exiguis conicis, stylo terminali unico donatis; lamina caudali unica crassiuscula, spinis ornata.*

“Differunt:

“*Orchestia platensis*, Kr. *Antennis superioribus* caput longitudine æquantibus aut vix superantibus; *antennis inf.* vix tertiam corporis partem longitudine æquantibus, pedunculo flagellum 14 articulatum parum excedente; *oculis ellipticis*; *primi pedis articulo* quinto apicem versus in ♂ dilatato, haud dilatato in ♀, ungue valido inermi; manu *pedis secundi* in ♂ lata ovali; *pedis septimi articulo* quarto in ♂ incrassato, in ♂ gracili, *lamina caudali* truncata; longitudine lineorum 6.

“*Orchestia Euchore* F. Müll. *Antennis superioribus* caput, *inferioribus* tertiam corporis partem, harum pedunculo flagellum 18 articulatum longitudine æquantibus; *oculis rotundis*; *primi pedis articulo* quinto apicem versus in ♂ dilatato, haud dilatato in ♀, ungue valido spinulis duabus in margine interiore armato; manu *pedis secundi* in ♂ ovali; *pedis septimi articulo* quarto in ♂ incrassato, in ♀ gracili; *lamina caudali* emarginata; long. 5”.

“*Orchestia Gryphus* F. Müll. *Antennis sup. capite brevioribus; inferioribus* in ♂ dimidiata, in ♀ quintam (?) corporis parte longitudine æquauitibus, flagello 20 articulato pedunculi dimidiata subæquante; *oculis rotundis*; *primi pedis articulo* quiuto uee in ♂, nec in ♀ dilatato, ungue valido spinula unica in margine interiore armato; manu *pedis secundi* lata, incisura profunda in ramos duos divisa, anteriorem longiore latiorem uuguigerum, posteriorem acuminatum; *pedis septimi articulo* quarto in utroque sexu gracili; *lamina caudali* emarginata; long. 4”.

Another notice, headed “Bemerkungen zu Zaddach's Synopseos Crustaceorum Borussicorum prodromus,” states that *Leptocheirus pilosus*, Zaddach, has in fact a very rudimentary, one-jointed accessory flagellum on the upper antennæ, which had escaped the notice of the author of the genus *Leptocheirus*, when the absence of an accessory flagellum was made part of the generic character.

1848. SIEBOLD, CARL THEODOR ERNST VON, born 1804, died April 7, 1885 (Friedländer, *Naturae novitates*).

Lehrbuch der vergleichenden Anatomie der wirbellosen Thiere. Berlin. 1848.

1849. BRANDT, JOHANN FRIEDRICH.

Symbolæ Sirenologieæ, quibus praeipue Rhytinæ historia naturalis illustratur auctore Joanne Friderico Brandt. (Conventui exhib. die 23 januarii 1845.) Appendix II. *De animalculo parasitico peculiariter Cyamo ? vel rectius forsan Sirenocyamo ? Rhytinæ* in *Rhytinæ cuticula a Stellero observato una cum Rhytina et Ascaridibus ejus deleto.* Mémoires de l'Académie impériale des Sciences de Saint-Pétersbourg. Sixième série. Sciences naturelles. Tome V. St.-Pétersbourg.

1849. pp. 153–157.

After quoting Steller's account, Novi Comment. Petropol. t. ii. pp. 298, 324, and 330, and considering how far it agrees or disagrees with the genus *Cyamus*, Brandt continues, "Ad stabiliendam tamen differentiam genericam aliorum Sireniorum ordinis animalium pedicularum cognitio adhuc optanda videtur. Quia de causa pro tempore parasitum Rhytinæ dubitanter (sicuti siguum interrogationis indicat) geueri Cyamorum quidem iuserimus, sed in parenthesi nomen hypotheticum Sirenocyamus interrogationis signo addito pariter exhibuimus antequam, quæ sequitur, descriptionem ejus in ordinem systematum redactam propinquimus.

"*Cyamus* (?) num genus proprium *Sirenocyamus* (?) *Rhytinæ*.

"Pedes mandibulares biarticulati, extremitate acutissimi et elevati. Pedum thoracicorum sex paria. Pedes thoracali anuulo inserti chelis similes, biarticulati. Appendices respiratoriae a Stellero non deseriptæ. (An characteres generis *Sirenocyamus*?).

"Characteres specifici.

"Habitus fere, ut videtur, Cyami gracilis. Caput oblongum, acutum. Antennulae geniculatae, duæ, breves, 1/2 lineam longe, e fronte exorrectæ. Annuli corporis pro numero pedum sex, dorso convexi, 1/3" lati, a primo ad ultimum annulum (caudam) sensim angustiores. Thoracis annulus sequentibus duplo latior, lentis dimidium refereus. Annulus ultimus seu caudalis orbicularis. Pedes (exceptis illis, qui ad latera thoracis erant adnati et chelas crassas, biarticulatas, aculeo flexili firmissime Rhytinæ cuticulae infixas referebant) graciliores, omnes aculeis præfiniti et sensim breviores; ultimi duo brevissimi ex annulo caudali emergentes corpusculum præfuiabant, ac dum animalculum gradiebatur dirigabant.

"Corpus dimidiatum plerumque uneiam longum, diaphanum.—Color candidus aut subflavus."

If the creature was correctly observed by Steller, the genuine *Cyami*, Brandt says, differ from it:—"Pedibus mandibularibus [maxillaribus] 5-articulatis, pedum corporis genuinoruu paribus quinis, omnibus quinque-articulatis, necnon appendicibus respiratoriis in secundo et tertio corporis annulo pedum loco conspicuis." He thinks that the *Rhytina*'s parasite may have been allied to the *Leptomeræ* rather than the *Cyami*, and contemplates the possibility of finding other *Sirenocyami* still living on other Sirenæ.

1849. CASPARY, ROBERT.

Gammarus puteanus Koch. Beobachtet von Dr. Robert Caspary. Mit Abbildungen. Tab. II. Verhandl. I. Naturf. Vereins für Rheinland, Jahrg. 6. Bonn, 1849. pp. 39–48.

In the full and fairly accurate description which Caspary gives, he obviously falls into error when he says that the intestinal canal (der Darm) runs from the head to the tenth segment in which it opens, the tenth segment in his reckoning being the second of the pleon. Of the last three peraeopods he says that "das Thier streckt sie über den Rücken hinaus, wie Fig. XIX. zeigt und kriecht, anf dem Rücken liegend, öfters auf ihnen." I think it may be safely said that the creature much more usually crawls with the ventral side downwards, the extremities of these peraeopods being extended upwards out of use.

Bate and Westwood are inclined to think "*Niphargus Kochianus*," Sp. Bate, identical with the specimens "described and figured by Caspary and Hosius, referred to in the synonyms under *N. aquilex*." But their *Niphargus kochianus* is expressly distinguished from *Niphargus aquilex* by its second and third pleon segments having the infero-posterior angle acute. Caspary's figure agrees with their *Niphargus aquilex* in having that part rounded.

1849. DANA, JAMES D.

Synopsis of the Genera of Gammaracea. The American Journal of Science and Arts, Second Series, Vol. viii.—No. 22. Nov. 1849. pp. 135–140.

The tribe of Amphipoda here includes the subtribes Gammaracea and Hyperiacea, the former of which consists of six groups or families.

Fam. I. ORCHESTIDÆ, with the genera *Talitrus*, Latreille, *Orchestia*, Leach, *Allorchestes*, Daua.

Fam. II. GAMMARIDÆ. Subfam. I. Lysianassinae, with the genera thus grouped:—

I. a. *Lysianassa*, Milne-Edwards; *Phlias*, Guérin; b. *Stegocephalus*, Kröyer. II. *Opis*, Kröyer; *Uristes*, new. III. *Anonyx*, Kröyer; *Stenia*, new. IV. *Pontoporeia*, Kröyer.

Subfam. II. Gammarinae, with these groups:—I. *Alibrotus*, Milne-Edwards; *Acanthonotus*, Owen. II. *Leptochirus*, Zaddach. III. A. * a. *Gammarus*, Fabr.; *Amphithoe*, Leach; b. *Photis*, Kröyer; *Oelicerus*, Kröyer. †. *Leucothoe*, Leach; *Erichthonius*, Milne-Edwards; *Pardalisca*, Kröyer. B. *Ischyroceras*, Kröyer. IV. A. *Lepidactylis*, Say; *Protomedea*, Kröyer; *Ampelisca*, Kröyer; *Aora*, Kröyer. B. *Phorus*, Kröyer.

Subfam. III. Isæinæ. A. *Isæa*, Milne-Edwards; *Anisopus*, Templeton. B. *Laphystius*, Kröyer.

Fam. III. Corophidæ. a. *Cerapodina*, Milne-Edwards; *Cerapus*, Say. b. * *Corophium*, Latreille; *Poilocerus*, Leach. † *Unciola*, Say; *Atylus*, Leach. ‡ *Clydonia*, Dana, new.

Fam. IV. Iciliidæ. *Pterygocera*, Latreille; *Icilius*, new.

Fam. V. Cheluridæ. *Chelura*, Philippi.

Fam. VI. Dulichidæ. *Dulichia*, Kröyer.

Fr. Müller having in 1848 denied the propriety of separating the *Orchestia* and *Talitri*, Dana remarks, "There is however a wide difference between the species having a styliform joint terminating the second pair of legs and those with a haul however minute or obsolescent. The only safe course appears to the writer to consist in drawing the line between species having a finger or claw however small or large, closing upon the fifth joint, and those species having an extended finger or claw not closing up."

The new genus *Allorchestes*, identical with *Nicea*, Nicolet, published in the same year 1849, and probably the same as *Hyale*, Rathke, 1837, is thus defined:—"Pedes primi secundique

subcheliformes. Antennæ superiores breviores, basi inferiorum longiores. Maxillipedes ad apicem unguiculati," with the following note, "The species of this genus have the aspect of many Amphithoe, and have probably been hitherto referred to that genus. They have the very short posterior stylets of the Orchestiae, and resemble them in habit and in the absence of a palpus to the mandible; while they differ in having the superior antennæ *longest* and in the stout spine or claw terminating the maxillipeds. The writer has dissected the mouth of nearly a dozen species of Allorchestes." The italicized word *longest* is no doubt only a slip for *longer*.

The subfamily *Lysianassinae*, which includes *Uristes* in its second, and *Stenia* in its third division, is defined as having:—"Antennæ superiores ad basin crassæ. Epimera grandia. Pedes sex postici non prehensiles."

The new genus *Uristes* has for its characters "Pedes primi subcheliformes, secundi non subcheliformes; reliqui non prehensiles;" "Antennæ sup. non appendiculatae. Pedes secundi vergiformes; tertii quartique brevissimi." As pointed out by Spence Bate, it is probably only founded on a misconception.

The new genus *Stenia* is characterised by "Pedes primi secundique subcheliformes, reliqui non prehensiles;" "Antennæ sup. non appendiculatae." This genus Dana subsequently dropped, as not distinct from *Anonyx*, Kröyer.

The new genus *Clydonia* is placed among those Corophidae which have "Digitu nulli 2-articulati," and further defined as having "Antennæ longæ, flagello crasso rigidoque, obsoletè articulato;" "Antennæ styliformes, rectæ. Pedes filiformes, non prehensiles, sex postici prælongi." Bovallius, 1885, identifies this genus with *Tyro*, Milne-Edwards, 1840.

The new genus *Icilius* is defined simply by the words "Pedes toti vergiformes, nulli prehensiles." Its companion in the Iciliidae, *Pterygocera*, Latreille, "Pedes postici sublamellati," is a synonym of *Lepidactylis*, Say (*Haustorius*, P. L. S. Müller), which Dana places among the Gammarinæ.

Dana observes in his notes that *Mæra* and *Melita* are separated by Leach, and *Amathia* by Rathke, from the genus *Gammarus*, that *Amphithoe* includes the *Deramine* and *Pherusa* of Leach, that *Eusirus* of Kröyer is not sufficiently distinct even for a subgenus, that Kröyer's *Microcheles*, Rathke's *Iphimedia*, and Owen's *Acanthosoma* are near *Amphithoe*, that *Siphonocetes* of Kröyer differs from *Podocerus* only in having the posterior legs longer than the four preceding, and that *Glauconome* of Kröyer has the hands and antennæ of *Unio*.

1849. LILJEBORG (subsequently LILLJEBORG) WILHELM, born 1816 (G. O. SARS).

Zoologisk resa i norra Ryssland och Finnmarken. Öfversigt af Kongl. Vetenskaps-Akademiens Förfhandlingar. Årg. 6. 1849. No. 1. Stockholm. pp. 16-37.

This letter from Liljeborg to Lovén is mentioned in Boeck's list, but I cannot find that it contains any information about the Amphipoda, or any mention of Crustacea, except the bare fact, p. 32, that at Tromsö in Norway he had observed some which he had not at the time of writing determined.

1849. LUCAS, H.

Exploration scientifique de l'Algérie pendant les années, 1840, 1841, 1842. Zoologie. Histoire naturelle des animaux articulés.

In the "Première Classe.—Crustacés. Troisième ordre, les Amphipodes. Première Famille, les Crevettines. Première Tribu, les Crevettines santeuses," he gives the following species,

103. *Talitrus saltator*, Mont.; 104. *Talitrus platycheles*, Guér.; 105. *Orchestia littorea*, Mont.; 106. " *Orchestia Montagui*," Sav. et Aud.; 107. " *Orchestia Perieri*," n. s.; 108. " *Orchestia Fischeri*," M.-Edw.; 109. " *Lysianassa Costa*," M.-Edw.; 110. *Lysianassa longicornis*, n. s.; 111. " *Amphithoe Vaillantii*," n. s.; 112. *Gammarus locusta*, Mont.; 113. *Gammarus fluviatilis*, Roes.; 114. " *Gammarus Olivii*," M.-Edw.; 115. *Gammarus peloponnesius*, Guér. In the "Deuxième Famille, les Hypérines. Première Tribu, les Hypérines Gammaroides," he gives 116. " *Vibilia Jeangerardii*," n. s.; in the "Deuxième Tribu, les Hypérines ordinaires," 117. *Phronima sedentaria*, Forsk.; and in the "Troisième Tribu, les Hypérines anormales," 118. *Typhis ovoides*, Risso. In the "Quatrième Ordre, les Læmodipodes. Première Famille, les Caprelliens," he gives 119. *Caprella tabida*, n. s.

Occasional notes are made upon the various species. The new ones are described and figured.

" *Orchestia Perieri*," pl. 5. fig. 1, called in the Brit. Mus. Catal., " *Allorchestes Pereiri*," now becomes *Hyale perieri*. *Lysianassa longicornis*, pl. 5. fig. 2, " Long. 10 millim. larg. 3½ à 4 millim.," is thus defined, " antennis primis sat elongatis, primo articulo infra fortiter spinoso; secundis elongatissimis; pedibus spinosis, posticorum primis articulis subtiliter denticulatis." Besides the very pronounced spine at the lower distal end of the first joint of the peduncle of the upper antennæ, we learn that " leur filet accessoire est assez court." " Les yeux sont très-grands et réniformes." The telson is " assez fortement creusé en euiller et terminé en pointe arrondie postérieurement. Les stylets terminaux des fausses pattes des trois dernières paires sont assez allongées." The highly useful information is also given that, " La première et la seconde paire de pattes ne présentent rien de remarquable." The figure 2b shows the upper antenna with a thick first joint having infero-distally a small process and a long spine, the second joint not much shorter than the first, and two and a half times as long as the third. Spence Bate adopts the name for a British species, to which he does not assign any spine on the upper antenna, and of which he says (Brit. Sess. Crust. i. p. 88), " the central tail-piece exhibits no peculiar character." According to G. O. Sars, 1882, *Lysianassa longicornis*, Sp. Bate, is the male of *Anonyx edwardsii*, Sp. Bate, and is renamed " *Orchomene Batei*," G. O. Sars, although the first gnathopods as figured and described by Bate and Westwood do not agree with the definition of the genus *Orchomene*. Heller in 1866 gives a fresh description and figures of *Lysianassa longicornis*, Lucas, with a long process instead of a spine on the upper antennæ. By the antennæ this species approaches Costa's genus *Ichnopus*.

" *Amphithoe Vaillantii*," pl. 5, fig. 3, " Long. 12 à 17 millim. larg. 3 à 4 millim.," is thus defined:—" flavescens, subtiliter viridi punctata; antennis aequalibus, fortiter ciliatis; pedibus primi paris brevibus, secundi paris elongatissimis, penultimo articulo valde emarginato, ad basin spinâ instructo; corpore lœvigate." In regard to this species see Note on Prof. Catta, 1876.

" *Vibilia Jeangerarlii*," pl. 5, fig. 4, " Long. 10 millim. larg. 3 millim.," is thus defined:—" rubro subtiliter laxèque maculata; antennis primi paris levigatis, anticè obtusè truncatis, secundi paris brevibus; pedibus levigatis, penultimo articulo paulisper arcuato; septimo segmento abdominis suprà trilobato, penultimo anticè transversim depresso." It is near " *Vibilia Peroni*," M.-Edw., but differs from it " par la tête, qui, à son sommet, est moins acuminée; le dernier article des antennes supérieures est aussi plus allongé et surtout beaucoup plus obtusément tronqué à sa partie inférieure que dans la *V. Peroni*." Moreover in *Vibilia jeangerarlii* the lower antennæ, he says, are a little more than half as long as the upper, while in the other species they are much longer than the upper antennæ.

Caprella tabida, pl. 5, fig. 6, is identified by Mayer with *Caprella acutifrons*, Latreille.

1849. NICOLET, HERCULE.

Historia fisica y politica de Chile segun documentos adquiridos en esta república durante doce años de residencia en ella y publicada bajo los auspicios del supremo gobierno por Claudio Gay ciudadano chileno. Zoología. Tomo tercero. Paris, MDCCXLIX.

The Crustacea occupy pages 115 to 318 of this third volume. In the first division, "Crustaceos maxilados," the "Anfipodos" and "Læmodipodos" are respectively the third and fourth orders. The Amphipods, pages 226 to 249, include the two subdivisions, "Gamarianos" and "Hiperineas." In the former, *Talitrus chilensis*, n. s., is established on a damaged specimen with the definition, "*T. antennis brevibus; pedibus anterioribus gracilibus; corpore supra levi, ad latera rugoso.*" A new genus follows, thus described:—

"ORQUESTOIDEA.—ORCHESTOIDEA. *Antennæ superiores minimæ, inferiores [inferioribus] multo breviores; articulo primo lato, quadriformi, fortiter depresso; secundo gracili, cylindrico; tertio secundo breviori, gracili, cylindraceo, tigilla brevissima, quinque articulata terminata. Antennæ inferiores maximæ, crassissimæ; articulo ultimo pedunculi elongato; penultimo ultimo crassiori, leviter breviori. Oculi magni. Palpus pedum maxillarum externarum quadriarticulatus, parum elongatus, crassus; articulo primo brevissimo; tertio quadriformi, apice truncato, in medio fortiter emarginato, quarto angusto brevi, turbinato. Mandibulæ robustæ, fortiter dentatae, palpo nullo. Pedes primi paris tarsus styliformi terminati; secundi paris subchiliformes manu maxima crassissima, ovata; sequentes unguiculati."*

The fuller description concludes with the observation, "los apéndices de los anillos abdominales son cortos y bifidos; el último segmento es muy corto y repentinamente replegado por abajo, lo que da á la extremidad posterior del cuerpo un aspecto truncado," to which he appends the remark by way of note, "la forma de las antenñas y la del cuerpo de estos Crustaceos representan á los Talitros, mientras que la disposición de sus patas del segundo par los incorpora á las Orquestias: pero las pata-quijadas esternas y sobre todo la forma de los tallos palíformes los separan completamente, siendo intermedios de ambos géneros, con quienes tienen muchas relaciones." The type species, *Orchestoidea tuberculata*, pl. 2, fig. 4, is defined as "*O. flavescens; corpore tuberculato; articulo primo pedunculi antennarum extus bituberculato; fronte in medio leviter angulato; pedibus villosis.*" Nothing is said about the female.

He then describes *Orchestia chilensis*, M.-Edw.; *Orchestia brevicornis*, n. s.; "*Orchestia Gayi*," n. s.; *Amphitoe chilensis*, n. s., pl. 2, fig. 5; "*Amphitoe Gayi*," n. s., pl. 2, fig. 6.

The new genus *Nicea* is thus defined:—"Antennæ superiores cæteris breviores. Caput crassum. Oculi ovati, oblique dispositi. Pedes breves, primi et secundi paris subchiliformes; manibus brevissimis. Mandibulæ brevissimæ, bilobatae, multidenticulatae, non palpigeræ. Labium sternale maximum." To the general description he adds that he has formed this genus upon a specimen which has various affinities with *Amphithoe*, but differs in the absence of the mandibular palp and the relative length of the antennæ, bringing it near to *Talitrus*, and above all by the considerable development of the bucal portion and the form of the maxillipeds; its dilated (rehecho) body resembles that of *Talitrus*. The type species, "*Nicea Lucasii*," pl. 2, fig. 7, is defined "*N. obscure fusco-virescens; corpore brevi, crasso, curvato, convexo; pedibus maxillaribus externis fortiter tuberculatis.*"

He next gives *Gammarus chilensis*, n. s.

This is followed by what Nicolet supposed to be a new genus, *Lalaria*, thus defined:—

"Antennæ superiores graciles, elongati, articulo secundo pedunculi primo longiore, cylindrico, tertio brevi, bitigellato. Antennæ inferiores pedunculo elongatissimo, tigilla brevissima.

Caput breve, anterius truncatum. Oculi parvi. Mandibulae palpigeræ, palpo triarticulato, articulo primo brevi, secundo tertioque elongatis, cylindraceis, fortiter ciliatis. Pedes maxillares externi palpis quinque articulatis; articulo ultimo unguiformi. Pedes quatuor primorum parum prehensiles; Pedes primi paris multo longiores, robusti, palpo spiniformi infra muniti; digito elongato, cylindraceo, unguiculato, terminati."

The type-species, *Lalaria longitarsis*, pl. 2, fig. 8, is defined:—

“*L. flavescentia; pedibus posterioribus longis pilis vestitis; pedibus anterioribus ciliatis.*”

In the “Hiperincas,” *Hyperia*, Latr., with *Lanceola*, Say, and *Hiella*, Straus, for synonyms, is thus defined:—

“*Corpus gibbosum, latum, anterius obtusum, posterius fortiter angustatum. Caput crassissimum, inflatum, verticale. Oculi magni, compositi. Antennæ minimæ in fossula capitis insertæ. Mandibulae robustæ, palpigeræ, duabus cristatis masticatoribus terminatae. Thorax septem annulatus. Pedes mediocre, angustati, ungue acuto terminati. Abdomen tribus primis segmentis magnis, appendicibus natatoriis elongatis munitis. Segmento quarto fortiter curvato, duobus ultimis caudiformibus.*”

The species “*Hyperia Gaudichaudii*,” M.-Edw., is described. He also describes Guérin’s genus *Primno*, with its type species, “*Primno macropo*” [macropa], and Guérin’s *Pronoë*, likewise with its type species, *Pronoe capito*.

Oxycephalus, M.-Edw., he thus defines:—

“*Caput maximum, depresso, elongatissimum, anterius acutum. Antennæ superiores crassæ, fractæ, capite multo breviores, infra rostro insertæ; antennæ inferiores graciles, cylindraceæ, setaceæ, thorace longiores. Oculi maximi. Pedes primi et secundi parum dydactiles; segmentis [sequentes] elongatissimi, graciles, subulati. Pedes septimi paris vel brevissimi, vel nulli. Segmenta primo secundo tertioque abdominis magna, pedunculo appendiculum natatoriæ crassissimo; segmenta quarto et quinto brevissima; sextum elongatissimum, appendice styliformi, acutissima, elongatissima, terminatum.*” A misprint here and there seems to have affected the Latinity of this passage. One species of this genus, the author says, pertains to Chili, namely, *Oxycephalus oceanicus*, Guérin, thus defined:—“*O. antennis superioribus oratis, articulo parrulo, acuto, terminatis; antennis inferioribus parvis, quinque articulato; articulis aequalibus.*”

In Order IV, “Lœmodipodos,” the “Caprelanas” contain the genus *Caprella*, which Nicolet assigns to Leach. He concludes the description of this genus with the words, “abdomen rudimentario, teniendo cerca de su base un par de apéndicitos estiliformes y biarticulados,” adding a note, “Conocemos tres especies de este género, é ignoramos por qué motivo el Sr. Milne-Edwards niega á las patas del segundo par las vijiguillas branquiales, puesto que la *C. longicollis* las tiene, y muy aparentes.”

Caprella longicollis, n. s., pl. 4, fig. 3, is thus defined and described:—“*C. fusca; capite elongato, antice globoso, postice cylindrico; antennis superioribus setiformibus, longissimis; antennis inferioribus brevibus: pedibus paris secundi tarse angusto, elongato, antice dilatato, postice subcylindrico.*”

“Cabeza una vez y media mas larga que el primer articulo del tórax, con su parte anterior globosa y en espinas, ocupado el tercio de su longitud; los otros dos tercios son cilíndricos, mucho mas pequeños y tan gruesos como la mitad anterior del primer segmento torácico; antenas superiores muy largas, fuertes en la base y disminuyendo insensiblemente de grosor hasta la extremidad del tallo multiarticulado; las inferiores son muy cortas, delgadas y filiformes; las patas del primer par están adheridas á la faz inferior de la parte globosa de la cabeza, cerca de la boca, son cortas, delgadas, y encuelan en una mano subglobosa; las del segundo par, al contrario, son muy largas y las termina una mano que ocupa la mitad de su total longitud, estrecha, levemente arqueada, repentinamente dilatada en el tercio anterior y subcilindrica cerca de su base; el segmento torácico á que estas patas se hallan adheridas es

irregularmente trianguliforme, y su ángulo anterior, que es el mas largo, sostiene la cabeza : en el posterior está inserto el segmento siguiente ; las patas ocupan el ángulo inferior, que tiene además dos vejigillas branquiales adaptadas á la base de las patas; los dos segmentos que siguen son, como el resto del cuerpo, subcilindricos, llevando cada uno dos vejigillas branquiales ; las patas del primero de los tres últimos pares son muy cortas y rudimentarias, y las de los otros dos prolongadas y subquiliformes, con el penúltimo articulo dentellado en el lado interno ; dos filetes espiniformes por bajo del abdomen.—Color moreno amarillento claro.—Longitud, 8 lin."

Caprella brevicollis, n. s., pl. 4, fig. 4, is defined :—

" *C. fusca* ; capite brevi, subgloboso ; antennis mediocribus ; pedibus secundi paris antice ovatis, subglobosis." It was taken with the preceding form.

Caprella spinifrons, n. s., is thus defined :—

" *C. capite brevi, antice subgloboso ; fronte spinoso ; antennis superioribus longis pilis ciliatis ; manibus secundi paris magnis, elongatis, intus fortiter emarginatis.*" This species was founded on a damaged specimen.

In the "Ciamianos," the genus *Cyamus* is described. The name of Lamarck is attached to it, as though he were the originator of the name. The species *Cyamus gracilis*, Roussel de Vauzème, figured on pl. 4, fig. 7, is defined with the words :—" *C. cinereo-virescens ; corpore elongato, subfusiformi ; appendicibus branquialibus elongatis, cylindraceis, simplicibus, ad basim bituberculatis.*"

The Atlas containing the figures referred to in these descriptions is dated 1854.

The new species, *Talitrus chilensis*, *Orchestia brevicornis*, *Orchestia gayi*, *Amphioxe gayi*, *Gammarus chilensis*, *Caprella brevicollis*, and *Caprella spinifrons*, are not included in the list of the Brit. Mus. Catal., 1862. *Caprella longicollis* is figured and described in that work, but as Mayer has pointed out, the species is by an error assigned to Lueas, and its habitat given as Algeria instead of Chili.

For the genus *Nicea* see Note on Rathke, 1837. The genus *Lalaria* is a synonym of *Aora*, Krøyer, 1845, and the species *Lalaria longitarsis* is identified by Spence Bate with Krøyer's *Aora typica*. *Caprella brevicollis* is considered by Mayer to include the female and young forms of *Caprella longicollis*, and, as *Caprellina longicollis*, the species becomes the type of a new genus founded by G. M. Thomson in 1879. This genus I propose to name *Caprellinopsis*, since *Caprellina* is preoccupied as the name of the group to which the genus belongs. *Caprella spinifrons* is left indeterminate by Mayer.

1849—SCHIØDTE, J. G.
1851.

Bidrag til den underjordiske Fauna. Det kongelige danske Videnskabernes Selskabs Skrifter. Femte Række. Naturvidenskabelig og mathematisk Afdeling. Andet Bind. Kjøbenhavn, 1851. pp. 1—39. Tab. i.—iv.

Specimen faunæ subterraneæ, 1849. m. 4 Tafeln. Aus den Abhandl. der Copenhagener Akademie der Wissenschaften. 5te Reihe. Bd. II. (Appears to be the same work as the above. See also Entom. Soc. Trans. I. 1850—51, pp. 134—157.)

Schiødte comments first on the slow growth of knowledge in regard to the subterranean fauna. In his historical review he mentions Tellkampf's *Triura cavernicola*, which, he says, "seems to belong to the order of Amphipoda," an obvious error in which he is followed by Boeck. At page 26, he institutes the new genus *Niphargus*, with this definition :—

"Ordo Amphipoda.—Familia Gammari.

"Oculi nulli. Antennæ superiores inferioribus longiores, flagello appendiculari minuto, biarticulato. Pedes ultimi paris stylo interiori brevissimo, exteriori valde elongato, biarticulato. *Niphargos.*"

The type species he names *Niphargus stygius*, which is figured on Pl. III. In the course of a full description, he thus distinguishes the sexes, "lamina basalis ultimi pedum paris duplo longior segmento. *Stylus* ejus *interior* in mare sextam decimam in femina vero septimam styli exterioris partem æquans longitudine, apice spinulis præditus duabus setaque pennata singula. *Stylus* exterior cylindricus; *articulus primus* laminam basalem in femina duplo, in mare autem triplo superans longitudine, fasciculis ornatus utrinque spinularum brevium, in mari obsoletioribus; fasciculis lateris exterioris e binis compositis spinulis setaque pennata singula; *articulus secundus* in femina dimidiam articuli primi partem complens fere longitudine, lateribus apiceque fasciculis præditis setularum; in mare longitudine fere articuli primi, glaber, laevissimus, apice solo fasciculato."

He concludes with the statements:—"Commoratur in locis depressioribus specus Adelsbergensis et Lueg, aqua repletis stillicidio abundante sedimentoque tectis fundi chrystallino. Agillime salit, captu difficilis; territus latebras fundi velocissime petit."

Schiødte next describes with great fulness, and figures, Koch's *Pherusa alba*. As *Pherusa* was more than once preoccupied, he gives a new generic name, *Titanethes*, in "Ordo Isopoda.—Familia Onisci.—Tribus Oniscini," the species becoming *Titanethes albus*. It is perhaps owing to Koch's use of the name *Pherusa*, earlier employed among Amphipods, that Schiødte's *Titanethes* has itself been spoken of as an Amphipod genus.

1850. BATE, CHARLES SPENCE, born March 16, 1819 (C. S. B.).

Notes on the boring of Marine Animals. In Notices and Abstracts of Communications to the British Association for the Advancement of Science, at the Birmingham Meeting, September 1849. pp. 73–75. London, 1850.

This paper, though mentioned in Boeck's list, does not refer to Amphipoda. Of Crustacea only *Pagurus* is mentioned.

The "Notes on Crustacea, Ann. Nat. Hist. VI. 1850, pp. 109–111. VII. 1851, pp. 297–300," also mentioned in Boeck's list, have no reference to Amphipoda.

Another paper by Spence Bate, in which no Amphipoda are mentioned, is likewise included in Boeck's list, "On some Crustacea dredged by Mr. Barlee in Shetland, Ann. Nat. Hist. X. 1852. pp. 356–357."

1850. DANA, JAMES D.

Zoology. *A new genus of Orchestidæ.* The American Journal of Science and Arts. Second Series. Vol. IX.—May, 1850. New Haven. Number XXVI. p. 295.

Dana here says:—"In a synopsis of the genera of Gammaracea, in this Journal, volume viii. p. 135, three genera of Orchestidæ are mentioned, *Talitrus*, *Orchestia* and *Allorchestes*. We here add a fourth; and for the purpose of giving a fuller comparative view of the four, and correcting a misprinted word, we insert the generic characters for the group.

“ Pedes primi non cheliformes nec subcheliformes, articulo styliformi confecti; secundi saepe subcheliformes, manu sive parvula et debili sive nullâ. Antennæ superiores basi inferiorum breviores.	<i>Talitrus</i> (Latreille).
“ 2. <i>Talitro</i> pedes primos antenasque similis. Pedes maris secundi valde subcheliformes, manu grandi.	<i>Talitronus</i> (Dana).
“ 3. Pedes primi secundique plus minusve subcheliformes. Antennæ superiores basi inferiorum breviores. Maxillipedes apicem obtusi.	<i>Orchestia</i> (Leach).
“ 4. Pedes primi secundique plus minusve subcheliformes. Antennæ superiores breviores, basi inferiorum longiores. Maxillipedes apicem unguiculati.	<i>Allorchestes</i> (Dana). ”

1850. DE HAAN, WILLEM, born February 7, 1801, died April 15, 1855 (Hagen).

Fauna Japoniea, auctore Ph. Fr. de Siebold. Crustacea elaborante W. de Haan. C. tab. Lith. LXV. Lugd-Bat. 1850.

During the publication of this fine work M. de Haan was stricken down with a grievous illness which confined him to his bed for years, but did not prevent his courageously completing the publication (Herklotz).

The only Amphipod dealt with is “ *Caprella Kröyeri*,” of which the author only had a dried specimen to describe, hence, Mayer says, in spite of the good figure, it cannot be determined with certainty, though he believes it to be synonymous with *Caprella æquilibra*, Say.

1850. HOSIUS, A.

Ueber die Gammarus-Arten der Gegend von Bonn. Von Dr. A. Hosius. (Hiezu Taf. III. und IV.). Archiv für Naturgeschichte. Sechszehnter Jahrgang. Erster Band. Berlin, 1850. pp. 233–248.

He complains that Gervais and Milne-Edwards, in attempting to distinguish *Gammarus fluviatilis* vel *röselii* from *Gammarus pulex*, disagree with one another, though both dealing with specimens from the neighbourhood of Paris. He assigns *Gammarus pulex* to Degeer and *Gammarus fluviatilis* to Rösel, but as he has never met with this latter species in rivers, he thinks that the name *Gammarus röselii* given it by Gervais ought to stand. He enters into a detailed comparison between these two species and the blind *Gammarus puteanus* of Koch. In regard to habitat, Hosius says that *Gammarus puteanus* is confined to wells, that he has only found *Gammarus röselii* in still or weakly flowing deep waters, but *Gammarus pulex* in strongly flowing, shallow, brooks, often only an inch deep. In Milne-Edwards' Manual, he says, we must cross out *Gammarus pulex*, put *Gammarus pulex*, Degeer, in place of *Gammarus fluviatilis*, and lastly insert *Gammarus röselii*, Gervais (or *Gammarus fluviatilis*, Rösel), and *Gammarus puteanus*, Koch.

1850. LILJEBORG, V.

Bidrag till den högnordiska hafsfäunan. Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar. Årg. 7. 1850. No. 3. (Sjunde Årgången. 1850. Stockholm, 1851). pp. 82–88.

In a letter to Hr Lovén, Liljeborg mentions that in Russian Lapland he had observed among other Crustacea, *Gammarus locusta*, Mont., Kröy.; “ *Anonyx Edwardsii*, Kröy.”; *Caprella*

lobata (Muell.), Kröy. In the neighbourhood of Tromsö, he mentions "Gammarus locusta Mont., Kröy. Varietas: Antennæ superiores inferioribus longiores, et earum pedunculi artieulum penultimum ped. antenn. infer. excedentes. Pardalisea cuspidata Kröy.—*Leucothoë norvegica* n. sp. L. clypeatae Kröy. sat affinis. Antennæ superiores inferioribus longiores, flagello pedunculo longiore, articulo primo secundum superante, et art. tertio minimo; flagellum antenn. infer. ultimo pedunculi articulo *brevius vel æquale*; manus pedum secundi paris maxima, dilatata, *apice vero acuminato*, aculeoque marginis posterioris terminali *validissimo et unguis æquali*; epimera quarti annuli thoraciei maxima, *latitudine vero altitudine parum majore*.—*Anonyx ampulla* (Phipps), Kröy.—*Caprella lobata* (Muell.). Kröy." Both by Spence Bate and Boeck *Leucothoë norvegica* is considered as probably identical with *Leucothoë clypeata*, Kröyer, 1842, becoming in that case *Metopa clypeata*. Bate and Westwood in their Appendix, vol. ii. p. 500, retain it as a distinct species, *Montagia norvegica*. Kröyer's *Leucothoe clypeata* they think may be the female of *Montagia pollexiana*, Spence Bate. Any one who has seen the figure of the hand of the second gnathopod of *Leucothoë norvegica* given by Liljeborg in the K. V. A. Handl., 1851, will be convinced that he has anticipated Bate's *Montagia pollexiana*, with which also his description minutely agrees. If this be a variety only of *Metopa clypeata*, as Boeck supposes, it is at any rate a very striking one. For the present it may stand as *Metopa norvegica*, Liljeborg, with *Leucothoë norvegica*, Liljeborg, *Montagia pollexiana*, Sp. Bate, and *Montagia norvegica*, Sp. Bate, and Bate and Westwood, for its synonymy.

1850. NATALE, GIUSEPPE DE.

Descrizione zoologica d'una nuova specie di plojaria e di alcuni crostacei del porto di Messina con poche considerazioni generali sulla natura delle appendici aculeiformi delle piante e degli animali. Messina, 1850.

After describing the insect, Tav. I. fig. 1, which he names "*Plojaria Ambigua*," n. s., at page 8 de Natale begins the following account of *Cheiropristis messanensis*:—"Il genere Cheiropristis (Tav. I. fig. 2.) formato dal Prof. Cocco, sopra certi Crostacei del nostro porto, ei son pareehi anni, merita di essere illustrato come singularissimo per le forme esterne.

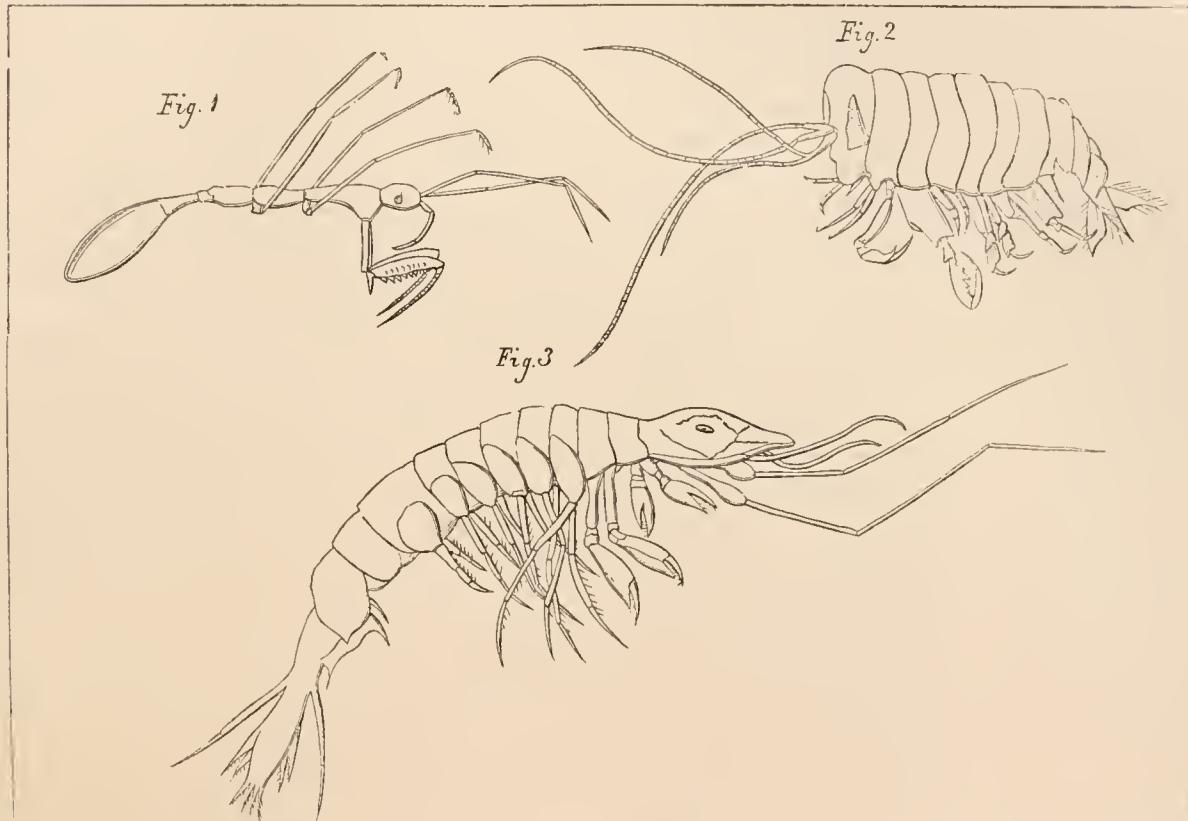

" La famiglia degl' Iperidi, tra i Crestacei Amphipodi, distinta da molti e razionali caratteri da quella dei Gammaridi; come si sa, può dividarsi in tre sottofamiglie. La prima, che si potrà dir degli Iperidi Gammaroidi, distinguersi bene dalle due altre; perchè sempre presenta nei suoi generi un piecol capo, un corpo compresso, con gambi palpiformi rudimentali ai piedi maseillari. Anzi, indipendentemente dagli altri caratteri, si potrebbe, come principale, assegnar la picciolezza relativa del capo per distinguere dalle due sottofamiglie seguenti le quali, tranne il solo *Oxycephalus*, ei presentano un capo grosso ed enorme. Ma di queste due la prima, che si disse dall' Edwards *Iperini Normali*, presenta le antenne del secondo pajo stiliformi, non ripiegabili su di sè; ed in ciò distinta dalla terza sottofamiglia detta degl' *Iperini Anormali*, le cui antenne ripiegabili su di sè costituir potranno di tre a quattro fratture.

" In quest' ultima sottofamiglia, che potrebbe dirsi dei Tifini, perchè il genere *Typhis* ne è il tipo, vanno finor classati tre generi; cioè: *Pronoë*, *Typhis* ed *Oxycephalus*. Distinti i due primi dal terzo ad un capo corto, arrotondato, e portante le antenne del primo pajo alla sua faccia anteriore, mentre il terzo ha un capo lunghissimo, e puntuto colle antenne del primo pajo inserite sulla sua faccia inferiore. Distinto il *Typhis* dalla *Pronoë*, poichè questa non presenta, come il primo, i piedi del secondo pajo prensili, ed il primo articolo dei piedi delle due ultime paja clipeiforme grandissimo. Dalla *Typhis*, non si conosce nostrale che l'unica

T. *Ovules* che, come vedremo in appresso contrariamente al parere di M. Edwards, differisce assai dall' *Orio Zancleus* del Prof. Coceo. La *Pronoë*, e l'*Oxycephalus* sono esotici a noi. Fra questi tre generi, che sinora comprendono la sottofamiglia degli Amfipodi, Iperidi, Tisini, deve oramai intrealarne un quarto, scoperto da parechi anni dal Prof. Cocco, e da lui chiamato *Cheiopristis*. Di esso daremo la descrizione ed il disegno sopra individui soggetti ad osservazione microscopica.

Tra i tre generi Iperini menzionati, più al *Typhis* rassomiglia il *Cheiopristis*. Com' esso, infatti, ha un capo corto e grosso, le antenne ripiegabili in fratture e le anche dilatate. Ma se ne distingue per importanti caratteri.

Tav. II

G. De Natale del.

Fig. 25.

I *Typhis* distinguonsi eminentemente per una specialità di struttura delle anche delle due ultime paga, che larghissime sono, e clipeiformi in modo che formano come due valve, le quali, riunite ed approssimate in mezzo, l'animale ripiegando i piedi, e la coda al di sotto, chiudono inferiormente il corpo, e gli danno la forma d'uno sferoide. La estremità posteriore della coda è senza appendie.

Il *Cheiopristis* però non presenta per nulla questa straordinaria dilatazione delle anche delle due ultime paga di piedi, le quali se non dilatate, sono incapaci ad occultare il corpo come fra due valve; la sua coda ha delle appendie; ma come il *Typhis* presenta i piedi del secondo pajo prensili, ma un pochino diversamente conformati.

Esso ha un capo corto, ma largo, verticale, ribattuto sul corpo, più largo arrotondato in sopra,

più stretto, con alcune smarginature sulla faccia inferiore. Le antenne, situate sul mezzo della sua faccia anteriore, sono inserite sopra due peduncoli cortissimi che si toccano alla base. Da ciascun peduncolo corrono infuori due altri articoli, di cui il secondo più lungo, e come che si biforcasse, caccia le due antenne, composte di un gran numero di articoli ripiegabili con fratture o no. Le inferiori sono sempre più corte delle superiori. Gli occhi son posti obliquamente ai lati del capo; son triangolari, coll'apice del triangolo in alto, e coll'angolo esterno della base che tocca il margine esterno del capo. Sotto il margine inferiore del capo, e cominciando d'avanti in dietro, stanno due palpi mascellari gracilissimi, corti, filiformi, sporgenti in avanti, con tre articoli distinti. Dietro questi si osservano due steli palpiformi, cortissimi, ad un'articolo poco distinto, e dietro di questi i piedi mascellari lunghetti, filiformi, di tre articoli di cui l'ultimo, appena visibile, curvato a gancetto sul penultimo. Esistono sette pajo di piedi diversi tutti di forma, come sette sono gli anelli toracici che li portano.—Il primo e secondo articolo del primo pajo son cortissimi e gracili, ma il terzo è lungo, dilatato, arcuato, e porta dietro due o tre pezzi corti interarticolari, l'ultimo articolo terminato da due robusti denti uno in avanti, e più lungo del precedente. I piedi poi del secondo pajo son di diversissima conformazione. Il lor primo articolo è largo, lungo, ad orli angolosi, laminare; al suo orlo articolare inferiore presenta una forte smarginatura in cui si annida un articolo stretto e gracile; questo porta un terzo articolo lungo quasi quanto il primo, ma dentato a sega sul suo orlo posteriore; un quarto articolo si attacca a quest'ultimo, mobilissimo, e si può piegare sul taglio di esso posteriore in modo da dar a questo articolo terminale l'apparenza d'una mano subcheliforme.

“ Il terzo pajo di piedi contrasta col precedente per la sua esiguità. È gracile, cortissimo, filiforme, con tre articoli appena distinti di cui l'ultimo a punta si finisce. Il quarto pajo ci presenta uno sviluppo molto conspicuo, come i due seguenti; in esso iufatti, il primo articolo è allungato sebbene un po' stretto; porta in giù di esso altri due articoli, di cui l'ultimo più grande dà inserzione al terminale che è edentulo, arcuato e piegato a gancetto su di quello. I primi articoli dei piedi del quinto e sesto pajo sono più larghi e forti, ma quel del sesto più di quel del quinto; ambedue dietro essersi articolati con parecchi auelli picciolini, esilissimi, terminansi con uno che è arcuato e piegato pure a gancetto sul penultimo. Il settimo pajo di piedi addimostrasi ad un solo articolo cortissimo, e visibile appena. L'addome in vero è pochissimo sviluppato, con due soli articoli di cui uno rudimentale, e se le molte analogie che legano il Cheiropristis ai Tifidi non si opponessero, noi, con ragioni evidenti, lo porremmo per quest'ultimo carattere tra i Ciamidi nei Lemodipodi. La coda terminasi per una natatoja mediana triangolare terminata a punta, frangiata di cigli lamellosi agli orli, e di due altre natatoje di forme subromboidale ai fianchi.

“ Il corpo è tozzo; è largo e corto, altissimo il torace, onde la larghezza si comprende due volte e mezzo nella lnnghezza totale. Alto uniformemente dal capo fino agli ultimi anelli toracici, esso si restringe notevolmente verso la coda, i cui anelli non han la metà dell'altezza del torace.

“ Data così la descrizione generica del Cheiropristis, i caratteri suoi specifici potrebbero formolarsi così brevemente.

“ *Cheiropristis Messanensis. (Cocco) Corpore antice tereti, superius roseo, allicante inferius, sesquiloniore quam alto. Antennis superioribus longissimis, inferioribus ultra earum dimidium porrectis; laminis caudæ lateralibus, subrhomboidalibus, media triangulari mucronata.*

“ Anco ai Typhis si rassomiglia il Cheiropristis per l'abitudine che ha di contrarre i piedi sotto il torace, in modo che, in tutti gl'individui che se ne prendono non comparisce di essi che il solo torace al di fuori, e non è che con la più gran pazienza del mondo che si arriva a svolgere i lor piedi senza romperli. È lungo da tre a quattro linee. In certi giorni dell'andato Decembre il mare ne gittò infiniti lungo la spiaggia presso al nostro porto; ma, d'allora in poi sono scomparsi.”

It will be seen in the note on Cocco, 1832, that in that year Cocco mentions a species which he calls *Cheiropristis hitorea*, but I can nowhere find allusion to any description of either the genus or the species, and am at length forced to conclude that Cocco never published auy. In this case *Cheiropristis messanensis* should be cited with de Natale's name both for genus and species. It is not easy to see what de Natale means by saying that the posterior extremity of the tail is without appendages in *Typhis*, while he affirms that in *Cheiropristis* the tail has appendages. *Typhis* has in fact three pairs of uropods, whereas he represents his *Cheiropristis messanensis* with only one pair. His statement that the abdomen of *Cheiropristis* has only two joints, of which one is rudimentary, can scarcely be trusted, and indeed does not agree with the figure, in which at least two fully-developed pleon segments are shown and a third not obscurely indicated. In the E. M. Catal., p. 325, under *Anchylomera sedentaria*, the *Phronima sedentaria* of Costa, Spence Bate say, "I am inclined to think that *Cheiropristis Messanensis* of Cocco belongs to this genus and probably to this species." In agreement with this opinion I consider the species to be *Anchylomera messanensis*, de Natale, in the subfamily Phrosininae. In comparing de Natale's description with others relating to species in the same genus, allowance must be made for the fact that he obviously took only a lateral view of his specimen, without dissection. In such a view, I know from experience that the broad fourth joint in the large third pereopods of *Anchylomera* may appear narrow, and that a telson in reality rounded may seem to be lanceolate. His attempt to disentangle the limbs without breaking them, may well excite the commiseration which he invites, since he had evidently not thought of the expedient of separating them from the body of the animal.

Of *Orio zanclaeus*, Cocco, de Natale says that Milne-Edwards judged inconsiderately in saying that it did not appear to differ from *Typhis*. Besides the characters here derived from a single damaged specimen in spirits, he gives a fuller account in the appendix.

He institutes a new genus to receive "*Ornithorampus Coccoi*," figured Tav. 1. fig. 3. This, though he calls it a new Crustacean, had been long before described by Cocco as "*Orio Ornithorampus*," with some doubt whether it should not be put in a separate genus. Of the necessity of this de Natale was convinced, but was somewhat doubtful whether it might not belong rather to the Isopoda than to the Amphipoda Hyperina. He describes it thus:—

"Esso si presenta d'una forma allungata e rotondetta. Il capo, convesso all'orlo superiore, finisce in avanti a modo di becco d'uccello; apparenza tanto più curiosa, in quanto che porta ai lati della sporgenza rostriforme, un solco che simula una specie di commissura. Gli occhi son piccolissimi, quasi invisibili, e segnati solo da due punti nerastri per ciascun lato del capo. I palpi mascellari gracilissimi ad articoli indistinti. I piedi mascellari con un'articolo basilare grosso e piriforme, che porta in fine tre filiformi articoli lunghissimi, fratti e piegati su di sè in un solco longitudinale inferiore del capo; una strozzatura separa il capo dal collo. Dal primo auello toracico, ed inferiormente, sembrano che prendessero inserzione i piedi mascellari, che son corti, tozzi, robusti, ineguali, ad articoli stretti e corti, di cui l'ultimo porta una vera mano cheliforme. Simile chela termina pure i piedi toracici del primo pajo, di cui il primo articolo è lungo, stretto, lineare; ma l'ultimo robusto, dilatato e terminato da mobile gancetto. Tutte le altre sei paja di piedi seguenti, in generale, tranne una varia lunghezza di esse, e degli articoli che le costituiscono, sono identiche. Il lor primo articolo è dilatato, foliaceo, diafano; i seguenti stretti, allungati simili a palpi, frangiati di peli agli orli. Il primo pajo tra esse è il più lungo, quindi vanno gradatamente decrescendo di lunghezza, fin l'ultimo che è cortissimo e con tre soli articoli lineari. I sette anelli toracici son quasi simili, della stessa altezza del capo. L'addome si compone di tre anelli ben conformati e distinti, ma l'ultimo porta inferiormente due lamelle vibratili, diafane, che si piegano l'una sull'altra come valve.—Queste lamelle

saran, come negl' Isopodi, una metamorfosi degli ultimi falsi piedi addominali? Questa domanda che sinor non abbiam potuto risolvere, a eausa del piccol numero d'individui che si venner fra le mani, ei impedirà di determinare il posto che dovrà occupare l'Ornithoramphus nella serie Carcinologica.—Manca l'addome di qualunque traccia di falsi piedi; ma la coda però si termina per un potente ed allungato articolo, che porta ai fianchi due lamelle filiformi a mo' di stiletto, che son le lamine nuotatrici laterali. Più indietro, ed in sotto, stanno da ciascun lato due lamelle triangolari, mobili, divaricabili tra esse; finisce la coda in un pezzo quadrifido terminale. Avendone rinvenuto uno, ancor vivente, gettato sulla spiaggia, al veder le lamelle terminali dell'addome vibrar fortemente, mi eorse in meute d'aver per le mani un'Isopoda. Questa idea mi venne confermata, qualor osservandolo al mieroscopio non mi fu dato osservar traecia aleuna delle vescicole brauchiformi, respiratrie che caratterizzano eminentemente gli Amfipodi. Per altro, la total mancanza di falsi piedi addominali, lo allontana da tutti gl' Isopodi; e se le lamelle vibratili si volessero considerare come trasformazione di tali piedi, converrebbe costituire, tra gl' Isopodi, una famiglia a parte, in cui esso solo si comprendesse.”

He finds it has great analogy with the Sphaeromidae, but other points tend towards placing it with the Typhidae.

“I caratteri specifici potranno così brevemente formolarsi. *Ornithoramphus Coccoi. Corpore hyalino, pellucido; capite subrotundato, rostro brevissimo, teretiusculo, longitudine altitudinis quintuplum fere æquante; capite longiore altitudine corporis. Oculis minimis; laminis caudæ lateralibus, anterioribus styliformibus valde elongatis.*

Having obtained five fresh specimens, de Natale was able to add an “appendice all' Orio zancleus.” In this he says, “Ecco descritto con le più rilevanti differenze, che dai Typhis, lo distinguono—

“Ha un corpo tozzo, breve, raccolto; un capo grosso, con un muso ottuso, e due enormi occhi triangolari, laterali, con l'apice in alto—Manca di qualunque traccia d'autenne superiori che nei Typhis esistono esistentemente inserite a capo al muso—Egli è vero che potrebbe supporsi, essersi tali appendici perdute e rotte; e come avviene di sovente nel deseritto Cheiropristis, ed in altri moltissimi; ma poichè tra tutti gli individui da me, e dal Prof. Coceo osservati, non ne è stato mai alcuno, che ne avesse offerto traccia; così ci è quasi certo di poter concludere che esse manchino affatto—Le autenue inferiori giaecono, come i palpi, bifratte, annidate, ripiegate in un ampio incavo sottocefalico—I piedi delle due prime pagaie terminansi a chela didattila, larga, dentata; ma gli articoli basilari del primo pajo sono lineari, mentre quelli del secondo pajo sono stranamente contorti, e dilatati—Quelli delle due pagaie seguenti sono gracili ambulatori terminati da valida uguetta—Di simil guisa terminansi i piedi del 5° e 6° pajo; ma il loro artieolo basilare è dilatato, foliaceo, applicato sui piedi anteriori nel riposo—Ma questa dilatazione è un rudimento in paragone a quella, che si vede nei Typhis, in cui può occultar sovr' essa la coda, e l'addome interamente. I piedi del 7° pajo sono rudimentali. Il torace alto quanto il capo non è rigonfio come nei *Typhis*; in questi, i tre primi anelli addominali sono grandi, ma sono picciolini nell'Orio. In quelli i falsi piedi hanno largo il peduncolo, le cui lamine terminali sono allungate striate a traverso, dentellate agli orli—Nell'Orio ciascun peduncolo porta quattro laminette stiliformi, acute, non rigide, né striate, né dentellate. Il 4°, 5°, 6° anello addominale costituiscono nel *Typhis* una coda bruscamente ripiegata in giù, con tre altre pagaie di falsi piedi, e due lamelle terminali. Nell'Orio i suddetti anelli più bassi del tronco, non sono piegati in giù, ma orizzontali, con nessuna traccia di falsi piedi, ma con sei pagaie d'appendici nuotatrici, laterali, oltre il pezzo stiliforme terminale—

“I caratteri specifici dell'Orio Zancleus saranno.

“Orio Zancleus (Cocco)—*Gryseo-Lutescente, punctis nigricantibus adsperso; altitudine longitudinis quartum, et ultra æquante; oculis triangularibus nigris; laminis caudæ lateralibus lanceolatis.*—

“ Negli Amfipodi Iperini Anormali si raecoglieranuo adunque i generi Typhis, Orio, Pronoe, Cheiropristis, Oxyecephalus, ed Ornitoramphus—La diversità generiea tra questi due ultimi potrà dedursi da che l’Oxycephalus presenta: occhi enormi, due paja d’antenne, sei anelli eou sei paja di falsi piedi addominali; l’Ornitoramphus mostra: occhi mieroseopiei, antenne nulle, tre anelli addominali senza traeia di falsi piedi, ma con lamelle vibratili branchiformi, ond’ è ehe meglio starebbe tra gl’Isopodi—I caratteri della famiglia, come furono stabiliti dall’Edwards per eouprender la Pronoe, il Typhis, e l’Oxyecephalus, son da modifieursi or ehe se ne trovano interrealati altri tre generi. Essi saranno: capo grosso, antenuce or patenti, or oeculite in una smarginatura sottocefalica, ma sempre ripiegabili in fratture—Così la famiglia de’ Tifni, verrà distinta da quella degl’Iperini Gammaroidi o Vibiliidi a capo costantemente pieciolino—e dagl’Iperini Ordinari ad antenne superiori subuliformi, ed alle inferiori nou ripiegabili in fratture.”

It may be presumed that in the account of *Ornithoramphus Coccoi*, by the terms “i piedi maseillari con un’artieolo basilare grosso e piriforme,” and “i piede maseillari, ehe son eorti” etc., de Natale intends respectively the second pair of antennæ and the first gnathopods. “I piedi maseillari,” may be either the first antennæ or the mandibular-palps. The species should be compared with that called *Oxycephalus typhoides*, by Claus, in 1879. This species, from Zanzibar and from the harbour of Messina, has “Kopf kugelig aufgetrieben, mit sehr tiefer Antennengrube und spitzem, ziemlich kurzem Schnabel. Naekengegend stark verengert. Die vorderen Antennen des Männchens gross, mit stumpfen Zahnpfoten an dem sehr gestreckten Schaft. Zweites Antennenpaar sehr lang, mit stark ausgebogenen Gliedern und kurzem Endgliede. Greifhand der vorderen Beinpaare mit ungezähntem, in eine lange Spizte ausgezogenem Rand.” Other particulars are given, concluding with “Das Caudaldoppelsegment mehr als zweimal so lang wie die kurze Schwanzplatte. Letztes Uropodenpaar sehr kurz.” It is clear from de Natale’s figure that he has fallen into a misapprehensiou in regard to the “mieroscopically small” eyes, as he indicates their very considerable extent.

In the account of *Orio zancleus*, de Natale denies the presence of upper antennæ, but fig. 3 on plate ii., here reproduced in fig. 26, evidently represents this species, though the fact is not stated in the text, and in this figure *three* antennæ appear.

Claus gives the following account of *Eupronoë maculata*, n. s., from Zanzibar:—“Körper gestreckt, 10–12 mm. lang, mit grosseu ramifieirten Pigmentflecken. Kopf ziemlich laug und vorn merklich versemälert. Der proximale eingekrümmte Abschnitt am Femoralgliede des vorderen Beinpaars so lang als der nachfolgende verbreiterte Theil. Scheerenfortsatz am Carpus des zweiten Beinpaars so lang als das Metaearpalglied. Distaler Theil des Femoralgliedes keulenförmig angeseh-wollen. Carpalglied des sechsten Beinpaars ohne Fortsatz. Femoralplatte des siebenten Beinpaars viel kürzer als die des vorausgehenden Beinpaars. Schwanzplatte trigonal am hinteren Ende verjüngt, lanzen-förmig zugespitzt.” In *Eupronoë armata*, n. s. (*Pronoë brunnea*, Dane?), he gives, “Körper mässig gestreckt, punktiert, circa 7–8 mm. lang, mit grossem, gerundetem Kopf.” A female *Eupronoë*, 4 mm. long, from Lagos, which is, he says, extremely near the preceding species, “entbehrt der kreisförmigen Einkrümmung an den vorderen Gnathopoden.” From these accounts it seems possible that Coeeo’s *Orio* may have anticipated Claus’s *Eupronoë*, but there are many difficulties in the comparison.

Fig. 26.

1850. NATALE, GIUSEPPE DE.

Su pochi Crostacei del porto di Messina. Lettera del Dottor Giuseppe de Natale al Sig. Achille Costa. Con una tavola. Napoli, 1850.

This paper is mentioned in Bocck's list. I was unable to obtain a sight of it until too late for an abstract to be inserted here. See appendix to the Bibliography.

1850. STEENSTRUP, JOHANNES JAPETUS SMITH, born March 8, 1813 (J. J. S. S.).

Foreløbig Bemaerkning om Forekomsten af en *Otion* og en *Cyamus* paa den faeroske Grindelval (*Delphinus globiceps* auct.). Videnskabelige Meddelelser fra den naturhistoriske Forening i Kjøbenhavn for Aarene 1849 og 1850, p. 95–96.

The *Cyamus* sp. n.? of this paper was afterwards described by Lütken under the name *Cyamus globiripitis*. Lütken, 1873, page 48 (276), assigns Steenstrup's paper to the Forening for 1843; Bocck gives it as above.

1850. WHITE, ADAM.

List of the specimens of British Animals in the Collection of the British Museum. Part IV. Crustacea. Printed by order of the Trustees. London, 1850.

The Introduction assigns this Catalogue to Mr. Adam White. The title shows the limitation of its scope compared with the "List of the specimens of Crustacea," drawn up by the same author in 1847. The nomenclature is somewhat varied, and numerous synonyms are here given for the terms adopted. The class CRUSTACEA is adopted from Brisson, 1756; Subdivision 1. Crust. Maxillosa, from Latreille, 1825; Legion II. Edriophthalma, from Leach, 1814–1815; Order III. Amphipoda, from Latreille. In this is placed Tribe 1. GAMMARITA, containing Fam. I. Orchestidae; Fam. II. Gammaridae; Fam. III. Podoceridae; Fam. IV. Chelnnridae; and Tribe 4 [2]. HYPERITA, containing Fam. I. Phronimadæ; Fam. II. Typhidae. Order IV. Læmodipoda, Latreille, contains Fam. I. Caprellidæ; Fam. II. Cyamidæ.

Naturally, many species in the former List do not occur in this which is confined to British Animals. Among the Gammaridae the additions are, *Opis typica*, Krøyer's Sea-Screw, from Ireland; *Anonyx albus*, British Coast; *Anonyx*, sp., Thompson, from Ireland; *Amphithoe punctata*, Johnston's Coast-Screw, referred to "Gammarus punctatus, Johnston, Zool. Journ. iii. p. 177; Thomp. (W.) Ann. Nat. Hist. xx. p. 243," but without any explanation of its relations to *Amphithoe punctata*, Say, mentioned in the earlier list. This is followed by *Amphithoe dubia*, referred to "Gammarus dubius, Johnston, Zool. Journ. iii. p. 178." In place of "Vertumnus Cranchii" of the earlier list, the following entry is made:—

"ACANTHONOTUS.

"Acanthonotus, Owen, Ross's Second Voyage, Appendix, p. xc. (1835).

"Oniscus, pt. O. Fabr. Faun. Grænl.

"Amphithoë, pt. Krøyer.

"Vertumnus, Leach, MSS.: White (1847).

"1. ACANTHONOTUS (VERTUMNUS) TESTUDO. Cranch's Sea-Screw.

"Jun. Oniscus Testudo, Mont. Linn. Trans. ix. p. 102, t. 5, f. 5 (fig. pessima); Leach, Ed. Enc. vii. p. 405.

"*Vertumnus Cranchii*, Leach, MSS.; White, *List of Crust. in Brit. Mus.* p. 89 (1847).

"*Acanthonotus (Vertumnus) Testudo*, White, *Proc. Zool. Soc. Lond.* 1850, t. f."

To the genus *Gammarus*, White now adds, *Gammarus subterraneus*, Leach, which he suspects may be "*Gammarus pulex*, var. jun.?" ; *Gammarus carinatus*, the Keeled Coast-Screw, "Johnston, *Zool. Journ.* iv. p. 52;" *Gammarus maculatus*, the Spotted Coast-Screw, *Johnston, Zool. Journ.* iii. p. 176; while *Gammarus campylops*, Leach, is now given as *Gammarus campylops*, the Bent-eyed Coast-Screw. In the Podoceridae, "*Jassa*, Leach, *Ed. Enc.* vii. p. 433 (1814 or 1815)," receives the two species in the earlier list assigned to *Cerapus*. To the well-known *Corophium*, is applied the English title of "Long-horned Mud-Liver." The Family Cheluridae is occupied by *Chelura terebrans*, "Sea Wood-borer," Philippi's names for the genus and species being rightly preferred to the older MSS. names, *Nemertes nesæoides*, Leach.

To the family Typhidae is added *Typhis nolens*, for "*Gammarus nolens*, *Johnston, Zool. Journ.* iii. p. 179."

Among the Caprellidae, Leach's *Caprella acanthifera*, Spined Skeleton-Screw, displaces the name *Caprella acuminifera*, Leach, and the additional entry is made of "*Caprella lobata*, Müller, *Kroyer, Voy. Scand. et Lapon. Crust.* pl. 25, f. 3, a.; *Thomp. (W.) Ann. Nat. Hist.* xx. p. 244." Lastly *Proto pedatum* becomes *Proto pedata*, Müller's Spectre Shrimp.

In the family Cyamidae, the species are given as "1. *Cyamus ceti*. Common Whale-louse," including in the synonymy *Cyamus erraticus*, Roussel de Vauzème, with *Oniscus ceti*, Linn., etc., etc.; "2. *Cyamus ovalis*. Oval whale-louse," and "3. *Cyamus gracilis*, Slender Whale-louse." A concluding observation says, "Here by many authors are placed Nymphon, *Pycnogonum*, and their allies."

Most of the species are designated by English names similar in character to those which have been quoted.

1850. WHITE, ADAM.

Descriptions of two species of Crustacea in the British Museum. Proceedings of the Zoological Society of London. Part XVIII. 1850. London. pp. 95-97.

After describing *Potamobius serratus* and *Gonodactylus cultrifer*, n. s., which are figured on Pls. XV. and XVI., White says, "On the same plate with *G. cultrifer* is figured an Amphipod, which may be the species figured by Colonel Montagu in the ninth Volume of the 'Linnean Transactions,' t. 5. f. 5, under the name of *Oniscus testudo*. I have named this on the plate *Acanthonotus Testudo*: it belongs to Prof. Owen's genus *Acanthonotus*: in the British Museum it bears Dr. Leach's manuscript name, *Vertumnus Cranchii*. The head is produced and pointed between the antennæ, and instead of the small number of segments assigned by Colonel Montagu to his *Oniscus*, there is the normal number of the various genera of Amphipoda."

It was afterwards recognised that this species has nothing to do with Montagu's *Oniscus testudo*, and that it does not belong to Owen's genus *Acanthonotus*, but to the neighbouring genus, *Epimeria*, of Costa, being in fact *Epimeria cornigera*, Fabr.

1851. BATE, C. SPENCE.

On a new genus and several new species of British Crustacea. The Annals and Magazine of Natural History. Ser. 2. Vol. 7. 1851. pp. 318-320. Pl. XI. figs. 1-8. Pl. X. fig. 10.

The species *Bellia arenaria* here figured and described was subsequently named *Sulcator arenarius*, but in the meantime Dana had recognised it as belonging to Say's genus

Lepidactylis, and S. I. Smith has identified it with *Lepidactylis chytiscus*, Say, which is the same as *Oniscus arenarius* of Slabber, for which P. L. S. Müller proposed the generic name *Haustorius*. The genus *Bellia* is thus defied:—"Back broad, round and smooth. Upper antennæ forked. Lower antennæ ciliated, having the second joint flattened. First pair of feet simple: second and third pairs didactyle, remainder simple. The three anterior pairs of feet much smaller than the rest; the lateral appendage to each annular segment, together with the joints of the three last pairs of feet, largely developed, so as to appear like scales. Natatory feet arranged in double parallel pairs." I may mention that this creature is very common in stretches of sand round the British coasts, and very vivacious in appearance when burrowing into the sand. While it is alive in sea-water, the circulation can, under the microscope, be very distinctly seen in the broad plates of the hinder peræopods.

"*Amphithoë Moggridgei*" here described and figured as new, was in the Brit. Mus. Catal., 1862, referred to *Amathia (Cancer) carino-spinosa*, Turton, but in the same year, 1862, in the "British sessile-eyed Crustacea," it was identified with *Amathilla sabini*, Leach, the *Amathilla homari*, Fab., of this Report.

1851. BRANDT, J. F.

Beiträge zur Kenntniss der Amphipoden (*Crustacea Amphipoda*) von J. F. Brandt. (Lu le 15 novembre 1850.) pages 133–144, and (Lu le 20 decembre 1850). pages 310–313. Bulletin de la classe physico-mathématique de l'Académie impériale des sciences de Saint-Pétersbourg. Tome neuvième. St-Pétersbourg, 1851. Pl. IX.

After reviewing earlier opinions on the distinctions between *Talitrus* and *Orchestia*, and the agreement of the two in regard to the second gnathopods of the females, he points out that in many other classes generic distinctions have been drawn from the peculiarities of a single sex, but that, apart from this, there is a real though somewhat fine distinction between *Talitrus* and *Orchestia* in regard to the first gnathopods. He therefore defines these as follows, recognising that "Der zweifelhaftc, vielleicht keinen echten *Talitrus* darstellende *T. Cloquetii* ist dabei ausgeschlossen":—"Genus *Talitrus* Bosc. e. p. *Talitrus* Leach, *Latr. M. Edw.* Dana. Pedum primi paris ultimus articulus in mare et femina subconicus, haud cheliformis vel subcheliformis, ungue elongato, parum flexili ipsius articuli marginem inferiorem longe superaute armatus.—Pedum secundi paris ultimus articulus in utroque sexu ungue obsoleto, margine ipsius inferiore breviore instructus.—Antennæ superiores basi seu pedunculo inferiorum breviores. Maxillipedes apice obtusi.

"Genus *Orchestia* Leach. *Latr. M. Edw.* Pedum primi paris ultimus articulus in maribus et feminis plus minusve apice dilatatus, ungue flexili, incurvo breviusculo armatus, quare subcheliformis.—Pedum secundi paris ultimus articulus marium semper maximus, cheliformis, in feminis mediocris vel parvus complanatus ungue obsoleto ipsius margine inferiore breviore instructus. Maxillipedes apice obtusi."

Talitrus cloquetii, if rightly represented in the *Description de l'Egypte* should, he thinks, form an intermediate genus (cine eigene Mittelgattung) between *Talitrus* and *Orchestia*, for which he proposes the name, *Talitrorchestia?* He would then follow Guérin in making three sections of the genus *Talitrus*, thus arranged:—

"Sectio A. Pedum par anterius secundo longius," with "Spec. 1. *Talitrus saltator* Montagu;" "Spec. 2. *Talitrus Beaucoudraii* M. Edw.;" "Spec. 3. *Talitrus brevicornis* M. Edw.;" "Spec. 4. *Talitrus tripudians* Kröyer."

"*Sectio B. Pedum primum et secundum par longitudine aequalia,*" with "Spee. 5. *Talitrus platyeheles* Guerin."

"*Sectio C. Pedes primi paris secundi paris pedibus breviores.* (*Subg. Talitrorchestia nob.*)," with "Spee. 6. *Talitrus Cloquetii* (Audouin) Savigny."

In further remarks on this last species, of the correct figuring of which he is with some reason rather suspicious, he considers that his proposed new genus or subgenus agrees with *Orchestia fem.* by the structure of the first gnathopods, but by the relations of the second gnathopods not entirely either with *Orchestia* or with *Talitrus*, except that in "*T. Cloquetii*" the first gnathopod appears shorter than the second (as in *Orchestia mas.*); a circumstance, he says, which led Guérin to make it the type of his Section C.

The genus *Orchestia* is arranged by Brandt as follows:—

"*Sectio I. Antennae superiores pedunculo inferiorum breviores.* (*Subgen. Orchestia nob.*)

"A. Pedum sextum et septimum par longitudine fere aequales vel septimum paullo longius.

"a) Marium septimi pedum paris tertius et quartus artieulus plus minusve dilatati et incrassati
Gen. *Orchestia* Leach MSS?

"a) Fortiter dilatati." "Spee. 1. *Orehestia littorea* M. Edw.; "Spee. 2. *Orehestia Montagui* Audouin," expressly including "*O. littorea* Rathke."

"β) Satis dilatati." "Spee. 3. *Orehestia Euehore* F. Müller;" "Spee. 4. *Orehestia platensis* Kröyer."

"γ) parum dilatati. (Gen. *Seamballa* Leach. MSS. e. p.)" "Spee. 5. *Orehestia ehilensis* M. Edw.;" "Spee. 6. *Orehestia gryllus* M. Edw.", the *Talitrus gryllus* of Bose.

"b) Marium septimi pedum paris tertius et quartus artieulus nee in maribus, nee etiam in feminis dilatati. (Gen. *Seamballa* Leach MSS. List of the Crust. in the Brit. Mus. p. 86.)

"α) Chelæ marium inferior margo edentatus." "Spee. 7. *Orehestia oehotensis* n. sp."

"β) Chelæ marium inferior margo plus minusve dentatus." "Spee. 8. *Orehestia Bottae* M. Edw., which he thus defines, on the supposition of the name belonging to a form brought by Nordmann from the Black Sea, "*O. Bottae* (maris nigri). Anteunæ inferiores corporis tertia parte longiores flagello 20-articulato instruetæ. Manus secundi pedum paris marium in marginis inferioris dimidio inferiore emiuentiis tribus munita, unoque terminali intus dentieulato instruta;" "Spee. 9. *Orehestia Deshayesii* Audouin *Seamballa Kuhliana* Leach. MSS. teste List of Crust. of the Brit. Mus. p. 86;" "Spee. 10. *Orehestia Gryphus* F. Müller;" "Spee. 11. *Orehestia Quoyana* M. Edw."

"B. Pedum sextum par septimo longius et latius." "Spee. 12. *Orehestia Fiseheri* M. Edw."

"*Sectio II. Antennæ superiores pedunculo inferiorum longiores.* (*Subgen. Allorchestina nob.*)," "Spee. 13. *Orehestia nidrosiensis* Kröyer;" "Spee. 14. *Orehestia Pereiri* Lueas."

"Die als Subgenus *Allorchestina* aufgestellte Gruppe siud Orehestien, welche in dem ansehnlichen Längenverhältnisse der obren Fühler zu den untern sich der Gattung *Allorchestes* anreihen und sich nur durch den Mangel der spitzen Kralle an den Maxillarfüssen davon unterscheiden. Dass *O. nidrosiensis* kein *Allorchestes* sei, geht aus Kröyer's Mittheilung hervor, denn er bezeichnet darin den '*ultimus pedum maxillarium articulus*' blos als '*conicus*.' Von *O. Pereiri* ist die Gestalt der Maxillarfüsse leider weder beschrieben, noch abgebildet, so dass sie möglicherweise ein echter *Allorchestes* sein könnte. Uebrigens nähert sich *O. nidrosiensis* wegen des *ultimus articularis pedum maxillarium conicus* auch mehr der Gattung *Allorchestes*, als die in der *Sectio I.* angeführten Orehestien."

"*Orchestiarum species non satis vel nonum descripta.*" "Spee. 15. *Orehestia Tristensis* (Seamballa Tristensis Leach. MSS.); "Spee. 16. *Orehestia megalophthalmos* (Seamballa megalophthalmos Leach. MSS.)." These two might come, he thinks, into his *Sect. I. a, γ* after *Orchestia gryllus* or into *Sect. I. b.* He considers "*Ouiseus gammarellus* Pall. Speiel. Zool. fasc. IX. p. 57, Pl. IV. fig. 8," and "*Oniseus Stroemianus* O. Fabrie. Faun. groenl. p. 261," also as doubtful species.

"Orchestiae ad alia genera spectantes." "Spec. 1. *Orchestia grandicornis* Kröyer . . . = *Allorchestes grandicornis*"; "Spec. 2. *Orchestia longicornis* M. Edw.," with *Talitrus longicornis*, Say, and *Scamballa longicornis*, Leach, MSS. This species, he thinks, is closely allied to, if not identical with, his own *Megalorchestes californianus*.

This portion of Brandt's paper concludes with remarks on *Orchestia gryllus*, for which the name *Scamballa Sayana*, Leach's MSS., is given in the List of Crust. Brit. Mus. 1847.

The remainder of the paper, pages 310–313, treats of "*Megalorchestia* eine neue Gattung der Amphipoden aus der Gruppe der Orchestiden." This new genus, he says, to some extent by the form of the first gnathopods inclines towards *Talitrus*, by the second gnathopods more to *Orchestia*, by the maxillipeds to *Allorchestes*, from which last it is again removed by the very short upper antennæ. For the name he says, "Ich bezeichne sie nach Maassgabe der Grösse der ihr zum Grunde liegenden Art als *Megalorchestia*." This genus is a synonym of *Orchestoidea*, Nicolet, 1849. Brandt defines it thus:—

"Pedum primi paris ultimus articulus etiam in maribus apice angustatus (Tab. 1. fig. 12).— Pedum secundi paris ultimus articulus marium semper maximus, cheliformis. Pedum maxillarium articulus ultimus angustatus, apice unguiculatus. Antennæ superiores pedunculo inferiorum breviores." The type-species, *Megalorchestia californiana*, is described and figured with much detail. The telson is described as "lamina caudalis simplex cordata in medio dorsi longitudinaliter impressa." The plate shows numerous details. *Talitrus longicornis*, Say, the *O. (Scamballa) longicornis* of Leach's MSS. is discussed as offering "? Spec. 2. *Megalorchestia longicornis*."

In regard to *Talitrus cloquetii*, see Note on Saviguy, 1825; the subgenus *Talitrochestia*, resting only on the obscure figure of that otherwise undescribed species, has never met with acceptance. Of *Orchestia ochotensis*, Spence Bate in the Brit. Mus. Catal., p. 369, says, "this species appears to differ but little from Dana's figure of *O. Pickeringii*." For *Orchestia nidrosiensis*, see Note on Kröyer, 1845.

1851. BRANDT, F.

Dr. A. Th. v. Middendorff's Reise in den Äussersten Norden und Osten Sibiriens. Band II. Zoologie. Theil I. Wirbellose Thiere. St. Petersburg, 1851. Krebse, bearbeitet von F. Brandt. pp. 79–148 (1–74). Pl. VI.

The Amphipoda occupy pages 130–144 (54–68) and 511 (74). They are placed in the Sub-class Crustacea Maxillata, Legio Edriophthalma, and embrace two sections, the Gammaracea and Læmodipoda. The new species *Orchestia ochotensis* is described and figured, figs. 18–26, and placed near to "*Orchestia Bottx*," provisionally so-named, from the Black Sea. (See the preceding Note.) Brandt reports, as taken by Wosnesenski in the Sea of Okotsk, *Anonyx ampulla*, Phipps, accepting this designation and a long list of synonyms from Kröyer, 1845, for numerous specimens which he had himself examined. On the authority of a letter from Lichtenstein, he adds to the synonymy "*Gammarus Gryllus* Lichenst. apud M.S. Mandt," but as he also specially refers to the Atlas of the Voy. en. Seaud. (Livr. 37) Pl. 13, fig. 2 a–z, there cannot be any doubt that the species intended is *Cancer (Anonyx) nugax*, Phipps. He also reports numerous well-preserved specimens of "*Anonyx Edwardsii*," Kröyer, as having been taken by Wosnesenski, along with one of the preceding species, out of the stomach of a whale captured in the Bay of Metschigmen. In the genus *Gammarus* he takes Section 1. A. a. Milne-Edwards, with "the inner branch of the third uropod as large as, or at least more than half as long as, the outer," to include "Spec. 1. *Gammarus locusta?*" from the river Doschkander flowing into the Sea of Okotsk; "Spec. 2. *Gammarus pulex*, De Geer," taken in the basin of the hot-springs of Natschik,

and "Spec. 3. *Gammarus sitchensis*," n. s., fig. 28, *a-c.*, from the Island of Sitcha, intermediate between *Gammarus locusta?* and *Gammarus puler* and *fasciatus*, Say. This Boeck unites to *Gammarus locusta*, in regard to which species Brandt makes vigorous efforts to disentangle the confusions of the early writers. Under β with "the inner branch of the third uropod not even, or at most, a quarter as long as the outer, and often only rudimentary, he places "Spec. 4. *Gammarus atchensis*," n. s., fig. 29, *a-c.*, from Atcha and Unalaschka; "Spec. 5. *Gammarus locustoides*," n. s., fig. 30, *a-c.*, from Ayan on the sea of Okotsk; "Spec. 6. *Gammarus ochotensis*," n. s., fig. 31, *a-c.*, from the same sea, and "Spec. 7. *Gammarus longicawla*," n. s., fig. 32, *a-c.*, allied to *Gammarus dentatus*, Kroyer, with which Spence Bate was inclined to unite it, while under the name of *Melita dentata*, Kroyer, Boeck actually does so.

A form from the Sea of Okotsk, which Brandt at first took for an *Amphithoe*, he decides to place in Dana's genus *Allorchestes* as *Allorchestes ochotensis*, n. s., fig. 27, *a-f.*, near to "*Amphithoe Marionis*," Milne-Edwards. To *Allorchestes* he also refers *Orchestia grandicornis*, Kröyer. Both should rather be referred to *Hyale*, Rathke. (See Note on Rathke, 1837.) Of the telson of his species Brandt says, "Der Schwanzanhang besteht aus zwei abgerundet-rhomboidalen, kurzen, am Ende verdickten, mit einzelnen Dornchen versehenen Plättchen," thus affording an additional reason against applying the name *Allorchestes* to species with an entire telson. In the Brit. Mus. Catal., 1862, on Plate 1a, for "4. O. Ochotensis," should be read 4. A. Ochotensis., for "6. O. Ochotensis," 9. O. Ochotensis., and for "9. O. brevicornis," 6. T. brevicornis.

Among the Læmodipoda Brandt gives, from Nichita Bay in the Sea of Okotsk, *Caprella affinis*, n. s., like *Caprella linearis*, Johnston (1835), but differing from it in the greater size of the hands of the first gnathopods, which are more than half the size of those of the second gnathopods, and in the much longer, untoothed, penultimate joint of the hinder pair of feet, which appears longer than the two preceding joints. *Caprella nichtensis*, n. s., he compares with *Caprella lobata*, Müller (Kröyer, *Voy. en Scand.* pl. 25. fig. 3). Mayer does not find himself able to identify either of these two unfigured, briefly described species, or even to decide whether they belong to the genus *Caprella* at all.

Spence Bate in his B. M. Catalogue finds a new genus, *Brawltia*, for a species which he refers to as "*Gammarus latissimus*, Brandt, *Voyage de Middendorff*," with "*Hab. (Arctic Asia?) Voyage de Middendorff*." The figures and description were taken by Sp. Bate from specimens which Professor Brandt had sent to the Museum at Paris, but the species *Gammarus latissimus* was instituted by Gerstfeldt in 1858, and was found by Maack in the Angara at Irkutsk.

1851. COSTA, ACHILLE.

March.

Fauna del Regno di Napoli.

Genere *Callisoma*; *Callisoma*, (Costa).

The genus *Callisoma*, named in 1840 by O. G. Costa, is now described:—"Generis characteres essentiales. *Antennæ superiores* capite paulo longiores, validissimæ, subulatæ, pedunculo crassissimo, bisetae: *inferiores* graciles, longiusculæ. *Pedes* quatuor antici graciles hand cheliformes, secundi longiores. *Epimera* articuli quarti thoracici clypeiformia, inferne postice producta. Characteres naturales. *Corpus* compressum, breviusculum, e latere subovatum. *Antennæ superiores* breves, capite idem ac inferiorum pedunculo paulo longiores; pedunculi articulo primo crassissimo, duobus sequentibus longitudine et crassitie decrescentibus; setis duabus pluri-articulatis, seta primaria crassa subulata, pedunculo breviore; secundaria minuta gracili. *Pedes* primi paris graciles, manu simplici unguiculata terminati: secundi anterioribus fere similes at longiores: trium parium posticorum articulo primo

dilatato scutiformi. *Epimera* satis lata: quarti articuli majora, inferne postice distincte producta, illa articuli quinti circum-dantia."

"*Callisoma punctata*, O. G. Costa," is described and figured. The short definition is:—

"C. corpore dimidio fere longitudinis alto, epimeris articuli quarti thoracis postice ad illorum quinti angulum infero-posteriorem usque productis; carneus, maculis punctiformibus crebris ordinatis rubro-sanguineis pictus; oculis nigris, antennis pedibusque pallidis.—Long. lin. 3½; alt., max. lin. 1 4/10."

"*Callisoma Hopei*" is also described and figured, being distinguished from *Callisoma punctatum* chiefly by the absence of the dendritic spots, and by the different development and shape of the side-plates. The genus *Lysianassa*, Milne-Edwards, and the type species *Lysianassa costæ*, Milne-Edwards, are described.

1851. The genus *Talitrus*, Latreille, is described, and *Talitrus platycheles*, Guérin, is described and April. figured. The genus *Orchestia*, Leach, is described, and the species *Orchestia deshayesii*, Audouin, is described and figured.

1851. HOPE, FREDERICK WILLIAM, born January 30, 1797, died April 15, 1862 (J. O. Westwood).

COSTA, ACHILLE.

Catalogo dei Crostacei Italiani e di molti altri del Mediterraneo per Fr. Gugl. Hope. Napoli, 1851. 48 pages. 1 Plate.

Though A. Costa's name does not appear on the title page the work appears to be at least as much due to him as to the Rev. F. W. Hope.

The Catalogue differs so strikingly from most catalogues of Amphipoda that I give the Amphipodan portion in full.

AMPHIPODA.

As genera incertæ sedis are given Hexona and Zuphea of Risso, with their respective species Parassitica and Sparicola. An addendum is given *Generi Amphithonotus. Guttatus, A. Costa, Napoli.*

Among the Asellidæ, Leach, are placed *Apseudes*, Leach (*Eupheus*, Risso), with the species *ligoides*, Risso; *Tanaïs cavolini*, Edw.; *Oliska penicillata*, Risso. The Pranizidæ, Hope, contain eleven species of *Praniza*, and *Ancaeus forficularis*, Risso.

The first Amphipod-species described, and the only one figured, is " *Callisoma Hopei, A. Costa,*" fig. 2. This is considered by Bocck as the type species of Costa's genns *Callisoma*; but the description says " Secunda haec generis *Callisoma* species facile a C. punctato distinguitur corpore minus elevato; colore roseo vel subflavescente immaculato; epimeris quarti articuli thoraci inferne postice ad illorum quinti articuli medium marginis inferioris, neque ad angulum infero-posteriorem nsque productis. Long. lin. 2." The *Callisoma punctatum*

from which it is here distinguished was named *Callisoma punctata* by O. G. Costa in 1840, but not described till 1851 (see preceding Note). It must be considered the type of the genus, as Spence Bate suggests, Brit. Mus. Catal., p. 84, note, though he had not been able to find the description of it. Costa's species *Gammarus montanus* from Lago del Matese, and *Gammarus longicaudatus* from the drinking water of Naples, are given here for the first time. They are not mentioned in the B. M. Catalogue, from which *Amphithoë inaequipes* and *Amphithoë gracilis* are also omitted. All these four are described at length in Costa's R. s. Crost. Amf. d. R. d. Napoli.

The genus *Amphithonotus*, A. Costa, is thus explained:—"Illi ex Amphithois speciebus constitutum est hoc genus, quæ dorsum vel omnino carinatum et spinosum, vel saltem quibusdam abdominis articulis si non et thoracis postice in spinam vel dentem productis habent; ex quo peculiarem habitum præbent. Amph. marionis, Edw.; panopla, Kroyer; carinatus, ejusd. et quæ sequuntur ad hunc genus pertinent." The type species, *Amphithonotus acanthophthalmus*, A. Costa, which is here said to be "affinis Amph. marionis," was afterwards, under the name *Amphithonotus marionis*, by Costa himself made a synonym of "Amphithoe marionis, Edw.," and must, as Boeck says, be included along with that species in the synonymy of *Dexamine spinosa*. The next species, given as *Acanthonotus guttatus*, A. Costa, and said to be very near to *Amphithoe carinata*, is evidently meant for *Amphithonotus guttatus*, as given in the addendum above mentioned. Costa in his subsequent work does not notice this, but silently transfers the species to his genus *Nototropis*, which Spence Bate and Boeck agree in referring to the genus *Atylus*, Leach, and also agree in misspelling *Nototropis*, though Costa gives the derivation νῶτος, back, and τρόπις, keel. The species *guttatus* is omitted from the B. M. Catalogue. Since both the species, *acanthophthalmus* and *guttatus*, belonged to genera already established, the genus *Amphithonotus*, created to receive them, must be considered to have perished at its birth.

The genus *Epimeria*, A. Costa, is thus defined:—"Hoc genus, Amphithois et Amphithonotis maxime affine, epimeris quarti et quinti articuli thoracis elatis, eæteris valde majoribus, simul elypeum saepius inferne emarginatum formantibus, diguoseendum. Dorsum fere ut in Amphithonotis."

Of this genus, Spence Bate remarks that it apparently "differs in nothing from *Acanthonotus* of Owen, of which probably it is a synonym." Boeck does not accept this view, but he identifies both the type species, *Epimeria tricristata*, A. Costa, and *Acanthonotus orenii*, Bate and Westwood, with *Gammarus corniger*, Fabricius, 1779, under the name *Epimeria cornigera*. The Brit. Mus. Catal., in rendering the above generic definition, says, "Coxæ of the first and second pairs of pereiopoda long, the rest considerably broader," but Costa's meaning is that the coxae or side-plates of the second and third pairs of pereiopods are prominent, very much larger than the rest.

In Hope's Catalogue it may be observed that he inserts *Orio ornithoramus*, Coceo, as well as *Ornithorampus cocoii*, Natale, although de Natale clearly explains that his species is the same as Cocco's. As to the genus *Carcinococcus* and the species assigned to it, de Natale, 1850, says, "Finalmente il mio Carcinococcus audrà tra gli Stomapodi Unicorazzati, Erictini—Dedicandoue la specie al mio Maestro il Prof. Costa di Napoli—ho voluto foggiarne il nome suo Carcinococcus; da quello dell' illustre Prof. Cocco, ad imitazione di Carlo Luciano Bonaparte che sopra uno Scopelino scoperto dal Ch. Ittiologo di Messina foggiò il suo Ichthiococcus—di cui le specie *Oratus*, e *Poweria* sono proprie del nostro porto." Hence these three species are here quite out of place. *Leucothoe parthenopaea* Costa subsequently withdrew. His later *Corophium acherusicum* and *Vibilia speciosa* probably answer to *Aulouinia acherusica* and *Elasmocerus speciosus*. There are several other genera and species named, of which I can give no account. Some of them are perhaps described in de Natale's letter to Achille Costa, of which I extremely regret that I have never been able to obtain or see a copy. (See Appendix.)

1851. LILJEBORG, WILH.

Bidrag till Norra Rysslands och Norriges fauna, samlade under en vetenskaplig resa i dessa länder 1848. Inlemnad d. 11 December 1850. Kongl. Vetenskaps-Akademiens Handlingar för år 1850. Sednare Afdelningen. (This continues apparently Kongl. Vetenskaps-akademiens Handlingar, för år 1849. Stockholm, 1851.) pp. 233–341.

At page 311 he mentions having observed "vid Schuretskaja i Ryska Lappland," among the Crustacea, "*Gammarus locusta*, Mont., Kröy.;" "*Anonyx Edwardsii*, Kröy.;" "*Caprella lobata* (Muell.); Kröy."

At page 346 occurs the heading, "Förteckning öfver de af mig i trakten af Tromsö i Norge observerade Däggdjur, Foglar etc." Among the Tromsö Crustacea are the following Amphipoda:—" *Gammarus locusta*, Mont.; Kröy. Varietas: Antennæ superiores inferioribus longiores, et earum pedunculi articulum penultimum pedunc. antenn. infer. excedentes.—*Pardalisca cuspidata*, Kröy.—*Pontoporeia femorata*, Kröy.—*Amphithoë albomaculata*, Kröy.—*Anonyx ampulla* (Phipps); Kröy.—*Ischyrocerus minutus*, n. sp. Antennæ superiores inferioribus insigniter longiores, flagello ultimum pedunculi articulum æquante, cireiter 6-articulato, articulis elongatis, flagello appendiculari vix dimidiata primi articuli flagelli proprii longitudinem æquante; ultimus pedunculi antennarum inferiorum articulus flagellum circ. 5-articulatum æquans; manus primi et secundi pedum paris fere æquales, subangusta. Forma minima. Tantummodo specimen unum, feminam oviferam, circ. 4 mm. longam e profundo majore accepi.—*Leucothoë norvegica*, n. sp. (Tab. xx. fig. 4)." For the description, see Note on Liljeborg, 1850. *Ischyrocerus minutus* is identified by Boeck with *Podocerus anguipes*, Kröyer, but it is more probably the same as the species described by Sars in 1882 as *Podocerus minutus*, n. s.

After some Isopods, Liljeborg also mentions "*Caprella lobata* (Muell.); Kröy."

1851. LILJEBORG, WILHELM.

Norges Crustacéer. Crustacea, a clariss. M. W. v. Dueben in Norvegia ad Christiansund et Bergen 1843–44 collecta. Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar. Årg. 8. 1851. No. 1. Stockholm. pp. 19–25.

Of the hundred and six species collected by v. Düben, numbers 34 to 70 belong to the Amphipoda. Many are merely named. On a few, notes are given as follows:—

"34. *Orrhestia litorea*, M. E.—Femina a mari tam diversa forma pedum secundi paris, ut illa formam typicam generis *Talitri* M. E. et hic eandem formam gen. Orchestiae efficere videatur. Femina *Talitro tripulanti* Kr. sat similis est; forma pedum secundi paris prorsus eadem est, longitudo vero pedum quarti et quinti paris diversa, quum hi pedes iisdem secundi paris longiores."

"42. *Anonyx norvegicus* n. sp.—*A. plauto* Kr. sat. affinis, diversus tamen: antennis superioribus feminæ et maris fere æqualibus, flagello circ. 14-articulato, flagello appendiculari 5-articulato, artic. primo ceteris vix longiore; antennis inferioribus superioribus insigniter—maris plus quam duplo—longioribus; epimero quarto postice profunde sinuato, epimero quinto mediocri, subquadrato, antecedentibus humiliore. Praeterea inter se similes." This in 1865 he identifies with *Anonyx gulosus*, Kröyer.

"51. *Amphithoe Pausilipii*? M. E.—Omnino ei similis, oculi vero non visibles."

- "57. *Gammarus Duebenii* n. sp.—Antecedenti [*Gammarus locusta*, Fabr.] simillimus, tamen distinetus: magnitudine minori; antennis magis hispidis, superioribus longioribus; flagello appendiculari breviore circuit. 5-articulato; tuberculis segmenti 4 : i, 5 : i et 6 : i abdominis pilis longis; ramis pedum spuriorum ultimorum insiguiter inaequalibus, interiore tertia parte minore &c. Haud infrequens videtur, quum multa adsiut specimina. Apud omnia ratio illa inter ramos pedum spuriorum ultimorum plane constat." This in 1854 he makes a synonym of *Gammarus locusta*.
- "59. *Gammarus Sundevallii*, H. Rathke. Femina mari dissimilis maibus ped. 1:i et 2:i paris minutis fere aequalibus." This is now known as *Cheirocratus sunderalli*.
- "60. *Gammarus assimilis*, n. sp.—Præedenti simillimus, preeipue diversus: pedibus maris secundi paris longiores [longioribus], manu elongata, fere reetangulari, infra pone unguem oblique truncata et tridentata, antice et postice aequaliter, non dense, pilosa. Inter feminam et marem dissimilitudo eadem ac præcedentis." This is now called *Cheirocratus assimilis*.
- "64. *Gammarus Zebra*, H. Rathke.—Generi *Isehyroereri*, Kr. potius adnumerandus."
- "65. *Ischyrocerus anguipes*, Kr.
- "66. I. (*Podocerus*) calcaratus (H. Rathke) Sine dubio eadem species ac anteedens, ejus calcar manus pedum secundi paris non evolutum, sed tantum tuberculo minnito indicatum."
- "68. Leucothoë—? Sine dubio juniores *L. clypeatae*, Kr. Femina ovifera minuta: antennis superioribus inferioribus brevioribus; manu pedum seemndi paris medioeri, ovata, margine posteriore medio uni-dentato; præterea *L. clypeatae* similis. Apud quædam speeimina minntissima, sed tamen ovifera, ovis solnmmodo paueis majoribus, antennæ fere eadem longitudine sunt, manus pedum secundi paris vero codem modo formatae." This is now known as *Metopa clypeata*.
Under "Loemodipoda (amphipoda)," he gives
- "70. *Caprella lobata* (Muill.); Kr.—Admodum variabilis. Aeulei partium superiorum corporis nullam distinctionem specificam prestare videntur. Feminæ plerumque supra suut aculeatae, earumque annuli thoraciei et manus breviores." This may belong to variety γ of Krøyer's *Caprella lobata*, which Mayer puts, with the other varieties, under *Caprella linearis* (Linné) Bate.

1851. PETERS, WILHELM CARL HARTWIG, born 1815 (Hagen).

Bericht über die Leistungen in der Naturgeschichte der Crustaceen, Araehnidien und Myriapoden während der Jahre 1849, 1850 und 1851. Archiv für Naturgeschichte. Siebzehnter Jahrgang. Zweiter Band. Berlin, 1851. pp. 393–467.

1852. BURGERSDIJK, LEONARD ALEXANDER JOANNES.

Specimen academicum inaugurale, continens annotationes de quibusdam crustaceis indigenis, quod . . . publico ae solemmi examini submittit LEONARDUS ALEXANDER JOANNES BURGERSDIJK, e pago Alphen Batavus, ad diem xix. m. JUNII A. MDCCCLII. Lugduni-Batavorum.

Burgersdijk is at great pains to diseriminate *Gammarus puler* from Rösel's speeies which Gervais named *Gammarus roeselii*. It will be useful to see in juxtaposition the synonymy, as he has drawn it up for each species.

- "*Gammarus pulex*
" *Krebsförmiger Wasserwurm*, FRISCH, Ins.
VII, p. 26, Tab. 18.
- "*Squilla pulex*, DE GEER, Mémoires, VII,

Krebse, II, pag. 132, Tab. 36, fig. 4, 5.
" *Gammarus puler*, LATREILLE, Hist. natur.
des Crust. et des Ins., VI, pag. 316, Tab.
57, fig. 1.
" *Gammarus Roeselii*, GERVAIS, l. l.
" *Gammarus pulex*, KOCH, libr. 1. Heft. 36.
. Taf. 21.
" *Gammarus Roeselii*, HOSIUS, l.l."
- (In reference to this list he notes that Sulzer's
and Geoffroy's figures are copied from
Roesel's figure.)

Zenker's varieties of *Gammarus puler*, *longirauulatus* and *brevirauulatus*, Burgersdijk says he has found mixed together (promiscue). After giving his reasons in full for the synonymy to *Gammarus pulex*, he adds, "Neque LINNÆUM neque FABRICIUM citavi, quia plures species confundebant, sic in LINNÆI Syst. Nat. Ed. XII, *Cancer pulex*, teste synonymia, continet *Gammarum Roeselii*, *Gammarum* hunc *pulicem*, et *Orchestia* speciem; *Gammarus Roeselii* etiam sub nomine *Canceris locustæ* militat; in FABRICII Ent. Syst. II, pag. 516 sub *Gammaro locusta* et *pulice* similis est confusio." From want of materials he refrains from discussing *Gammarus puteanus*, KOCH, called by Gervais *Gammarus pulex minutus*, and concludes the subject with the remark, "si tribus hisce speciebus, *G. Roeselii*, *pulici*, *puteano* additur *G. ambulans* FR. MÜLLER (WIEGM. Arch. 1846, I, pag. 296), nulla omissa erit e speciebus aquæ dulcis, quæ hucusque in Europa repertæ sunt." Here however he reckons without the *Gammarus (Niphargus) pungens* from the warm springs in Italy, of which we find notice in Ray.

A short chapter is given on *Gammarus locusta*, for which he cites as authorities Leach, Desmarest, KRÖYER, Milne-Edwards and Zaddach. He thinks that Guérin's figure in the Iconographie, Crust. Tab. 26, probably represents *locusta*, but points out that the upper antennæ in fig. 7 are shorter, in fig. 7a much longer, than the lower. Nor does he include in the synonymy Montagu's *Cancer (Gammarus) locusta*, since it has the upper antennæ much shorter than the lower.

1852. COUCH, RICHARD QUILLER, born March 14, 1816, died May 8, 1863 (W. Pengelly).

On some of the rarer forms of Cornish Crustacea. Transactions of the Natural History and Antiquarian Society of Penzance. Volume II. 1851–1855. Penzance, 1864. (Report for MDCCCLX, apparently published in 1852.) pp. 95–99.

In "Class Crustacea, Subclass *C. mandibulata*," Couch gives definitions of the two genera *Caprella* and *Proto*. In the first he describes 1. *Caprella plasma*, Montagu's Cancer phasma; 2. "*C. Acanthifera*," for which he gives "*C. Acanthifera*, Johnston, Mag. Nat. History, Vol. vi., p. 40, fig. 7a;—Vol. viii. fig. 70, p. 671.", as his authority; 3. "*C. Pennantii*," with references to "*Cancer Atomos*, Stew. Elem., Vol. ii., p. 317; *Astacus Atomos*, Pennant, Brit. Zool., Vol. iv., Pl. 13, fig. 2;"; 4. "*C. Linearis*," with reference to *Cancer linearis*, Liu., *Cancer lobatus*, Stewart, *Caprella linearis*, Johnston; "the head is obtuse, and the species the shortest and stoutest of any found in our seas, with no spine along the whole of the dorsal surface." *C. spinulata* (Couch), is thus described:—"Long and slender; the head is larger than the next articulation, and without a spine; the occipital articulation with a spine near its posterior margin, and there is one on the next ring above the brachiae; there are two on the third, one above the branchiae, one near its posterior margin, and one on the centre of each of the others. Superior antennæ as long as the body, basal joint small, the second about four times as long as wide, the third long and slender and slightly enlarged towards its distal extremity, the last multi-articulate and ciliated; the inferior antennæ much smaller than the others; at the lower part of the head two pedipalpi, small and bifid at their extremities. The hand very large, moveable joint long, slender, and hooked, and at its point, when bent, touches a spine on the hand." Mayer thinks these characters would suit *C. acanthifera*, but recognises the uncertainty. The "occipital articulation with a spine" is a little suggestive of *Aeginella spinosa*, Boeck. Lastly, he describes *Proto pedatus*, without naming any authority.

1852. DANA, JAMES D.

Conspectus Crustaceorum quæ in Orbis Terrarum circumnavigatione, CAROLO WILKES e Classe Reipublicæ Federatae Duee, lexit et descriptis JACOBUS D. DANA. Pars III. Amphipoda. No. I. Proceedings of the American Academy of Arts and Sciences. Vol. II. From May, 1848, to May, 1852. Boston, Cambridge, 1852. pp. 201–220.

This paper contains only Dana's own new species. In "Subtribus 1. Gammaracea. Familia 1. Orchestidae. *Palpus mandibularis* obsoletus. *Corpus compressum*, epimeris latis. *Styli rauales* duo postici breviores," he gives genus I. *Talitrus*, Latreille, "Pedes primi styliformes, secundi vel non subcheliformes vel manu debilissimâ confecti. Antennæ primæ basi inferiorum breviores," with the species *Nori-Zealandia*, *gracilis*, *ornatus*: genus II. *Talitronus*, Daua, "Pedes secundi manu valido prehensili confecti. Alias *Talitro* similis," with the species *insculptus* which he afterwards identified with *Orchestoidea tuberculata*, Nicolet, as an *Orchestia*, dropping both his own genus *Talitronus* and *Orchestoidea* of Nicolet; genus III. *Orchestia*, Leach, with the species *sylvicola*, *tenuis*, *rectimanus*, *spinipalma*, *scutigerula*, *nitida*, *dispar*, *quadrimanus*, *serrulata*; genus IV. *Allorchestes*, Dana, with the species *compressa*, *verticillata*, *hirtipalma*, *gracilis*, *peruviana*, *humilis*, *australis*, *brevicornis*, *Nori-Zealandia*, *intrepida*, *orientalis*, and *Allorchestes?* *graminica*.

In "Familia II. Gammaridæ. *Mandibulæ* palpigeræ. *Corpus* sæpius compressum. *Antennæ* flagello confectæ, non pediformes. *Styli caudales* duo postici sive longi sive breves. *Animalia saltatoria vel natatoria,*" he gives the following arrangement, "Subfamilia I. Lysianassinæ. *Antennæ primæ* basin crassæ. *Epimera* grandia. *Pedes* sex postici non prehensiles," including *Lysianassa Brasiliensis*, *Uristes gigas*, *Stenia Magellanica*. "Subfamilia II. Gammarinæ. *Antennæ primæ* basin tenues. *Epimera* sive *grandia*, sive *angusta*. *Pedes* sex postici non prehensiles. Genus I. *Gammarus*. *Pedes* primi secundique subcheliformes, digito uni-articulato, reliqui non prchensiles, sex posticis similibus. *Antennæ* secundæ sub primas insitæ, primæ appendiculatae," with the species described under various sections and subsections, of two main divisions, "I. Manus pedum 2dorum pollice elongato non armata," containing the species, *asper*, *Suluensis*, *albidus*, *hirsuticornis*, *emissarius*, *tenuis*, *furcicornis*, *tenellus*, *orientalis*; "II. Manus una paris secundi validissime cheliformis, pollice valde elongato; altera parvula. (*Gen. Mæra, Leachii.*)," containing *Gammarus (Mæra) quadrimanus*, *Gammarus (Mæra) valilus*, *Gammarus (Mæra) setipes*, *Gammarus (Mæra) pilosus*. "Genus II. Amphitoë. *Gammare* affinis. *Antennæ* superiores non appendiculatae. A. *Antennæ* superiores longiores," including in this division, under sections and subsections, species named *peculans*, *fissicauda*, *pubescens*, *Amphitoë (Melita) inaequistyli*, *Peruviana*, *tenuicornis*, *Indica*, *rubella*, *fucorum*, *Tongensis*, *peregrina*, *breripes*, and under "B. *Antennæ* superiores breviores. (*Genus Iphimedia, Rathke.*)" *Iphimedia simplex* and "*Iphimedia (Acanthosoma, Owen) nodosa*." "Genus III. *Edicerus*. (*Kröyer*). *Amphitoë* pedes 4 anticos membraque buccalia affinis. *Pedes* septimi valde elongati, tenues, fere filiformes. *Epimera* medicoria," with the species *Edicerus Novi-Zealandiæ*. "Genus IV. *Erichthonius?* (*M. Edwards*). *Antennæ* elongatae. *Pedes* primi plus minusve cheliformes, secundi valde cheliformes, digito biarticulato, pollice prominente. *Epimera* sat angusta aut latiuscula. *Cauda* subsaltatoria. "Erichthonii gressorii (caudâ non saltatoriâ), *M. Edwards* auctoritate, et *epimera* carentes. Forsan genus hic descriptum Erichthonio discrepat et novum. Hoc credente, genus *Pyctilus* (a πύκτης, pugil) in manuscriptis auctore institutum est," with the species *Erichthonius (Pyctilus?) macrodactylus* and *Erichthonius (Pyctilus?) pugnax*. "Familia III. Corophidæ. *Corpus* plus minusve depresso, lineare, ab domine recto, articulos normali, epimeris angustissimis vel obsoletis. *Mandibulæ* palpigeræ. *Antennæ* pediformes. *Animalia gressoria*. Genus I. *Corophium*. *Pedes* secundi non subcheliformes digito nullo 2-articulato. *Antennæ* 2dæ flagellis carentes," has only the obscure species *Corophium quadriceps*, described from a specimen perhaps not adult. "Genus II. *Clydonia*. (*Dana*). *Corpus* elongatum, paulo depresso. Ab domen 6-7 articulatum. *Antennæ* quatnor; duæ elongatae, styliformes, rectæ et rigidæ, articulo basali brevi, reliquâ parte longissimè subulatâ obsoletè multi-articulatâ. *Pedes* tennes, 6 postici longè filiformes, quintis longissimis," has the species *Clydonia gracilis* and *Clydonia longipes*, "C. gracilis, similis." *Bovallius*, 1886, identifies this genus with *Tyro*, *Milne-Edwards*. "Familia IV. Icilidæ. *Corpus* valde compressum, latum, vix lineare, ab domine articulos normali, valde inflexo. *Pedes* plerumque latè expansi instar Aranei. *Antennæ* quatuor flagellis confectæ, non pediformes. *Animalia gressoria*. Genus *Icilius*. *Antennæ* elongatae, secundæ longiores. *Pedes* non prehensiles, toti vergiformes, apicem inguenlati. *Styli caudales* sex furcati." This genus receives the single species, *Icilius oralis*, of which the specific name was afterwards changed without notice into the better Latin *ellipticus*. In regard to his *Amphitoë breripes*, in which the second gnathopod is large in the male but small in the female, *Dana* adds to his description the remark, "Microcheli, generi non vero, ut mihi videtur, femina *A. breripeulis* forsitan pertinet."

1852. DANA, JAMES DWIGHT.

On the Classification of the Crustacea Choristopoda or Tetradecapoda. The American Journal of Science and Arts. Second Series. Vol. XIV. November, 1852. New Haven. Number XLI. Appendix. pp. 297-316.

"The term Choristopoda, applied to the Tetradecapoda, alludes to the subdivision of the thorax into segments, each devoted to a separate pair of legs; this is a prominent peculiarity of the species, distinguishing them from all the Podophthalmia, and with rare exceptions from the Entomostraca."

"The Amphipoda are uniformly characterized by having—

"1. The three posterior pairs of thoracic legs thrown backward and more or less obliquely forward, and constituting one series, while the four anterior pairs are thrown forward and outward, in another series; this arrangement may be represented by the figures 4:3, (or 2+2:3, as the four pairs of the first series are often in two sets of two pairs each).

"2. The branchial appendages thoracic.

"3. The abdominal members in two sets, the three anterior pairs subnatatory, the three posterior styliform—an arrangement represented by the figures 3:3."

From these he distinguishes the Isopoda, and places *Arcturus*, *Tanais*, &c., in an intermediate group or tribe called Anisopoda.

"The Amphipoda contain two prominent divisions, distinguished by the organs of the mouth, the eyes and general habit, the Gammarus and Hyperia sections, as laid down by Edwards. The addition of the Læmipoda to the Amphipoda introduces a third division. The sections are hence:—

"Subtribus I. CAPRELLIDEA.—Maxillipedes elongati, palpiformes. Caput oculique mediocres. Abdomen obsolescens.

"Subtribus II. GAMMARIDEA.—Maxillipedes elongati, palpiformes. Caput oculique mediocres. Abdomen appendicibus sex natatoriis sexque styliformibus instruetum.

"Subtribus III. HYPERIDEA.—Maxillipedes abbreviati, lamellati, operculiformes. Caput grande, oculorum corneis plerumque tectum. Appendices abdominales ac in Gammarideis, latius lamellatae.

"The Caprellidea have the habit of certain of the Anisopoda, and their short abdomen calls to mind the Isopoda. They therefore properly stand first among the Amphipoda."

The first subtribe, Caprellidea, contains:—Fam. 1. Caprellidae, with the genera, 1. *Proto*, Leach; 2. *Protella*, Dana. "Mandibulae palpigeræ. Branchiae segmentis 3tio 4toque affixa. Pedes 3tii 4tique obsoleti artienlo 1mo styliformi excepto;" 3. *Caprella*, Lamk.; 4. *Ægina*, Kröyer; 5. *Cercops*, Kröyer; 6. *Poralirius*, Kröyer. Fam. 2. Cyamidæ, with one genus *Cyamus*.

On subtribe II. Gammaridea, he remarks:—"Among the Gammaridea, the author finds that the posterior caudal stylets offer important characters for distinguishing natural groups or genera, and upon this ground, some new genera have been recognized among the Corophidæ and Gammaridæ, and others that have been rejected are sustained. Thus *Iphimedia* is distinct from *Amphithoe*, *Mæra* and *Derothoe* from *Gammarus*, etc.]" He then gives Fam. 1. Dulichidæ. G. 1. *Dulichia*, Kröyer. Fam. II. Cheluridæ. G. 1. *Chelura*, Philippi. Fam. III. Corophidæ. Subfam. 1. *Clydoninæ*.—"Styli caudales sex simplices, subulati." *Clydonia*, Dana, Amer. J. Sci. [2], viii, 140.

"Subfam. 2. Corophinæ. Antennæ plns minusve pediformes. Styli caudales 1mi 2dique biramei. A. Digitus nullus 2-articulatus. 1. *Styli caudales* 3tii minuti, simplices, 2li 1mique ramo externo cultriformi." G. 1. *Corophium*, Latr.; G. 2. *Siphonæcetes*, Kröyer.

"2. *Styli caudales* 3tii minuti, rix errecti, simplices, 2li 1mique ramis extus non præcipue

spinosis nec cultriformibus, interdum nudis." G. 3. *Platophium*, Dana.—"Corpus superne visum subellipticum, abdomine bene inflexo. Antennæ flagello brevi sœpe instruetæ, inferiores longiores, superiores appendiculatae. Pedes 1mi 2dique subbehelati, 2dis validioribus. Pedes 10 postici mediocres." G. 4. *Cyrtophium*, Dana. " *Platophio similis*. Anteunæ superiores non appendiculatae." 3. *Styli caudales* 3tii parvuli, biramei, ramo externo non uncinato, 2di 1mi quæ ramis extus non præcipue spinosis nec cultriformibus." G. 5. *Unciola*, Say. "4. *Styli caudales* 3tii paulo elongati, biramei, ramo externo uncinato." G. 6. *Podocerus*, Leach.—"Pedes 1mi 2dique subbehelati, 2dis validioribns. Antennæ superiores breviores, non appendiculatae. [An maris digitus 2dus interdum 2-articulatus Kröger teste.]" In a note he observes, " *Jassa* of Leach may without inconvenience be united to *Podocerus*, as there is no essential generic difference between them." The same remark has been applied by later writers to the next genns, G. 7. *Cratophium*, Dana, "Pedes 1mi 2dique subbehelati, 2dis validioribus. Antennæ superiores breviores, appendiculatae." "B. Digitus 2dus 2-articulatus." G. 8. *Cerapus*, Say. "Antennæ pediformes, subæquæ, flagellis earentes. Pedes 1mi 2dique prehensiles, 1mis parvulis, 2dis manu bene confectis. Styli caudales 3tii biramei, ramis subæquis, longiuseulis, [Tubum membranaceum inhabitat]," in which definition the account of the third uropods is rather to be remarked than accepted; G. 9. " *Cerapodina*, Edw. (*Cerapus*, Templeton);" G. 10. *Erichthonius*, Edw.

Subfam. 3. *Iciliæ*. "Antennæ non pediformes nec subpediformes, flagellis sat longis basique sat brevi instructæ. Styli caudales ac in *Corophinæ*." G. 1. *Icilius*, Dana. Pedes toti unguiculati et tenues, 4 antie longi, non prehensiles, ciliati, 10 postici fere similes. Antennæ superiores breviores non appendiculatae." G. 2. *Pterygocera*, Latr.

Fam. IV. *Orchestidæ*, is introduced with the note:—"The author gives a different arrangement of the species of *Orchestidæ* from that published in this Journal, [2], viii, 135 and ix, 295, and rejects the genus *Talitronus*, there instituted. He follows Fr. Müller (Archiv f. Nat., 1848, 53) in considering the *Talitri* and *Orchestia* as forming a single genus, his recent investigations confirming this view. The *Gammaridæ* also are rearranged." He then gives "G. 1. *Orchestia*.—Maxillipedes non unguiculati. Antennæ 1mæ basi 2darum breviores. Epimeræ 5tae 4tis paree breviores.

"Subgen. 1. *Talitrus*.—Pedes 1mi *maris feminæ* manu non instructi.

"Subgen. 2. *Talorchestia*, D.—Pedes 1mi *maris ae* in *Talitro*, *feminæ* manu parvulâ instructi.

"Subgen. 3. *Orehestia*.—Pedes 1mi *maris feminæque* manu plus minusve instructi.

"G. 2. *Allorchestes*, Dana.—Maxillipedes unguiculati. Antennæ 1mæ minores, basi 2darum longiores. Epimeræ 5tae 4tis sæpissimis multo breviores." On the three subgenera see the following note. In the proposed arrangement the older name *Talitrus* should have been assigned to the genns, rather than *Orchestia*.

Fam. V. *Gammaridæ*, contains—

Subfam. 1. *Stegocephalinae*. G. 1. *Stegocephalus*, Kröyer.

Subfam. 2. *Lysianassinae*. G. 1. *Lysianassa*, Edw.; G. 2. *Phlias*, Gnérin; G. 3. *Opis*, Kröyer; G. 4. *Uristes*, Dana, with a reference to "Amer. J. Sc. [2], viii, 135. The genus *Stenia* is rejected;" G. 5. *Anonyx*, Kröyer; G. 6. *Urothoe*, Dana, "Epimeræ permagnæ, 5tis parvis. Antennæ 1mæ breviores, appendiculatae, basi sat elongato. Styli caudales postiei longi, biramei, ramis foliaceis, ciliatis. Mandibulæ palpo 3-articulato."

Subfam. 3. *Leneothoinæ*.—"Antennæ superiores basi plus minusve graciles. Maxillipedes elongati, angusti, artieulo longo unguiformi confecti, *lamellis internis perbrevisibus*. Mandibulæ sive palpigeræ sive non palpigeræ, processu molari earentes. [An semper?] Epimeræ magnæ." G. 1. *Stenothoe*, Dana, "Epimeræ permagnæ, 4tæ maximæ, 5tae parvulae. Pedes 4 antie subbehelati, 2dis validioribus. Antennæ superiores longiores, non appendiculatae. Mandibulæ non palpigeræ, processu molari earentes. Styli caudales 1mi

2lique ramis bene subulati, 3tii simplicissimi, subulati, spinâ crassâ confecti." G. 2. *Leucothoe*, Leach.—"Epimerae magnæ, 5tæ parvulae. Pedes 4 autici subchelati, 2dis validioribus. Antennæ superiores longiores, non appendiculatae. Mandibulæ palpigeræ. Styli caudales toti biramei, ramis subulatis."

"[Cujus sedis est *Microcheles*, Kröyer, Amphithoe affinis, cui mandibulæ processu molari carentes: quoque *Amphithoe Marionis*, Edw., cui mandibulæ non palpigeræ.]"

Subfam. 4. Gammarinæ, with various divisions and subdivisions, contains G. 1. *Acanthonotus*, Oweu; G. 2. *Alibrotus*, Edw.; G. 3. "Leptochirus," Zaddach; G. 4. *Iphimedia*, Rathke, D. "Epimerae magnæ, 4tæ maximæ, 5tis multo brevioribus et vix bilobatis. Styli caudales postici ramis duobus oblongis consimilibus apice setigeris et non uncinatis instructi. Antennæ 1mæ sæpius breviores," with a note, "Dexamine of Leach, may perhaps be included here," to which he adds that the genus *Hyale* of H. Rathke, contains no characters in its description by this author which do not apply equally well to species of *Iphimedia*; G. 5. *Oedicerus*, Kröyer, "Iphimedix affinis;" G. 6. *Amphithoe*, Leach, D. "(includes *Pherusa* of Leach)"; "Epimerae magnæ, 5tæ maximæ, vix bilobatae lobo posteriore minimo. Styli caudales postici ramis duobus dissimilibus instructi, ramo externo apice recurvatum bi-unciuato, interno compresso apice non spinuloso sed pilis parce ciliato. Antennæ 1mæ sapissime longiores;" G. 7. *Gammarsus*, Fabr. D., with notes upon *Amathia*, Rathke, and *Eusirus*, Kröyer; G. 8. *Photis*, Kröyer; G. 9. *Melita*, Leach, D. "Epimerae 5tæ 4tis multo breviores (sic an semper?). Styli caudales uno ramo longo, sive subcylindrico sive foliaceo, altero brevi vel obsoleto. [Digitus in manus latus sæpe claudens]. Antennæ 1mæ sæpius longiores." To *Photis* and *Melita* he assigns "Antennæ 1mæ non appendiculatae," and then under "antennæ 1mæ appendiculatae," he places G. 10. *Mæra*, Leach, D.—"Epimerae et styli caudales postici ac in *Melitâ*." Under the heading "Styli caudales postici simplicissimi, ramo uno brevi et nudo, apice paulo reflexo et spinas duas perbreves paulo exsertas gerente," he places G. 11. *Dercothoe*, Dana.—"Epimerae mediocres, 5tæ bene bilobatae, 4tis sæpius vix breviores. Pedes 1mi 2dique digito uni-articulato confecti"; G. 12. *Pyctilus*, Dana (*Erichthonius*, Edw.?)—"Epimerae mediocres vel breves corpore linearis, subdepresso. Antennæ longæ, flagellis sat longis. Manus 1mæ articulis 4to 5toque sæpe instructæ, digito uni-articulato; 2dæ digito 2-articulato;" G. 13. "(An hujus sedis?) *Pardalisca*, Kröyer. He then gives in a separate section, G. 14. *Atylus*, Leach; G. 15. *Ischyrocerus*, Kröyer.

The second main division of the Gammaridæ has "Pedes 10 postici partim prehensiles." Subfam. 5. Pontoporinæ. G. 1. *Lepidactylis*, Say; G. 2. *Pontiporeia*, Kr.; G. 3. *Amphilisca*, Kr.; G. 4. *Protomedieia*, Kr.; G. 5. *Aora*, Kr.; G. 6. *Phoxus*, Kr. Subfam. 6. Isæinae. G. 1. *Isæa*, Edw.; G. 2. *Anisopus*, Templeton. He doubts whether *Laphystius*, Kröyer, belongs to the *Isæinæ* or *Corophidae*.

Of "Subtribus III. Hyperidea," he says, "In the first family of the Hyperidea, (the *Hyperidæ*), neither of the 5 posterior pairs of legs are subchelate, and the antennæ are not folded up beneath the head or thorax. In the second (the *Phronimidæ*), one or more of the 3 posterior pairs of legs are subchelate or much enlarged, apparently for grasping in coition, and the antennæ are as in the Hyperidæ. The third family (the *Typhidæ*), differs from both the preceding in the concealment and folding of the inferior antennæ beneath the head or thorax, and in many of the species, the abdomen closes up against the venter."

The Hyperidea he arranges thus:—Fam. 1. Hyperidæ. "Antennæ 2dæ exsertæ. Abdomen in ventrem se non fleetens. Pedes 5ti 6ti 7mique formâ longitudineque mediocres, 5tis 6tisque non pererassis nec prehensilibus." Subfam. 1. Vibiliæ. G. 1. *Vibilia*, Edw. Subfam. 2. Hyperinae. G. 1. *Lestrigonus*, Edw.; G. 2. *Tyro*, Edw.; G. 3. *Hyperia*, Latr.; G. 4. *Meteucus*, Kröyer; G. 5. *Tauria*, Dana, "Antennæ ac in *Hyperiâ*. Pedes 2di non prehensiles, articulo 4to apice inferiore non expanso uero producto"; G. 6. *Daira*,

Edw.; G. 7. *Cystisoma*, Guérin. Subfam. 2 [3]. *Synopinæ*.—"Corpus gracilis. Palpus mandibularis sat brevis, latissimus. Oculi grandes." G. 1. *Synopia*, Dana.—"Caput subtriangulatum, non oblongum. Pigmentum oculorum unicum. Pedes 1mi parvuli, prehensiles; 2di setis longiusculis confecti; 4ti subprehensiles; 5ti 6ti 7mique subæqui." Fam. II. Phronimidæ. "Antennæ 2dæ exsertæ. Abdomen in ventrem se non flectens. Pedes 5ti 6tive sive crassi sive elongati, saepius prehensiles, quoque 3tii 4tique saepe prehensiles." Subfam. 1. Phroniminæ. G. 1. *Phronima*, Latr.; G. 2. *Primno*, Guérin. Subfam. 2. Phrosininæ. G. 1. *Anhyllomera*, Edw. (*Hieraconyx*, Guérin); G. 2. *Phrosina*, Risso (*Dactylocera*, Latreille); G. 3. *Themisto*, Guérin. Subfam. 3. Phorcineæ. G. 1. *Phorcus*, Edw.

Fam. III. Typhidæ. "Antennæ 2dæ sub capite thoracce celatae et saepius replicatae. Abdomen in ventrem saepe se flectens. Pedes 6 postici interdum abbreviati, articulo 1mo operculiformi, interdum longitudine mediocres." Subfam. 1. Typhinæ.—"Abdomen in ventrem se flectens." G. 1. *Dithyrus*, Dana,—"Pedes 5ti 6tique articulo 1mo late lamellati, articulis reliquis omnino obsoletis. Antennæ 2dae breves, sub capite celatae, non replicatae, articulo 1mo longiore quam 2dus." G. 2. *Typhis*, Risso.—"Pedes 5ti 6tique articulo 1mo late lamellati, articulis reliquis paulo abbreviatis. Antennæ 2dæ biplicatae, articulo 1mo longiore quam 2dus." G. 3. *Thyropus*, Dana, "(Species *Typhis ferox* (Edw.) is here included),"—"Pedes 5ti 6tique articulo 1mo late lamellati, articulis reliquis paulo abbreviatis. Antennæ 2dæ 4-5-plicatae, sub thoracis laterc celatae, articulo 1mo multo breviore quam 2dus." Subfam. 2. Pronoinæ.—"Abdomen in ventrem se non flectens. Caput non oblongum, antennis frontalibus." G. 1. *Pronoe*, Guérin.—"Pedes 2di non prehensiles. Pedum 6 posticorum articuli 1mi lati, reliquâ parte paris 7mi fere obsoletâ." G. 2. *Lycæa*, Dana.—"Pedes 1mi 2dique subchelati. Articuli pedum 6 posticorum 1mi angusti, subæqui, reliquâ parte paris 7mi paulo abbreviatâ." Subfam. 3. Oxycephalinæ. "Abdomen in ventrem se non flectens. Caput oblongum, antennis 1mis superficiem capitidis inferiorem insitis." G. 1. *Oxycephalus*, Edw.; G. 2. *Rhabdosoma*, White.

1852. DANA, JAMES DWIGHT.

United States Exploring Expedition, during the years 1838, 1839, 1840, 1841, 1842, under the command of Charles Wilkes, U.S.N., Vol. XIII. Part II. Philadelphia. 1852. pp. 689—1618. (Whether this Part really appeared before 1853 seems rather doubtful.)

Pages 8-12 of Part I. contain preliminary notes on the classification of the Edriophthalmia. In Part II. the pages referring to Amphipoda are from 691-696, 805-1018, 1440-1443, 1518-1524, 1595-1596.

Taking the Edriophthalmia as Subclass II. of the Crustacea, he makes the Choristopoda, or Tetradecapoda, the first order of this subclass, and thus defines it:—"Cephalothorax multi-annulatus, segmentis thoracis numero septem, pare pedum utroque ad segmentum singulum pertinente, segmento anteriore cephalico brevi. Pedes thoracis pediformes, saepissime unguiculati. Abdomen paribus appendicem pluribus infra instructum. Appendices branchiales sive thoracici sive abdominales." Of this order he makes three divisions, the Amphipoda, Anisopoda, and Isopoda, rejecting the subdivision of *Lamipoda*, introduced by Latreille. "The Amphipoda," he says, "are uniformly characterized by having—

1. The three posterior pairs of thoracic legs in one series, and the four anterior pairs in two other series of two pairs each. The branchiae are thoracic.

"2. The abdominal members in two sets, the three anterior pairs subnatatory, the three posterior styliform."

Of the intermediate Anisopoda, he says, "They have—

"1. Like *Amphipoda*, the three posterior pairs of thoracic legs in one series, and the four anterior in a different series.

"2. Like *Isopoda*, the three posterior pairs of abdominal members are not styliform, only the last having this character."

In discussing the question whether the Amphipoda or Isopoda should rank the higher, he remarks, in favour of the Amphipoda, the position of the branchiae on the thorax, as thoracic branchiae characterize all the higher Crustacea. On the other hand, he considers that they show inferiority, by the elongated abdomen, with natatory appendages below, and by the usually long antennae, both these being Macroural characters. Further, the anterior set of legs includes four pairs, an evidence, he considers, of less concentration of force in the cephalic ganglia; they have a less compact body, are less apt to take to a habitat on dry land, and above all, have often the two "dorsal cords" distinct between the ganglia, while in the Isopods there is but a single cord. This double cord is seen in none of the higher Crustacea.

In Tribe III. the Amphipoda (p. 805), he recognizes two types of structure, one, the Hyperidea, with small, operculiform maxillipeds, large faceted eyes covering most of the large head, the extremity of the abdomen broad and depressed, the natatory abdominal appendages usually oval, lamellar; "in the other type, the outer maxillipeds are elongated and palpiform, the eyes are small, the head of moderate size, the abdomen, when not obsolete, narrow, and the natatory abdominal appendages usually slender. This second type comprises two groups. In one section, the Caprellidea, the abdomen is obsolescent. In the other, the Gammaridea, the abdomen is fully developed, with three pairs of natatory appendages, and as many of styles." This section embraces the typical Amphipods, the Gammari, Talitri, and the like.

His three subtribes, Caprellidea, Gammaridea, and Hyperidea, he divides and subdivides into families and subfamilies, which are defined as follows:—

Subtribe I. Caprellidea. Family I. Caprellidæ.—Corpus anguste elongatum, fere filiforme. Antennæ 2dæ longitndine mediocres. [Species non parasiticæ.]

Fam. II. Cyamidæ.—Corpus late depressnm. Antennæ 2dæ rudimentariae. [Species parasiticæ.]

Subtribe II. Gammaridea. Fam. I. Dnlichidæ.—Habitus Caprelloideæ. Corpus lineare, epimeris obsolete. Pedes 6 postici longi, subprehensiles. Abdomen 5-articulatum.

Fam. II. Cheluridæ.—Corpus fere cylindricum, epimeris mediocribns. Abdomen abnormale, segmentis 4to 5toqne coalitis et oblongis, stylis inter se valde dissimilibus.

Fam. III. Corophidæ.—Gressoriae, pedibus partim lateraliter porrectis. Corpus plus minus depressnm, sive latum sive lineare, epimeris perbrevibus, interdum obsolete. Abdomen formâ appendicibusque normale. Antennæ saepe pediformes.

Fam. IV. Orchestidæ.—Saltatoriae, pedibus nullis lateraliter porrectis. Corpus compressum, epimeris magnis. Abdomen appendicibus normale. Antennæ non bene pediformes. Styli caudales 1mi 2dique biramei; 3tii simplices, brevissimi et ultra 2dos non prolongati. Mandibulae non palpigeræ. Maxillæ 1mæ palpo sive parvulo et 1-articulato sive obsolete iunctæ.

Fam. V. Gammaridæ.—Saltatoriae vel natatoriae, pedibus nullis lateraliter porrectis. Corpus saepius compressum, raro subdepressum, epimeris sive magnis sive parvis. Styli caudales laxiores, duobus altimis oblongis saepiusqne ultra 2dos prolongatis, raro simplicibus. Mandibulae saepissime palpigeræ. Maxillæ 1mæ palpo 2-3-articulato (rarissime 1-articulato) iunctæ.

Subtribe III. Hyperidea. Fam. I. Hyperidæ.—Antennæ 2dæ exsertæ. Abdomen in ventrem se non fleetens. Pedes 5ti 6tique 7mique formâ longitudineque mediocres, 5tis 6tisque non percrassis nec prehensilibus.

Fam. II. Phronimidae.—Antennae 2dæ exsertæ. Abdomen in ventrem sc non flectens. Pedes 5ti 6tique sive crassi sive elongati, saepius prehensiles, quoque 3tii 4tique saepè prehensiles.

Fam. III. Typhidae.—Antennæ 2dæ sub capite thoraceque celatae et saepius replicatae. Abdomen in ventrem saepè se flectens. Pedes 6 postici interdum abbreviati, articulo 1mo operculiformi, interdum longitudine mediocres.

The family Caprellidae is not subdivided by Dana into subfamilies, but he distinguishes three sets of genera in the following manner ; 1. *Pedes thoracis* numero 14, containing the genera *Proto*, Leach, and *Protella*, Dana. 2. *Pedes thoracis* 3tii 4tique omnino obsoleti, containing *Caprella*, Lamarck, *Aegina*, Kröyer, *Cercops*, Kröyer. 3. *Pedes* 3tii 4t 5tique obsoleti, with the single genus *Podalirius*, Kröyer.

The family Cyamidae contains but a single genus. So also in the Gammaridea, the families Dulichidae and Cheluridae have but one genus apiece.

The family Corophidae is subdivided into three subfamilies.

1. Clydoninæ.—Styli caudales :—1mi 2dique slices, subulati.
2. Corophinæ.—Antennæ plus minusve pediformes. Styli caudales 1mi 2dique biramei.
3. Iciliæ.—Antennæ non pediformes nec subpediformes, flagellis sat longis basique sat brevi instructæ. Styli caudales ac in Corophinis.

The family Orchestidae contains the genus *Orchestia* with three subgenera, *Talitrus*, *Talorchestia*, and *Orchestia*, and the genus *Allorchestes*, but no subfamilies.

The family Gammaridae contains the following subfamilies :—

1. Stegocephalinæ.—Antennæ breves, superiores basi crassæ. Mandibulæ acie denticulatâ instructæ, palpo brevi, unarticulato, intus dentato. Epimeræ permagnæ.
2. Lysianassinæ.—Antennæ breves, superiores basi crassæ. Mandibulæ apice parce dentatæ et enspidatæ, acie vix instructæ, palpo 2-3-articulato. Maxillipedes lamellis internis grandibus. Epimeræ permagnæ.
3. Leucothoinæ.—Antennæ superiores basi plus minusve graciles. Maxillipedes elongati, angusti, articulo longo unguiformi confecti, *lamellis internis perbrevibus*. Mandibulæ sive palpigeræ sive non palpigeræ, processu molari carentes. [An semper ?]. Epimeræ magnæ.
4. Gammarinæ.—Antennæ 1mæ basi graciles. Maxillipedes sat lati, lamellis internis sat elongatis. Mandibulæ acie denticulatâ instructæ et alterâ accessoriâ quoque processu molari et palpo 3-articulato. Pedes 10 postici non subprehensiles.
5. Pontoporeinæ.—Pedes 3tii 4tique plus minusve prehensiles ; 6 postici non prehensiles.
6. Isæinæ.—Pedes quatuor vel sex postici subprehensiles.

In the Hyperidea, the family Hyperidae is subdivided into three subfamilies :—

1. Vibiliæ.—Corpus formâ paulo Gammaroideum. Caput oculique mediocres. Maxillipedes palpo parvulo instructi. Palpus mandibularis tenuis.
2. Hyperinæ.—Caput tumidum. Oculi pergrandes. Palpus mandibularis tenuis.
3. Synopinæ.—Corpus gracilis. Palpus mandibularis sat brevis, latissimus. Oculi grandes.

The family Phronimidae contains three subfamilies :—

1. Phroniminæ.—Abdomen versus basin sat gracile. Pedes 5ti magnâ manu didactylâ vel monodactylâ confecti, 3tii 4ti extremitate graciles, non prehensiles. [Antennæ breves.]
2. Phrosininæ.—Abdomen versus basin sat crassum. Pedes 5ti prehensiles, monodactyli ; quoque 3tii 4tique prehensiles. [Antennæ sat breves.]
3. Phorcinae.—Pedes 5ti 6tique valde elongati et crassi, sed manu non confecti. [Antennæ breves.]

In regard to the genera into which the subfamilies are distributed many observations are called for. Among the Corophinæ, genus 3, *Platophium*, Dana, has been considered to be the same as genus 4, *Cyrtophium*, Dana, but Haswell under another name revives the distinction. See Note on Haswell, 1885. Genus 7, *Cratoplium*, Dana, yields to genus 6, *Podocerus*, Leach. Genus 9, *Cerapodina*, Edw., belongs to genus 8, *Cerapus*, Say. *Pterygorera*,

Latreille, the second genus of the Iciliæ, is the same as *Lepidactylis*, Say, which appears later on as genus 1, of the Poutoporeiuæ.

The genus *Orchestia* and its three subgenera, *Talitrus*, *Talorchestia*, *Orchestia*, are defined word for word as in the previous paper, the definition of *Talorchestia*, therefore, still being, "Pedes 1mi maris ac in *Talitro*, feminæ manu parvulâ instructi," but, to agree with Dana's other statements, and with the facts of the case, the definition of *Talorchestia* should evidently read:—Pedes 1mi *feminæ* ac in *Talitro*, *maris* manu parvulâ instructi. It is probably owing to this oversight that the British Museum Catalogue speaks of the males of this subgenus as *Talitri* and the females as *Orchestiae*. The three subgenera have since been generally accepted as genera. The whole subject is somewhat involved. The genus *Talitrus*, Latreille, at its first appearance in Bosc. vol. i. p. 78, is thus defined:—"Quatre antennes simples; les intermédiaires supérieures, et plus courtes que le pédoncule des latérales et intérieures; dix à quatorze pattes."

"Exemple du genre. *Gammarus locusta*, Fab.—*Oniscus gammarellus*, Pallas."

In vol. ii. p. 148, a fuller definition is given:—"Quatre antennes simples; les intermédiaires, supérieures, plus courtes que le pédoncule des inférieures. Corps allongé, couvert de pièces crustacées, transverses, presque égales, et appendiculées sur leur côtés. Dix à quatorze pattes; les antérieures terminées par des mains. Des appendices bifides à l'extrémité du corps."

In 1813, Leach carved a new genus out of *Talitrus*, giving for *Talitrus* the character "Pedes quatuor antici in utroque sexu subæquales monodactyli;" for the new genus *Orchestia*, "Pedum paria quatuor antica monodactyla, pari secundo manu compressa magna, foeminae pari antico monodactylo secundo didactylo." Thus the original definition of *Talitrus* is set at naught, and those members of the group which have "the anterior feet terminated by hands" are assigned to *Orchestia*. Milne-Edwards distinguishes the two genera only by the second gnathopods, with a large subcheliform hand in *Orchestia*, non-prehensile in *Talitrus*. He takes no notice of the distinction of sex in *Orchestia* to which Leach refers.

In 1848 Friedrich Müller called attention to the fact that the females have sometimes the characters of one genus, while the males have those of another, the females in certain *Orchestiae* being true *Talitri*. In Dana's words and according to Dana's definitions, "in one group, the individuals of both sexes are *Orchestiae*; in another, the males are *Orchestiae* and the females *Talitri*; in a third, both sexes are *Talitri*.

A further complication is introduced into the group by the genus *Orchestoidea*, Nicolet, or *Talitronus*, Dana. In this it appears that the females are *Talitri*, while the males are *Talitri* in the first gnathopod and *Orchestiae* in the second. The genus comes therefore nearer to *Talorchestia* than to *Orchestia*. Dana's generic name was, according to Dana, published in the same year with Nicolet's, but may yield precedence, since Dana rejected his own genus, and, so far as I can make out, dates the publication from the time when his paper was *read*, rather than from the time when it was technically *published*. On p. 1595, among the addenda et corrigenda, he says:—"Orchestoidea tuberculata of Nicolet, (loc. cit., Pl. II. f. 4) is the author's *Talitronus insculptus*, and the genus *Talitronus* was instituted and published by the author on July 1, 1849. The name has been since rejected by him for *Orchestia insculpta*; and as Gay's specific name is the older, it will become *Orchestia tuberculata*. We suspect that his *Talitrus Chilensis* is what we have considered the female of the *O. insculpta*." *Megalorchestia*, Brandt, 1851, is an additional synonym.

The second genus which Dana assigns to the *Orchestidae*, is clearly distinguished from his first genus, *Orchestia*, in the following manner:—"Allorchestes;—Maxillipedes unguiculati. Anteunæ 1mæ miiores, basi inferiorum sepiissime longiores. Epimeræ 5tæ 4tis saepius multo breviores."

Further on, p. 883, he adds to the generic description, "Feet of first and second pairs subchelate,

Posterior stylets very short and quite simple, as in *Orehestia*." He also observes that in some species the carpus of the second pair of legs in males is "produced downwards back of the hand, between the hand and the anterior extremity of the third joint (while in *Orehestia*, the third joint is never separated from the hand by a portion of the carpus, and the carpus is always short, transverse, and is situated wholly above the third joint)." But while *Allorehestes* is with sufficient clearness distinguished from *Orehestia*, its own position is otherwise involved in some obscurity.

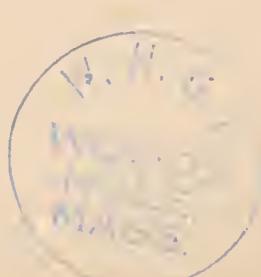

On page 1595, among the addenda et corrigenda, Dana remarks, "The genus *Nicea* of Nicolet (loc. cit.) may possibly be the same with *Allorehestes*; but the essential characteristics are not given, excepting the non-palpigerous character of the mandible. Even if identical, the genus does not antedate the author's, as the description of *Allorehestes* was first published on July 1st of 1849. The maxillipeds are peculiar in having the surface tuberculate, and the inner lamella is dentate only at apex, and there sparingly."

Neither Dana, in describing *Allorehestes*, nor Nicolet, in describing *Nicea*, mentions the form of the telson. Hence, in Mr. Faxon's opinion, the names were synonyms, and he agrees with Spence Bate and Heller in allotting the name *Allorchestes* to the species which have the telson entire, and the name *Nicea* to those in which the telson is divided. As shown in the note on Rathke, 1837, I myself consider it right to assign the name *Hyale* to the latter, and *Hyalella* to the former.

In passing on to the Gammaridae, it should be noticed that, in defining the subfamily Stegocephalinæ, Dana follows Kröyer in erroneously assigning a palp to the mandibles. The genus *Uristes* which he places among the Lysianassinae is evidently based on misconception, as Spence Bate has acutely pointed out. The description in Dana evidently corresponds with the figure, and of this Spence Bate observes (B. M. Catalogue, p. 89, note), "In the figure, Dana has drawn one of the first pair of pereiopoda instead of the second pair of gnathopoda. The meros *always* overrides the carpus in the pereiopoda, and underrides it in the gnathopoda." Dana places *Alibrotus*, Milne-Edwards, among the Gammarinæ, but it more probably belongs to the Lysianassinae. He separates *Mæra*, Leach, from *Melita*, Leach, on the ground that the former has the first antennæ appendiculate and the latter not so, whereas in both genera the upper antennæ have an accessory flagellum. His three species of *Mæra* have been transferred by Spence Bate to *Melita*, and his *Melita tenuicornis* to *Mæra*, though with the notice that if the original description of this species, assigning no secondary appendage to the upper antennæ, is to be relied on, a new genus must be formed for its reception, along with *Melita Fresnelii*, Savigny-Audouin. Axel Boeck rests the discrimination of the two genera apparently only on these two points, that in *Melita* the third joint of the mandibular-palp is elongate, and the inner branch of the third uropods very small, while in *Mæra* the third joint of the mandibular palp is not very long, and the inner branch of the third uropods is nearly as long as the outer.

The genera *Derothoë*, Dana, and *Pycilus*, Dana, are by S. I. Smith made synonyms of *Erithonius*, Milne-Edwards. *Anisopus*, Templeton, which Dana places in his subfamily, Isæinae, is doubtless identical with the later genus, *Sunamphitoë*, but the name *Anisopus* was preoccupied. In his notes Dana observes that *Glauconome* of Kröyer has the hands and antennæ, and apparently the other characters of *Unciola*, Say; to that genus it has in fact since been united by S. I. Smith. He also remarks that *Bellia* of C. Spence Bate (afterwards named *Sulcator*) falls to *Lepidactylis*, Say.

Among the Hyperidae, the genus *Lestrigonius*, M.-Edw., is now generally considered to belong to *Hyperia*, Latr., though Streets keeps it distinct. Dana gives two genera, distinguished from one another and from *Hyperia* by differences in the gnathopods, viz., *Metoecus*, Kröyer, and *Tauria*, Dana. These two Boeck unites as completely synonymous under the name *Tauria*, *Metoecus*, though the older, being preoccupied; but Bovallius, 1886, considers

Tauria, Dana, distinct alike from *Hyperia*, with which Spence Bate united it, and from *Metoecus*, with which Boeck made it synonymous. *Daira*, Milne-Edwards, is altered by Dana, on page 1596, to *Dairilia*, on the ground that *Daira* was preoccupied. This new form of the name is incorrectly given as *Dairinia* in the British Museum Catalogue, owing probably to the misprint in Dana's own work, on page 1442. It is given correctly on pages 1519, and 1545 and 1604; Bovallius, 1885, says, "I am quite sure that Dana was wrong in introducing the animals described by him into the genus *Daira* of Milne-Edwards;" he is of opinion that *Paraphronima*, Claus, comes nearest to, if it be not identical with, the *Daira* of Milne-Edwards. *Synopia*, Dana, the single genus of his subfamily *Synopinæ*, must be transferred to the Gammaridea, as Claus has already pointed out. In some of the species of this genus, besides the confluent principal eyes to which the generic name refers, there are two small subsidiary groups of ocelli; hence the expression "pigmentum oeulorum unium" in the generic character is unsuitable.

For the readjustment of the other two families of the Hyperidea see Notes on Claus, 1879.

In treating of the Orchestidae, which he takes as the type of the Amphipoda (p. 849), Dana describes in detail the head and its (theoretical) segments. He considers that the sides and top of the head correspond to the first antennary and ophthalmic annuli, one or both; that the epistome and lateral plates adjoining it represent the sternal and episternal pieces of the second antennary annulus [against which view see Spence Bate, British Assoc. Report, 1885, p. 26]; that the labrum and a lateral piece above the mandible represent the sternal and episternal pieces of the mandibular annulus; that the back piece of the lower part of the head which supports the maxillipeds is the proper episternal of the maxilliped annulus, while the first and second maxillary annuli are not represented, unless combined with the maxilliped segment at the back of the head.

Pages 1395–1413 contain an interesting essay on the classification of Crustacea. "The fundamental idea," the author says, "which we shall find at the basis of the various distinctions of structure among the species is, the *higher centralization of the superior grades, and the less concentrated central forces of the inferior*." "This centralization is literally a *cephalization* of the forces. In the higher groups, the larger part of the whole structure is centred in the head, and contributes to head functions, that is, the functions of the senses and those of the mouth. As we descend, the head loses one part after another, and with every loss of this kind there is a step down in rank. This centralization may be looked for in the nervous cords; but the facts are less intelligibly studied there than in the members, the production and position of which measure the condition of the forces." At the close he criticises the names Podophthalmia and Edriophthalmia, on the ground that though all stalk-eyed Crustacea may belong to the Podophthalmia, there are many sessile-eyed species which cannot be grouped with the Edriophthalmia. In the classification which follows, pages 1414–1415, he renames his Subclass II., Tetrade-capoda, which he thus defines:—"Annuli cephalothoracis cephalici numero septem. Oculi sessiles. Appendices branchiales simplissimæ, sive thoraeicæ sive abdominales. Cephalothorax multi-annulatus, carapace carens, pedibus seriatis instructus. Abdomen appendiebus seriatis instructum, raro obsolescens." The epithet *simplissimæ* applied to the branchial appendages must be qualified in regard to some species of Amphipoda.

The work concludes with an essay on the Geographical Distribution of Crustacea, pages 1451–1592, in which many interesting conclusions are deduced from the facts at Dana's command. When he comes to speak (p. 1581) of the "origin of the geographical distribution of Crustacea," he says, for the origin of the existing distribution of species "two great causes are admitted by all, and the important question is, how far the influence of each extended. The first, is *original local creations*; the second, *migration*." The form of his answer to this question would probably have been different had his book been

written ten or twenty years later, but he fully admits that migration "is an actual fact in nature, interfering much with the simplicity which zoological life in its diffusion would otherwise present to us."

The new species, published either in this work or in the two preceding papers also dated 1852, are as follows:—in Subtribe I. Caprellidae. Fam. I. Caprellidae; *Proto elongatus*, identified by Mayer with *Proto ventricosa*, O. F. Müller; *Protella gracilis*, the only addition to the variously-worded definition of *Protella* being, "pedes sex ultimi subaequī"; *Caprella robusta*, according to Mayer the young of *Caprella acutifrons*, Latr.; *Caprella cornuta*, with a variety named *obtusirostris*; *Caprella attenuata*, which Mayer thinks may be the same as *Caprella scaura*, Templeton; of this a variety is named *subtenuis*; *Caprella globiceps*, which he thinks may be a variety of *Caprella dilatata*, Kröyer; the last-named species, which Dana figures and describes, is held by Mayer to be synonymous with *Caprella acutifrons*, Latr.; *Caprella januarii*, Kröyer, which Dana figures and describes, is referred by Mayer to *Caprella equilibra*, Say; Dana himself suggests that the animal which he figures as the female may be a distinct species, for which in that case he proposes the name *Caprella humilis*; after *Caprella globiceps* he describes *Egina ? tenella* and *Egina ? aculeata*, suggesting that the latter may be the female of the former.

Subtribe II. Gammaridea. Fam. III. Corophidæ. Subfam. 1. Clydoninæ. *Clydonia gracilis*; *Clydonia longipes*, which with the preceding species should, according to Bovallius, be transferred to the genus *Tyro*, M.-Edw., among the Hyperidea; Subfam. 2. Corophinae. *Corophium ? quadriceps*, a species, as Dana himself intimates, of doubtful position, and probably immature, since the length is given as "nearly one line;" *Platophium brasiliense*; *Cyrtophium orientale*; *Cratophium validum*, named by Sp. Bate, in the Brit. Mus. Catal., *Podocerus validus*; his *Gammarus orientalis* he here calls *Cratophium orientale*, and Sp. Bate, in the B. M. C. renames it *Podocerus orientalis*. Subfam. 3. Iciliæ. *Icilius ellipticus*, which had been originally named *Icilius ovalis*.

Fam. IV. Orchestidae. *Orchestia (Talitrus?) novi-zealandiae*, with the suggestion, since proved correct, by G. M. Thomson, that it may be the female of *Talorchestia quoyana*, M.-Edw.; *Talitrus brevicornis*, M. Edw., which he next describes, is, he says, "near the *novi-zealandiae*," according to the B. M. C. "Dana likewise considers it a true *Talitrus*, unless it should be the female of *Talorchestia Quoyana*," but I do not find this alternative in Dana's own work; his next species *Orchestia (Talitrus) insculpta* had been originally published as *Talitrus insculptus* for the male and *Talitrus ornatus* for the female; in the addenda he calls it *Orchestia tuberculata*, Nicolet, for which the Brit. Mus. Catal. restores Nicolet's name *Orchestoidea tuberculata*; *Orchestia (Talitrus) brasiliensis* is named *Orchestoidea brasiliensis* in the B. M. C.; *Orchestia (Talitrus) pugettensis* is named *Orchestoidea pugettensis* in the B. M. C., but as only the female of this species is described, and the Catalogue states that in *Orchestoidea* "the female is a true *Talitrus*," it is difficult to see how the determination is arrived at; *Orchestia (Talitrus?) scabripes* is transferred to *Orchestoidea* in the B. M. C.; *Orchestia (Talorchestia) gracilis*, of which the female had been already published by Dana as *Talitrus gracilis*, is now *Talorchestia gracilis*, having in the male "feet of first pair with a small, narrow hand," p. 862; *Orchestia (Talorchestia?) quoyana*, Milne-Edwards, is now accepted as without doubt a *Talorchestia*; in the subgenus *Orchestia* he places *Orchestia scutigerula*, comparing it with *Orchestia chilensis*, M.-Edw.; *Orchestia capensis*; *Orchestia chilensis?*, Milne-Edwards, the female only, which is accepted in the B. M. C. without a ?; *Orchestia nitida*; *Orchestia serrulata*; *Orchestia tenuis*; *Orchestia sylvicola*, a species which G. M. Thomson, 1880, unites with *Orchestia novae-zealandiae*, Sp. Bate, and *Orchestia tenuis*, Dana, describing it as "a strictly terrestrial form, always occurring among dank vegetation, bush soil, etc., and drowning very rapidly in water; extremely common;" Mr. Thomson says, "it is singular that Prof. Dana should have

described the male only of *O. sylricola*, for it has been frequently noticed, both by Professor Hutton and myself, that males are extremely rare," but in fact, though the B. M. C. only describes the male, Dana's description is of the female, and the male form of uncertain habitat, of which he appends a description, is left doubtful between *Orchestia sylricola* and *Orchestia tenuis*: *Orchestia spinipalma*; *Orchestia talitensis*, taken "at fifteen hundred feet elevation, on the Island of Tahiti, several miles from the sea," must be transferred back to the name *Orchestia rectimana* under which it was originally published; *Orchestia dispar*; *Orchestia quadrimana*; *Orchestia larvaiensis*; *Orchestia pickeringii*. To the genus *Allorchestes* thirteen species are assigned, of which (with one exception) the true generic position remains uncertain, as no information is given as to the telson; the specific names are "1. *Gaimardi*? (Edw.), D.," in place of *compressa*, Dana, the doubtful correction being accepted as certain in the B. M. C.; Dana says, "the description by Edwards agrees with our specimens in most points, though differing in making the posterior stylets end in two rudimentary branches, instead of one," a critical point on which the B. M. C. gives no information; 2. *verticillata*, to which *Allorchestes peruviana*, Dana, is referred as "female of *A. verticillata*?", the suggestion being here made that Kröyer's *Orchestia grandicornis* from Valparaiso is an *Allorchestes* near to *verticillata*; 3. *hirtipalma*; 4. *gracilis*; 5. *humilis*, "female?"; 6. *australis*; 7. *brericornis*; 8. *novi-zealandiae*, the male of which had been originally described as a separate species under the name *intrepida*; 9. *orientalis*; 10. *Allorchestes* (?) *graminea*, called *Allorchestes gramineus* in the B. M. C., which omits the important observation made by Dana, "the reniform eye of this species leads me to doubt the correctness of arranging it with the *Allorchestes*, and as I made no dissection, I am not sure that its mandible has no palpus, or that its posterior stylets are simple;" 11. *media*, changed into *medius* in the B. M. C.; 12. "*Hawaiensis*"; 13. "*Pugettensis*." Since Mr. Faxon has ascertained that in *Allorchestes media* the telson is cleft, this species should, according to Mr. Faxon's view, be called *Nicea media*, but, according to my view, *Hyale media*.

- In Fam. V. Gammaridae, Subfam. 2. Lysianassinae, begins with the species "Lysianassa? *Brasiliensis*," which from the character of the lower antennae is no doubt described from a male specimen, but of what genus there is no decisive evidence; the next species *Lysianassa nasuta* is likewise of doubtful genus; *Uristes gigas*, as Spence Bate has pointed out, is founded on a confusion, the first pereopod having been described as the second gnathopod; the species has not yet been assigned to any definite position, which the description of the mandibles "with a pointed dentate apex," the abdomen ending "in an oblong seventh joint" and "the antepenultimate segment of abdomen acute behind" ought to find for it; "Anonyx *Fuegiensis*," having been originally called *Stenia magellanica*, must receive the name *Anonyx magellanicus*; *Urothoe rostratus* is changed by Boeck into *Phoxus rostratus*, leaving the next species *Urothoe irrostratus*, as the type of the genus. Subfam. 3. Leucothoinae, contains *Stenothoe validus*. In subfam. 4. Gammarinae, Dana places *Iphimedia simplex*, in the B. M. C. renamed *Atylus simplex*; *Iphimedia nodosa*, which according to Dana "is allied to the *Acanthosoma hystrix* of Owen;" *Iphimedia fissicauda*, which he had previously called *Amphithoe fissicauda*, and which the B. M. C. renames *Atylus fissicauda*; *Iphimedia capensis*, of which he says, "this species is very near the *Gammarus Othonis*, Edwards, but there is no appendage to the superior antennae," and which in the B. M. C. is called *Atylus capensis*; *Iphimedia pugettensis*, which the B. M. C. sets in a new genus *Grayia*, with only one other species, called *Grayia imbricata*, this latter being probably the young of *Amathilla horvathi*, Fabr.; Dana's *Iphimedia pugettensis* should in my opinion be called *Pleustes pugettensis*; *Ellicerus novi-zealandiae*, in the B. M. C. called *Ellicerus norvegicus*, with the appended remark that, "*Grayia Pugettensis* may belong to this genus (certainly not to *Iphimedia*)"; the name is again altered by Thomson and Chilton into *Ellicerus neo-zelandicus*; to *Amphithoe* Dana assigns seven species, *rubella*, *orientalis*,

tongensis, peregrina, brevipes, brasiliensis, jilicornis, names hitherto unimpeached, except that, in regard to *brasiliensis*, the B. M. C. observes that "the description of this species closely resembles that of *A. Gaudichauvii* of Edwards, the chief distinction being the length of the flagellum of the inferior antennæ," but a more important distinction is that in Milne-Edwards' species the first joint of the first and second pereopods is "*ovalaire* (au lieu d'être presque linéaire comme d'ordinaire);" of the species assigned by Dana to *Gammarus*, Spencer Bate leaves only one in that genus; *Gammarus asper* is called in the B. M. C. *Megamora aspera*; *Gammarus suluensis*, as to which Dana says "[*An femina* G. asperi ?]," is called in the B. M. C. "*Megamora Suluensis*," but seeing that the mandibular palp has the second joint much shorter than the first, it probably belongs to a distinct genus, perhaps including *Gammarus asper*, since Dana says of these two, "they are alike in the very slender mandibular palpi without a ciliated arrangement of hairs on the apical joint"; *Gammarus albifrons* in the B. M. C. becomes *Megamora albida*; *Gammarus lenius* is called *Microleuropus tenuis* in the B. M. C., with the remark appended that "this species closely resembles *M. anomalus* of the British coast;" *Gammarus furcicornis*, in the B. M. C. *Mera furcicornis*; *Gammarus tenellus* in the B. M. C. *Mera tenella*; *Gammarus fuegiensis*, of which Dana makes, and, as it were, in the same breath retracts, the suggestion that it may "be the female of the *G. tenellus*," is called in the B. M. C. "*Mera Fuegiensis*"; *Gammarus quadrimanus*, in the B. M. C. *Mera quadrimanus*; *Gammarus brasiliensis* called "*Gammarella Brasiliensis*" in the B. M. C., although contrary to the definition of the genus *Gammarella* the upper antennæ are twice as long as the lower, and the third uropods are evidently regarded as biramous; *Gammarus pygmaeus* the B. M. C. leaves unaltered. Between the last and the following species Dana places a heading, "appendix to the genus *Gammarus*." This section begins with *Gammarus ? peruvianus*, called in the B. M. C. "*Megamora Peruviensis*;" this species was originally called by Dana *Amphithoe peruviana*, and is here said to be "near the *G. brasiliensis* in many characters;" *Gammarus ? pubescens*, previously called *Amphithoe pubescens*, is named in the B. M. C. *Gammarella pubescens*, but it is difficult to see on what grounds, since the upper antennæ are "almost twice as long as the other pair," and the third uropods are not described; *Gammarus ? indicus* in the B. M. C. is named "*Megamora Indica*;" *Melita tenuicornis*, doubtfully including what was originally *Amphithoe tenuicornis*, male, and *Amphithoe (Melita) inaequislylis*, female, is given in the B. M. C. as *Mera tenuicornis*, though with some doubt as to the genus, because the species is described "as having no secondary appendage to the superior antennæ;" *Mera valida* in the B. M. C. is named *Melita valida*; *Mera selipes*, in the B. M. C. *Melita selipes*, is distinguished by the most trivial characters in the description from the following species *Mera anisochir*, of which the synonyms given are *Gammarus anisochir*, Kröyer, and *G. (Mera) pilosus*, Dana, this becoming in the B. M. C. *Melita anisochir*: Dana's figures, however, of the two species *selipes* and *anisochir* suggest the possibility of more considerable differences than those which he mentions in the text. A fuller definition than in the previous paper is then given of the new genus *Dercothoe*.

"*Epimeræ mediocres, 5lae subæquæ bilobatae, 4lis vir breviores. Margo frontis lateralis juxta oculos æpe valde saliens. Styli caudales postici simplicissimi, sat longi, ramo brevi, subconico, apice paulo reflexo e quo spinis dualibus brerissimis exsertis. Antennæ superiores sapient longiores, appendiculatae.*" He adds, "the posterior stylets are like those of *Pyctilus*, and unlike those of any of the preceding genera. The earpus in the legs of the first pair is often as long as the head, and sometimes longer. The two very short spines at the apex of the posterior stylets are full half as broad as long."

The new genus *Pycilus* is more fully defined as follows:—

"*Epimeræ sat breves. Pedes 1mi 2dique prehensiles, reliqui non prehensiles, secundarum digito 2-articulato, manu 1-articulatu. Antennæ elongatæ, secunda subtus primas affixæ. Styli*

caudales postici ac in Dercothoe." He adds, "the genus is near *Erichthonius* (Edwards), if not identical with it. The stress which is laid by Milne-Edwards on the rudimentary character of the epimerales of the anterior thoracic segments, and his reference of his species to the Corophidae or gressorial Amphipods, leads us to doubt the identity. The posterior stylets have the same form as in *Dercothoe*, and the form of the head, the projecting eyes, and general habit, are nearly as in that genus. The approximation is so close, that the genera are evidently of one and the same group; we have no evidence in the antennæ, caudal stylets, or legs, that the species in every case are gressorial. The antennæ are slender, with long flagella. The epimerales are broader than in some Gammari. The caudal stylets are rather long." He also says that "a female *Pyctilus*, bearing eggs, has been observed by the author, which has the same form of hands as is characteristic of the group *Erichthonius*," and that "in this genus as well as the preceding, the first joint of the legs of the fifth and sixth pairs is very broad, while that of the seventh is narrow."

Spence Bate makes *Erichthonius* and *Pyctilus*, and inclines to make *Dercothoe*, synonymous with *Cerapus*, Say. Boeck puts them all three under that genus, which S. I. Smith has shown to be distinct from them all. S. I. Smith unites *Dercothoe* and *Pyctilus* as synonyms of *Erichthonius*, but still without noticing the breadth of the side-plates in (some at least of) Dana's species, which, as Dana himself observes, makes the identification with *Erichthonius* doubtful. In the work of Bate and Westwood, vol. i. p. 453, Dana is supposed to have "founded his genus *Pyctilus* upon a misconception of the figure of *Erichthonius difformis*," but Dana clearly alludes not to the mistake in the figure, but to the express words of the generic account, "l'état rudimentaire des pièces épimériennes des premiers anneaux du thorax," in the Hist. des Crust., vol. iii. p. 59.

Dana's species are named *Dercothoe emissitius*, previously *Gammarus emissitius*; *Dercothoe speculans*, previously "Amphithoe speculans (by mistake for speculans)"; *Dercothoe? hirsuticornis*, previously *Gammarus hirsuticornis*; *Pyctilus macrodactylus*, previously *Erichthonius? macrodactylus*; *Pyctilus pugnax*, previously *Erichthonius pugnax*; *Pyctilus brasiliensis*.

In Family 1. Hyperidæ, Subfam. 2. Hyperinæ, contains *Lestrigonus ferus*; *Lestrigonus fuscus*; *Lestrigonus rubescens*; *Lestrigonus Fabreii?* Edwards; all which may perhaps belong to the genus *Hyperia*; the genus *Metacetus*, Kröyer, ought, Dana thinks, to be merged in *Hyperia*, to which he assigns the species *Hyperia agilis*; *Hyperia trigona*. The genus *Tauria* is thus defined:—

"Antennæ quatuor breves, basi approximatæ, 1mæ crassiusculæ. Pedes nulli subcheliformes nec subprehensiles, 7mi vix abbreviati," with the type-species, *Tauria macrocephala*.

The new genus *Cyllopus* is thus defined:—

"Tauriæ affinis. Pedes 7mi valde abbreviati. Antennæ 1mæ et 2dæ ad basin inter se remota;" with the type-species *Cyllopus magellanicus*.

Daira? *debilis*, *Daira?* *depressa*, *Daira inæquipes*, are at page 1596 transferred to the generic name *Dairilia* (not *Dairinia*, as in the B. M. C. and elsewhere), *Daira* being preoccupied; but if Bovallius, 1885, is right in assigning Dana's species, not to *Daira*, Milne-Edwards, but to *Thamyris*, Spence Bate, among the Lycæidæ, the name *Dairilia*, Dana, will displace *Thamyris*, by right of priority. The definition given by Dana is as follows:—

"Antennæ 1mæ non conspiruæ, 2dæ exsertæ. Pedes 1mi 2dique plus minusve prehensiles: tarsi pedum reliquorum breves. Rami stylorum caudalium longi." It is placed in the second division of the subfamily, which have "Antennæ totæ breves. Capit oculique pergrandes."

Subfam. 3. Synopinæ, contains the single genus *Synopia*, with the further definition, "Frons subæratus. Antennæ 4 longæ, apertæ, 1mæ appendiculatæ. Pedes 2 antici subcheliformes; prorimi duo vergiformes, quatuor sequentes subprehensiles, digito 2-articulato: reliqui medios, unguiculati." Claus observes that this genus belongs to the *Gammarina*,

and Dana himself notices the resemblances. The species assigned are *Synopia ultramarina*, (with the suggestion that one of the forms figured may be a distinct species to be called *Synopia gracilis*), and *Synopia angustifrons*; in the former he speaks of the eye as single, occupying "the whole breadth of the triangular head," but in the latter species he speaks of "the eyes" in the plural. Bovallius, in 1886, makes the "Amphipoda Synopidea" a separate tribe, in which "the first family, Synopidae, is the most closely related to the Gammarids."

In Family II. Phronimidae, Subfam. 1, Phronimiæ, contains only *Phronima atlantica*, Guérin, not figured, the brief notes indicating that *Phronima sedentaria*, Forskål, is in question.

Subfam. 2. Phrosininae, contains *Anchylomera purpurea*; *Anchylomera thyropoda*, "length, one line; specimen probably not mature"; *Themisto antarctica*.

Subfam. 3. Phoreciæ, contains only *Phorcus hyalocephalus*, on which Dana remarks, "This species has most of the characters mentioned for M.-Edwards' *Phorcus Raynaulii*: but, he observes, that the antennæ are 'un peu renflées vers le milieu'; while, in this species, the basal portion is stout ellipsoidal. Moreover, he states, that the second thoracic ring is very much developed, and the fifth pair of legs is shorter than the sixth."

In Family III. Typhidae, Subfam. 1. Typhinae, begins with the genus *Dithyrus*, with the following addition to the definition:—

"Abdomen ad ventrem optimè claudens. Caput transversum, pigmentis non grandibus. Antennæ 2dæ sub capite celatae, breves, non replicatae. Pedes 6 postici coxis latissimè elypeati, parte pedum reliquæ obsoletæ. Pedes 4 antici subcheliformes. Abdomen 5-articulatum, segmento ultimo triangulato." In the appended remarks Dana says, "the abdomen, unlike that of *Thyropus*, is shorter than the thorax." This genus is identified by Claus with *Typhis*, Risso, and as *Typhis* is preoccupied, *Dithyrus* (not *Eutyphis*, Claus), takes its place. The species for which Dana instituted the genus is called *Dithyrus faba*.

The genus *Thyropus* receives the additional definition:—

"Abdomen ad ventrem claudens. Caput transversum. Pigmenta oculorum non grandia, quatuor. Antennæ 2dæ longæ, sub thoracis latere celatae, 4-5-plicatae, articulo 1mo multo breviore quam 2dus. Pedes 6 postici coxis late elypeati, articulis reliquis paulo abbreviati."

Remarks are appended to distinguish the genus from *Typhis*, together with the statement that, "this genus includes the *Typhis ferox* of Edwards, Crust., iii. 96." For *ferox*, *ferus* should be read. The type-species is *Thyropus diaphanus*. Claus, Platysceliden, 1879, considers that *Typhis ferus* probably belongs to his genus *Hemityphis*; on the other three genera he says there can be no doubt, "dass *Dithyrus* und *Typhis* bei Dana lediglich als weibliche Formen zu *Thyropus* als dem männlichen Typus zu beziehen sind," loc. cit., p. 7, and he gives the heading, "*Eutyphis*=*Typhis*, Risso, (*Thyropus*, Dana, Sp. Bate♂ = *Dithyrus* Dana ♀, *Platyscelus* Sp. Bate♀)," but he further says, "Die Untersuchung einer grossen Anzahl kleinerer und grösserer Typhiden aus sehr verschiedenen Meeren hat mich davon überzeugt, dass Charakterisierung der Gattungen auch nach Beseitigung der durch die sexuellen Verschiedenheiten veranlassten Irrtümer viel specieller gehalten werden muss, und dass in der *Edward'schen* Gattung *Typhis*, dem *Dana'schen* *Thyropus*, eine Reihe von Gattungen enthalten sind." p. 9. At p. 17 he suggests that *Thyropus diaphanus*, Dana, may be the same as his own new species, *Tanyscelus sphaeroma*.

Subfam. 2. Pronoinæ, contains *Pronoe brunnea*, which may, in Claus's opinion, be the same as his *Eupronoë armata*, and *Lycæa ochracea*, as type-species of *Lycæa*, the following addition being made to the definition of that genus:—

"Pigmenta oculorum grandia. Antennæ 2dæ sub capite celatae et replicatae et flagello longiusculo confectæ. Pedes 4 antici subcheliformes, reliqui mediocres; 2 ultimi breviores; coxae posticæ angustæ. Abdomen in ventrem se non flectens."

Claus, 1879, agrees with Spence Bate that this definition scarcely suffices to distinguish *Lycæa* from *Pronoë*, but for independent reasons he considers Dana's genus fully tenable.

In his notes Dana recognizes *Leptomera*, Latr., as a synonym of *Proto*, Leach. He remarks, p. 830, "it is possible that the *Podocerus Leachii* (Kröyer), should form a distinct genus, as the animal lived in a tube like a Cerapus." At p. 832, he says, "Glauconome of Kröyer has the hands and antennæ and apparently the other characters of Unciola. Say describes the hands of the second pair in Unciola as *aluctyle*; but they still are probably like those of Glauconome." In a note to *Anonyx*, Kröyer, he explains that he omits the genus *Ephippiphora*, White, from his synopsis, on account of its insufficient description. As to "*Leptocheirus pilosus*," Zaddach, he asks, p. 910, "May the form be female only?" In a note on "*Iphimedia*, Rathke, D.," he says, "Dexamine of Leach, may perhaps be included here," and "the genus *Hyale* of H. Rathke," he says, "contains no characters in its description by this author, which do not apply equally well to species of Iphimedia." "*Amphithoe*, Leach, D.," he says, "includes *Pherusa* of Leach." In a note on "*Gammarus*, Fabr., D.," he mentions *Amathia*, Rathke, and *Eusirus*, Kröyer, but does not give them a place in the synopsis. The note on *Lepidactylis*, Say, remarks, "here falls *Bellia* of C. Spence Bate." In the addenda, p. 1595, he observes, "Page 908:—*Callisoma*, Costa (loc. cit.), appears to be identical with *Lysianassa*"; "Page 910.—*Niphargus* is the name of a new genus near *Gammarus*, proposed by Schiödte"; "Page 913. The genus *Lalaria* (*L. longitarsis*) of Nicolet (loc. cit., Pl. 2, f. 8), is between the Gammariidae and Corophidae, and appears to be identical with *Aora* of Kröyer, which was also from Valparaiso."

1852. LILJEBORG, WILHELM.

Hafs-Crustaceer vid Kullaberg. Crustacea marina ad Kullaberg in Scania mense Septembris 1851 observata. Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar. Årg. 9. 1852. No. 1 & 2. (Nionde Årgången. 1852. Stockholm, 1853). pp. 1–13.

Among the Crustacea of this district already noticed by others, Liljeborg mentions "*Caprella linearis*, Latr., Örsted, De regionibus marinis, p. 73." He observes that in *Ampelisca macrocephala* as in "*Ampelisca Gaimardi* Kröyer (Voy. en Scandinavie etc. t. 23, f. 1. a, à)" there are four eyes instead of the two to which the Amphipoda had hitherto been limited. In these four he found no trace of facets, or cones, and concludes therefore that they are simple, as given in the original definition of the genus with a query. In the species which he describes as *Ampelisca Eschrichtii?* Kröy., he found only two eyes, but with creatures that burrow in the mud at considerable depths, he thought the eyes too unimportant to justify a generic distinction depending on their number. However, in 1855, as *Haploops tubicola*, this species became the type of his new genus *Haploops*. Goës subsequently discovered that *Haploops* agreed with *Ampelisca* in having four eyes. In specimens preserved in spirits the lower pair have a tendency to disappear. Liljeborg was the less inclined to lay stress upon the eyes from noticing that in certain Amphipoda which live at great depths, they are entirely wanting, "as, e.g., in the genus *Stegocephalus*, Kröyer, and probably *Pardalisca* and *Ediceros* Kr." As the last of these examples shows, it must not be too easily taken for granted that eyes are wanting, because they have not been detected, in species of Amphipoda, though Liljeborg's conclusion is justified that the possession of two eyes, given by Milne-Edwards as a general character for the order, cannot be attributed to it without reserve.

In the Latin description of "*Ampelisca Eschrichtii?* Kröy.," corresponding as above-mentioned to *Haploops tubicola*, is included a description of the male, which refers to a separate species, called in 1855 *Haploops carinata*. He here remarks that Örsted, "(Naturhist. Tidsskr.

2:dra ser. 1 band., p. 403)," includes among the Crustacea from Dröbak, a species under the name of *Ampelisca rotundata* Kröyer, a name which lapses for want of attendant description.

Ampelisca macrocephala, n. sp., is described, this being a species which in 1851 Liljeborg had supposed to be "*Ampelisca Eschrichti* Kröyer." *Amphithoë podoceroides*, Rathke, he found much smaller here than on the coasts of Norway.

Amphithoë compressa, n. s., here described, and thought to be very like *Amphithoë tenuicornis*, Rathke, was called *Atylus compressus* by Spence Bate, and later identified by Boeck with *Atylus swammerdami*, M.-Edw.

Amphithoë pygmaea, n. s., is identified by Boeck with *Photis reinhardi*, Kröyer, 1842. Liljeborg thought it something like *Iphimedia obesa*, Rathke, which, he remarks, had anticipated Kröyer's *Microcheles armata*, 1846. In the list of v. Dneben's Crustacea, 1851, he had given "44. *Iphimedia obesa*, H. Rathke. 45. *Microcheles armata* Kr." He therefore here observes that the latter had proved to be a young specimen of *Oedicerus saginatus*, Kr.

Under *Gammarus locusta* (Lin.), he gives "G. Duebeni Liljeb." as a synonym, and this description, "Oculi reniformes nigri, antennæ superiores longiores, flagello appendiculari 5-7 articulato; rami pedum spuriorum ultinorum insigniter inaequales, interior exteriore saltem tertia parte minor.—Vulgaris."

He describes *Gammarus maculatus*, n. sp., the name being preoccupied by Johnston, and the species being, as Liljeborg afterwards recognised, Montagu's, now known as *Melita obtusata*. *Gammarus longipes*, n. s., which he thinks very like his own *Gammarus assimilis*, 1851, was called *Autonoë longipes*, by Bruzelius.

In "*Hyperia Latreilli* M.-Edw.", he notes that the young differ from the adult in respect to the antennæ. An account is appended by S. Lovén of the tubes constructed by *Ampelisca eschrichti*, Kröyer. Several specimens taken on one occasion in their tubes, proved to be all females. The close proximity of the tubes taken on another occasion suggested that the species might be gregarious.

1852. SUTHERLAND, PETER C. WHITE, ADAM.

Journal of a voyage in Baffin's Bay and Barrow Straits in the years 1850–1851, performed by H.M. Ships "Lady Franklin" and "Sophia," under the command of Mr. William Penny, in search of the missing crews of H.M. Ships Erebus and Terror. London, 1852.

"In the neighbourhood of Berry Island dredging was frequently attended to," and "the display," he says, "of animal and vegetable life before us, when the dredge was emptied, was really wonderful. Whole heaps of Mollusea, Crustaceans, Annelidans, and Echinodermata could be seen tumbling out from among masses of sea-weed." Sutherland says that the sea-bottom there is "the habitat of myriads of creatures belonging to the genus *Caprella*, *Cyclops*, *Gammarus*, etc." (p. 140). On p. 142 he gives a striking account of the voracity of the Gammarinæ, naming especially *Gammarus arcticus*. Whether it were a dead seal or a live sucking-fish (*Lepidogaster*), short work was made of their prey.

In the Appendix, vol. ii. pp. ccvi, ccvii, White describes, according to Boeck, "*Gammarus nugax*, Sab., *Acanthonotus tricuspidis*, Kr., *Amphithoë Edwardsii*, Sab., and *Stegocephalus inflatus*, Kr.; a species of *Anonyx*, and lastly *Caprella cercopoides*, n. s., which falls to *Caprella septentrionalis*, Kr." Mayer in 1882 thinks that, judging by the figure, Boeck's view of *Caprella cercopoides* is probably correct.

1853. BURGERSDIJK, L. A. J.

Land- en Zoetwater schaaldieren. (In Bouwstoffen v. e. Fauna v. Nederl. I. bl. 164.) 1853.

This work is included in Maitland's list of authorities, 1875. He refers to it only for one of the localities of *Gammarus pulex*.

1853. COSTA, ACHILLE.

Fauna del Regno di Napoli.

The genus *Guerinia*, Hope, is described, with the type species *Guerinia nicaensis*, which is figured.

Phronima, Latreille, is described, and the type species *Phr. sedentaria*, Forskål, to which *Pisitoe levifrons*, Rafinesque, is united as a synonym, while *Phronima custos*, Risso, though not included in the synonymy, is declared in the "observations" to be also identical with Forskål's species. The genus *Phrosine*, Risso, is described, and of Risso's two species, *Phrosine semilunata* is fully described and figured, while *Phrosine macropthalmia*, which Costa had not himself seen, is briefly alluded to. Costa would have preferred to name the two respectively *cornuta* and *inermis*. He considers *Pisitoe bispinosa*, Rafinesque, though inaccurately described, probably the same species as *Phrosine semilunata*.

1853. COSTA, ACHILLE.

Descrizione di tre nuovi crostacei del Mediterraneo discoperti dal Rev. G. F. Hope. Estratta dal fascicolo 83° della Fauna del Regno di Napoli. 10 pages. 3 plates.

This work is obviously due to the pen of Achille Costa, although the new genus, and two out of the three species, are attributed to Hope.

The new genus *Guerinia* is thus described:—"Generis characteres essentiales. Pedes primi paris validissimi, prehensiles, manu magna valide uncinata; secundi graciles, haud prehensiles, ungue destituti. Antennæ superiores bisetæ; seta primaria articulo primo maximo. Oculi magni, reticulati, dorso fere contigui.

"Characteres naturales. Corpus crassum, parum compressum, dorso rotundatum. Caput autice horizontaliter rotundato-productum. Oculi maximi, dorso sub-contigui, totam fere capitidis superficiem occupantes, distincte reticulati. Antennæ superiores bisetæ; seta primaria articulo primo valde elongato, valido: inferiores infra et inter superiores insertæ, basi contiguae. Pedes primi paris manu magna crassa, ungue valde arcuato armata: secundi longi, graciles, articulo ultimo ciliis fimbriato, ungue nullo; reliqui simplices. Abdomen lamina horizontali terminatum."

In the observations that follow, this Crustacean is regarded as a sort of link between the Amphipoda and the parasitic Isopods, such as *Anilocra*. By Spence Bate, in the Brit. Mus. Catalogue, it is placed between *Lafystius* and *Lepidactylis*. The type species is named *Guerinia nicaensis*, and is beyond doubt generically, perhaps also specifically, identical with the later "*Trischizostoma Raschii*," Esmark and Bocck, 1860. Bocck, who had obviously not met with Costa's paper, fully describes the mouth-organs, and points out that the relations of the genus are with the Hyperidæ, Orchestidæ and Lysianassidæ. He places it by itself

in the second tribe of the Amphipoda, which he calls Prostomatæ, subsequently classing them as the first family of his second division, Gammarina. He states that the large finger of the first gnathopod is hinged, not as usually to the anterior, but to the lower hinder, angle of the hand, and directed forwards. That this is not shown in Costa's figure may have arisen from an accidental twisting of the hand in the specimen figured, or perhaps the artist had the unwonted feature before him, but could not believe his own eyes, and took the liberty of correcting nature, or we may argue from the researches mentioned below that Costa's specimen had not reached the age at which the peculiarity is developed. Boeck further differs from Hope by describing and figuring the third joint on the second peræopod as greatly expanded, by representing the first joint of the fifth peræopod in the complete figure as drawn out on the lower hinder angle instead of rounded off, and by describing the telson as split at the point, while in Hope's figure it is rounded and entire. But the figure of the telson in Boeck shows no slit, and the downward produced angle of the first joint of the peræopod is in the text and in a separate figure attributed to the fifth pair of feet, that is, the third peræopod, so that I am inclined to unite the two species in spite of differences which seem to me more likely to be due to inadvertence in the observers than to diversity in nature. This conclusion, independently arrived at, is more or less confirmed by the recent investigations of Bovallius, who, in 1886, describes and figures with great clearness and detail "the adult female" and "the young male" of Boeck's species, placing it in his new tribe of Amphipoda Synopidea. He is evidently, like Boeck, unaware of Costa's *Guerinia*, but he throws light upon it by showing that the position of the finger of the first gnathopods is normal in young specimens, and that in these the third joint of the second peræopod is not greatly expanded. On the other hand, he represents the telson as deeply excavated in the young, but in the adult female as having a smoothly rounded termination. "The description of Boeck," he says, "is not quite accurate; it seems that he has taken some characteristics from the adult animal and others from very young ones."

The second species described and figured is "*Callisoma Barthelemyi*, Hope." The differences mentioned, having to do, it seems, exclusively with comparative measurements, are probably not of specific value. The name is not included in the Brit. Mus. Catal., and the species is entered by J. V. Carus, 1885, as "non descripta." The description is as follows:—"C. antennis superioribus capite thoracisque articulo primo simili vix longioribus, seta primaria pedunculo parum breviore, inferioribus thoracis articuli septimi ♂, quinti ♀ marginem anticum attingentibus; epimeris quarti paris postice tertium anticum marginis inferi sequentium non ultra productis; pedibus spuriis abdominalibus fere æque terminatis. Long. lin. 3; lat. liu. 1. "Osservazioni. Molto affine al *Call. Hopei*, A. Cost., dal quale nondimeno differisce per la falsa unghietta de' piedi anteriori assai più lunga, per le antenne in ambedue i sessi rispettivamente più corte, per gli epimeri del quarto anello un poco men prolungati posteriormente."

The third Crustacean of this paper is "*Jæra Hopeana*," Costa, an Isopod.

1853. COSTA, ACHILLE.

Relazione sulla memoria del Dottor Achille Costa, di Ricerche su' Crostaeei Amfipodi del Regno di Napoli. Rendiconto della Società reale Borbonica. Academia delle scienze. Nuova Serie. Anno 1853. Bimestre di Settembre ed Ottobre. Napoli, 1853. pp. 166–178.

The report on Costa's paper is dated Napoli, 17 Settembre 1853, and signed by Giovanni Gussone, Giovanni Guarini, Benedetto Valpes. The characters of the new genera and species are

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

Xxx 35

given in Latin. See Note on Costa, 1857. The names of the genera are *Araneops*, *Ichnopus*, *Egidia*, *Nototropis*, *Probolium*, *Elasmopus*, *Ceradocus*, *Microdeutopus*. The new species are *Orchestia mediterranea*, *Orchestia constricta*, *Araneops diadema*, *Araneops brevicornis*, *Lysianassa spinicornis*, *Lysianassa loricata*, *Lysianassa humiliis*, *Ichnopus taurus*, *Egidia pulchella*, *Nototropis* (sic) *spinulicaula*, *Amphithonotus spiniventris*, *Probolium polypriion*, *Amphithoe babirussa*, *Amphithoe gazella*, *Amphithoe tenella*, *Amphithoe aquilina*, *Amphithoe crassicornis*, *Amphithoe penicillata*, *Amphithoe elongata*, *Amphithoe microura*, *Amphithoe semicarinata*, *Elasmopus rapax*, *Gammarus plunicornis*, *Gammarus obtusunguis*, *Gammarus unguiserratus*, *Gammarus scissimanus*, *Gammarus punctimanus*, *Gammarus bispinosus*, *Gammarus orchesiipes*, *Leucothoe denticulata*, *Eriothonius bidens*, *Microdeutopus gryllotalpa*, *Corophium acherusicum*, *Vibilia speciosa*, *Hyperia pupa*.

1853. GOSSE, PHILIP HENRY, born 1810 (Hagen).

A Naturalist's rambles on the Devonshire coast. London, M.DCCC.LIII.

At page 367, after describing the chambers in the peduncle of *Clrysaora cyclonota*, Gosse says, "a little shrimp-like creature, about half an inch in length, with large lustrous green eyes (*Hyperia medusarum*), makes these chambers his residence." "There were three or four specimens on this *Clrysaora*, and I have found it parasitic on other large Medusæ. But there were also on the one I am describing a vast number of minute white specks, which on examination proved to be little *Crustacea*, and, as I suspect, the larvæ of this species. They are not larger than a grain of sand, shaped somewhat like a toad, with the abdomen distinctly separated, narrow, and bent abruptly under, in the manner of the *Brachyura*. (See Plate xxii. fig. 15.)"

At page 379 (see also page 82), he discusses "The Mantis shrimp." He says "one can never take a living specimen of that beautiful zoophyte *Plumularia cristata*, without finding its numerous pinnated branches inhabited by curious Crustacea of the genus *Caprella*." He compares them with the Spider Monkeys of South America, with the tropical genus *Mantis* among insects, and for mode of progression, to the caterpillars of geometric moths. He has "seen the large red species swim, throwing its body into a double curve like the letter S, with the head bent down, and the hind limbs turned back, the body being in an upright position." He thinks that the capture of prey is helped by the sudden clutchings of the lower antennæ. "They consist of four or five stout joints, each of which is armed on its inferior edge with two rows of long stiff curved spines, set as regularly as the teeth of a comb, the rows divercating at a rather wide angle." "The first and second pair of legs," he says, "(but especially the latter), have the last joint but one developed to a great size, while the terminal joint is so formed as to shut down upon it just as the blade of a clasp-knife does upon the handle. Then to add to the efficiency of this instrument of prehension, the great joint which represents the haft is armed with a double row of spines set at an angle so as to make a groove, into which the blade falls, and this latter is cut along each side of its edge into fine teeth like those of a file." He finds "several species even on the same small fragment of weed, if it be tolerably well peopled with *Plumularia* or *Pedicellina*, some much larger than others, and beautifully mottled with transparent ruby colour on a clear horn, and distinguished by variations in the relative size, in the shape, and in the armature of these formidable weapons; and there is a species larger still, of a dull purplish-red hue. But all have pretty much the same manners, except that the smaller species are more agile." It is obvious that the differences mentioned may only refer to age and sex, instead of being specific, as Gosse supposed, but undoubtedly on the Devonshire coast, *Caprella acanthifera*, *Caprella fretensis* and *Caprella acutifrons* may all be found in very close proximity.

At page 382 he introduces "The Caddis Shrimp," which has its tubes on *Chondrus crispus*, and which he proposes to name "*Cerapus Whitei*." Bate and Westwood with some hesitation call it *Siphonæcetes whitei*, Boeck doubtfully places it among the synonyms of *Cerapus abditus*, Templeton. At present the species remains indeterminate.

1853. LUCAS, HIPPOLYTE.

Essai sur les animaux articulés qui habitent l'île de Crête. Revue et Magasin de Zoologie pure et appliquée. 1853. No. 10. Paris. (Also, according to Hagen, in a separate form, Paris, 1853.)

Of Amphipoda he enumerates, pp. 465–466, "*Talytrus platycheles*," Guérin; *Gammarus fluvialis*, Roesel, which he says, "Habite les sources d'eau douce de Stito, dans les environs de la Canée"; and *Gammarus marinus*, Leach, which "se plaît dans les sources saumâtres de l'Arnegro de Retino."

1853. QUATREFAGES, A. DE.

On the phosphorescence of some Marine Invertebrata. Annals and Magazine of Natural History. Vol. XII. Second Series. London, 1853. See also *Annales des Sciences Naturelles*, vol. liv. 3rd Series, and *Silliman's American Journal of Science* for March and July, 1853.

In a list, "cited almost entire from M. van Beneden, in which are enumerated the various species of invertebrate animals whose phosphorescence has been established," (p. 18), the only Amphipods mentioned are *Erythrocephalus macrophthalmus* [*melanophthalmus*] and *Gammarus pulex*. At page 183 the remark is made, that "the *Talitri*, so numerous on our sandy shores," "become luminous by contact with the phosphorescent water," not being phosphorescent in themselves.

1853. WESTWOOD, J. O.

The Annals and Magazine of Natural History. Vol. XII. Second Series. London, 1853. p. 44.

It is mentioned that in April 1853, Mr. Westwood communicated to the Linnean Society the discovery in a well near Maidenhead of *Niphargus stygius*, Schiødte, an animal hitherto only found in the caverns of Adelsberg. This has been since separated from Schiødte's species under the name *Niphargus aquilex*.

1854. NICOLET, H.

Atlas de la historia física y política de Chile por Claudio Gay. Fauna. Paris, MDCCCLIV.

Plates of "Crustaceos," numbered 1, 2, 3, 4, have on 1, 2, and 4 the inscription "H. Nicolet ad nat. del," and on Number 3 "Nicolet del." The figures of Amphipods on Plate 2 are named at the foot of the plate as follows:—"4 *Orchestoidea tuberculata* Nic. 5 *Amphioe chilensis*

Nic. 6 A——— *Gayi*, Nic. 7 *Nicea Lucasii* Nic. 8 *Lalaria longitarsis* Nic." Similarly those on plate 4 are named "4 *Caprella longicollis* Nic. 5 C——— *brevicornis* Nic." "7 *Cyamus gracilis* Anct." Anct. is perhaps a misprint for auct. an abbreviation of *auctorum*, but in the text, vol. 3, p. 256, 1849, *Cyamus gracilis* is properly referred to Roussel de Vauzème.

1854. SCHAUROTH, VON.

Ein Beitrag zur Paläontologie des deutschen Zechsteingebirges. Von Herrn v. SCHAUROTH in Coburg. Zeitschrift der Deutschen geologischen Gesellschaft. VI. Band. 1854. Berlin, 1854.

At page 560, the 15th article of this paper is headed "*Palaeocrangon problematica* SCHLOTH. Taf. XXII. Fig. 2." Schlotheim's specimen of his *Trilobites problematicus* is, Schauroth says on the authority of Bronn's Nomenclator, no more to be found. Schlotheim's collection went into the Berlin Museum, but there Beyrich informed him the specimen no longer existed, and had been in vain searched for by Quenstedt. Schauroth considers that a little fossil from the Zechsteindolomite of Pössneck is the same species as that which Schlotheim described and figured. It has the exterior "überall chagrinirt und überdies mit verschiedenen Höckern geziert." "Das Kopfschild ist von der Seite geschen fast dreieckig und zeigt an der vorderen Seite knotige Erhöhungen, welche als Insertionstellen der Fühler, Fresswerkzeuge und selbst der Augen gedeutet werden dürften." "Das Brustschild ist das grösste von allen Segmenten." The back is carinate, and the general appearance agrees very nearly with Kirkby's *Prosoponiscus problematicus*, but Schauroth seems to have regarded the pleon as the head. He thinks the nearest palæozoic forms are to be found in *Gitoerangon* and *Adelophthalmus*. Identifying it, rashly as I think, with Schlotheim's species, he says, "Ich schlage vor dieses Geschlecht *Palaeocrangon* (aus παλαιός und ἡ κραγγών, ähnlich dem Richter'schen Gitoerangon, gebildet) zu nennen, den Körper selbst also *Palaeocrangon problematica* SCHLOTH. zu bezeichnen."

1854. STIMPSON, WILLIAM.

Synopsis of the Marine Invertebrata of grand Manan; or the region about the mouth of the Bay of Fundy, New Brunswick. Smithsonian Contributions to knowledge. (Accepted for publication, January, 1853). Washington, 1854.

The Island of Grand Manan "is more properly an archipelago than an island." "It is surrounded on all sides by deep-water (a hundred fathoms or more)." Stimpson adopts Dana's division of the Tetradeapoda into Isopoda, Anisopoda and Amphipoda. In the second division he describes *Tanaïs filum*, n. s. Among the Amphipoda he gives *Caprella lobata*, Kröyer, which is *Caprella linearis*, Linn.; *Caprella sanguinea*, Gould, and *Caprella longimanus*, n. s., both of which in Mayer's opinion are too briefly described for recognition, though the latter may be *Caprella acanthifera*, Leach. *Caprella robusta*, n. s., which Spence Bate renamed *Cuprella stimpsoni*, because the name *Caprella robusta* was preoccupied by Dana, is restored to its original name by Mayer, on the ground that Dana's *Caprella robusta* falls to *Cuprella acutifrons*, Latr. *Caprella robusta*, however, must be considered to have lapsed as a synonym. *Aegina spinosissima*, n. s., is by A. Boeck with a ?, and by Mayer without one, made a synonym of Boeck's later name *Aegina echinata*. This identification is disputed by G. O. Sars, 1885. "*Caprella spinosissima*, Norman," from the

"Porcupine" Expedition, was given in Sir Wyville Thomson's Depths of the Sea, by mistake (according to Norman in Mayer, Caprelliden, p. 35, note 1) for *Caprella spinosissima*, Stimpson. Norman, however, in 1886, gives "Caprella spinosissima, Norman = C. horrida, Sars." A specimen supposed to be the female of the species in question was sent by Norman to Mayer, and proved to be in fact an *Aegina*, which in Mayer's opinion may represent a new species, to which he would in that case assign the name *Aegina spinosissima* Norman, but that is surely pre-occupied by Stimpson's species. That the specimen figured in the Depths of the Sea is a *Caprella*, I have satisfied myself by dissection of the mouth organs, and in fact it no doubt falls to the name *Caprella horrida*, Sars (see Note on G. O. Sars, 1885). *Unciola irrorata*, Say, is mentioned. *Podocerus nitidus*, n. s., is described. The new genus *Leptotheö*, which Spence Bate identifies with *Mæra* of Leach, is thus defined:—

"Body linear, segments well separated, epimera very small; superior antennæ longest, with a long accessory flagellum; inferior ones subpediform; legs of the first two pairs with subcheliform hands, those of the second pair being largest, with multiarticulate fingers. Caudal stylets of the last pair very long, with equal lanceolate rami on short peduncles. This genus differs from *Podocerus*, Leach, in possessing accessory flagella to the superior antennæ; and from *Cratophium*, Dana, in its long nonuncinate terminal stylets, and in having the superior antennæ longest." The type species is "*Leptotheö Danae*," now called *Mæra danae*. Stimpson's *Cerapus rubricornis* which "inhabits flexible tubes, of sizes corresponding to that of the individuals, composed of fine mud and some animal cement by which it is agglutinated," is identified by S. I. Smith with *Ericthonius difformis*, Milne-Edwards. His *Cerapus fucicola* is identified by Sp. Bate with *Podocerus cylindricus*, Say, while Boeck doubtfully places both these designations under *Podocerus anguipes*, Krøyer, *Podocerus cylindricus*, however, being the eldest of the names. S. I. Smith gives *Podocerus fucicola* as an independent species, naming *Podocerus cylindricus*, Say, not Bate, *Corophium cylindricum*. Stimpson's *Cerapus fasciatus* is allowed by Sp. Bate to remain in that genus with a ? It cannot stay in that genus as defined by S. I. Smith, since the figure of the pleon shows that there are at any rate five rami on each side to the nropods, whereas in *Cerapus* there are only four. Stimpson doubtfully identifies *Orchestia gryllus*, Gonld, with *Talitrus gryllus*, Bosc. His *Allorchestes littoralis* is recognised by S. I. Smith as *Hyale littoralis*. The tail is said to terminate in an arched lamella, which may be a way of expressing that it is cleft.

Lysianassa spinifera, n. sp., according to Spence Bate, Brit. Mus. Catal., p. 120 (omitted from index), "seems to be closely related to" his genus *Phædra*. It is thus described:—"Body smooth and shining, slightly compressed, but rounded above, broadest anteriorly, tumid at the head, and much compressed at the abdomen, which constitutes nearly one-half the length of the body. Epimera not very large. Head rounded, with a prominent down-curving rostrum, and rather large red eyes. Superior antennæ two-thirds as long as the inferior ones, thick at their bases, but tapering suddenly after the juncture of the long accessory flagellum, which is nearly one-half the length of the principal one. Inferior antennæ with very thick basal articles, and equalling in length two-thirds that of the body, their flagella constituting more than one-half their length. Legs hairy, all terminating in short hooked fingers; those of the first two pairs slender, longer than the rest, with the antepenultimate article in each a little expanded, but scarce sufficiently to form a hand. Posterior legs much shorter than usual, and provided along their edges with short spine-like hairs. First three segments of the abdomen serrated above on their posterior edges; last three compressed above into sharp spine-like projections, of which the middle one is the longest. Caudal stylets of the first pair very long and slender, projecting beyond the sharp extremities of the second pair, which are short, while those of the third pair are

long, with long lanceolate rami projecting beyond the others. The tail terminates in two long spines. Colour wine-yellow; inferior antennæ annulate with reddish. Length, 0·32 inch. Dredged in forty fathoms, on a soft muddy bottom off Long Island, G. M." It is scarcely necessary to remark that the armature of this species must distinguish it in a striking manner from the Lysianassinae in general. Of his *Anonyx nobilis*, Stimpson says that it most resembles *Anonyx appendiculatus*, Kröyer, but the distinctions he mentions do not suffice to separate the two species, and *Anonyx appendiculatus* itself is not distinct from *Anonyx nugax*, Phipps. *Anonyx politus*, n. sp., according to Spence Bate, has nothing in the description to distinguish it from *Anonyx holboelli*. *Anonyx holboelli* of Bate, according to Boeck, = *Anonyx gulosus*, Kröyer, from which it may be inferred that *Anonyx politus* is a synonym of *Anonyx gulosus*, which is itself probably the same as "*Oniscus Cicada*," Fabricius. The new species *Anonyx pallidus* and *Anonyx exiguis* are both endorsed by Spence Bate, as also *Stenothon clypeata* and *Leucothoë grandimanus*, although of the latter he observes, "this species closely resembles *Leucothoë articulosa*. The only differences seem to be the small coxae, the length of the dactylos of the first pair of gnathopoda, and the colour of the American species." It may be noted that the dactylos of the first pair of gnathopoda in Stimpson's drawing agrees with that of *Leucothoë (articulosa) spinicarpa*, so that the species must be considered doubtful.

Oniscus serratus of Otho Fabricius is here named *Acanthonotus serratus*, a name which Boeck alters into *Acanthonotozoma serratum*. *Amphilithonotus cataphractus*, n. sp., is regarded by Boeck as a type for the genus which he calls *Tritropis*, a preoccupied name, altered by S. I. Smith to *Rhachotropis*. *Amphilithonotus*, Costa, had lapsed as a synonym of *Dexamine*.

Amphilithoë virescens is identified by Spence Bate with *Amphilithoë punctata*, Say. *Amphilithoë maculata*, Stimpson says, "differs from the last species in being more robust and of a much harder structure; also totally in coloration." As the Amphipoda are sometimes extremely soft just after shedding the skin, one is inclined to believe that Stimpson may have laid too much weight on the texture of the integument, in separating this species from the preceding one. *Iphimedia vulgaris*, which is said to differ from *Amphilithoë inermis*, Kröyer, by "its larger eyes and epimera, and much longer caudal stylets," is renamed by Sp. Bate *Atylus vulgaris*. *Amphilithoë inermis* is taken by Axel Boeck as type of his genus *Pontogeneia*.

The new genus *Monoculodes* is thus defined:—"Body tumid anteriorly; head rostrate, with the eyes so close together as to appear one. Superior antennæ without accessory flagellum; inferior ones subpediform. Legs of the first two pairs with large subcheliform hands, formed of the last two articles of each; the antepenult joints having their inferior apices produced into slender thumbs. Legs of the posterior five pairs unguiculate, those of the last pair being exceedingly long. Caudal stylets all biramous; the rami being equal. Maxillipeds large, elongated, with unguiform terminal articles, and internal lamellæ of about one-half their length. Mandibles palpigerous." Stimpson adds, "this genus resembles *Eusirus* in the structure of the hands, and *Œdicerus* in its long posterior feet." The type species is *Monoculodes demissus*. The next two species mentioned are *Gammarus sabinii*, Leach, and *Gammarus macrophthalmus*, n. sp., the latter of which is named by Spence Bate *Gammaracanthus macrophthalmus*. *Gammarus pulex*, which Stimpson names as equivalent to *Cancer pulex*, Lin., *Oniscus pulex*, Mull., O. Fabr., and *Gammarus locusta* of Montagu, Kröyer and Gould, is referred by Spence Bate, who had received specimens from Stimpson, to *Gammarus ornatus*, Milne-Edwards, and later on by Stimpson himself to *Gammarus locusta*, J. C. Fabr. *Gammarus purpuratus*, identified both by Bate and Boeck with *Gammarus dentatus*, Kröyer, is placed by Bate in his genus *Megamæra*, by Boeck in the genus *Melita*, Leach.

The new genus *Ptilocheirus* is thus defined:—"Body broad, as in the *Corophidae*; epimera large and strong, much higher than broad. Mandibles with greatly elongated palpi; maxillipeds with their internal lamellæ of half their own length. Superior antennæ appendiculate, inferior ones subpediform. Legs of the first pair subchelate, very thick and strong throughout their length, in the male; those of the second pair plumose, without hands, but minutely unguiculate; those of the third and fourth pairs small, slender, and tapering, with the last three articles forming a kind of hooked finger, but with no dilated hand; posterior three pairs strongly unguiculate; those of the last pair much the longest. Caudal stylets all biramous, those of the first two pairs with a strong spine projecting from the inferior apex of the peduncle, along with the rami."

"This genus resembles in most characters *Leptochirus*, Zaddach, and may perhaps prove the same; that name, however, is preoccupied in insects. It has relations with the *Pontoporiæ* in its plumose hairs, and somewhat in the structure of the legs of the third and fourth pairs; while it also approaches those genera of the *Gammarinæ* which recall the *Corophidae*." Since, however, Zaddach's genus was not, as Stimpson spells it, *Leptochirus*, but *Leptocheirus*, Boeck seems to have done rightly in giving it precedence, so that *Ptilocheirus pinguis*, which Spence Bate has named *Protomedea pinguis*, will now stand as *Leptocheirus pinguis*.

The new genus *Pseudophthalmus*, or as Stimpson spells it, *Pseudophthalmus*, is thus defined:—"Body greatly compressed, with large epimera. Head with an irregular deposition of blackish or reddish pigment anteriorly, in which are one or two orbicular clear spots on each side, without facets. Maxillipeds with five articles, of which the terminal one is oval; internal lamellæ with combs of spines at their apices. Mandibles palpigerous. Antennæ very slender, the superior ones with their basal articles much thickened, and without accessory flagella; inferior ones arising much behind the bases of the superior ones. Legs of the first and second pairs sometimes with small subcheliform hands, shorter than the antepenult segment, but often simply unguiculate; those of the third and fourth pairs elongated, tapering, with their second joints very small, the third expanded into a hand; posterior pairs short; last pair with very broad basal joints. Caudal stylets all biramous. Tail terminating in a thin laevella. Epimera and third and fourth pairs of legs with plumose setæ along their edges."

This genus had already been described by Kröyer under the name *Ampelisca*. The briefly described type species, *Pseudophthalmus pelagicus*, has become, therefore, *Ampelisca pelagica*. *Pseudophthalmus limicola*, according to Boeck, is obviously synonymous with *Ampelisca tenuicornis*, Lilljeborg. Spence Bate describes further from Grand Manan, "*Pseudophthalmus ingens*, Stimpson, MS.," which he had received from the author. Being an inch and a half in length, it is well named *Ampelisca ingens*. *Phoxus fusiformis* is identified by Spence Bate with *Phoxus plumosus*, Kröyer, which Boeck places in his genus *Harpinia*. "*Phoxus Kroyeri*" of Stimpson Spence Bate accepts, renaming his own later "*Phoxus Kröyeri*," *Phoxus simplex*. Boeck, on the other hand, gives up "*Phoxus Kröyeri*," Stimpson, as insufficiently described.

1854. WILLIAMS, THOMAS.

On the Mechanism of Aquatic Respiration and on the Structures of the Organs of Breathing in Invertebrate Animals. The Annals and Magazine of Natural History. Vol. XIII. Second Series. London, 1854.

On page 294 he discusses *Chitine*. On page 295 he says, "Every Crustacean is a water-breathing, every Insect an air-breathing animal. To this rule there can be found no real, many

apparent, exceptions." Of the heart, p. 296, he says, in the Pœcilopoda, Isopoda, Amphipoda and Læmodipoda, it is tubular in form, and occupies the mid-region of the dorsum, sends off arteries before, behind, and laterally, and receives the venous blood through lateral venous orifices." "*Caprella linearis*," is figured, pl. xvii. fig. 6., and portions of *Talitrus* on pl. xviii., to illustrate the circulatory system and the anatomy of the branchial organs. He remarks, p. 302, of the Amphipodan family, "the thoracic limbs are commonly said to be transformed into brauchiæ at their bases. The depending edges of the dorsal plates (the epimeral of the tergal arc) are however much more suitably organized than the proximal articulations of the legs. They are penetrated by a very dense system of cauals. The epidermis is reduced to an extremely thin and transparent lamina. The component hexagonal cells may be readily observed. The outer or epidermal lamina is united to the opposite parallel lamina by dots of parenchyma. The blood streams in the intermediate passages. These parts therefore correspond in ultimate structure in the most exact manner with leaves of the branchiae of the Crab."

1855. BARTELS.

Gammarus pulex im Menschenmagen von *Bartels*. Mit einem Zusatz von Troschel. Verhandlungen des naturhistorischen Vereines der preussischen Rheinlande und Westphalens. Zwölfter Jahrgang. Neue Folge; Zweiter Jahrgang. Bonn, 1855. pp. 113–116.

Troschel points out that there are possibilities of mistake in such accounts, the more especially as Bartels was not an eye-witness of what had occurred. The specimens sent belonged to *Gammarus pulex*, Gervais.

1855. BATE, C. SPENCE.

On the Homologies of the Carapace and on the Structure and Function of the Antennæ in Crustacea. Annals and Magazine of Natural History. 2d Ser. Vol. XVI. London, 1855. pp. 36–46. (Read at the Linnaean Society, April 17, 1855.)

The subject of this paper, so far as it concerns the Amphipoda, is discussed at large in the British Association Report by Mr. Spence Bate, for 1855.

1855. BELL, THOMAS, born 1792, died 1880 (W. P. Sladen), and WESTWOOD, J. O.

The last of the Arctic Voyages; being a narrative of the expedition in H.M.S. Assistance, under the command of Captain Sir Edward Belcher, C.B., in search of Sir John Franklin, during the years 1852–53–54. With notes on the natural history, by Sir John Richardson, Professor Owen, Thomas Bell, J. W. Salter, and Lovell Reeve. Vol. II. London, 1855.

At page 404 the Amphipoda begin, and contain mention of "*Gammarus Sabini*, Leach;" "*Gammarus loricatus*, Sabine;" "*Gammarus boreus*, Sabine;" "*Gammarus Kroyeri* (n. s.). Plate XXXIV. fig. 4. Antennis superioribus inferioribus dimidio longioribus, abdominis segmentis quatuor anterioribus in medio, secundo et tertio ad angulum inferiorem posticum, in dente productis," the English description being followed by the remark that

"This species has a very close resemblance to *Amphitoe bicuspis* of Kroyer. It is however a true *Gammarus*, as the accessory filament of the superior antennæ does exist, although extremely small. *Hab.* Wellington Channel, in thirty-five fathoms." The name was preoccupied by Rathke, in 1843, and the species is identified by Boeck with *Melita dentata*, Krøyer, 1842. This is followed by "*Lycianassa lagena*, Kroy.;" "*Amphitoe larviuscula*, Kroy.;" "*Amphitoe Jurinii?* (Kroy.), a specimen in a broken state occurs, which may probably be of this species," given in the Brit. Mus. Catal. as a synonym of *Pherusa fucicola*, Leach; "*Acanthosoma hystrix*, Owen.;" "*Stegocephalus* (Kroy.) *Ampulla* (Phipps), Plate XXXV., fig. 1," which is re-figured by Westwood, "the figures hitherto published" by Phipps and Herbst (copying from Phipps) being "exceedingly imperfect and incorrect." Those in Krøyer's great work had probably not come under the author's notice.

At page 407 the Læmodipoda contain "*Caprella spinifera* (n. s.), Plate XXXV., fig. 2. Segmentis omnibus corporis spinis armatis." Figure 2e shows the mandible with its long three-jointed palp, which transfers this species to the genus *Ægina*. In the explanation of the plate it is thus given "2e, 'palpigerous mandibles?'" "2h, terminal segments of the body seen from above," is followed by "2i, the same seen sideways, showing a pair of short exartientate filaments attached to the last leg-bearing segment, and a pair of similar appendages, accompanied by a pair of larger two-jointed ones, attached to the minute terminal representative of the abdomen." This species is identified by Spence Bate with *Ægina spinosissima*, Stimpson, 1854.

Mr. Bell concludes by saying, "For the elaborate anatomical details of the plates, and for the greater part of the description of them which I have adopted, I have to acknowledge my obligation to Mr. Westwood."

1855. DANA, JAMES DWIGHT.

The Crustacea; United States Exploring Expedition during the years 1838, 1839, 1840, 1841, 1842, under the command of Charles Wilkes, U.S.N. Vol. XIII. Part. II. Philadelphia; printed by C. Sherman, 1852. Atlas, Philadelphia, 1855. 96 Plates. Amphipoda, Pl. 54-69.

Most of the drawings for this magnificent work were, the author states, made during the years 1838-1842, in the course of the cruise of the expedition. It is greatly to be regretted that the portions of the text and the sets of plates relating to the different groups of Crustacea cannot be separately procured. As it is, the work is rare, expensive, and unwieldy to handle, alike difficult for the carcinologist to get or to do without.

After the engraving, but before the colouring, of the plates, a large part of the original drawings were destroyed by fire in Philadelphia. The loss occasioned by this catastrophe is not likely to be soon repaired.

With the exception of *Phronima atlantica*, Gérin, Dana here figures all the species of Amphipoda which he describes as brought home by the expedition.

1855. GOSSE, P. H.

Notes on some new or little-known Marine Animals. The Annals and Magazine of Natural History. No. XCI. July 1855, and No. XCV. November 1855. Vol. XVI. Second Series. London, 1855. pp. 27-36, 307.

At page 30, in the "Order EDRIOPHTHALMA. Fam. CYAMIDÆ. Genus CYAMUS (Fabr.)," Mr. Gosse introduces "*C. Thompsoni* (mihi). Plate III. fig. 11. Body about $\frac{1}{6}$ th of an (ZOOL. CHALL. EXP.—PART LXVII.—1887.) XXX 36

ineh in length. Five pairs of feet equally developed; all five-jointed; all with the penultimate joint large and ovate. Third and fourth segments each furnished with a single small oval appendage." "It was attached to one of two specimens of *Hyperoodon bidens*, the capture of which in Portland Roads was recorded in the 'Annals of Nat. Hist.' for November 1854." This species has since been made the type of a new genus, *Platycyamus*, Lütken. See Note on Lütken, 1873.

At page 307, in the "Fam. COROPHIADÆ," *Unciola irrorata*, Say, is recorded from Weymouth.

1855. GOSSE, P. H.

A Manual of Marine Zoology for the British Isles. Part I. London, MDCCCLV.

In "Subkingdom III. Annulosa," Gosse places "Class IV. Crustacea." These are divided into two sections:—

"Mouth prolonged into a sucker, *Thelastia*.
"Mouth armed with jaws, *Dactia*."

The first section includes the Pyenogonidæ and other families. "Section II. Dactia," is divided into three orders, *Entomostraca*, *Edriophthalma*, *Podophthalma*. The Edriophthalma are distinguished from the other two by the following characters:—"The modified legs performing the office of gills; eyes sessile, immovable; thoracic feet for walking, usually seven pairs; no carapace." It is thus subdivided:—

"Abdomen a rudimentary tubercle, without distinct members. Branchial vesicles suspended from the thorax, *Læmodipoda*.

"Abdomen well developed, and provided with five or six pairs of members.
"Branchial vesicles almost always absent from the thorax. First five pairs of abdominal members almost of the same form, unsuited to locomotion, and apparently serving as gills, *Isopoda*.

"Branchial vesicles under thorax. First five pairs of abdominal members diversely formed, and serving for locomotion, *Amphipoda*."

To "Suborder I.—LÆMODIPODA," he assigns "*Caprella* (Lamk.). Body lengthened, slender, cylindric; both pairs of antennæ well-developed; feet long, but wanting on the second and third segments of the thorax," with the species *linearis* (fig. 223), *lavis*, *acuminifera*, *acutifrons*, *phasma*, *tuberculata*, *lobata*, *acanthifera*, *longispina*; "*Leptomera* (Gærin). As *Caprella*, but all the segments of the thorax furnished with feet," with the species *pedata* (fig. 224); and "*Cyamus* (Lamk.)," with the species *erraticus*, *ovalis*, *gracilis*, *Thompsoni* (fig. 225). His "L. pedata" can be recognised from the figure as *Proto ventricosa*, but the figure of *C. linearis* is useless. No authorities are mentioned for the species, nor are any descriptions given.

"Sub-Order III. AMPHIPODA" is thus subdivided:—

"Fourth and fifth abdominal segments united; fourth and fifth abdominal appendages dissimilar, *Cheluracea*.

"Abdominal segments distinct; abdominal appendages similar,

"Foot-jaws covering only the bases of the preceding appendages, and forming a lip with three plates, but deprived of palps, *Hyperiacea*.

"Foot-jaws very large, covering the whole mouth, and forming a lip terminated by four great horny plates and two very long palps, *Gammaracea*."

In the first Tribe, the Cheluracea, stands, as might be expected, only *Chelura terebrans*, Philippi (fig. 250). In "Tribe II. HYPERIACEA," he places "*Hyperia* (Latr.). Second pair of antennæ style-shaped and unfolded; body inflated. H. Latreillei. Fig. 251; n. s. [H.] galba," and, "*Typhis* (Risso). Second antennæ folding on themselves so as to form three

or four elbows ; first joint of fifth and sixth feet forming great oval plates, concealing all the others. T. monoculoides. Fig. 252 ; mag. $\frac{5}{4}$. [T.] nolens." Figure 252 is not a *Typhis*, but probably the *Cancer Gammarus monoculoides* of Montagu, now called *Stenotheö monoculoides*. It should be noticed that the letters *n. s.* after Fig. 251, do not mean *new species*, but *natural size*.

Tribe III. *Gammaracea*, are thus subdivided :—

Body depressed ; epimera very small or obsolete ; abdomen straight, normal ; three last pairs of false feet tipped with swimming-plates ; antennæ foot-shaped,

Corophiadæ.

" Body much compressed ; epimera very large, scale-like, and encasing the bases of the first four pairs of feet, posterior extremity formed for leaping.

" Superior antennæ longer than the footstalk of the inferior, and much longer than the head ; mandibles carrying long palps ; antennæ lash-like,

Gammaridæ.

" Superior antennæ much shorter than footstalk of inferior, and scarcely longer than head ; mandibles without palps,

Orchestiadæ."

" Family I. *COROPHIADÆ*, contains 1. "*Cerapus* (Say). Second feet fanged ; fang two-jointed ; all the antennæ without many-jointed lashes at the tip. *C. pelagicus*. [*C.*] *falcatus*. *C. Whitei*. Fig. 253 ; mag. $\frac{6}{4}$;" 2. "*Podocerus* (Leach). First and second feet fanged ; fang one-jointed ; inferior antennæ without lashes. *P. variegatus*. [*P.*] *pulchellus*. Fig. 254 ; mag. $\frac{2}{1}$;" 3. "*Corophium* (Latr.). Second feet not fanged ; inferior antennæ without lashes. *C. longicorne*. Fig. 255 ; mag. $\frac{2}{1}$;" 4. "*Unciola* (Say). First and second feet fanged ; all the antennæ tipped with many-jointed lashes ; superior pair furnished with a minute appendage at the base of the lash. *U. irrorata*. Fig. 256 ; mag. $\frac{4}{1}$."

The small figure of *Cerapus whitei* seems to show a second gnathopod with a dilated wrist and narrow hand quite unlike the small cup-shaped wrist and dilated oval hand depicted for *Cerapus whitei* in "A Naturalist's Rambles on the Devonshire Coast," but the figure in this work is too small to build any argument upon. The generic description, it should be observed, says "fang two-jointed."

" Family II. *GAMMARIDÆ*, contains *Gammarus* (Fabr.), with the species *locusta* (Fig. 257), *marinus*, *campolops*, *pulex*, *grossimanus*, *longimanus*, *Cranchii*, *punctatus*, *carinatus*, *maculatus* ; *Amphithoe* (Leach), with the species *punctata*, *fucicola*, *obtusata*, *Moggridgei*, *rubricata* (Fig. 258), *dubia*, *spinosa* (Fig. 266), *carino-spinosa* (this and *spinosa* being bracketed as " = *Dexamine* (Leach) ;" *Leucothoe* (Leach), with the species *articulosa* (Fig. 259) ; *Acanthonotus* (Owen), with the species *testudo* ; *Anonyx* (Kröyer), with the species *albus* (Fig. 261) and *elegans* ; *Opis* (Kröyer), with the species *typica* (Fig. 262).

" Family III. *ORCHESTIADÆ*, contains *Talitrus* (Latr.), with the species *locusta* (Fig. 263) ; *Suleator* (Bate), with the species *arenarius* (Fig. 264) ; and *Orchestia* (Leach), with the species *littorea* (Fig. 265) and *Deshayesii*.

As " *Genera apparently intermediate between the Edriophthalma and Podophthalma*," he places the Family *CUMADÆ*, containing the genera *Cuma* (M.-Edw.), *Alauna* (Goodsir) ; *Bodotria* (Goodsir).

1855. LEYDIG, FRANZ.

Zum feineren Bau der Arthropoden. Archiv für Anat. und Physiol. Jahrgang, 1855. pp. 376–476. Taf. xv.–xviii.

See Note on Leydig, 1878. Pages 444, 445, 452 of this work are mentioned in the references.

1855. LILJEBORG, W.

Om Hafs Crustaceer vid Kullaberg i Skåne. Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar. Tolfte Årgången, 1855. Stockholm, 1856. pp. 117–138.

This is an appendix to the contribution of 1852. Attention is called to the neglect of the sexual characteristics in the Amphipoda, a better acquaintance with which would probably necessitate some changes in the established genera and species. As marks of the female, Liljeborg notes relatively larger epimera, more or less developed ovarian appendages by the side of the branchiae, smaller antennæ and gnathopods, and often the presence of eggs in the pouch. Under the heading “*Crustacea marina ad Kullaberg in Scania mense Julii 1852 collecta*,” he records, with full descriptions of the new species, *Ampelisca levigata*, n. s.; *Ampelisca tenuicornis*, u. s.; “*Gammarus Sabini*,” Leach; *Gammarus angulosus*, H. Rathke; *Gammarus poecilurus*, H. Rathke; *Gammarus erythrophthalmus*, n. s.; *Gammarus macronyx*, n. s.; *Leucothoë articulosa* (Montagu), with a long description, an account of its differences from *Leucothoe furina* (Savigny), and a concluding observation that Kröyer’s *Leucothoë clypeata* and *glacialis* as well as *Leucothoë norvegica* Liljeborg can scarcely be included in this genus; *Ischyrocerus minutus*, Liljeborg, with a description, and a discussion of its relationship to *Ischyrocerus auguipe*, Kröyer, and *Ischyrocerus latipes*, Kröyer, which are both, he says, several times larger than *Ischyrocerus minutus*; *Erithonius difformis*, M.-Edwards, with a long description, and a discussion of the relationship of *Erithonius* to *Podocerus*, etc.; *Laphystius sturionis*, Kröyer, with a description; *Caprella lobata* (O. F. Müller); *Leptomera pedata* (Abildgaard).

Gammarus erythrophthalmus has been confused by Boeck, as we learn from G. O. Sars, with a different species. Liljeborg’s account of his species is as follows:—“Corporis forma sat robusta; epimera parva. Longit. circ. 7 millim. Oculi magni, reniformes, rubri. Frons inermis. Dorsum laeve. Annuli tres postici abdominis siue aculcis. Anteunae longitudine mediocres, hirsutæ; superiores inferioribus parum longiores, pedunculi articulo primo ceteris crassiore, quam secundo vero breviore. Articulus secundus tertio non multo longior. Flagellum pedunculo paullo brevius, articulis circ. quindecim. Flagellum appendiculare longum, articulis sex. Antennæ inferiores poue superiores fixæ. Pedunculus earum eidem anteunarum superiorum circ. longitudine æqualis, articulo basali infra processu longo, articulo secundo non plane apicem articuli primi pedunculi antenn. superiorum attingente, articulo tertio et quarto inter se circ. æqualibus. Flagellum articulis duodecim. Pedum thor. primi et secundi paris manus valde inæquales, haec illis multo majores. Illæ ferc ovatae, carpo magnitudine circ. æquales, præsertim postice setosæ. Margines postici palmae et carpi angulum acutum formantes; apud marem et feminam inter se similes. Haec apud marem validæ, carpo multo majores, oblique triangularis, margine antico arcuato, postico infra oblique truncato, crenulato, setifero, processibusque tribus brevibus instructo. Apud feminam paullo minores sunt, ovatae, et postice tantum processibus duobus præditæ. Pedes tertii et quarti paris sequentibus breviores, articulo tertio sat dilatato, ungue vero forma solita. Pedes sexti et septimi paris ceteris longiores, inter se circiter æquales, apicem pedum abdominalium ultimorum attingentes, articulo basali valde dilatato. Rami pedum abdominalium ultimorum conici vel stiliformes, supra et ad apicem aculeati, inter se et trunco longitudine circ. æquales, antecedenates paullum superantes. Appendix caudalis brevis et crassa, postice truncata, supra postice eminentiis duabus parvulis lateralibus aculeatis.—Color flavescenti-albidus fasciis dorsalibus lutescentibus. Rarus; in retibus piscatorum e 14–16 orgyarum profundo acceptus.” From all known species within the genus (*Gammarus*) it differs, he says, by its red eyes. It is not an uncommon species, I may remark, on the south coast of Devonshire.

For *Eriechthonius*, Milne-Edwards, Liljeborg proposes the following new definition:—"Caput ab annulo primo thoracico disjunctum. Antennæ mediocres, non pediformes, et flagello appendiculari carentes. Capitis testæ lobuli oculiferi mucronati. Pedes primi et secundi paris subcheliformes, illi his minores. Femur pedum tertii et quarti paris dilatatum, et eodem pedum sequentium latius. Pedes abdominales ultimi vel sexti paris tantum uno ramo apicali, unguiformi. Appendix caudalis duplex, utrinque processu brevi formata."

Under the heading, "Tillägg och annürkningar vid de uti den förra uppsatsen öfver Crustacea i hafvet vid Kullaberg i Skåne lemmale beskrifningarna," in place of "Ampelisca Eschrichti? Kröyer; Liljeborg: Övers. af Kongl. Vet. Akad:s. Förh. 1852, p. 6," he describes *Haploops*, n. g., thus:—

"Oculi duo simplices, nitutissimi. Caput mediocre. Corpus compressum, epimeris modicis. Antennæ sat tenues, interdum longissimæ, appendice carentes, neque inferiores pone superiores insertæ. Mandibularum pars dentalis bifida. Palpus mandibularis longus, triarticulatus, processui magno, articulo primo palpi longiori, adfixus. Maxillæ solito modo formatæ. Laminæ maxillarum secundi paris breves et latæ, exteriore majora, interiores subtilissime ciliatæ. Palpus maxillarum tertii paris quadriarticulatus, articulo secundo reliquis majore, et articulo ultimo minimo, non unguiformi, apice setifero. Pedes primi et secundi paris graciles, et sequentibus minores, tamen subcheliformes, manu et ungue parvis instructi. Pedes tertii et quarti paris fere æquales, ungue longo et parvum arcuato, et articulo penultimo et antepenultimo sensim confluentibus, ut una cum ungue quasi digitum mobilem forment, et hi pedes quodammodo prehensiles sint. Pedes quinti et sexti paris æquales, antecedentibus duobus paribus breviores, pone vergentes, ungue parvulo retro flexo, articulo basali valde dilatato, et articulo secundo et tertio brevibus. Pedes septimi paris articulo basali eodem antecedentium minore, oblongo, fere rectangulari, articulo quinto minimo, fere rudimentari, et unguis loco stilum minimum setiferum gerente. Pedum abdominalium ultinum par antecedentia superans, ramis duobus lamellosis. Appendix caudalis unica parva, lamellosa et profunde divisa. Mares et feminæ inter se parum dissimiles. Feminarum pedes thoracici appendice flabelliformi, ova tegente, carentes, ejusque loco appendicem linearem minutam habentes." The assigning of only two eyes to this genus is perhaps due to an error of observation.

"*Haploops tubicola*, mibi," is described as the type species, with the same reference as that for the genus. This is followed by the description of "*Haploops carinata*, mihi," with a reference to "Ampelisca Eschrichti? mas, Liljeborg; l. c."

Additional characters are given for the genus *Ampelisca*, Kröyer. *Ampelisca macrocephala*, Liljeborg, is redescribed, with a note that it stands very close to "*Ampelisca Eschrichti*," Kröyer. *Gammarus maculatus*, Liljeborg, is recognised as a synonym of *Cancer Gammarus obtusatus*, Montagu, and *Gammarus longipes*, Liljeborg, is redescribed. The latter has been referred by Bruzelius to his genus *Autonoë*, of which Boeck retains it as the type.

1855. LILJEBORG, V.

Öfversigt af de inom Skandinavien hittills funna arterna af slägget GAMMARUS Fabr. af V. Liljeborg. (Inlemnad den 10 Maj 1854). Kongl. Vetenskaps-Akademiens Handlingar för år 1853. Stockholm, 1855. pp. 443–460.

Accepting the genus *Gammarus* as defined by Milne-Edwards, Liljeborg here refers to a subdivision of it or a subgenus, for which he proposes the name *Gammaropsis*, those species which have the third uropods not laminar but stiliform, conical, and the telson single, tuberculiform. He notes that *Gammarus zebra*, Rathke, is a *Podocerus*; he describes his own species *Gammarus mutatus*, which Boeck identifies with *Gammarus locusta*; he

unites *Gammarus krøyeri*, Rathke, to *Gammarus paecilurus* of the same author, both of which are synonyms of *Gammarus marinus*, in Boeck's view. Under the *Gammaropsis* division he describes *Gammarus erythrophthalmus*, n. s., which Boeck accepts as type of the genus *Gammaropsis*. Spence Bate and Bruzelius did not take account of the name *Gammaropsis*, as in Liljeborg it was only provisional, but to *Eurystheus erythrophthalmus*, Spence Bate, Boeck gives the name *Gammaropsis erythrophthalmus*. G. O. Sars, however, maintains that the species which Boeck describes under this name is not Liljeborg's species, "which, among other things, has the secondary flagellum on the upper antennæ considerably longer and consisting of numerous articulations, the lateral angles of the head rounded off, and the third pleon-segment's lower hinder angles not acute. Lastly, in Boeck's species, the pigment of the eyes is not red as in the typical form but black." A point which Sars does not mention is that in Boeck's species the fourth pleon-segment has, on the middle of the hinder rim, two small teeth, whereas Liljeborg expressly says "annuli abdominis supra sine aculeis." On the other hand, Boeck says nothing of the colour of the eyes, and Liljeborg says nothing as to the other points mentioned by Sars, except that the accessory flagellum is long, six-jointed. As Boeck does not appear to have himself taken the species which he describes, he probably had no means of ascertaining the colour of the eyes, but it still remains rather remarkable that both in his species and in Liljeborg's, the hands of the second gnathopods should be tridentate in the male and bidentate in the female. To Boeck's species Sars gives the name *Gammaropsis melanops*. For the opinion that *Gammarus (Gammaropsis) erythrophthalmus*, Liljeborg, had been earlier described as *Gammarus maculatus*, see Note on Johnston, 1827-1828. The other species here described as new, *Gammarus (Gammaropsis) macronyx*, is assigned by Boeck to *Protomedieia fasciata*, Krøyer.

The subdivision or subgenus *Gammaropsis* is thus defined:—

"† Rami pedum spuriorum ultimorum depressi, lamellosi. *Gammarus.*"

"†† Rami pedum spuriorum ultimorum stiliformes, conici. Appendix caudalis unica, tuberculiformis, *Gammaropsis.*" a) Pedes thor. 3:ii et 4:ti paris solito modo formati. *Gammarus erythrophthalmus*, n. s. b) Pedes thor. 3:ii et 4:ti paris forma singulari, ungue longissimo, parum arcuato, articulo 5:to et 6:to una formato. *Gammarus anomalus*, H. Rathke; *Gammarus longipes*, Liljeborg; *Gammarus macronyx*, n. s.

1855. LINDSTRÖM, G., born 1829 (G. O. Sars).

Bidrag till kändedomen om Östersjöns invertebrat-fauna. Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar. Årg. 12. 1855. No. 2. Stockholm, 1856. pp. 49-73.

Lindström here describes the new genus *Bathyporeia* as follows:—"Antennæ superiores articulo primo pedunculi magno et tumido, flagello appendiculari perpusillo. Antennæ inferiores pedunculo gracili, fere duplo longiore pedunculo superiorum. Mandibulæ apice valde acuminate, palpo triarticulato, articulo secundo crasso. Palpus pedum maxillarium articulatus, articulo secundo lato et foliaceo, articulo tertio gracili, curvo et non ut plerumque ad apicem articuli præcedentis, sed, palpi quasi appendicularis modo, ad marginem exteriorem affixo. Pedes thoracici primi paris perbreves, debiles, articulo ultimo pyriformi, ungue valido. Pedes secundi paris præcedentibus duplo longiores, ungue carentes. Pedes tertii quartique paris inter se similes, ultimo articulo longo, gracili, curvo, ungue rudimentario. Quinti paris pedes femore magno, clypeiformi, articulo tertio lamelloso, articulo quinto sine ungue. Epimera parva, margine inferiore setis instructo. Pedes natatorii forma vulgari. Pedes spurii quarti quintique paris breves. Pedes spurii

sexti paris forma singulari: pars basalis duplo longior quam latior; ramus finalis interior rudimentarius et forma folii acuminati; ramus exterior magnus, biarticulatus; articulo primo lamelloso, parte basali ter longiore; articulo secundo parvo, acuminato, setis instrueto."

The type species is described under the name *Bathyporeia pilosa*, and figured Tab. ii. figs. 1-11. *Pontoporeia affinis*, n. sp., is thus described:—"Oculi nigri, elongati. Antennæ inferiores superioribus longiores; antennæ superiores flagello appendiculari triarticulato. Annulus abdominalis quintus setis illis, quas habet P. femorata, carens. Partes femorales pedum, ut etiam epimera, ornatae textura singulari cellulosa, quæ globulis adiposis formata est." It is figured Tab. ii. figs. 1-4. Lindström comments on the relationship of his species to the Arctic *Pontoporeia femorata*, to which, in the fuller description, he recognises it as coming very close. It was the only Amphipod he found at 40 fathoms, the greatest depth his dredging reached. Subsequently, he seems to have given up its specific distinctness. See Note on Möbius, 1873. *Gammarus locusta*, he says, may be found wherever sea-weed grows. He notes too, that there are certain forms of Crustacea which can stand great variations in the saltiness of the water they inhabit. He mentions also *Amphitoë rathkii*, Zaddach, and *Corophium longicorne*, Latr.

1855. MEISSNER, GEORG.

Beobachtungen über das Eindringen der Samenelemente in den Dotter (*Gammarus pulex*). Zeitschrift für wissenschaftliche Zoologie. VI. pp. 272-294. Taf. IX. 1855.

1855. SCHIØDTE, J. C.

Om den i England opdagede Art af Hulekrebs af Slægten *Niphargus*. Oversigt over det Kgl. danske Vidensk. Selskabs Forhandlinger. Kjøbenhavn, 1855. pp. 349-351.

This paper is intended to show that the English well-shrimp, which Schiødte named *Niphargus aquilex*, is distinct from his *Niphargus stygius*, out of the caverns of Adelsberg and Lueg in Carniola. Bate and Westwood, i. 317, say that Schiødte has been misled into describing *Niphargus aquilex* with "dorso carinato," by examining dried specimens, but on other grounds they incline to agree with his discrimination of the two species in question.

1855. STIMPSON, WILLIAM. or 1856?

Descriptions of some of the new Marine Invertebrata from the Chinese and Japanese Seas. By Wm. Stimpson, Zoologist to the U.S. Surveying Expedition to North Pacific, Japan Seas, cte. Lt. John Rodgers, Commander. [From the Proceedings of the Academy of Natural Sciences, May and June, 1855.] Vol. VII. 1854, 1855. Philadelphia. 1856.

The Amphipoda of this paper include *Phoxus geniculatus* and *Phoxus obtusus*, both, in Boeck's opinion, insufficiently described for identification. The three-jointed outer ramus of the last uropod in *Phoxus geniculatus* probably only indicates a two-jointed ramus with a terminal spine. *Dercethoë? productus* is another among the many riddles presented by

these numerous species briefly described and unfigured. The expression, "posterior caudal stylets with short rami, the outer ones uniform, the inner minute, spine-like," though not very intelligible, does not seem to suit either the genus *Cerapus* or the genus *Nanaria* which are suggested by Spence Bate as alternatives for the reception of the species. *Amphithoë filigera*, *Gammarus flabellifer*, *Gammarus tenuicornis*, *Leucothoë stylifera* have not so far as I know been subjected to criticism or re-examination. *Allorchestes rubricornis*, *Allorchestes penicillata*, and *Allorchestes japonica*, in none of which is the telson described, will, I suppose, until further knowledge stand in the genus *Hyale*. *Orchestia pollicifera* is transferred by Spence Bate to *Talorchestia*, as the description shows that in this species the male is of the *Orchestia-*, the female of the *Talitrus-*, form. The next species described is *Corophium contractum*, and the two last are *Caprella luctator* and *Caprella gracilis*, which from the brief descriptions Mayer finds absolutely impossible to determine. Future investigation in the same locality may perhaps settle what species Stimpson meant by *Caprella luctator* with its second gnathopods "large, tridentate below, teeth unequal," and by *Caprella gracilis* "with a slender curved rostrum."

1855. STIMPSON, WILLIAM.
or 1856?

Description of some new Marine Invertebrata. By Wm. Stimpson, Zoologist to the U.S. Surveying Expedition to North Pacific, Japan Seas, etc., under direction of Commander C. Ringgold, U.S.N. [From the Proceedings of the Academy of Natural Sciences, July, 1855.] Vol. VII. 1854-5. Philadelphia. 1856.

Under the heading Choristopoda are given four new species of *Anthura*. After these comes *Caprella solitaria*, which Mayer pronounces absolutely unrecognisable; *Iphimedia obesa*, named apparently in ignorance of Rathke's species, and renamed "*Iphimedia Stimpsoni*" in the British Museum Catalogue, p. 374. Mr. Haswell in his Australian Catalogue gives *Iphimedia? ambigua*, but does not mention Stimpson's species, which was taken also at Port Jackson. Mr. Haswell does not specify reasons for doubting the genus of his species. There is more obvious reason for hesitating to keep Stimpson's species in Rathke's genus as he speaks of the gnathopods having "equal subcheliform hands of moderate size," whereas in species of *Iphimedia* (Rathke, not Dana) they are generally very small.

Œdicerus fossor is described at some length. It was taken at Botany Bay. Mr. Haswell considers that his own species *Œdicerus arenicola* from Shark Island, Port Jackson, may be identical with it. *Gammarus rubro-maculatus* from Port Jackson, referred to the genus *Mæra* by Mr. Haswell, is now considered by that author to cover his own species *Mæra spinosa* and *Mæra ramsayi*, and Mr. Chilton's *Mæra festiva*. Differences in the form of the second gnathopods had been the chief ground of distinction, but he finds "on examining a series of specimens, a perfect series of gradations in this respect from the form figured by Stimpson to typical forms of *M. spinosa* and *M. Ramsayi*." There are no references to any figure of Stimpson's species either in Mr. Haswell's own works or in the British Museum Catalogue or in the copy of Mr. Stimpson's work kindly lent me by Mr. Spence Bate.

Leucothoë affinis, from False Bay, Cape of Good Hope, will be difficult to distinguish from its immediate relations. *Anonyx variegatus* from Simon's Bay, Cape of Good Hope, has been taken again in the same locality by the Challenger Expedition. It is re-described as *Lysianassa variegata* in the Brit. Mus. Catalogue.

1856. BATE, C. SPENCE.

On the British Edriophthalma. [From the Report of the British Association for the Advaneement of Seienee, for 1855. Meeting held at Glasgow in September]. London. 1856. pp. 18–62. Plates XII.–XXII.

This Report considers the seeond division of Crustacea as *Edriophthalma*, using Leach's term as synonymous with *Tetradecapoda* of Blainville, and *Choristopoda* of Dana, though recognising that not all sessile-eyed Crustacea belong to the division, and that not all members of it have fourteen legs. Dana's view is accepted that the *Læmodipoda* of Latreille cannot rank as an order parallel to the *Amphipoda*, but his order of *Anisopoda* is not approved, the true view being supposed to be that *Læmodipoda* and *Anisopoda* should be separated from *Amphipods* and *Isopods* proper as subordinate groups.

In a discussion headed "The Homologics," the following opinion is advanced :—“The epistome appears with little doubt to be the inferior aspect of the mandibular ring, whieh is seen on the external lateral surfacee of the head, and which can be identified from the fact of its carrying the mandibles. This relation of the epistome to the mandibular segment is not admitted by Mr. Dana, who rather, from analogy with the higher types, than by direct evidencee of the subject before him, identifies the epistome as belonging to the inferior (or external) antennal segments.” Two modes of expressiou are applied to the Amphipod extremity or telson. In one it is spoken of as the twenty-first ring, only “to be contemplated in the charaeter of an obsolete segment with its rudimentary appendages;” in the other, “it is a rudimentary appendage, modified upon the type of the preeeding threc” (pairs of appendages). I may here remark that Milne-Edwards, Hist. Nat. des Crust., pl. i. p. 23, regards the telson definitely as the twenty-first ring or segment. He considers that the cleft telson in certain species of Amphipods offers a striking example of the division of a ring into two symmetrical and lateral halves. He adds in a note that this is seen in *Gammarus othonis*, *Gammarus locusta*, &c.; but that in most Amphipods these rudiments of the seventh abdominal segment are completely wanting. This is a very strange observation for him to make, and quite the reverse of the fact. Huxley, The Crayfish, p. 161, regards the telson as a median outgrowth of the sixth abdominal segment, which has become moveably artieulated therewith.

After a detailed account of the mouth-organs, gnathopods and peræopods, Mr. Spenee Bate produces many arguments to show that the epimeron or side-plate in the Amphipoda “belongs to the leg and homologically is the first joint (or coxa), and that it is not a lateral or separate portion of the annular segments of the body of the animal, and in faet that no side pieces or epimerales exist.” He maintains the following propositions :—

- “ 1st. That seven joints are the normal number in the legs of all the Malacostracons Crustacea.
- “ 2nd. That the branehia is normally an appendage of the leg and attached to the coxa.
- “ 3d. That the moveable power of the leg is always between the coxa and the leg, and never between the coxa and the body.
- “ 4th. That the coxa (the so called epimeral) in *Amphipoda* overlaps the segment to which it is attached, and except by a small portion only, is not united by the whole of the margin in juxtaposition with the segment.
- “ 5th. That there are no epimerales where there are no legs.
- “ 6th. That epimerales are found in no other type, except the *Edriophthalma* among Crustacea.” It does not seem inconsistent with these arguments to suppose that the first joint of the leg is in fact coalescent with the side plate, and that the side plate is a protective outgrowth from the segment.

The microscopic structure of the Integumentary Skeleton is discussed; the process of moulting described; the fact noticed that the Amphipoda do not appear to be capable of throwing off a wounded limb; the "auditory cilia" of the upper antennæ are considered; the denticle at the base of the lower antennæ is regarded as an olfactory organ; this is now generally recognized as a duct for the excretion from the antennal gland. The internal structure of an Amphipod is very fully described. Some remarks are made upon the development of the young. The paper concludes with a list of all the then known British species, including many new ones in various genera to be subsequently described. The names which do not reappear, or reappear with important changes, in Mr. Spence Bate's list in 1857, are as follows:—*Montagua dubius*, perhaps represented by "*Montagua Alderii*"; *Scopelochirus brevirostris*, for which appears *Scopelochirus crenatus*; "*Amanonyx Guerinianus*," omitted; *Westwoodia coerulea*, altered to *Westwoodia caerulea*; *Westwoodia carinata*, altered to *Kroyera carinata*; *Gammarus elegans*, altered to *Urothoë elegans*; *Thersites Guilliamsoniana*, altered to *Thersites Guilliamsoniana*; *Podocerus pelagicus*, Edwards, omitted; *Siphonocetus dubius*, omitted; *Læstrigonus Fabreii*, Edwards, omitted; *Ægina longispina*, Kröyer, referred to Dana's genus, *Protella*; *Caprella lavis*, Goodsir, omitted; *Caprella acanthifera*, Leach, placed as a synonym of "*Caprella acuminifera*, Edwards"; *Caprella acutifrons*, Desm., omitted; *Caprella phasma*, Latr., omitted, "*C. Phasma?* (Latr.)" being given as a synonym to *Protella longispina*.

Plates xii. to xxii. give valuable illustrations of the structure, both external and internal of the Amphipoda. They do not, however, supply the want of descriptions, so as to give any scientific value to the names of new genera and species here first published. On plate xvi. the terms applied by Milne-Edwards to the seven joints of a leg or equivalent appendage are contrasted with their abbreviated equivalents as used by Mr. Spence Bate, (1) *Coxopodite* shortened to *coxa*, (2) *Basopodite* to *basis*, (3) *Ischiopodite* to *ischium*, (4) *Meropodite* to *meros*, (5) *Carpopodite* to *carpus*, (6) *Propodite* to *propodus*, (7) *Dactylopodite* to *dactylos*. In view of their forthcoming work on the British Sessile-eyed Crustacea, the following Table was drawn up in concert by Messrs. Bate and Westwood on this occasion:—

Classis CRUSTACEA. Subclassis I. MALACOSTRACA.

EDRIOPHTHALMA (Legio II).

Order.	Division.	Subdivision.	Group.	Tribe.	Family.	Division.	Subfamily.	Genus.

1856. DANA, JAMES DWIGHT.

Catalogue and descriptions of Crustacea collected in California by Dr. John L Le Conte. Proceedings of the Academy of Natural Sciences of Philadelphia. Vol. VII. 1854, 1855. Philadelphia, 1856. pp. 175–177.

The Amphipoda are thus described :—

“*Orchestia Pickeringii*, D., Rep. Crust. Exp. Exp. p. 882, pl. 59, f. 9.

“*Orchestia Californiensis*, D. Oculi majusculi. Antennæ 1mæ perbreves ; 2dæ crassæ, dimidio corporis multo longiores, marginibus subtilissime setulosæ ; flagello parce longiore quam articulum precedens, depresso, ferme 18 articulato, articulis non oblongis, partim transversis. Pedes 1mus articulo 4to angusto, infra unâ spinâ armato ; 5to angusto, breviore, processu parvo infra armato, apice oblique truncato ; ungi brevi, vix digitiformi. Manus 2da grandis, subovata, infra palmâ subexcavatâ, spinam versus apicem acutam gerente, digito sat longo. Pedes sex postici spinulis brevibus multis ornati.—Long. 7”.

“The 7th pair of legs is but little longer than the 6th, and much longer than the 5th.

“*Allorchestes angustus*, D. Epimerae perlatæ, 4tâ multo latiore quam longa, 5tâ angustâ subæque bilobatâ. Pedes 1mi debiles, manu paulo oblongâ, apice truncatâ, palmâ terminali bilobatâ, carpo subtriangulato. Manus secunda, subovata, palmâ rectiusculâ, inermi, parce pubescente ; carpus brevis, processu tenui infra prolongatus. Pedes sequentes nudiusculi, marginibus articulorum postici nudis, spinulis totis parvulis et remotis. Long. 4½”.

“Owing to the broad epimerales, the animal is narrow with high sides.”

1857. Anonymous (? HALLIDAY).

Description of Crustacea (with a Plate). The Natural History Review: A quarterly journal of zoology, botany, geology and palæontology. No. I. January, 1857. London and Dublin.

The Latin diagnoses are given of Schiødte's genus *Niphargus*, and his species *stygius* and *aquilex*. The full account of the former is given in English, as applying equally to the latter, except for the differences mentioned in the diagnoses. As these amounted to little more than assigning a smooth back to *stygius* and by mistake a keeled one to *aquilex*, Spence Bate was misled by this paper, he says, to assume the identity of the two species.

The paper also gives the Latin diagnosis of *Bathyporeia*, Lindström, and in English the full description of *Bathyporeia pilosa*, the type species. A comparison is instituted between this genus and *Anonyx*, Kr., and the observation made that “the form of the first pair of feet has a remarkable resemblance to that in *Anonyx*.” As no particular species of *Anonyx* is mentioned, it is difficult to estimate the merit of this comparison.

1857. BATE, C. SPENCE.

A Synopsis of the British Edriophthalmous Crustacea. Part 1. Amphipoda. The Annals and Magazine of Natural History. Number CX., for February 1857. Ser. 2, Vol. 19, pp. 135–152. London, 1857. 21 pages.

The classification adopted in the genus *Orchestia* is that given by Dana, including the three subgenera, *Talitrus*, *Talorhestia* and *Orchestia*. The new species briefly described are *Orchestia lavis*, later removed to *Orchestia mediterranea*, Costa ; “*Allorchestes Danai*,” in

the Brit. Mus. Catal., transferred to *Allorchestes nilssonii*, Rathke; *Allorchestes imbricatus* now *Hyale pontica*, Rathke; " *Galanthis Lubbockiana*," which does not differ from *Allorchestes imbricatus*; *Montagu marina*, now *Stenothoë marina*; " *Montagu Alderii*," now *Metopa alderii*, according to Boeck; *Montagu pollexiana*, now *Metopa pollexiana*, according to G. O. Sars, but see also Note on Liljeborg, 1850; *Danaia dubia*; " *Lysianassa Audouiniana*," by Boeck referred to *Aristias (Anonyx) tumidus*, Kröyer; *Lysianassa marina*, afterwards referred to *Lysianassa atlantica*, Milne-Edwards; *Scopelochirus crenatus*, later transferred to *Callisoma crenata*; *Tetromatus typicus*, transferred by Spence Bate to *Ampelisca gaimardi*, Kröyer, by Axel Boeck re-established as an independent species, *Ampelisca typica*, Spence Bate, while the species described by Boeck is said by G. O. Sars to be undoubtedly the male of *Ampelisca tenuicornis*, Liljeborg, with which again Bate's species does not agree. Hoek, Carcin. p. 145-6, decides for calling it *Ampelisca carinata*, which (with Norman) he supposes to be the male of *Ampelisca equicornis*, Bruzelius; " *Tetromatus Bellianus*," transferred by Spence Bate to *Ampelisca belliana*, by A. Boeck to *Ampelisca levigata*, Liljeborg; *Westwoodia cecula*, afterwards changed to *Westwoodilla cecula*; *Kroyera carinata*, changed to *Monoculodes carinatus*; " *Phoxus Kröyerii*," transferred to *Phoxus simplex*, Spence Bate; " *Phoxus Holboli*," afterwards recognised as Kröyer's species of the same name; *Sulcator marinus*, later transferred to *Urothoë marinus*; *Darwinia compressa*, identified by Boeck with *Laphystius sturionis*, Kröyer; " *Acanthonotus Owenii*," afterwards referred to *Acanthonotus (Oniscus) testudo*, Montagu, then reinstated as *Acanthonotus owenii*, and finally, Brit. Sess. Crust, vol. ii. p. 528, referred to *Epimeria (Gammarus) cornigera*, Fabricius; *Dexamine bispinosa*, placed by Boeck in his genus *Halirages*; " *Dexamine Gordoniana*," afterwards recognised as a synonym of *Atylus (Amphitoë) swammerdamii*, Milne-Edwards; " *Calliope Leachii*," later referred to *Calliopus (Amphithoë) leviusculus*, Kröyer; " *Lembos Cambriensis*," transferred to *Microdeutopus (Gammarus) anomalus*, Rathke; *Lembos versiculatus*, transferred by Spence Bate to the genus *Microdeutopus*, by Boeck thought probably to belong to *Autonoë*; " *Lembos Damnoniensis*," later recognised as synonymous with *Microdeutopus gryllotalpa*, Costa; *Lonchomerus gracilis*, later placed in Kröyer's genus *Aora*, as *Aora gracilis*; *Eurystheus tridentatus*, later seen to be a synonym of *Gammarus erythrophthalmus*, Liljeborg, and by Boeck therefore named *Gammaropsis erythrophthalmus*, though he seems, according to G. O. Sars, to have confused with it a different species; *Gammarella orchestiformis*, later found to be synonymous with *Gammarella (Gammarus) brevicaudata*, Milne-Edwards; *Gammarus inaequimanus*, subsequently found to be a synonym of *Melita (Cancer Gammarus) palmata*, Montagu; *Gammarus? pallidus*, afterwards placed in a new genus as *Liljeborgia pallida*; *Urothoë elegans*, stated scarcely to differ from *Urothoë irrostratus* of Dana, but separated from it because forms from the Sooloo Sea can scarcely be supposed to belong to the same species as British forms—an unsafe ground of distinction; " *Thersites Guilliamsoniana*," afterwards found to be a synonym of *Bathyporeia pilosa*, Lindström; *Thersites pelagica*, the ♂ of the preceding species; *Leucothoë procera*, subsequently made a synonym of *Leucothoë (Lycesta) furina*, Savigny; " *Pleonexes Gammareoides*," later named *Amphitoë gammareoides*, and probably belonging to the division that has been named *Sunamphitoë*, the *Anisopus* of Templeton; *Amphithoë littorina*, referred by Boeck to *Amphithoë podoceroïdes*, Rathke, probably the same as *Amphithoë rubricata*, Montagu; *Sunamphitoë hamulus*; *Sunamphitoë conformata*, probably the male of the preceding species; (in this and the preceding genus the spelling -*thoë* was afterwards adopted for the termination of the names); " *Cyrtophium Darwinii*," better named *Platophium darwinii*; *Erithonius difformis*, here entered without name of any author for the species, but afterwards in the Brit. Mus. Catal. distinguished from *Erithonius difformis*, Milne-Edwards, and made synonymous with *Cerapus abditus*, Templeton; " *Siphonocetu*

Kröyeranus, afterwards assigned to *Siphonacetes (Cerapus) whitei*, Gosse, with a suggestion in the Brit. Sess. Crust., p. 467, that it may probably be the female of *Siphonacetes typicus*; by Boeck it is united to *Cerapus abelitus*, Templeton; *Siphonocetus crassicornis*, by G. O. Sars renamed *Cerapus crassicornis*; *Dyopedos porrectus*, afterwards named *Dulichia porrecta*; *Dyopedos falcatus*, afterwards named *Dulichia falcata*; “*Proto Goodsirii*,” no doubt the same as *Proto ventricosa*, O. F. Müller.

The new genera are explained as follows:—Family I. Orchestidæ; thus defined:—“The upper antenna shorter than the lower. The coxae well-developed; the posterior pleopoda short and robust, the last being single.” Genus 3, *Galanthis*, “Lower antenna scarcely longer than the upper. Mandible non-palpigerous. Posterior pleopoda Orchestiform. Telson divided.” This genus, in the Brit. Mus. Catal., is made a synonym to *Nicea* of Nicolet, in my view identical with *Hyale*, Rathke.

“Family II. Gammaridæ. Body compressed. Legs long and slender. Posterior pleopoda well-developed, the last being generally the longest.

“Subfamily I. Stegocephalides. Antennæ subequal. Coxæ of the four anterior legs immensely developed.”

Genus 1, *Montagua*, “Upper antenna without secondary appendage. Mandibles non-palpigerous. Hands of both gnathopoda subcheliform. Posterior pleopoda single-branched. Telson entire.” The name *Montagua* was pre-occupied. The genus falls to the earlier *Stenothoë* of Dana. Spence Bate included in it some species which had the mandibles palpigerous; these have been referred by Boeck to his genus *Metopa*. *Probolium*, Costa, is likewise a synonym of *Stenothoë*. Costa did not describe the mandibles, but in the type-species, *Probolium polypyrion*, Boeck found them to be non-palpigerous.

Genus 2, *Danaia*, “First pair of gnathopoda simple; last pair of pleopoda with a single stylet.” In the British Sess. Crust., vol. i. p. 67, a fuller definition is given as follows. “Antennæ subequal. Superior antennæ without secondary appendage. Mandibles destitute of a palpiform appendage. First pair of gnathopoda simple. Second subchelate. Telson single.” Boeck in 1870 established a new genus *Cressa*, with type-species, *Cressa Schiödtei*, distinguished from Bate’s *Danaia* by having a very long triarticulate mandibular palp. G. O. Sars, 1882, says that my figure of *Danaia dubia*, 1876, shows clearly that it is identical with Boeck’s *Cressa Schiödtei*. In that case the later definition of *Danaia* requires amendment. My own specimens of *Danaia dubia* were destroyed by an accident, before my attention was called to the special interest attaching to the mandibles.

“Subfamily II. Lysianassides. Upper antenna short, pyriform. Second gnathopod long, feeble, and obsoletely subcheliform.” Genus 4, *Scopelocheirus*:—Upper antenna furnished with a secondary appendage. First pair of gnathopoda terminating in a brush; second cheliform. Telson double.” This genus had been anticipated by *Callisoma*, Costa. See Brit. Mus. Catal. p. 84.

“Subfamily III. Tetromatides. Eyes four; not compound. Upper antenna in advance of the lower.” Genus 6, *Tetromatus*:—“Head projecting forward as a snout. Upper antenna proceeding from the extremity; lower situated far posteriorly. Mandible palpigerous. Gnathopoda but imperfectly prehensile.” This genus was soon after recognised as equivalent to *Ampelisca*, Kröyer.

“Subfamily IV. Pontoporeoides. The shell of the head developed anteriorly beyond the head so as to look like a hood. Upper antenna situated in advance of the lower.” Genus 7, *Westwoodia*:—“Shell of the head produced to a point. Upper antenna not appendiculated. Telson entire.” The name *Westwoodia* being pre-occupied was soon after altered to *Westwoodilla*. Genus 8, *Kröyera*:—“Head like *Westwoodia*. Hands of gnathopoda well-developed, and formed by the *carpus* being produced so as to meet the apex of the *dactylos*.” In the Brit. Mus. Catal., p. 104, *Kröyera carinata*, the only species assigned to the genus

in this Syuopsis, is referred to the genus *Monoculodes*, Stimpson. But in the Catalogue the name *Kröyera* is retained for a genus thus defined:—"Cephalon produced and anteriorly depressed. Eyes not coalesced into one. Superior antennæ not appendiculate. First pair of gnathopoda subchelate; carpus inferiorly produced along the inferior margin of the propodos. Second pair chelate; carpus produced along the inferior margin of the propodos. Fifth pair of pereiopoda considerably longer than the preceding. Posterior pair of pleopoda biramous. Telson squamiform, entire." Boeck spells the name as *Kröyeria*, and then rejects it, as pre-occupied in a different group of Crustacea, in favour of his own later name, *Pontocrates*. *Kröyera* having in fact lapsed as a synonym of *Monoculodes* could not properly be revived, and must therefore yield to *Pontocrates*, Boeck, unless it should prove that *Kröyera carinata* has a right to be restored. See Note on J. Sparre Schneider, 1885.

"Subfamily V. Gammarides. The upper antenna not in advance of the lower, and never rudimentary. Gnathopoda generally preheusile. Last pair of posterior pleopoda terminating in two stylets which are more or less fringed with cilia." Genus 11. *Darwinia*:—"Pereion inflated. Upper antenna without secondary appendage. All the feet terminating in simple hooks, not subcheliform." This genus Boeck identifies with *Lafystius*, Kröyer. Genus 15. *Calliope*, now *Calliopius*, is given from Leach, MS., and thus defined:—"Upper antenna without secondary appendage. All the feet with strong semi-prehensile claws. Telson single. Mandible palpigerous." Genus 17. *Lembos*:—"Upper antenna with secondary appendage small. First gnathopod larger than the second. First of the posterior pereiopoda very short, the last very long. Telson rudimentary." Afterwards referred to *Microdeutopus*, Costa. Genus 18. *Lonchomerus*:—"Like *Lembos*. Meros of first gnathopod produced into a long spine." Afterwards identified with *Aora*, Kröyer. Genus 19. *Eurystheus*:—"First gnathopod smaller than the second. Upper antenna with secondary appendage. Telson cylindric;" recognised later by Spence Bate as belonging to a special division of the genus *Gammarus* which Liljeborg established; but the fact was not recognised, as Boeck points out, that to this division Liljeborg gave the name *Gammaropsis*, which therefore supersedes *Eurystheus*. Genus 20. *Gammarella*:—"Antennæ like *Gammarus*, and upper with secondary appendage. Last pair of pleopoda with a single branch. Telson single." Genus 25. *Thersites*:—"Upper antenna with second joint of peduncle produced from the inferior side of the first. Second gnathopod terminating in a brush. Telson double;" afterwards recognised as identical with *Bathyporeia*, Lindström.

"Family III. Corophiidae. With the segments of the pleon not fused together." Subfamily I. Podocerides:—"The peduncle of the upper antenna much shorter than that of the lower. Lower antenna very strong, and used in climbing. Last pair of pleopoda terminating in short strong hooks." Genus 1. *Pleonexes*:—"Upper antenna without secondary appendage. Peduncle of the lower antenna reaching nearly to the extremity of the upper antenna. The gnathopoda subcheliform. Posterior pereiopoda prehensile." Afterwards referred to *Amphithoë*, Leach. Genus 3. *Sunamphitoë*:—"Second gnathopod larger than the first. Posterior pleopoda with one branch squamiform, the other terminating in two hooks. Telson terminating in a single strong hook." This is doubtless the same as Templeton's *Anisopus*, but the name *Anisopus*, being pre-occupied, must yield to *Sunamphitoë*.

"Family VIII. Dyopodidae. The last segment of the pereion and the last of the pleon absent. Coxæ of last two pereiopoda fused with the body of the animal." Genus 1. *Dyopedes*:—"The sixth and seventh pairs of legs attached to the sixth segment of the pereion. The last pair of pleopoda absent. Telson single." This was afterwards found to coincide with *Dulichia*, Kröyer, and Dana's name *Dulichidæ* was therefore accepted for the family.

1857. BATE, C. SPENCE.

British Amphipoda. Annals and Magazine of Natural History. Vol. XIX.
2d Ser. London, 1857. p. 271.

In a letter dated February 16, 1857, Mr. Spence Bate says "having had an opportunity, since the publication of the synopsis of the British Amphipoda, of comparing the necessary works at the British Museum, I am enabled to make the following corrections and addenda:— After *O. littorea* read (Leach). After *O. Deshayesii* read (Savigny). *Acanthonotus Owenii* (mihi) is *A. testudo* of (Montagu). *Thersites* (mihi) must yield to *Bathyporeia* (Lindström), and probably the species *B. Guiliamsonia* is the *pilosa* of that naturalist. *Leucothoë procera* (mihi) is probably *furina* of Savigny; and also the genus *Dyopedos* (mihi) is *Dulichia* of Kröyer; consequently the family *Dyopediidae* will for the future be changed to *Dulichiadæ*."

1857. BATE, C. SPENCE.

British Edriophthalma. The Annals and Magazine of Natural History.
Vol. XX. 2d Series. London, 1857. pp. 524–5.

He here divides *Talitrus* "into two genera, as has been done by Nicolet and Stimpson," adopts *Orchestoidea*, Nicolet, which is synonymous with *Megalorchestia*, Stimpson, thus producing the classification, *Talitrus*, *Orchestoidea*, *Talorchestia*, *Orchestia*. "*Lysianassa Chausica* in the synopsis (not Edwards's) is evidently *L. longicornis* of Lucas (Exped. to Algiers)." "The genus *Tetromatus*, mihi, *Pseudophthalmus*, Stimpson, is synonymous with *Ampelisca* of Kröyer." Hence, he says, the subfamily *Tetromatides* should be re-named *Ampeliscades*. *Pontoporeides* is given up as name of a subfamily, because *Pontoporeia* of Kröyer must go to the "*Lysiassides*." *Phoxides* is proposed as subfamily for *Phoxus*, etc. "*Phoxus Kröyerii*, mihi, will be changed into *P. simplex*," the other name being pre-occupied. "After *P. Holbölli*, read Kröyer instead of mihi" in the synopsis. "The genus *Lonchomerus* is evidently that of *Latasia* of Lucas (Exped. to Algiers)." "There is to be added to the genus *Siphonocetus* of Kröyer the species *Cerapus Whitei* of Gosse; this may probably be synonymous with *S. Kröyeranus*, mihi." "*Cyamus gracilis* (Gosse) should have been *C. Thomsoni*, Gosse." There are also two or three other notes about names of species.

1857. BATE, C. SPENCE.

On a new Amphipod. *Iphimedia Eblanæ*. Dublin Natural History Society.
pp. 58–59. Pl. XVI. Fig. 1–7. October, 1857. The Natural History Review.
Vol. IV. London, Dublin, 1857. pp. 229–230. Pl. 16. fig. 1.

This species is in my opinion but doubtfully distinct from *Iphimedia obesa*, Rathke, the variations being perhaps only due to age or sex.

1857. COSTA, ACHILLE.

Ricerche sui crostacci Amfipodi del regno di Napoli. Memorie della Reale Accademia de Scienze di Napoli. Vol. I. Napoli, 1857. pp. 165–235. Tav. I.–IV.

The introduction briefly reviews the progress of knowledge in regard to the Amphipoda since 1830, and gives an account of the results at which Costa had himself arrived.

He classifies the "Amfipodi genuini" in this way:—Fam. I. GAMMARIDEI. Subfam. I. AMPELISCINI. Genera *Ampelisca*, *Araneops*. Subfam. II. TALITRINI. Genera, *Orchestia*, *Talitrus*. Subfam. III. LISIANASSINI. Genera, *Lysianassa*, *Callisoma*, *Ichnopus*, *Alibrotus*, *Phlias*, *Acanthonotus*. Subfam. IV. GAMMARINI. Genera, *Egidia*, *Melita*, *Amphithoe*, *Amphithonotus*, *Nototropis*, *Epimera*, *Probolium*, *Gammarius*, *Ceradocus*, *Elasmopus*. Subfam. V. LEUCOTOMI. Genus, *Leucothoe*. Fam. II. PODOCERIDEI. Subfam. VI. PODOCERINI. Genera, *Erithonius*, *Cerapodina*, *Cerapus*, *Podocerus*. Subfam. VII. UNCIOLINI. Genera, *Microdeutopus*, *Unciola*. Subfam. VIII. COROFINI. Genus, *Corophium*. To illustrate the incompleteness of this classification, he notices that he has forthwith to add two other genera, "Pontoporeja," Krøyer, and "Bathyporeja," Lindström.

Of his new genus *Araneops*, he gives the following description:—"Caput elongato-conicum. Ocelli quatuor in capitis margine antico positi. Antennæ superiores unisetæ; inferiores longiores, pone illas insertæ. Epimera quatuor anteriora infra valde producta, media augustiora. Pedes primi et secundi paris subæquales, prehensiles, ungue intus serrato; tertii et quarti cylindracei, ungue longo, articulum antepenultimum, ultimis duobus simul valde majorem, apice attingente. Pedes quinti, seti [sexti] et septimi paris articulo primo valde elato, laminari." He recognises its close affinity with *Ampelisca*, Krøyer, of which it is in fact a synonym. The type species, *Araneops diadema*, Tav. i. fig. 1, is set down by Sp. Bate, Heller, and J. V. Carus, as a synonym of "*Ampelisca Gaimardi*," Krøyer, by Boeck as a synonym of *Ampelisca tenuicornis*, Lilljeborg, 1855. Costa's second species, *Araneops brevicornis*, Tav. i. fig. 2, is by Carus named *Ampelisca brevicornis* (Marion), but by Boeck made a synonym of *Ampelisca macrocephala*, Lilljeborg, 1852.

After mentioning *Orchestia littorea*, Costa describes his species *Orchestia mediterranea*, and *Orchestia constricta*, the latter of which Heller identifies with "*Orchestia Montagui*," And.

Of *Lysianassa*, Costa describes and figures his three species, 1. *Lysianassa spinicornis*, Tav. 1, fig. 4, a species not to be confused with *Lysianassa (Ichnopus) spinicornis*, Lilljeborg, 1865; 2. *Lysianassa loricata*; 3. *Lysianassa humilis*, which Heller thinks may be the same as "*Lysianassa Costa*," M.-Edw., which Costa mentions as being found with it.

Callisoma punctatum, Costa, and *Callisoma hopei*, A. Costa, are mentioned, but as nothing is said of *Callisoma barthelemyi*, Hope, it may be presumed that Costa had ceased to consider it a distinct species.

The genus *Ichnopus*, evidently by the derivation intended to be *Ischnopus*, is thus defined:—

"Antennæ longæ, graciles, superiores bisetæ. Pedes quatuor anteriores longi, graciles, filiformes, haul prehensiles, primi unguicolo minuto infra pectinato terminati; secundi submembranacei, manu apice longe fimbriata, unguicolo vix conspicuo." From *Callisoma*, which it resembles in the gnathopods, it differs, he says, in the antennæ, while from *Alibrotus*, which it resembles in the antennæ, it differs in the gnathopods. He adds, "è in questo genere che abbiam trovate quelle appendici simili alle branchie de' decapodi, inserite all'origine de' piedi toracici in forma piramidale, con uno stelo mediano, ed una serie di lame da cadaun lato, accolte le une alle altre, e decrescenti dalla base all'estremità, che rappresenta l'apice della piramide." For this form of the branchiae, see also Grube's account, 1866, of his *Lysianassa longicornis* ♀, (which is probably Costa's *Ichnopus taurus*), and Boeck's remark, De Sk. og arkt. Amph. p. 323, that it is especially characteristic for many species of the genus *Atylus*, that, like *Ichnopus*, their branchiae have "en ophoist Ribbe langs Midten, hvorfra der udgaar talrige Folder som Sideribbe i et Blad." I have called attention to a similar structure also in *Byblis kallarthros* from Singapore. The type species of Costa's genus, *Ichnopus taurus*, is figured Tav. i. fig. 3.

The genus *Egidia* is thus defined:—

"Antennæ superiores bisetæ; inferiores articulo primo inermi. Pedes quatuor anteriores minuti, prehensiles, subæquales; tertii paris articulo ultimo spatuliformi; quarti compressi, valde

elati, articulo ultimo tantum tereti; reliqui simplices." This genus is not noticed in the Brit. Mus. Catal. Boeck points out that it is a synonym of Dana's genus *Urothoë*, 1852, which, he says, "can better be seen from Costa's drawing of *Egidia pulchella* than from his description." The type species, *Egidia pulchella*, is figured Tav. iv. fig. 3.

Of *Melita*, Leach, a fresh definition is given, and *Melita palmata*, Montagu, is figured, Tav. ii. fig. 4.

The genus *Nototropis* is thus defined:—

"*Antennæ superiores unisetæ. Pedes quatuor anteriores prehensiles, filiformes, subæquales. Corpus valde compressum, dorso acute carinatum, saxis segmentis aliquot in spinum productis; epimeris mediae magnitudinis.*" Spence Bate, Heller and Boeck make this a synonym of *Atylus*, Leach, and Costa's two species, *Nototropis guttatus*, Tav. i. fig. 7, and *Nototropis spinulicauda*, Tav. i. fig. 8, are both united by Heller under the name "*Atylus Costæ*." As Costa identifies *Nototropis guttatus* with "*Acanthonotus guttatus*, A. Cost. in Hop. Cat. p. 46," the specific name *guttatus* must obviously take precedence of Heller's specific name "*Costæ*," which will enter into the synonymy, along with *spinulicauda*, if, as seems probable, that is not a distinct species.

The genus *Amphithonotus* is thus defined:—

"*Corpus modice compressum, dorso capitis thoracisque rotundato, abdominis carinato, segmentis pluribus abdominis, aut etiam ultimis thoracis postice spinosis. Antennæ superiores unisetæ. Pedes quatuor anteriores prehensiles, filiformes, subæquales.*" This genus, already briefly characterized in Hope's Catalogue, 1851, is a synonym of *Dexamine*, Leach, and the species *Amphithonotus acanthophthalmus*, which, together with *Amphithoe marionis*, Edw., Costa here places in the synonymy of *Amphithonotus marionis*, is by Boeck identified without doubt with *Dexamine spinosa*. The remaining species, *Amphithonotus spiniventralis*, Tav. ii. fig. 1, is likewise by Grube and Boeck assigned to the genus *Dexamine*.

The genus *Epimeria*, already instituted in 1851, is here more fully defined:—

"*Antennæ superiores unisetæ. Pedes quatuor anteriores prehensiles, filiformes, subæquales. Corpus dorso in postica thoracis parte ac in abdomine carinatum et spinosum. Epimera quarti et quinti articuli thoracis maxima, simul clypeum semilunare formantia. Abdomen lamina horizontali terminatum.*" The type species, *Epimeria tricristata*, Tav. ii, fig. 2, is identified by Bate and Westwood, ii, p. 528, and by Boeck, with *Gammarus corniger*, Fabricius, so that it becomes *Epimeria cornigera*, Fabr.

The genus *Probolium* is thus defined:—

"*Antennæ superiores uniselæ. Pedes quatuor anteriores prehensiles, primi minores, secundi ralde majores, manu maxima. Corpus dorso rotundatum inerme, utrinque loricatum, lorica ex epimeris tertii et quarti articuli connatis præcipue constituta.*" The type species is *Probolium polypriion*, Tav. ii. fig. 3 (not 5), which Boeck found, upon examination, to be without mandibular-palp. The genus he was accordingly able to identify with *Stenothoë*, Dana, 1852. The second gnathopods in *Stenothoë polypriion* have a remarkable likeness to those of *Microprotopus maculatus*, Norman.

Under *Amphithoe*, Leach, Costa places several species; Section A, 1. "*Amphithoe Prevostii*," M.-Edw., which is rather to be called *Hyale prevostii*; 2. *Amphithoe babirussa*, A. Costa, Tav. ii, fig. 5, called *Allorchestes Babicus* in the Brit. Mus. Catal.; 3. *Amphithoe gazella*, Tav. ii, fig. 6; 4. *Amphithoe aquilina*, Tav. ii, fig. 7; 5. *Amphithoe tenelta*, Tav. ii, fig. 8, which, with the two preceding species, may be called *Hyale gazella*, Costa himself noticing that *aquitina* is intermediate between the other two; in Section AA, 6. *Amphithoe inæquipes*, Tav. ii, fig. 10, already established in 1851; 7. "*Amphithoe Pausylipi*," a change in the spelling of "*Amphithoe Pausilipæ*," M.-Edw., 1830; 8. *Amphithoe crassicornis*, Tav. iii, fig. 1; 9. *Amphithoe penicillata*, Tav. ii, fig. 9, which is probably a synonym of "*Amphithoe Vaillantii*," Lucas, 1849 (see Note on Catta, 1876); 10. *Amphithoe gracilis*, Tav. iii, fig. 4;

11. *Amphithoe elongata*, Tav. iii, fig. 5 ; 12. *Amphithoe micrura*, Tav. iii, fig. 2, referred by Spence Bate to *Pherusa fucicola*, Leach ; in agreement with Costa's own suggestion ; 13. *Amphithoe semicarinata*, Tav. iii, fig. 3, identified by Heller with *Gammarella brevicaudata*, M.-Edw., Costa himself suggesting that it may be the female of his own *Gammarus punctimanus*, for which see below.

The genus *Elasmopus* is thus defined :—

“*Antennæ superiores bisetæ ; inferiores articulo primo inermi. Pedes quatuor anteriores prehensiles, secundi primis maiores ; sex postici elati, laminares, articulo ultimo tantum tereti.*”

By Spence Bate and J. V. Carus this is made a synonym of *Podocerus*, Leach, but Boeck points out that the cleft telson, the laminar branches of the third uropods and the large side-plates exclude that identification. The type species is *Elasmopus rapax*, Tav. IV. fig. 5.

In the genus *Gammarus*, Fab., Costa mentions numerous species ; 1. *Gammarus locusta*, Fab.; 2. *Gammarus marinus*, Leach ; 3. *Gammarus fluvialis* (to which he gives the confused synonymy, “*Astacus fluvialis*, Roes.—*Squilla pulex*, Deg.—*Gammarus Roeselii*, Gerv.—*Gammarus fluvialis*, Edw.”) ; 4. *Gammarus plunicornis*, Tav. IV. fig. 1 ; 5. “*Gammarus Olivii*,” M.-Edw. ; 6. *Gammarus pulex* (with the synonymy, *Cancer pulex?* Lin.—*Gammarus pulex*, Fab.—*Gammarus fluvialis*, Edw. An. Sc. nat.—*Gammarus pulex*, Zenk., Edw. Suit. à Buff.) and the remark “Trovasi nelle acque dolci, al pari del *gamm. fluvialis*” ; 7. *Gammarus unguiserratus*, Tav. IV. fig. 2, accepted as a *Gammarus* by Sp. Bate and J. V. Carus, though the back “perfettamente liscio” does not agree with their definition of the genus, while by the upper antennæ much longer than the lower, the side-plates not very deep, and the three pairs of uropods reaching equally far back, it establishes a provisional claim to stand in the genus *Mæra* (Leach) Sp. Bate ; 8. *Gammarus longicaudatus*, Tav. IV. fig. 6, already mentioned in Hope, Catal. p. 45, a species “trovato nelle acque potabili fluenti della città,” apparently identical with *Niphargus aquilex*, Schiödte ; 9. *Gammarus montanus*, Tav. IV. figs. 7, 8, also from Hope's Catalogue, “raccolto nel lago del Matcse,” and said to come very near the preceding species, but to differ essentially in the third uropods “notabilmente più corti, sorpassando di poco quelli del quarto [anello] ; per modo che il primo articolo dell' appendice primaria è poco più lungo del peduncolo, ed il secondo è poco più della metà del primo,” differences perhaps not of the highest importance (see Bate and Westwood, i. pp. 315, 317) ; 10. *Gammarus obtusunguis*, A. Cost. (n. sp.) Tav. III. fig. 8, referred by Heller to *Gammarella brevicaudata*, M.-Edw., as the male form, and so accepted by Carus on the authority of Sp. Bate, who however retains *Gammarus obtusunguis*, Costa ; Heller's identification being indeed not a little doubtful from the great difference between the second gnathopods of Costa's form and those of *Gammarella brevicaudata*, ♂, as generally known ; 11. *Gammarus scissimanus*, Tav. III. fig. 7, named by Heller *Mæra scissimana*, and clearly the same as *Amphithoe truncatipes*, Spinola, from Italy, mentioned in White's Catalogue, 1847, and afterwards described as *Mæra truncatipes* by Sp. Bate, in 1862, Costa's specific name *scissimanus* therefore taking precedence ; 12. *Gammarus punctimanus*, Tav. III. fig. 6, referred by Heller, no doubt correctly, to the male of *Gammarella brevicaudata*, M.-Edw., the likeness to which is noticed by Costa himself ; 13. *Gammarus bispinosus*, Tav. III. fig. 9. The Brit. Mus. Catal., p. 224, gives *Gammarus punctatus*, Costa, seemingly by mistake for *Gammarus punctimanus*, with the observation, “Costa says that it is nearly allied to *Gammarella brevicaudata*. It appears to me to be nearly allied to the genus *Melita*.”

The genus *Ceradocus* is thus defined :—

“*Antennæ superiores bisetæ ; inferiores processu trabeculiformi cuspidato, cum earum pedunculi articulo primo articulato anteaque porrecto præditæ. Pedes quatuor anteriores prehensiles, secundi multo maiores ; sex postici articulo primo tantum dilatato.*” The process of the

lower antennæ, from whieh Costa derived the name, and, as he thought, the most striking peculiarity, of this genus, is rarely absent from the Gammarina. Spence Bate made the genus a synonym of *Melita*, Leach, Grube referred it to *Megamora*, Spence Bate, and Heller to *Mara*, Leach. The type species *Ceradocus orchesiipes*, Tav. iv. fig. 4, becomes *Mara orchesiipes*.

In the genus *Leucothoë*, Leach, Costa describes *Leucothoe denticulata*, A. Costa, with a reference to "Fn. Nap. Tav. ix., fig. 3. (senza testo)," and the remark that it is "diversa dalla *L. furina* per le proporzioni degli artieoli delle antenne, e pel margine unguicolare dell mani del secondo paio fornito di dentelli più fini e tutti eguali." It has been identified with *Leucothoe spinicarpa*, Abildgaard, from whieh *Leucothoe furina*, Savigny, is only separated by subtle distinctions. Costa points out that his *Leucothoe parthenopaea*, in Hope's Catalogue, needs confirmation.

A fresh definition is given of *Erithonius*, Milne-Edwards, in which genus Costa describes, 1. *Erithonius difformis*, Milne-Edwards, *Mas*, and 2. *Erithonius bidens*, A. Costa, Tav. iv. fig. 9, which J. V. Carus names *Cerapus bidens*, while Boeck makes it a synonym of *Cerapus abditus*, Templeton. S. I. Smith having shown that *Cerapus* is distinguished from *Erithonius* by having the second uropods uniramous, the species assigned to either of these genera without description of the pleon are left in confusion. The peculiar form of the second gnathopods in the male seems to be common to both genera.

After mentioning *Podocerus calcaratus*, Rathke, Costa defines the genus *Microdeutopus* as follows:—

"Antennæ superiores seta multi articulata terminata; setaque accessoria rudimentali prælitæ; inferiores pediformes. Pedes quatuor anteriores prehensiles; primi paris majores, in sexubus difformes, (mas) carpo maximo, manu parva, unguiculum gerente: (fem.) manu majora fere ut in g. *Amphithoe*: secundi minuti, filiformes." The type species is *Microdeutopus gryllotalpa*, A. Costa, Tav. iv. fig. 10.

Corophium acherusicum, A. Costa, is not figured, but thus described:—"Antennæ superioribus brevioribus et gracilioribus; inferioribus corporis fere longitudine, validissimis, pedunculi articulo tertio infra ad apicem spinis duabus vel tribus decrescentibus armato (mas); brevioribus, minus crassis, inermibus (fem.); pedibus secundi paris ungue infra bidentato.—Long. lin. 2." Boeck and Carus doubtfully identify this with *Corophium crassicorne*, Bruz.

In the "Amphipodi anomali," Costa gives *Vibilia speciosa*, A. Costa, and a reference to Fn. Nap. tav. ix. fig. 1 (senza testo). Carus gives as doubtful synonyms of "*Vibilia Jeangerardi*," Lucas, both this species and *Vibilia mediterranea*, Claus.

Hyperia pupa, A. Costa, Tav. iv. fig. 11, is thus described:—"Pedibus quarti paris illos tertii paulo superantibus, quinti paris ceteris distinete longioribus; sexti et septimi decrescentibus: pedibus spuriis abdominalibus quintis quartis brevioribus, sextis pedunculo brevissimo, appendicibus valde inæqualibus, interna majori laminam apicalem paulo superante, externa augusta quarto breviore.—Long. lin. 3½." Unfortunately only a gnathopod and part of the pleon are figured, but there is enough to show that this species does not belong to *Hyperia*, but more likely to a genus of the Lycæidae.

Costa further mentions *Phrosina semilunata*, Risso, *Phronima sedentaria*, Forsk., and *Typhlos ovoides*, Risso.

1857. HUXLEY, THOMAS HENRY, born 1825 (Hagen).

Medical Times and Gazette. Vol. XXXVI. p. 467. 1857.

Bate and Westwood, vol. i. p. xvi, say that Professor Huxley here gives the name of *Endophragmal archi* to the long processes in the head of *Talitrus*, by whieh the stomach is supported in its position.

1857. KIRKBY, J. W.

On some PERMIAN FOSSILS from DURHAM, Plate VII. The Quarterly Journal of the Geological Society of London. Volume the Thirteenth, 1857. London. MDCCCLVII. pp. 213–216.

For a fossil from the Magnesian limestone of Durham, which Kirkby considers to be the same as *Trilobites problematicus*, Schlotheim, and *Palaeocrangon problematica*, Schlauroth, he gives the name *Prosoponiscus problematicus*, deriving the new generic name “from πρόσωπον a face or mask, and ὄντος, oniscus,” as better expressing the affinities of the fossil. “In all,” he says, “six specimens have been obtained; two from Humbleton Quarry, three from Field House, Ryhope, and one from Tunstall Hill.” He does not say on what he relies for the generic characters, but describes the fossil as follows:—referring first to a specimen “showing the cephalic segment or carapace, with two body-segments attached (Pl. VII. figs. 1, 2, 3).”

- “The carapace is about as long as four of the succeeding body-rings, somewhat less in depth, and slightly compressed laterally; it is carinated along the back and wedge-shaped in front; the eyes are large, round, and prominent, and are placed far forward; from the lower part of each eye runs an indented line, at a short distance from the margin, up to the dorsal region, where it curves forward.
 - “The other five specimens consist of body-rings (2 to 6 in number) and the two great posterior or caudal segments; and are very similar to the figures given by Schlauroth. In one of the Durham specimens (fig. 7) there are six body-rings, and two posterior segments; the others (figs. 4, 5, 6) have likewise the two latter segments, but not so many of the former. The body-segments are narrow, almost uniform in size, but varying a little in depth, the central ones appearing to be the most produced; they overlap each other and the penultimate segment posteriorly; they are slightly compressed, and have traces of a median dorsal ridge; those in front have their extremities turned a little forward, while the posterior ones are bent in the contrary direction. The large penultimate segment is greatly developed laterally; it is strongly carinated dorsally; its ventral margins are slightly convex, as is also the posterior border, which has a deep notch not far from the dorsal ridge; the ridge or keel of this segment is very prominent except anteriorly, where at each side of the dorsal ridge is a transverse swelling; it is compressed also posteriorly. The next segment, which is the hindermost known, is more compressed than the preceding one, and considerably smaller.
 - “None of the English specimens show the true external surface, nor have any traces of feet or of antennæ been found.
 - “The specimen with the carapace (figs. 1–3) is one-eighth of an inch long. The largest of those with the body-segments only (fig. 4) is nearly half an inch in length.”
- Since *Prosoponiscus* is no more appropriate to an Amphipod than *Palaeocrangon*, it is obvious that Schlauroth's earlier name must take precedence.

1857. LEYDIG, FRANZ.

Lehrbuch der Histologie des Menschen und der Thiere. Frankfurt a/M. 1857.

Leydig in 1878 gives references to this work, pages 341, 342, 362, 441, with regard to the adipose body, the liver, and the circulation in *Gammarus*.

1857. LINDSTRÖM, G.

Note on the Invertebrate Fauna of the Baltic Sea. By G. Lindström. The Annals and Magazine of Natural History. Number CXIV. pp. 496–497. Vol. XIX.—Seeond Series. London, 1857.

This is a good resumé of the account given by Lindström in 1855, Öfv. K. Vet.-Ak. Förh., pp. 49–73, of life at various depths in the Baltic. A reference for a like account is given to the “Bibliothèque Univ. de Genève, January 1857, p. 71.”

1857. LUCAS, HIPPOLYTE.

Animaux nouveaux ou rares reueillis pendant l'expedition dans les parties centrales de l'Amérique du Sud, de Rio de Janeiro à Lima, et de Lima au Para; executée par ordre du gouvernement françois pendant les années 1843 à 1847, sous la direction du comte Francis de Castelnau. Tome troisième. Entomologie par M. H. Lucas. Paris, 1857.

At page 13 he describes *Lysianassa magellanica*, with a reference to “Ann. des sc. nat., 3^e série, t. ix, p. 398,” and figures it “de grandeur naturelle,” pl. i. fig. 3. “Longueur, 70 millim., largeur, 31 millim.”

Schiødte remarks upon the Amphipoda at page 72, "Den almindeligste grønlandske Tanglopp er ligesom paa vore Kyster *Gammarus locusta* Mont. (*Oniscus pulex* Fn. grønl. 231). Som en Art, der ogsaa undertiden stiger op i Tangen og ligeledes er aadselædende, nævner Fabricius en *Oniscus cicada* n. 233), der af Krøyer ansees for at være en Anonyx og nærmest A. gulosus Kr. (Naturh. Tidsskr. N. R. I. 611); hvorledes den samler sig ved Blodet af en draebt Sælhund og om dens Krigsforhold til *Gammarus locusta* berettes p. 256 og 259. Som forekommende par Strandbredderne nævner Fabricius endnu to andre, ikke nærmere bekendte Amphipoder, *Oniscus arenarius* n. 234 og *O. Stromianus* n. 235."

1857. SCHUR.

Systematische Aufzählung der Crustaceen, Araehnidien und Myriapoden welche ich bisher in der Umgebung von Trier aufgefunden habe. Jahresbericht der Gesellschaft für nützliche Forschungen zu Trier vom Jahre 1856. Trier, 1857. pp. 53–55.

He only mentions one Amphipod:—"Gammarus Pulex (Canc. pulex L.). In Quellen und Bächen; nicht selten."

1857. STIMPSON, WILLIAM.

On some Californian Crustacea. Proc. Califor. Acad. Nat. Sci. Vol. I. 1854–1857. (April 28, 1856). 2d Edition. San Franeiseo. 1873. pp. 95–99.

The species here described are "*Caprella Californica*," *Corophium spinicorne*, "*Orchestia Traskiana*," *Allorchestes seminuda*, *Mæra confervicola*, for all of which see next paper.

¹ "Det turde fortjene en nærmere Undersøgelse, om den af Fabricius og Prof. Krøyer beskrevne, paa Keporkaken (*Balænoptera boops*) levende *Cyamus* virkelig er samme Art som ægte *Cyamus Ceti Lin.* fra Grønlandshvalen."

1857. STIMPSON, WILLIAM.

The Crustacea and Echinodermata of the Pacific Shores of North America.
[Extracted from the Journal of the Boston Society of Natural History, Vol. VI.]
Riverside, Cambridge. 1857. 92 pages. Pl. xviii.-xxiii. Amphipoda, pp. 73-82.

Cuprella californica is accepted somewhat doubtfully by Boeck. Mayer, without definitely uniting Boeck's species with Stimpson's, refers each to *Ulinearis* L. *Corophium spinicorne*, Stimpson, was apparently unknown to Spence Bate, as in the Brit. Mus. Catal. he makes a new *Corophium spinicorne*, which Boeck identifies with *Corophium crassicorne*, Bruzelius. *Corophium salmonis*, which Stimpson took, "not in a very good state of preservation," out of the stomach of a salmon, had almost better have been left there, instead of being drawn forth to create a very indistinct species. *Erichthonius rapax*, n. s., here described, is redescribed by Boeck in his Californian Amphipod-fauua, and transferred to the genus *Cerapus*, but if S. I. Smith's definition of the latter genus be accepted, Stimpson's name *Erichthonius rapax* must be restored, as the second uropods are biramous. *Orchestia scabripes*, Dana, is here referred to *Megalorchestia*, Brandt, which is superseded by the earlier *Orchestoidea*, Nicolet. *Megalorchestia californiana*, Brandt, is here distinguished from *Megalorchestia scabripes*, in common with which it is referred to the genus *Orchestoidea* in the Brit. Mus. Catal. *Orchestia californiensis*, Dana, 1854 [1856], is here mentioned, a species which does not appear in the Brit. Mus. Catal. *Orchestia traskiana* is described, and distinguished from two closely allied species, *Orchestia pugettensis*, and *Orchestia pickeringii*, Dana. *Allorcheses seminuda* is described and distinguished by minute characters from *Allorcheses pugettensis*, Dana. *Allorcheses plumulosus*, n. s., is distinguished from *Allorcheses seminula* by characters doubtfully of specific value. Both species are described as common at San Francisco. Dana's species *Allorcheses angustus*, *Gammarus pugettensis*, and *Iphimedia pugettensis*, and Brandt's *Gammarus silchensis* and *Gammarus atchensis* are recorded. *Moera confervicola*, Stimpson, is renamed *Gammarus conferviculus*. It "differs from *G. Atchensis* in the smoothness of the dorsal surface of the first three abdominal segments." The last species described is *Phoxus grandis*, n. s. Like several others from this paper, it is not recorded in the Brit. Mus. Catalogue. The description is as follows:—"This species is of a much larger size than is usual in the genus. Body broad and robust. Rostrum lamelliform, expanded over the bases of the superior antennæ, with a broadly rounded extremity. Superior antennæ bi-flagellate, the inner flagella very little smaller than the outer ones; both 12-articulate; penultimate article of peduncle entirely concealed beneath the rostrum. Inferior antennæ a little longer than the superior ones; terminal article of peduncle broad at its extremity where its outer angle is produced and rounded; its inner angle bearing the 15-articulate flagellum. Eye transversely oblong. Feet covered with simple hairs. Those of the first and second pairs with small subcheliform hands; those of the third and fourth pairs with the third and fourth articles dilated, the fifth slender, the sixth very small. Feet of the posterior three pairs very much widened; those of the sixth pair largest. Caudal stylets of the first and second pairs with short styliform rami, the inner ones being a little shorter than the outer ones; those of the third pair with long, flattened, equal rami, the outer ones spinulose along their outer edges, both fringed with long setæ on the inner sides. Terminal caudal spines of considerable length. The color is yellowish-white. Length, half an inch. It was dredged on a sandy bottom in ten fathoms, in the channel near the entrance of San Franeisco Bay."

1857. VALETTE ST. GEORGE, ADOLPHE JEAN HUBERT, Baron de la, born November 14, 1831 (Valette).

De Gammaro puteano. Dissertatio inauguralis. Accedunt duæ tabulæ æri incisæ. Berolini, 1857. pp. 5–16.

The *Gammarsus puteanus*, Koch, of this dissertation is referred by Bate and Westwood to *Niphargus aquilex*, Schiødte. La Valette gives numerous measurements of the animal at different ages and in both sexes, as well as of various parts of it. The statement of Hosius that the third joint of the mandible-palp in all Gammari ends in an incurved nail will not, he says, apply to *Gammarus puteanus*. He never found more than two articulations in the secondary flagellum of the antennæ. In the very short, leaf-like branch of the third uropods, he could not find the plumose seta described by Caspary, though he found, as Caspary had done, several setæ on the long two-jointed branch. He corrects some oversights committed by Milne-Edwards and Hosius in regard to the telson, and denies the statement of Caspary that the first peræon-segment carries branchiæ, and of Hosius that all the feet but the first are furnished with them, there being in fact only five pairs.

He reckons 12 ganglia in the nerve-chain; refers doubtfully to the cone at the base of the 2d antennæ as subservient to the sense of hearing; describes the organs on the antennæ since known as "ealceoli," questioning whether they may be olfactory organs, and remarking by the way that their size increases towards the end of the antennæ, which, however, I may say, is certainly not the case in all Amphipods. He describes the œsophagus, stomach and intestinal canal, mentions the liver-tubes as having been already observed by Siebold and Leydig in *Gammarus pulex*, and further states that the intestinal canal about the beginning of the fourth pleon-segment sends forth two cæcal tubes directed forwards. He thinks that these may have a renal function, but cannot decide the question, not having succeeded in obtaining evidence of the presence of uric acid. Together with other anatomical observations he notices that the heart has three pairs of lateral valves for the introduction of the venous blood, situated in the second, third, and fourth peræon-segments. For his priority in this observation, Delage by an oversight has omitted to give him his due credit.

1857. WHITE, ADAM.

A popular history of British Crustacea; comprising a familiar account of their classification and habits. London, 1857.

In the preface White says, "the general arrangement is that of the classical 'Histoire Naturelle des Crustacés,' by Professor Milne-Edwards. Among the *Amphipoda*, I have been chiefly guided by Mr. Spence Bate's synopsis, published in the February number of the 'Annals and Magazine of Natural History.' Of the 'Division EDRIOPHTHALMA, Leach,' the two Orders, Amphipoda and Læmodipoda, occupy from page 158 to page 220.

Of *Talitrus locusta* he says, "it is to this species Archdeacon Paley alludes in the 26th chapter of his 'Natural Theology,' as an instance of the abundance of happiness in the lower creatures." The notion appears to be that as children skip when they are in good spirits, the skipping of Talitri must be due to mental emotion rather than the structure of their tails. Mr. Halliday's observation, Ent. Mag. iv. 252, is cited, that a small beetle, *Cillenom laterale*, feeds on this sandhopper.

On plate x., which is due to Mr. Spence Bate, there is figured *Orchestia littorea*, var., which Spence Bate subsequently identified both with his own *Orchestia laevis*, and the earlier *Orchestia mediterranea*, Costa.

As first genus in the family Gammaridae, *Opis*, Krøyer, is here mentioned, on account of a species from Ireland, said to be *Opis typica*, which does not appear in the Synopsis. "Montagu monoculoides, Montagu, sp." is figured. In the genus *Anonyx*, is introduced, besides the species of the Synopsis, "*Anonyx albus*. A small species, of a white colour; has been found at Clevedon, in Somersetshire, by the Rev. A. Norman. It is perhaps to this genus that the *Gammarus nolens*, Johnston, Zool. Journ. iii. p. 179, may be referred; it is about three or four lines long; the antennæ have a whorl of short spines at each joint; the arms and legs are monodactyle. It is found at Berwick amongst confervæ." *Anonyx elegans*, Thompson, another species not mentioned in the Synopsis, likewise appears here. "*Anonyx Edwardsii*," is figured as Krøyer's, on the authority of Spence Bate, but wrongly according to Boeck, 1870, and Sars, 1882. *Tetromatus typicus*, Spence Bate, is figured.

White notes that the name *Westwoodia* is pre-occupied among Hymenopterous insects. *Iphimedia obesa*, Rathke, is figured, pl. x. fig. 6. "*Acanthonotus Owenii*" of the Synopsis is here given as *Acanthonotus testudo*; the name which White himself gave to the species afterwards known as *Epimeria cornigera*, Fabr. After describing *Dexamine spinosa*, figured pl. x. fig. 7, White says, "to the genus *Dexamine* belongs the *Cancer carino-spinosus*, Turton, which Mr. Spence Bate has more fully described under the name *Gammarus Moggridgei*." In regard to Bate's "*Lembos Websterii*," which has "first hand with a thumb on propodos," and his "*Lembos Damnoniensis*," which has "first hand with a thumb on carpus," he merely says, "Mr. Bate has described two other species from the south of England—*L. Websterii* and *L. Damnoniensis*—both furnished with a thumb on the first hand," as though it was indifferent whether the thumb was on carpus or propodos.

He omits, not without reason, the description in the Synopsis of *Gammarus pulex*, Fabr., borrowed from Milne-Edwards. He also omits the "*G. l. subterraneus*, Leach," and accepts *Gammarus maculatus*, Johnston, without hesitation.

The "*Niphargus Stygius*," of Westwood, he changes into *Niphargus aquilex*, Schioedte, and asks whether this may not be the *Gammarus subterraneus* of Leach.

He notices under *Bathyporeia*, Lindst., that "Mr. Spence Bate now refers his genus *Thersites* to this, and the species *T. Guilliamsoniana* to *Bathyporeia pilosa*."

Leucothoe procura, Spence Bate, at its author's own instigation, is identified with *Leucothoe furina*, Savigny.

Some account is given from Say of *Cerapus tubularis*, though not a British species, to introduce an account from Gosse of his *Cerapus whitei*. D'Orbigny's account of *Corophium longicorne*, figured pl. xi. fig. 1, is quoted from, and mention made that Gosse had taken *Unciola irrorata*, Say, in our seas.

Jassa pelagica, Leach, figured pl. x. fig. 8, and *Jassa fulcata*, Montagu, are given, with a notice that "Mr. Spence Bate believes that this genus [*Jassa*] is founded merely on females of the preceding" [*Podocerus*], and the further remark that "it is perhaps to this genus [*Jassa*] that the *Gammarus spinipes* of Dr. Johnston is referable (Zool. Journ. iv. p. 417)."

Under *Amphithoe*, Leach, besides the species assigned in the Synopsis to *Amphitoë*, Leach, White gives "*Amphithoe obtusata*, Leach's Coast Screw," which is Montagu's species, both before and since known as *Melita obtusata*. He also gives *Amphithoe dubia*, evidently as the name of Johnston's *Gammarus dubius* from Berwick, and therefore not to be confounded with *Amphithoe dubia* of the Brit. Mus. Catal., which is the *Anisopus dubius* of Templeton.

The name *Sunamphitoë* is altered to *Synamphithoe*, obviously on philological grounds.

Chelura terebrans, Philippi, is figured pl. xi. fig. 2. Allman's remarks on its habits are quoted.

The "Tribe HYPERITA" is then described as follows:—"Head very large. Mandibles large, generally ending in crests rather than teeth. First pair of jaws, of three joints, the two last lamellar, the thorax of six or seven joints; some of the legs prehensile and of curious

form ; end of abdomen adapted for swimming but not for leaping. The species of this tribe are more or less parasitic, some of them being attached to Fishes, and others to Medusæ." The "Fam. Phronimadæ," and "Fam. DULICHIADÆ, Spence Bate," are placed in this tribe. To the Phronimade he assigns 1. *Hyperia*, with the species "*Latreillii*," Milne-Edwards, figured plate xi. fig. 3, and *oblivia*, Milne-Edwards, remarking that Spence Bate regards "*Hyperia Latreillii*" as synonymous with "*C. Gammarus Galba*" of Montagu ; 2. *Metoecus*, Krøyer, with the species "*Metoecus Medusarum*, O. Fabr., sp.," as described by Gosse ; 3. *Phronima*, with the species *sedentaria*, figured pl. xi. fig. 4, the account of which is followed by the remark, "We have apparently in the British Islands more than one species of the family *Typhiliæ*; they are not well made out. The antennæ in this family are inserted on the lower part of the head, and are folded three or four times on each other." This is no doubt added to explain the omission of *Typhis nolens*, Johnston, which is included in the Synopsis.

The "Fam. DYOPEDIDÆ" of the Synopsis, with the genus *Dyopedos*, Spence Bate, and the two species *Dyopedos porrectus* and *Dyopedos falcatus* here become on Spence Bate's authority "Fam. DULICHIADÆ, Spence Bate," Gen. *Dulichia*, Krøyer, species, *Dulichia porrecta*, Spence Bate, and *Dulichia porrecta*, Spence Bate.

Of "Order II. LÆMODIPODA," White remarks that "Mr. Spence Bate merges this Order in *Amphipoda*." Several of Gosse's observations on the shape and habits of *Caprella* are quoted. The arrangement, not of the Synopsis, but of White's own Catalogue of British Crustacea, 1850, is here followed. *Caprella tuberculata*, Goodsir, is figured pl. xi. fig. 5, a representation which, but for the size of the species, would suggest rather *Caprella acutifrons*, Latreille, than *Caprella tuberculata*, Bate and Westwood, or *Caprella linearis* (Linn.), Bate; the figure appears to have been copied on a reduced scale from Goodsir, with the line indicating the natural size reduced to match ! *Caprella lobata*, Müller, of the Catalogue, does not re-appear. *Caprella spinosa*, Goodsir, is added, and described as similar to *Caprella phasma*, Montagu, but differing "chiefly in the first thoracic segment having five spines." Its segments also, he says, are considerably longer, and adds that "Mr. Bate refers this with doubt to the genus *Protella* of Dana, and to the species named *Ægina longispina* by Krøyer." To *Proto* he adds the species "*Proto Goodsirii*," Spence Bate.

The "Fam. CYAMIDÆ" are thus described :—

"Body depressed, oval. Eyes compound ; two very small ocelli on vertex ; antennæ very close together at the base. Five pairs of legs, more or less prehensile ; second and third joints of the thorax without legs, but bearing very long cylindrical respiratory appendages, which are generally bent over the back. The species of this family are parasitic on the whale and dolphin. They gnaw the rough thick skin of these marine animals more or less deeply. There seem to be several species of *Cyamus*, attacking different parts of the bodies of these bulky beasts, some preferring the head and others the fins and other parts of the body."

"Gen. CYAMUS, Latr. Head small, truncated, united to first thoracic segment. The characters of the genus are those of the family.

"CYAMUS CETI, *Whale Louse* (Plate XI. fig. 6.)—Branchial appendages simple, and furnished at the base with two unequal and pointed upper edges. Under the fins, etc., of the whale.

"CYAMUS OVALIS.—Body much wider than in last, four pairs of branchial appendages in both sexes, those of third ring with a single short slender appendage at the base, those of the fourth ring with two of unequal length. Lives in clusters on the hard projections of head of whale.

"The *Cyamus gracilis* and *Cyamus Thompsoni* are also recorded as British ; the latter was found on a dolphin and is described by Mr. Gosse."

Savigny's mistake about the eyes is retained in the description of the family. The figure of *Cyamus ceti* is criticized by Lütken as not good. Lütken also thinks it quite unreasonable

that English authors should include Roussel's South Sea species, *Cyamus ovalis* and *Cyamus gracilis*, in the English Fauna. Only on the supposition, he says, that the Cyamid parasites on the Southern Whale are possibly also to be found on the Basque Whale, could these species be included in the Fauna of Great Britain.

1858. BATE, C. SPENCE.

Description of Two Rare Crustaceans from the Coast of Durham, one of them a New Species. Transactions of the Tyneside Naturalists' Field Club. Volume IV. Part I. Newcastle-upon-Tyne, 1858. pp. 15–16. Pl. II.

Kroyera arenaria, Spence Bate, the new species, is thus described:—

“Antennæ inferiores quam superiores sunt longiores. Gnathopoda secunda sunt cheliformes; carpi producuntur ultra dactylorum extremitates. Super regiones dorsales posteriores, nullæ dentes.”

“This species differs from the one on which the genus was founded, chiefly in the absence of the earinated dorsal ridge, and in the peculiar form of the second gnathopoda. In *K. Carinata* they are subcheliform, but the *carpi* are produced so that they reach beyond the extremity of the fingers—a peculiarity I never saw in any other Crustacean.” After further description, Mr. Spence Bate says, “this genus belongs to the subfamily *Phoxides*, the habits of which are not much known.” If *Kroyera carinata*, the type species, be identified with *Monoculodes*, the name *Kroyera* would lapse as a synonym, and Boeck's *Pontocrates*, 1860, would take its place. On the other hand Spence Bate's specific name *arenaria* has precedence of Boeck's *norvegicus*, 1860, so that if Boeck is right in identifying his species with Bate's, the species becomes *Pontocrates arenarius*, Spence Bate, sp., with *Œliceros norvegicus*, Boeck, 1860, and *Pontocrates norvegicus*, Boeck, 1870, for its synonyms. But for a different view see Note on J. S. Schneider, 1885.

The other species here mentioned is *Sulcator arenarius*, Spence Bate, properly *Haustorius arenarius*, Slabber, a species by no means rare.

1858. BATE, C. SPENCE.

On the nidification of Crustacea. The Annals and Magazine of Natural History, 3 Ser. Vol. I. 1858. pp. 161–169, 317. Ann. Sci. Nat. ix. (Zool.) 1858. pp. 255–264. Trans. Plym. Inst. & Devon & Corn. N. H. Soc. 1858, pp. 1–9. Pl. I.

Interesting particulars are given in regard to the homes constructed in various ways by creatures belonging to the genera *Cerapus*, *Unciola*, *Siphonacetes*, *Amphithoë*, *Podocerus*, *Corophium*, *Chelura* and *Phronima*. The connection between the animal's structure and the character of its dwelling, in regard to the *Podoceriles*, *Corophiides* and *Chelura* respectively is pointed out. The nature of the habitation of *Phronima sedentaria* had not as yet been decisively made out.

1858. BATE, C. SPENCE.

On some new Genera and Species of Crustacea Amphipoda. The Annals and Magazine of Natural History. 3 Ser. Vol. I. May, 1858. pp. 361–362.

From the Collection of the Royal College of Surgeons are described the following:—

“*Macrocephalus*, n. g.

“*Cephalon horizontaliter porrectum. Antennæ inferiores nullæ. Pedum roxa corpore fusæ.*

Pleopoda posteriora tria duplicatis partibus divisa. *Telson* cylindraceum. *Macrocephalus longirostris* n. s. *M. cephalo* perlunge rostrato (rostro corporis totius $\frac{2}{3}$ longitudinem æquante). *Antennæ* superioribus rudimentariis. *Gnathopodis* primi et secundi parium chelatis. *Carpis* dactylorum apice productis. Presented by Sir E. Belcher.

“*Pleustes*, n. g. *Cephalon* rostro productum. *Antennæ* superiores quam inferiores longiores. *Coxæ* anteriores quatuor permagnæ. *Gnathopoda* subæqualia et subcheliforme. *Pleopoda* posteriora in duplicatis partibus divisa. *Telson* squamiforme. *Pleustes tuberculata*, n. s. *P. pereii* segmentis omnibus, *plei* anterioribus duobus tuberculo dorsali medio ornatis. *Pereii* segmentis posterioribus tribus, *plei* omnibus lateraliter tuberculatis. Segmentis pereii omnibus, *plei* anterioribus duobus coxarum marginibus tuberculatis. *Pereiopodis* posterioribus tribus *caxis* tuberculatis. *Pleopodis* posterioribus appendice interiore permagno.

“*Amphitoë lacertosa*, n. s. Ut genus sed *gnathopodo* secundo permagno et chelato. Arctic regions.

“*Lysianassa bidenticulata*, n. s., *L. antennis* inferioribus superiores non superautibus. *Gnathopodis* primi *propodo carpo* longiore. *Gnathopodis* secundi *carpo propodo* longiore. *Plei* segmento tertio margine posteriori denticulis duobus utrinque producto.”

In the Brit. Mus. Catal., Spence Bate identifies *Macrocephalus longirostris* with the earlier *Oxycephalus armatus*, M.-Edw., which had been made the type of the genus *Rhabdosoma* by Adams and White. *Pleustes tuberculata* is identified by Boeck with *Amphitoë panopla*, Krøyer, and as *Pleustes panoplus*, is accepted as type of the genus *Pleustes*. *Lysianassa bidenticulata*, in the Brit. Mus. Catal., becomes a synonym of *Lysianassa nugax*, but by Miers and G. O. Sars its right to specific distinction is vindicated. Sars names it *Socarnes bidenticulatus*, Bate.

1858. BEMMELEN, A. A. VAN.

Bijdragen tot de Kennis onzer inlandsche Diernamen. (In Bowstoffen v. e. Fauna v. Nederl. II. bl. 132). 1858.

R. T. Maitland in 1875 includes this work in his list of authorities. In regard to *Orchestia litorea*, Leach, he refers to it for the remark that “Deze soort en *Talitrus saltator* worden aan onze stranden zee-luizen, zee-vlooien en strand-vlooien genoemd.”

1858. CHENU, and DESMAREST, E. (See under the date 1874.)

1858. GERSTFELDT, GEORG.

Ueber einige zum Theil neue Arten Platoden, Anneliden, Myriapoden und Crustaceen Sibirien's, namentlich seines östlichen Theiles und des Amur-Gebietes. (Aus den *Mémoires des Savants étrangers* T. VIII. besonders abgedruckt.) St. Petersburg. 1858. pp. 20-31 (280-291), 35-36 (295-296).

The first species mentioned among the Amphipoda is *Gammarus pulex*, de Geer, which he considers to be as much at home in the whole of Siberia as in Europe, while “the *Gammarus* from the hot springs of Natschik in Kamtschatka, of which Brandt makes mention, stands at least very near it, if it be not quite identical.” This comes under section α of the genus, in which “das Innenglied des 6. falschen Fusspaars ist so lang oder mindestens halb so lang als das äußere (Brandt).”

Section β , in which “das Innenglied des 6. falschen Fusspaars ist noch nicht oder höchstens ein Viertheil so lang als das äußere und oft nur rudimentär,” contains the following:—

"Spec. 2. *Gammarus verrucosus*, mh. n. sp. Corpore lateraliter compresso ; thorace et abdomine inermibus, segmentis postabdominalibus praesertim, secundo et tertio, tuberculis numerosis spinosis iustructis ; ramo stylorum caudalium posticorum externo longissimo, margine longe ciliato," found in the Angará at Irkutsk, with *Gammarus atchensis*, Brandt, for its nearest relation. This species is partially described and figured in the Brit. Mus. Catal., but thereby a misapprehension referred to "Brandt, Middendorff's Sibirische Reise." Spence Bate's description of the pleon includes a feature not alluded to by Gerstfeldt in the "infero-posterior angle of the third segment produced into a long upturned tooth." Dybowski, however, in his account and figure of the species, does not give this tooth or anything more than an ordinary angle to the segment in question.

Spec. 3. " *Gammarus Maackii*, mh. n. sp. Corpore lateraliter compresso, thorace et anteabdomine inermibus ; segmentis postabdominalibus singulis duabus vel quatuor carinis spiciosis armatis ; ramo stylorum caudalium posticorum externo longissimo, margine breviter aculeato." It comes near to *Gammarus ochotensis*, Brandt, and is almost as common in the Angará at Irkutsk as *Gammarus verrucosus*. In the Brit. Mus. Catal., where it is figured, it is attributed to Brandt, instead of Gerstfeldt. It is redescribed by Dybowski in 1874, but not figured.

As distinguished from the foregoing species, in which "Die Rückenseite des 4. und 5. Schwanzgürteles erscheint mit Stacheln besetzt," in the following species the fourth and fifth pleon-segments are dorsally "stachellos."

"Spec. 4. *Gammarus cancellus*, Pallas," is described, with "tuberculorum (dorsalium) par quintum maximum." In 1862 Spence Bate took this as type of his new genus *Pallasea*. In 1874 Dybowski again describes it as *Gammarus cancellus*, Pallas, of which he describes and figures a variety named *Gerstfeldtii*.

"Spec. 5. *Gammarus cancelloides*, mh. n. sp.," from the Angará at Irkutsk, is thus described :— "Gammarus Cancello Pall. similis, tuberculis tamen dorsalibus minus elevatis ; a capite ad caudam crescentibus, neque vero pari quinto, sed paribus octavo et nono maximis ; in segmentis thoracis et anteabdominis carinarum lateralium loco tuberculis valde prominentibus." Spence Bate, in the Appendix to the Brit. Mus. Catal., inclines to regard this as a variety of *Pallasea cancellus*, but Dybowski retains it as a distinct species, *Gammarus cancelloides*, Gerstfeldt, of which he gives a description and figures.

"Spec. 6. *Gammarus latissimus*, mh. n. sp.," also from the Angará at Irkutsk is thus described :— "Corpore latissimo, fere onisciformi ; fronte producto et quatuor paribus aculeorum, mediis duobus verrucis impositis, armato ; segmentis thoracis et anteabdominis carinatis et tubercula supra lamielas laterales sita versus declivibus ; segmentis postabdominalibus tuberculis lateralibus destitutis, anterioribus tribus tuberculis dorsalibus, quorum duo posteriora aculeata, praeditis." As already explained, this species was subsequently under a misapprehension attributed to Brandt in the Brit. Mus. Catal., and is there made the type of a new genus *Brandtia*. Dybowski, who had not met with it in Lake Baikal, retains it under the name *Gammarus latissimus*, in 1874.

Among those *Gammari* in which "der Hinterrand des 3. Postabdominalsegmentes und meist auch derjenige der beiden vorhergehenden verlängert sich in der Mittellinie in Art eines Zahnes oder Stachels nach hinten," Gerstfeldt places "Spec. 7. *Gammarus kürgensis* mh. n. sp. Corpore lateraliter compresso, margine posteriore trium anteriorum segmentorum postabdominalium et interdum etiam nonnullorum aut omnium anteabdominis et thoracis in spinam acutam tenuemque segmento sequenti incumbentem producto," "aus einer Pfütze an der Kürge." This does not appear to be mentioned in the Brit. Mus. Catal. Nor does it appear in Dybowski's long list of species from Lake Baikal. The fuller description is as follows :—"Der Körper ist ziemlich stark seitlich zusammengedrückt ; die Stirn hält nur ein kurzes dreieckiges Spitzchen ; die Augen sind oval-nierenförmig. Die nur schwach

bchaarten Fühler haben etwa die halbe Länge des Körpers und von ihnen überragen die oberen mit ihrem letzten Drittheile die unteren; das Ende des Stieles der oberen Antennen reicht nur bis zum Anfauge des letzten Stielgliedes der unteren oder wenig weiter; erstere besitzen an der Hauptgeissel 10–14, an der kleinen Nebengeissel, welche nur wenig länger ist als das erste Glied der Hauptgeissel, 2–3 Glieder; die Geissel der unteren Antennen übertrifft ihren Stiel kaum an Länge und besteht aus 4–5 Gliedern. Die vorderen Füsse sind mit Haaren, Wimpern und Stacheln besetzt. Die vorderen Hände sind kleiner als die hinteren, aber verhältnismässig breiter, rhomboidal und am Vorderrande schräg abgestutzt, wogegen die hinteren grösser und nameutlich länger und fast eiförmig erscheinen; bei beiden Paaren ist der Innenrand an der oberen Hälfte mit kleinen Zähnchen, an der unteren mit stachelartigeu Borsten besetzt.—Der Hinterrand der drei ersten Schwanzsegmente und gleichzeitig zuweilen derselbe Rand aller oder einiger Brustbauchringe verlängert sich in der Mittellinie des Rückens in einen nach hinten gerichteten, feinen, spitzen, dornartigen Fortsatz, welcher dem nächstfolgenden hinteren Segmente aufliegt und nur bei gekrümmter Lage des Rückens sichtbar wird.—Das 4. und 5. mit Stacheln besetzte Afterfusspaar gehen etwas über das Ende des Körpers hinaus und das letzte falsche Fusspaar trägt auf ziemlich langem Basalgliede zwei am Raude mit Stacheln versehene, fast gleich lange Blättchen, die kürzer als die Basis erscheinen.—Die Seitenplatten der Körperringe vor der Basis der Füsse sind verhältnismässig lang.—Die Farbung ist gelblich und die Länge des Körpers beträgt nur $2\frac{1}{2}$ ".

“Von den *Gammarus*-Arten mit nach hinten verlängerten Rückenkielen der ersten Schwanzsegmente, von. *G. Sabinii* Leach, *G. loricatus* Sabine, *G. angulosus* Rathke, *G. (Amathia) carinatus* Rathke, *G. mucronatus* Say (*G. boreus* Sabine, Suppl. to the Appendix of Capt. Parry's first voy. ccxxix. u. Ann. des sc. nat. 1830, xx, p. 368) etc. entfernt sich *Gamm. kürgensis* dadurch, dass er nur feine Stacheln, jene aber höhere zahnförmige Rückenkämme besitzen. Näher scheint ihm in dieser Beziehung *G. albidus* Dana (Unit. Stat. expl. exped. Crust. II., 948 u. Atlas Tab. 65, fig. 4) von Tongatabu zu stehen.”

The principal divisions of the genus *Gammarus* here adopted by Gerstfeldt are taken from Milne-Edwards' Hist. nat. des Crustacés.

1858. HANCOCK, ALBANY, born 1806, died October 24, 1873 (R. Howse).

Remarks on certain Vermiform Fossils found in the Mountain Limestone Districts of the North of England. Annals and Magazine of Natural History. Ser. 3. Vol. II. December 1858. pp. 443–457. Pl. XIV.–XIX. (Read at the British Association Meeting, Leeds, September 22, 1858). Also in Transactions of the Tyneside Naturalists' Field Club. Vol. IV. Part I. Newcastle-upon-Tyne, 1858. pp. 17–33, Pls. III. IV.

The fossil marks are explained by comparison with those which Crustaceans make at present. The tracks or runs of *Sulcator arenarius* are carefully described and figured. On sandy shores upon the north-east coast of England, “they are to be seen,” Mr. Hancock says, “everywhere between tide-marks, but are most numerous about half-way down the beach, on inclined, oozy, glistening spots, where the sand is firm, and yet the moisture so profuse that it mirrors the light.” The phenomenon is far from being confined to the north-east coast; it was moreover noticed by Say in his account of *Lepidactylis*, in 1818. Besides the tunnelling of *Sulcator arenarius*, the surface track of *Kroyera arenaria* is likewise described and figured. It is curious that no mention should be made of the species which, so far as my experience goes, is much commoner than *Kroyera arenaria* in the situations

described, namely, *Bathyporeia pilosa*, which leaves its little labyrinthine tracks, and sometimes short straight ones, in vast numbers over such stretches of sand as Mr. Hancock describes. In regard to the species *Sulcator arenarius* and *Kroyera arenaria*, see Notes on Sp. Bate, 1851, 1857, and 1858.

1858. SAUSSURE, HENRI F. DE.

Mémoire sur divers crustacés nouveaux des Antilles et du Mexique. Mém. de la Société de Physique et d'Histoire naturelle de Genève. Tom. XIV. P. 2. Genève 1858. pp. 417-496. Ordre des Amphipodes, pp. 474-475. Fig. 33.

The new species described is called *Amphitoe aztecus*. "Habite; Le Mexique; pris en abondance dans une citerne de Vera Cruz." W. Faxon says, "After an examination of a large number of *Hyalella dentata* and *H. inermis* from Utah, I am satisfied that they are but varieties of one species. The form with dorsal teeth on the first and second abdominal segments is very probably synonymous with *Amphitoe aztecus* Saussure and *Allorchestes Knickerbockeri* Bate, as pointed out by Professor Smith himself." *Hyalella azteca* will therefore, in my opinion, be the best name for Saussure's species.

1859. BATE, C. SPENCE.

On the fossil Crustacean found in the magnesian limestone of Durham, and on a new species of Amphipod (1858). Quart. Journ. Geol. Soc., Vol. XV. 1859. pp. 137-140, Pl. VI. figs. 1-8. Nat. Hist. Review. VI. 1859 (Proc.) pp. 163-166.

The fossil Crustacean is that supposed to be identical with the *Trilobites problematicus* of Schlotheim and by Schlauroth named *Palaeocrangon problematicus*, which Kirkby changed into *Prosoponiscus problematicus*, thus far the only British fossil Amphipod. See Notes on H. Woodward, 1871 and 1877.

The new Amphipod is *Phædra antiqua*, founded on a damaged specimen, which closely agreed with the fossil fragments. The new genus *Phædra* is thus defined in the Brit. Sess. Crust., vol. i. p. 208 :—

Phædra :—"Cephalon produced anteriorly. Segments of the pereion short, of the pleon long. Superior antennæ shorter than the inferior, furnished with a secondary appendage. Posterior pair of pleopoda considerably elongated, biramous. Telson simple or notched."

1859. BATE, C. SPENCE.

On the genus *Niphargus*, Sehiödte. Dublin Univ. Zool. and Bot. Assoc. Proc. I. 1859. pp. 237-240. Figs. 1-4.

After a discussion of earlier notices of well-shrimps, the new species *Niphargus fontanus* and *Niphargus kochianus* are figured and described, a new genus *Crangonyx* is instituted, with the species, *Crangonyx subterraneus*, to the description of which is appended the remark, "it is not improbable that this may be the *Gammarus subterraneus* of Leach; but we have no means of ascertaining."

The name *Crangonyx* is derived from *κραγγόνυξ* and *νύξ*.

The genus is thus defined :—"Like *Gammarus*, but not having fasciculi of spines upon the

posterior segments of the pleon, and having the posterior pair of pleopoda unibranched. Telson single."

De Rougemont is inclined to unite all these three species under *Gammarus puteanus*, Koch. The matter perhaps is not yet ripe for final determination.

1859? BRUZELIUS, RAGNAR MAGNUS, born 1832.

Bidrag till kännedomen om skandinaviens Amphipoda Gammaridea. Med Taflorna I.-IV. Till k. vet. akad. inlemnad d. 17 mars 1858. K. Svenska Vetenskaps Akademiens Handlingar, 3:dje Bandet N:o 1. (1859-60). Stockholm, 1862. pp. 1-104.

In a brief notice of earlier classifications, Bruzelius explains that he follows Dana, and divides the Scandinavian Amphipoda Gammaridea into four families, Dulichidae, Orchestidae, Corophidae, and Gammaridae, but defines the latter two differently from Dana. He mentions the writings on the Amphipoda with which he was acquainted. He then gives a definition and general description of the group.

In "Familia I. DULICHIDÆ, Dana," he places *Lætmatophilus*, n. g., thus defined:—

"Corpus elongatum, gracile. Antennæ longæ, superiores flagello appendiculari destitutæ et processu magno frontali affixæ. Mandibulæ palpo triarticulato, maxillæ primi paris lamina interna inchoata et tuberculi-formi, palpo biarticulato instructæ. Palps pedum maxillarium e quatuor articulis compositus. Pedes primi secundique paris thoracis manu subcheliformi armati, articulo quinto manum formante, ungne ex uno tantum articulo constante. Reliqui pedes thoracis fere æquales, elongati, graciles, ungnibus validis armati. Pedes abdominales quarti paris elongati, ramis binis styliformibus instructi, pedes quinti paris e singulis articulis constantes." The type species, *Lætmatophilus tuberculatus*, n. s., pl. i. is described.

In "Familia II. COROPHIDÆ, Dana," Bruzelius arranges the genera *Corophium*, "*Erichtonius*," *Jassa*, *Podocerus*, *Autonoe*, *Amphithoe*. To *Corophium*, Latreille, he assigns, 1. *Corophium longicorne*, Fabricius, which he describes; 2. *Corophium crassicorne*, n. s., pl. i. fig. 2; 3. *Corophium affine*, n. s. He next describes *Erichtonius*, as he spells it, with the type-species *diformis*, Milne-Edwards, to which he makes "*Podocerus Leachii*," Kröyer, a synonym.

He re-establishes *Jassa*, Leach, to receive *Podocerus capillatus*, Rathke; but *Jassa*, Leach, had lapsed as a synonym of *Podocerus*, Leach, and the genus *Janassa*, under which name Boeck revives *Jassa*, Bruzelius, is only separated from *Podocerus* by absurdly trivial distinctions. To *Podocerus*, Brñzelius assigns 1. *anguipes*, Kröyer, of which he remarks that *Gammarus zebra*, Rathke, is in all probability the female; 2. *calcaratus*, Rathke, which Boeck makes a synonym of *falcatus*, Montagu.

The new genus *Autonoe* is thus defined:—

"Corpus subdepressum, epimeris medioribns ant parvis. Antennæ superiores graciles, flagello proprio multiarticulato et flagello appendiculari instructæ. Antennæ inferiores non subpediformes. Palpus mandibule triarticulatus, maxillæ primi paris biarticulatus et pedum maxillarium e quatuor articulis compositus. Pedes primi secundique paris manibus instruti. Pedes abdominales ultimi paris biramei, ramis styliformibus."

To this genus Bruzelius assigns, 1. *Autonoe punctata*, n. s., pl. i. fig. 3, which is a synonym of *Aora gracilis*, Spence Bate; 2. "*Autonoe anomala* (Rathke) ?," pl. i. fig. 4, since called *Microdeutopus anomalus*; 3. *Autonoe grandimana*, n. s. pl. i. fig. 5, which Boeck identifies with *Microdeutopus gryllotalpa*, Costa, with which Bruzelius himself compares

it; 4. "Autonoe erythrophthalma (Liljeborg)," for the *Gammarus (Gammaropsis) erythrophthalmus* of Liljeborg, since called *Gammaropsis erythrophthalmus*; 5. *Autonoe longipes*, Liljeborg, for *Gammarus longipes*, Liljeborg, 1852, which Boeck accepts as the type of the genus *Autonoe*; 6. *Autonoe macronyx*, Liljeborg, pl. i. fig. 6, for *Gammarus macronyx*, Liljeborg, 1853, identified by Boeck with *Protomedea fasciata*, Kröyer, 1842. To *Amphithoe*, Leach, Bruzelius assigns the species, 1. *podoceroides*, Rathke, with *albomaculata*, Kröyer, for a synonym, and 2. *pygmæa*, Liljeborg, which Boeck identifies with "*Photis Reinhardi*," Kröyer, 1842.

In "Familia III. ORCHESTIDÆ, Dana," Bruzelius places, 1. *Orchestia*, Leach, with the species *littorea*, Leach, including *Euchore*, F. Müller; 2. *Allorchestes*, Dana, with the species "*Allorchestes Nilsoni* (Rathke)," in the synonymy of which he gives "*Amphithoe Prevosti?*, H. Rathke; *Amphithoe Nilssonii*, H. Rathke; *Orchestia Nidrosiensis*, Kröyer"; remarking also that he feels tolerably certain that Rathke's and Kröyer's species are identical with the one he himself describes, but of Milne-Edwards' he is doubtful, as the figure seems to show two rami on the last nropods. Brandt's subgenus *Allorchestina* he considers unnecessary.

In "Familia IV. GAMMARIDÆ, Dana," Bruzelius describes nineteen genera. The species which he calls *Anonyx nanus*, Kröyer ‡, was called *Anonyx nanoides* by Lilljeborg in 1865, while the *Anonyx minutus*, Kröyer, which he thinks perhaps identical, is called *Orchomene minutus* by Boeck. "*Anonyx Kröyeri*," n. s., pl. ii. fig. 7, was transferred to *Callisoma* by Spence Bate. *Pontoporeia furcigera*, n. s., pl. ii. fig. 8, is said by Sars in 1882 to be the same as the earlier *Pontoporeia femorata*, Kröyer. Bruzelius says that in his species the accessory flagellum of the upper antennæ has three joints as against two in Kröyer's species, and that *Pontoporeia furcigera* is much smaller than *femorata*, while he has always found that in individuals of the same species the number of joints in the flagella increases or diminishes with the size of the animal. Also the fork-like process on the fourth segment of the abdomen is considerably larger than in *Pontoporeia femorata*.

For *Gammarus*, Fabricius, Bruzelius draws up a scheme including thirteen species, which have since been distributed among various genera. "*Gammarus Loveni*," n. s., pl. ii. fig. 9, was transferred to *Mæra* by Spence Bate. *Gammarus lævis*, n. s., pl. ii. fig. 10, was identified by Spence Bate with *Gammarus longimanus* (Leach), Thompson, which Spence Bate places in the genus *Megamæra*. *Gammarus brevicornis*, n. s., pl. iii. fig. 11, is identified in Bate and Westwood with *Liljeborgia pallida*, Speuce Bate.

The new genus *Eriopis*, is thus defined:—

"Corpus elongatum, parum compressum, epimeris parvis. Antennæ superiores pedunculo gracili et flagello appendiculari perpusillo instructæ; inferiores subpediformes. Mandibulæ duobus ramis, tuberculo molari et palpo triarticulato instructæ. Maxilla primi paris palpo biarticulato ornata. Palpus pedum maxillarium e quatuor articulis compositus. Pedes primi secundique paris manu (articulo quinto) subcheliformi armati. Tria paria posteriora pedum thoracis postice gradatim longiora. Rami pedum abdominalium ultimi paris valde inæquales; interior brevis, exterior abdominis longitudinem fere æquans, duobus articulis complanatis instructus." This genus is identified by Boeck with *Niphargus*, Schiødte, 1851, which had hitherto contained only fresh-water species. *Eriopis elongata*, n. s., pl. iii. fig. 12, "habitat in locis profundi maris Bohniæ." This is called by Boeck *Niphargus elongatus*.

The new genus *Paramphithoe* is thus defined:—

"Corpus compressum, epimeris mediocribus aut magnis. Oculi duo compositi. Antennæ superiores graciles, articulo tertio pedunculi articulis flagelli crassiore, sed flagello appendiculari carentes. Mandibula palpo triarticulato. Palpus maxillæ primi paris biarticulatus, pedum maxillarium e quatuor articulis compositus. Pedes primi secundique paris manu subcheliformi instructi. Pedes septimi paris reliquis pedibus uno duplo longiores. Pedes

abdominis ultimi paris biramei, ramis elongatis." To this genus Bruzelius refers nine species; in section *a*, "dorsum magis minusve carinatum, posticum saepe dentibus armatum," 1. *Paramphithoe panopla*, Kröyer, by Bate, Boeck and Sars now called *Pleustes panoplus*; 2. *Paramphithoe pulchella*, Kröyer, by Bate called *Pherusa pulchella*, by Boeck *Pleustes pulchellus*, by Sars, 1882, *Paramphithoe pulchella*; 3. *Paramphithoe hystrix*, Owen, for which see Note on Lepechin, 1780; 4. *Paramphithoe compressa*, Liljeborg, identified by Boeck with "*Atylus Swammerdamii*," Milne-Edwards; in section *b*, "dorsum rotundatum, segmentis duobus aut pluribus postice dentatis;" 5. *Paramphithoe bicuspis*, Kröyer, by Bate referred to *Pherusa*, by Boeck to *Pleustes*, by Sars, 1882, back to *Paramphithoe*; 6. *Paramphithoe tridentata*, n. s., pl. iii. fig. 13, by Boeck in 1870 named *Halirages tridentatus*; 7. *Puramphithoe elegans*, n. s., pl. iii. fig. 14, by Boeck identified with *Dexamine bispinosu*, Spence Bate, under the name *Halirages bispinosa*; in section *c*, "dorsum rotundatum, earina et dentibus destitutum;" 8. *Paramphithoe laeviuscula*, Kröyer, now known as *Calliopus laeviusculus*; 9. *Paramphithoe norvegica*, Rathke, now known as *Calliopus norvegicus*, Rathke. Thus it appears that all the species assigned to *Paramphithoe* by the founder of the genus fall to older genera, with the exception of Owen's *hystrix* and the new species *tridentata*; this latter he defines:—"Caput rostro perpusillo instruetum. Dorsum rotundatum, lave, segmenti septimi thoracis, primi secundique abdominis margine medio posteriore dentem aetum formante. Antennæ superiores inferioribus longissimis multo breviores. Pedes primi secundique paris manu fere oblongo-ovali, medioeris magnitudinis, instructi. Appendix caudalis indivisa, margine posteriore truucato et dentato." If Boeck's *Acanthozone* is accepted as the generic name for Owen's *hystrix*, *Paramphithoe tridentata*, Bruzelius, remains over to represent the new genus, and would, I imagine, take precedence of Boeck's *Halirages*, unless we may argue that the genus instituted by Bruzelius lapsed through the want of any suitable desiguation, coupled with the want of any species selected as the type.

After describing *Acanthonotus serra*, Kröyer, *Dexamine tenuicornis*, Rathke, and *Iphimedia obesa*, Rathke, Bruzelius proceeds to define the genus *Ampelisca*, Kröyer, identifying with it Costa's *Araneops*. He assigns to it six species (1) *equicornis*, n. s., pl. iv. fig. 15; (2) *tenuicornis*, Liljeborg; (3) *lavigata*, Liljeborg; (4) *macrocephala*, Liljeborg; (5) "*Gaimardi*," Kröyer, by Boeck in 1870 named "*Byblis Gaimardi*"; (6) *Ampelisca carinata*, n. s., pl. iv. fig. 16, in which the front part of the back is rounded, and which therefore differs from the *Ampelisca Gaimardi* (*Tetromatus typicus*), Spence Bate, which has "cephalon and pereion laterally compressed and dorsally cuneated."

Bruzelius next describes *Haploops tubicola*, Liljeborg; *Haploops carinata*, Liljeborg; *Bathyporeia pilosa*, Lindström. In the last he has noticed the variations in the antennæ, which subsequently occasioned the institution of new species.

In the genus *Ædiceros*, he describes (1) *Ædiceros obtusus*, n. s., pl. iv. fig. 17, identified by Boeck with *Leucothoe phyllonyx*, M. Sars, under the name *Aceros phyllonyx*; (2) *Ædiceros affinis*, n. s., pl. iv. fig. 18, by Boeck called *Monoculodes affinis*, as also earlier by Spence Bate, who gives it priority over his own *Monoculodes stimpsoni*, whereas J. S. Schneider inclines to identify *Monoculodes affinis*, Boeck, with *Monoculodes stimpsoni*, Bate, and definitely makes *Ædiceros affinis*, Bruzelius, a synonym of *Monoculodes carinatus*, Spence Bate; (3) *Ædiceros saginatus*, Kröyer.

He describes "*Leucothoe clypeata* (Kröyer)?" which Boeck calls "*Metopa Bruzelii*," Goës. Bruzelius notices that his specimens differed somewhat in the antennæ and gnathopods from Kröyer's description, but was content to regard them as the young of Kröyer's species. Sars, in 1882, considers that the form described by Boeck is not the true *Metopa Bruzelii*, Goës, but a distinct species, which he names *Metopa borealis*, distinguished by its more considerable

size, shorter antennæ, and differences in the gnathopods. He gives its length as 3 mm. The length given by Bocck is 2 mm. Bruzelius says the body's length is about 2 mm. *Leucothoe norvegica*, Liljeborg, is next described. Of this he says in a note that it is possibly the male, and *Leucothoe clypeata* the female of one and the same species, an opinion in which Bate and Boeck agree with him.

After describing *Leucothoe articulosa*, Montagu, and " *Laphystius Sturionis*," Kröyer, he defines the new genus *Nicippe* :—

"Corpus crassiusculum, cipimeris mediocribus. Antennæ graciles, superiores flagello appendiculari ornatæ. Mandibulæ dissimiles, palpis e ternis articulis compositis instructæ, altera processu accessorio sive ramo interno carens, altera eodem prædita. Palpus maxillæ primi paris biarticulatus. Pedes maxillares laminis minutis et palpis e quaternis articulis compositis. Pedes primi secundique paris manu subcheliformi armati. Tria paria posteriora pedum thoracis postice gradatim longitudine crescentia. Pedes abdominis sexti paris biramei, ramis uniarticulatis." The type species is *Nicippe tumida*, n. s., pl. iv, fig. 19. Lastly he describes *Pardalisca cuspidata*, Kröyer.

1859. BRUZELIUS, RAGNAR M.

Bidrag till kännedomen om Amphipodernas inre byggnad. Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar. Årg. 16. 1859. No. 1. pp. 1-18. Tafl. I. (Traduit par M. le Dr. Creplin, dans Wiegmanns Archiv für Naturgeschichte, T. 25, Sars.)

The investigations were made upon " *Gammarus locusta*, Linné, and *Amphithoe podoceroides*, Rathke." Sars, 1867, in regard to the inner structure of the Amphipoda, says, " nous devons les études les plus consciencieuses et les plus exactes au savant suédois, M. Ragnar Bruzelius, qui a écrit sur ce sujet un mémoire accompagné d'une planche lithographiée dans 'Öfversigt af Vetenskaps-Akademiens Förhandlingar, 1859.' Ainsi que le lecteur le verra dans la suite, mes recherches sur cette espèce [*Gammarus neglectus*] s'accordent parfaitement, dans tous les points essentiels, avec les communiquations de ce naturaliste, fait qui mérite ici une attention particulière, attendu que les renseignements fournis par d'autres savants, entre autres par M. Spence Bate, semblent s'en écarter sous plusieurs rapports."

1859. DANIELSEN, D. C., born 1815 (G. O. Sars).

Beretning om en zoologisk Reise foretagen i Sommeren 1857. Nyt Magazin for Naturvidenskaberne. 11te Binds 1ste Hefte. Christiania, 1859. (The Volume, "Ellevte Bind," is dated 1861.)

Amphipoda are mentioned on pages 7-9, but without any descriptions. One new species is noted under *Edicerus*, Kröyer, "O. arcticus n. spec. Af denne nye Art fandt jeg nogle faa Exemplarer ved Vadsøe paa sandig Leerbund fra 40-60 Favne." This is regarded by Boeck as a synonym of *Ediceros lynceus*, M. Sars, 1859.

1859. GEGENBAUR, CARL, born 1826 (Carus), 1827 (Hagen).

Grundzüge der vergleichenden Anatomie. Leipzig, 1859. Arthropoden. pp. 193-286.

For an account of this work remodelled, see Note on Gegenbaur, Grundriss, &c., 1878.

1859. GERVais, PAUL, et BENEDEN, P. J. VAN.

Zoologie Médicale. Exposé méthodique du règne animal basé sur l'anatomie, l'embryogénie et la paléontologie comprenant la Description des espèces employées en médecine de celles qui sont venimeuses et de celles qui sont parasites de l'homme et des animaux. Tome premier. Paris, 1859.

The Crustacés are the Classe Quatrième of the "Deuxième Embranchement. Animaux articulés."

Of the "Sous-classe des Crustacés Édriophthalmes," the authors say, page 486, "les Édriophthalmes sont généralement partagés en trois ordres, nommés *Isopodes*, *Amphipodes* et *Lémodipodes*, auxquels on en ajoute maintenant un quatrième pour les *Pycnogonides*, qui semblent être, à plusieurs égards, un arrêt de développement des Lémodipodes cyamidés." This view of the *Pycnogonides* is no longer generally held. On page 488, they define the Ordre des Amphipodes, dividing it into two families, "les *Gammaridés* et les *Hypéridés*." To the former belongs the genus Crevette (*Gammarus*), of which they have at least three species in France, "deux d'entre elles vivent dans les eaux d'eau et dans les étangs (*Gammarus pulex* et *Roeselii*) ; ce sont ces Crevettes que l'on trouve souvent dans le cresson. La troisième n'a encore été observée que dans l'eau de puits. Elle est plus petite que les précédentes et étiolée. Nous l'avons appellée *Gammarus lacteus*." This can scarcely be called a scientific description of a new species; but see Notes on Gervais, pp. 156, 160.

In the family of the Hyperidés, les Phronimes (g. *Phronima*) are mentioned with the species *sedentaria*. The Lémodipodes are divided into, "1° les Caprellidés," with the genus *Caprella*, and "2° les Cyamidés," after briefly defining which they say, "L'ancien genre CYAME (*Cyamus*), qui constitue à lui seul cette famille, comprend plusieurs espèces que l'on trouve sur le corps des grands Cétacés. On les nomme *Poux de Baleines*. "Le Cyame du Dauphin (*Cyamus delphini*, Guérin) doit former un autre genre que nous nommons *Isocyamus*." Nothing is said of the characters of this new genus. The Pyenogonides, among other habitats, live "sur le corps des poissons."

1859. HOGAN, ARTHUR R.

On the habits and localities of *Niphargus fontanus* (*n. s.*), *N. Kochianus* (*n. s.*), and *Crangonyx subterraneus* (*n. g. & s.*), Spence Bate. The Natural History Review, and Quarterly Journal of Sciencee. Vol. VI. 1859. London, 1859. pp. 166–169.

This paper discusses the habits, food-supply and habitat of the species described in the immediately preceding paper by Spence Bate. As to their food, Mr. Hogan says, "some water drawn from the pump at Ringwood, has been proved, by microscopic examination, to contain numerous animalcules; and this will probably turn out to be the case with all other waters in which Niphargi are found." Some six or seven specimens of *Niphargus aquilex*, from a well near Tunbridge Wells in Kent, lived in my room from January 28, 1886, till March 3, 1886. As they all died at about the same time, it may have been the coldness of the night which killed them. Though they were very active in walking about the bottom of their jar, whenever I happened to look at them during their life-time, I never saw them attempt to swim. Another set of about a dozen were placed in a jar, $5\frac{1}{4}$ inches high by $2\frac{3}{4}$ inches broad, on June 15th, 1886. Two of these were females with eggs. These two died within a couple of days, surrounded by some rapidly developed parasitic growth.

The rest lived on for a considerable time, the last not dying till November 24th, 1886. The water in which they were at first placed came from their native well, and contained a very little sediment. Every four days a small portion was poured away and replenished with water from the town waterworks.

1859. KINAHAN, JOHN ROBERT, born 1828, died February 2, 1863 (Busk).

Notes on dredging in Belfast Bay, with a list of species. (Proceedings of Dublin Natural History Society.) The Natural History Review, and Quarterly Journal of Science. Vol. VI. 1859. London, 1859. pp. 79–85.

In the list of Crustacea Amphipoda, Professor Kinahan avails himself of a list of William Thompson's collection furnished him by Spence Bate. Twenty-eight names of species are given, among them being *Orchestia lavis* and *Orchestia deshayesii* (Savigny). *Gammarus fluvialis* is mentioned and distinguished from *Gammarus pulex*, but the proper use of the names is evidently inverted. "*Hyperia Galba*" was found "in thousands in Acalephæ, floating through the Bay." The next entry is "*Lestrigonus Fabricii* (?).—This occurred with the last, but in fewer numbers. It is singular that in the supplement to Parry's 'Voyage,' this is figured as having occurred also along with the last. Can there be any intimate connexion, such as sexual, between them? I find some trifling differences between my specimen and *L. Fabricii* (Milne-Edwards), but await my friend Spence Bate's judgment on the point. I strongly suspect that Gosse has mistaken this animal for *Metoicus medusarum*, the distinction between the genera being such as to easily cause a mistake. This is doubtless the species W. Thompson failed to identify, owing to the bad condition of his specimens." The name borrowed from Milne-Edwards should no doubt have been "*Lestrigonus Fabricii*," not "*Lestrigonus Fabricii*."

1859. LACHMANN, JOHANNES.

Über einige Parasiten des Brunnen-Flohkrebse (Grammarus puteanus). Sitzungsberichte der niederrheinischen Gesellschaft für Natur- und Heilkunde zu Bonn. Sitzung vom 2. März 1859. Verhandlungen des naturhistorischen Vereins der preussischen Rheinlande und Westphalens. Sechszehnter Jahrgang. Neue Folge: Sechster Jahrgang. Bonn, 1850. (Appendix ? pp. 33. 37.)

Grammarus is obviously in error (maintained throughout the paper), for *Gammarus*. The parasites found by Lachmann in the intestine (Darm) of the well-shrimp, are said to belong to the puzzling group of the Gregarines.

1859. SARS, MICHAEL, born 1805, died 1869 (G. O. Sars).

Oversigt over de i den norsk-arctiske Region forekommende Krebsdyr. Forhandlinger i Videnskabs-Selskabet i Christiania Aar 1858. Christiania 1859. pp. 122–163. Amphipoda, pp. 129–150.

The Amphipoda recorded are; 29. *Anonyx ampulla* (Caucer) Phipps; 30. *Anonyx gulosus* Krøyer; 31. *Anonyx Vahlii* Krøyer; 32. *Anonyx Holboellii* Krøyer; 33. *Stegocephalus* spec.,

a species found by Krøyer but left indeterminate; 34. *Pontoporeia femorata* Krøyer; 35. *Pardalisea cuspidata* Krøyer; 36. " *Ampelisea Gaimardii*" Krøyer; 37. " *Ampelisea Eschrichtii*" Krøyer; 38. *Ampelisea lævigata* Liljeb.; 39. *Amphithoë serra* Krøyer, with the remark that the fourth side-plate is much too small in the figure in Krøyer's Grønl. Amphip., it being both in Norwegian and Greenland specimens, which Sars had examined, double as long as the third and somewhat deeper. 40. *Amphithoë eristata* (*Aeanthonotus*) Owen, a species said to be very like *Amphithoe serra*, but still more like a remarkable new species from the coast of Norway, *Amphithoë parasitica*, which is fully described, the Latin description being:—" *A. serræ affinis, dignoscitur carina in medio dorso segmenti thoracici quinto oriunda et usque ad segmentum quartum abdominis porrecta, postice in quoque segmento in dentem triangularem acutum desinente; oculis magnis, paululum ovalibus, convexis; epimero quarto et quinto insolitu magnitudine, anterioribus duplo longioribus, quarto infra et antice, quinto infra et postice in spinam fortem conico-acuminatam exente (in epimero quarto uncinatam, in quinto rectam); pedibus thoracicis primi et secundi paris magnitudine mediocri et manu subcheliformi præditis; antennis fere æqualibus aut inferioribus paulo longioribus, dimidiam longitudinem corporis parum superantibus.*" This species was referred to *Acanthosoma* by Boeck in 1860, to *Aeanthonotus* by Sp. Bate in 1862, and subsequently identified by Boeck with *Epimeria cornigera*, Fabrieius.

A full description is given by Sars of Owen's *Amphithoë cristata*, which "in the short form of the body, the sharp serrate-like back, and strong development of the fourth and fifth side-plates much resembles *Amphithoë serra* and still more *Amphithoë parasitica*, but is distinguished from both inasmuch as the dorsal carina extends over all the pereon-segments and the four first of the pleon (while in both those species it is wanting on the four first pereon-segments) or, as Owen expresses it, 'segmentis 4 antieis in erista continua superne elevatis.' Where, however, the same author adds, 'reliqvis in spinis retrosum in clinatis productis,' he is so far incorrect as in fact these spines or processes are entirely wanting on the last three abdominal-segments." By Boeck this species is called *Acanthonotozoma cristatum*. The list continues with 41. *Amphithoë hystrix* (*Acanthosoma*) Owen. Comparing his specimens with Krøyer's description, Grønl. Amph., p. 260, Sars was inclined to regard the Norwegian form as a distinct species from the Greenland, but by comparison of these with Owen's figure, which he says is more correct than his short description, he was convinced of the identity of the forms from the two localities. To Krøyer's description he offers corrections;—"Hovedet har i Midten af Panderanden et meget lidet, men tydeligt, horizontalt, *tilspidet* Horn, ikke, som Krøyer siger, kun en stump Vinkel. *De øverste Følere ere noget mere en halvt eller næsten Totrediedele saa lange som de nederste* (efter Krøyer næae de ikke disses halve Længde); Skafets første Led udsender fra Enden af sin øverste Rand en opad og udad rettet stærk og spids Torn, som næsten er ligesaa lang som selve Leddet (efter Krøyer er denne Torn lang mindre) eller som andet Led, det tredie Led er kun halvt saa langt. *Svøben*, undersøgt kun hos et enket Exemplar, bestod af 79 Led (efter Krøyer 'af 20 Led og derover'), af hvilke de 7 (efter Kr. de 4) første Led have i deres underste Rand smaa Haarknapper, men af alle de følgende Led viser, som Krøyer meget rigtigt anfører, kun hvert andet Led Haar og hvert andet er blottet for dem. Svøbens første Led er af Længde som Skafets tredie Led (efter Kr. er det betydeligt længere). *I de nederste Føleres Svøbe taltes hos det samme Exemplar 111 Led* (efter Kr. bestaaer den 'af i det mindste 50 Led'). *De syv Brystsegmenter ere*, som Krøyer rigtig fremstiller det, *bedækkede med 5 eller*, naar man regner Sidepladernes Pig med, 7 Rækker af Pigge; *Bagkroppens 2 første Segmenter rige derimod hvert 9 Pigge* (af hvilke de 2 nederste ere de mindste), *det tredie 5, det fjerde 3, det femte og sjette 2* (idet Piggen paa Midtlinien af disse Segmente mangler), og det syvende ingen. Heraf sees, at det rette Forhold ikke rigtigt fremstilles af Krøyer, naar han kun angiver 7 Pigge paa Bagkroppens andet Segment og slet ingen paa det femte og sjette.

Owen's Afbildning stemmer derimod med Hensyn til alle disse Pigges Form, Antal og Anordning ganske overeens med Forholdet hos vor norske Form. Mindre noægigtig er hans Beskrivelse, naar det hælder, at 'fjerde og femte Caudal-segment havo 3 og de andre kun 2 Pigge.' Dette er urettigt for det femte Segments Vedkommende, som i Virkeligheden kun har 2 Pigge, saaledes som Owen's Fig. 7 ganske rigtigt udviser. Det første Brystsegment har, som baade Owen og Krøyer angive, 10 Pigge, idet de 3 midterste ere dobbelte; den forreste Pig paa Midtlinien er den længste og ligger horizontalt fremad strakt og ligesom et Horn fremragende over Hovedet.—Hos Exemplarer af $\frac{1}{4}$ ' Længde befandtes alle Kroppens Pigge allerede fuldkommen udviklede ligesom hos de voxno. Alle Sideplader ende nedentil med en Pig, den fjerde og femte, hvilke ogsaa ere længere end de andre, hver med 2 Pigge. Da hverken Owen eller Krøyer har iagttaget Dyret i levende Tilstand, tilfoies sluttelig, at Kroppens Farve er guulbrun, Brystfødderne og Følerne med rosenrøde Ringe, oftest ere ogsaa Kroppens Pigge i Spidsen rosenrøde. Øjnene ere brunsorte, temmelig store (ikke 'smaa og hvide,' som Owen siger), cirkelrunde, halvkugleformig fremragende, deres ydre Flade viser talrige polygonale Facetter." For discussion of the species of *Acanthosoma*, Boeck's *Acanthozone*, see Note on Lepechin, 1778. Buchholz, in his description of "*Acanthozone hystrix* Owen," in 1874, does not allude to Sars's description. The long and strong spine of the upper antennæ which Sars mentions is not shown in Buchholz's figure, though to an unfigured small specimen he attributes "am ersten Basalglied der obere Antenne ein ziemlich langer schlanker, am äussern obere Ende befindlicher Stachel."

- The next species is 42. *Amphithoë panopla* Krøyer ?, in regard to which Sars finds that "Bagkroppen hos vor norske Form er meget mere knudret," and after mentioning some other variations from Krøyer's description, suggests the name *Amphithoë panoploides*, in case the Norwegian form should prove to be specifically distinct, which, however, Boeck does not consider it to be. 43. *Amphithoë latipes* Sars, nov. spec., is by Boeck called *Amphithoopsis latipes*. 44. *Amphithoë serraticornis* Sars, nov. spec., is identified by Boeck with *Calliopius leviusculus*, Krøyer; 45. *Amphithoë fulvocincta* Sars, nov. spec., becomes in Boeck's work *Halirages fulvocinctus*; 46. *Amphithoë macrocephala* Sars, nov. spec., is identified with *Dexamine bispinosa*, Spence Bate, as *Halirages bispinosus*; 47. *Amphithoë albomaculata* Krøyer (*A. podoceroides* H. Rathke), is probably *Amphithoë rubricata*, Montagu. Of the following many are discussed elsewhere; 48. *Ediceros saginatus* Krøyer; 49. *Ediceros lynceus* Sars, nov. spec.; 50. *Gammarus locusta* (*Cancer*) L.; 51. *Gammarus mutatus* Liljeb.; 52. " *Gammarus Sabinii*" Leach; 53. *Gammarus dentatus* Krøyer, redescribed; 54. *Gammarus fissicornis* Sars, nov. spec., by Boeck called *Lilljeborgia fissicornis*; 55. *Podocerus capillatus* H. Rathke; 56. *Ischyrocerus minutus* Liljeb.; 57. *Leucothoë norvegica* Liljeb.; 58. *Leucothoë phyllonyx* Sars, nov. spec., by Boeck made the type of a new genus, as *Aceros phyllonyx*; 59. *Glauconome leucopis* Krøyer, in regard to which Sars says that the eyes which Krøyer describes from examples in spirits as "smaa og lidet tydelige," are in the living animal "stærkt iøjnefaldende ved deres afstikkende opak melkehvide Farve," and "paa de 3 første Abdominalsegmenter findes paa hver Side af Ryggen en lav, men temmelig bred, conisk-tilrundet Knude, som ikke omtales af Krøyer, og efter Figuren i Gaimard's Voyage en Scandinavie, Crust. Tab. 19 Fig. 1, synes ogsaa disse Segmenter at være ganske glatte. De under disse 3 Segmenter siddende saakaldte 'falske Fødder' finder jeg temmelig store (ingenlunde 'smaa og korte' som Krøyer Siger)."

1859. VALETTE, ST. GEORGE, A. J. H. DE LA.

1860.

Ueber die Entwicklungs-geschichte der Amphipoden. Sitzungsber. Niederrhein. Gesell. f. Natur- u. Heilkunde zu Bonn, XVI. pp. 94-98, 1859.

Studien über die Entwicklung der Amphipoden. Mit 2 Tafeln. Halle. 1860.
14 pages. 2 Plates.

The ovaries are described as lying dorsally upon the gut and liver-tubes on either side of the heart, forming two cylindrical tubes closed at either end, reaching from the second to the sixth pereon-segment with an oviduct opening in the fourth segment. The inner surface is covered by an epithelium layer which is supported by a *Tunica propria* of finely granular appearance, and that in turn is surrounded by an outer skin which is homogeneous. [Bruzelius traces the ovaries from the first to the seventh segment, with the opening of the oviduct at the base of the marsupial plate of the fifth segment. G. O. Sars traces the ovaries from the second to the seventh, with the opening of the oviduct as stated by Bruzelius in the fifth segment]. Neither la Valette nor Bruzelius could discover the lobes of which according to Spence Bate (1855) the ovary of *Gammarus* is composed.

The first origin of the Amphipod-egg is derived by la Valette from an epithelial cell of the ovary.

In eggs not far developed he found a sharply defined membrane, a finely granular content, a germinal vesicle and many germinal spots. With further development of the egg-cell violet-coloured drops appear in the hitherto colourless contents, which soon as smaller or larger strongly refracting globules fill the whole egg and conceal the germinal vesicle. The coloured yolk develops itself within the cell-membrane.

La Valette could never succeed in observing zoospores in immediate proximity to the egg or within it. Of the two skins of the egg one in later stages of the embryo's development sometimes disappears, but the one remaining is not, he says, as Meissner supposes, the chorion or outer, but always the inner, or yolk-skin. The inner skin has a finely shagreened appearance; the outer is completely homogeneous.

He thus sums up his view of the earlier stages of the development of the egg. An epithelial cell of the ovary increases in size, its nucleus becomes the germinal vesicle and fills itself with germinal spots, while within the cell-membrane the development of the fine-grained yolk begins. Along with this and perhaps partly at its expense along with the increasing size of the egg appears the violet yolk. The former he calls the formation-yolk, the latter the nourishment-yolk, which at successive stages changes from violet to brown-red and finally to yellow-brown. The formation-yolk divides and perhaps with it the germinal vesicle. In this way arise the yolk-balls including a nucleus, and these after continued division by hardening at the periphery obtain a membrane and become the cells of the embryo-skin. When this has completely sheathed the nourishment-yolk, the whole egg-content draws back on one side from the egg-skin, and by a constriction on that side is divided into two unequal portions still connected on the opposite convex side. On the side where the constriction has taken place the cells of the embryo-skin put out protuberances, marking the position of arteries, mouth-organs and limbs.

A full discussion follows of the micropylar apparatus of the Amphipod-egg, which Meissner first discovered in *Gammarus pulex*. It is confined to the inner or yolk-skin, the outer skin or chorion being completely closed. It lies, not as Meissner supposed, at the pole of the egg, but near the greatest diameter of its breadth. At its central point is a small tap with two small openings. The apparatus occurs at the part of the egg corresponding with the back of the embryo and the third pereon-segment of the developed animal. It is attached to a spherical sack which extends into the heart of the embryo, and which is still observable in

a young animal just escaped from the pouch, though it afterwards disappears. In regard to the use of the apparatus, reference is made to the observations of Leukart [Leuckart] upon the development of the Pupiparæ, showing that the micropyle may have another function than the reception of zoosperms, namely to act as a funnel for the introduction of nourishment. In the case of Amphipods la Valette suggests that it may serve as a respiratory apparatus. He recognises that the outer egg-skin is completely closed, as well as the sack in connection with the micropyle, but he thinks that both might be permeable to the medium surrounding them.

1860. BOECK, AXEL, born 1833, died 1873 (G. O. Sars).

Bemærkninger angaaende de ved de norske Kyster forekommende Amphipoder. Forhandlinger ved de Skandinaviske Naturforskeres ottende Møde i Kjøbenhavn 8–14de Juli 1860, pp. 631–677.

Boeck thinks it likely that the division of the Amphipoda into the three principal groups, Hyperidæ, Gammaridæ, Caprellidæ, will always retain its value, while with growing knowledge the minor subdivisions must be subject to variations. In his own classification he has paid regard, he says, not only to the form of feet and tail, but even more particularly to parts less open to view, the mouth-organs, the marsupial lamellæ and the branchiæ. Besides the characters already in use, namely the presence or absence of palps in maxillæ and mandibles and the number of joints to the maxilliped, he considers the form of the inner plate in the first pair of maxillæ and its garniture of hairs to be of high importance. He attaches weight also to the arrangement of teeth and hairs at the upper end of the oesophagus, although from the difficulty of the investigation he will not for the time delay over these points. He calls attention to a double armature of teeth which the males of many species possess as opposed to the females, and which he notices especially in the mandibles and first and second maxillæ. This, on which he no longer lays stress in his great work, is no doubt only a misapprehension caused by the appearances which precede the moulting of the Crustacean skin.

In his Classification of the Norwegian Amphipoda Boeck places first the tribe Hyperidæ, Dana, because he considers it to be united by a new and very remarkable form, *Trischizostoma*, to the family Orchestidæ, as well as to the genera *Anonyx* and *Opis* among the Gammaridæ.

In the subfamily Hyperinæ he places " *Hyperia Galba*, Mont. (*Latreillii Edw.*)"; *Hyperia spinipes*, n. s.; *Lestrigonus exulans*, Kroyer, and " *Lestrigonus Boeckii*," n. s. (presumably named after Professor Chr. Boeck), both of which he subsequently united with *Hyperia galba* as synonyms of *Hyperia medusarum*, O. F. Müller.

In the second tribe, Prostomatæ, Boeck, he places the single new genus and species, " *Trischizostoma Raschii*," Esmark and Boeck, in which, however, the genus at least is assuredly a synonym of *Guerinia*, Hope and Costa.

In the third tribe, Gammaridæ, for the first family Orchestidæ, he refers to two genera occurring on the Norwegian coasts, but only makes mention of " *Allorchestia Nilsonii*," Rathke's species which has since been named *Hyale nilssonii*. In the second family, Gammaridæ, he gives the following new species, *Anonyx serratus*, which he afterwards named *Orchomene serratus*; *Anonyx pinguis*, which becomes *Orchomene pinguis* in his later work; *Anonyx obtusifrons*, changed later on into *Menigrates obtusifrons*; " *Anonyx Bruzelii*," dropped out of his later works except for a reference in the Index of De Skand. og. Arkt. Amph., to p. 157, from which it may be inferred that he identified his species with *Anonyx gulosus*, Krøyer; *Ichnopus spinicornis*; *Urothoë norvegica*. He then mentions *Bathyporeia pilosa*, Lindström,

from the description and figures of which his own specimens somewhat varied. His next new species is *Pontoporeia armata*, which he afterwards named *Priscilla armata*. The genus *Ædicerus*, Krøyer, he thinks should form two separate divisions, one containing *saginatus*, Kr., *affinis*, Bruz., *lynceus*, Sars, and *norvegicus*, n. s., the other *novi-zealandia* Dana, and *obtusus*, Bruz. For the latter division he institutes a new genus, *Aceros*, using a name pre-occupied among Aves (although there with a different meaning and pronunciation), and taking *Aceros obtusus*, Bruzelius, as the type, which he afterwards named *Aceros phyllonyx*, Sars. His new species, *Ædicerus norvegicus*, he renamed in 1870, *Pontocrates norvegicus*, giving it as a synonym *Krøyeria arenaria*, Spence Bate, 1863. Spence Bate's genus is in fact not the pre-occupied *Krøyeria* but *Kroyera*, which perhaps lapsed as a synonym of *Monoculodes*, and the species *Krøyeria arenaria* dates, not from 1863, but 1858, taking precedence, therefore, of Boeck's *norvegicus*. Boeck next gives *Ampelisca spinipes*, n. s., stating that it is very like *Ampelisca æquicornis*, Bruzelius. For a specimen described by Lilljeborg as *Leucothoë articulosa*, Montagu, he proposes a distinct name "*Leucothoë Lilljeborgii*," which in his later works he hesitates to uphold. He recognises that *Leucothoë articulosa* should be called *Leucothoë spinicarpa*, Abildgaard. Making *Probolium*, Costa, a synonym of the earlier *Stenothoë*, Dana, he adds a new species "*Stenothoë Danai*," which he afterwards found to be synonymous with *Stenothoë (Montagu) marina*, Spence Bate, 1855. After pointing out the resemblances between *Eusirus* and *Leucothoë*, he adds a new species, *Eusirus longipes*. For *Gammarus brevicornis*, Bruzelius, and *Gammarus fissicornis*, M. Sars, he establishes a new genus, *Iduna*, a name pre-occupied among Birds and Annelids, and consequently in Boeck's later works giving place to the synonymous *Liljeborgia*, Sp. Bate, 1862. *Iduna brevicornis* he afterwards identified with *Liljeborgia pallida*, Sp. Bate. To *Dexamine* he adds a new species, "*Dexamine Thea*." For *Amphithoë compressa*, Lilljeborg, he establishes the new genus, *Epidesura*, which was dropped when later on he found the species in question to be *Atylus (Amphithoë) swammerdamii*, Milne-Edwards, 1830. He makes a new species, "*Gammarus Batei*," of which no notice is taken in his subsequent works, probably because he thought it too obviously a *Gammarus locusta* to be worth further mention. To the genus *Paramphithoë*, Bruzelius, he leaves the species *panopla* and *pulchella*, but establishes a new genus *Amphithopsis* to receive the species, *bicuspis*, *elegans*, *laviecula*, *tridentata*, and the two new species *Amphithopsis glaber* and *Amphithopsis longicaudata*, the former of which he transferred first to *Paramphithoë*, and afterwards to *Pleustes*, retaining the latter as type of the genus *Amphithopsis*. He discusses the genus *Acanthonotus*, Owen, which he afterwards called *Acanthonotozoma*, and the neighbouring genus, *Iphimedia*, Rathke. To *Acanthosoma*, Owen, he assigns the species, *Acanthosoma hystrix*, Owen, *Amphithoë parasitica*, Sars, and *Epimeria tricristata*, Costa. He afterwards found reason to name the first *Acanthozone cuspidata*, Lepechin, and the other two, *Epimeria cornigera*, Fahricius.

In his third family, Corophidæ, Dana, Boeck places a new genus, *Podoceropsis*, with a new species, "*Podoceropsis Sophia*" (afterwards *Sophia*), for its type. After some discussion of species which he considers to belong to *Leptocheirus*, Zaddach, and to *Gammaropsis*, Lilljeborg, respectively, he describes a new species, *Amphithoë grandimana*, and a new genus, *Hela*, with a new species, *Hela monstrosa*, for its type. The name *Hela*, being pre-occupied, has been changed by S. I. Smith to *Neohela*.

The fourth tribe he calls Caprillidea. In it he places *Proto pedata*, afterwards recognized as *Proto ventricosa*; *Ægina longispina*, Krøyer, he here assigns to *Protella*, though he afterwards called it *Ægina phasma*, Moutagu, it being properly *Protella phasma*; to *Ægina*, Krøyer, he adds the new species, *Ægina (Caprella) echinata*, Esmark, which he afterwards claims as his own species, and *Ægina levigata*, which, according to Mayer, is the young of *Ægina longicornis*, Krøyer. He next establishes a new genus, *Æginella*, with a new

species, *Aeginella spinosa*, as type, also assigning to this genus *Aegina tenella*, Dana, and *Aeyina aculeata*, Dana, but in both cases according to Mayer without good reason for so doing. To *Caprella*, Lamarck, he adds three new species, " *Caprella Esmarkii*," *Caprella laticornis*, *Caprella punctata*, the two first of which Mayer identifies with *Caprella equilibra*, Say, and the third a little doubtfully with *Caprella septentrionalis*, Kroyer. Boeck himself in his last work inclines to identify *Caprella esmarkii* with *Caprella equilibra*.

In this work the descriptions of new genera are not very formally drawn out. That of *Trischizostoma* follows the statement that three specimens, all females, were captured by Professor Rasch off Sondørnør, by sinking a dead bird, if he remembered rightly, to a depth of about 100 fathoms, and is given thus:—"Det største Individ maalte 45 m., og den er saaledes en af de største blandt Amphipoderne. Legemet er stærkt bygget, noget sammentrykt fra Side til anden; Ryggen rund uden Kiøl; Hovedet springer fortil frem i et langt og bredt Rostrum, der dækker Røddelene af de øvre Antenner; Øinene ere meget store og dække som hos *Hyperiderne* næsten hele Hovedets Sider samt støde næsten sammen oven til; de øvre Antenner ere de korteste; Skafret lidet og kort; Svøben dannes af et noget langt, paa den indre Side haarbedækket første Led, samt 12 til 14 andre kortere; Bisvøben bestaaer ligledes af et langt første og to meget mindre følgende Led. De nedre Antenner ere en Trediedeel længere end de øvre; Skafrets tre første Led ere meget korte; de to følgende længere og indbyrdes af samme Længde, hvorhos det første af disse er paa den nedre Side saagtakket; Svøben bestaaer af henved 20 Led. De stemme saaledes overeens med Antennerne hos *Hyperidæ* og Slægten *Anonyx*. Munddelene see ud som en trespaltet fremstrakt Tubus, som er dannet af den overordentligt forlængede Overlæbe og de omdannede Maxillarfødders ydre Plader. Indenfor denne Tubus, efter hvilken Slægtsnavnet er givet, findes de spidse, stærkt forlængede, men spade Mandibler og Maxiller, der lige et Slags Braadde. Maxillarfødderne ere forsynede med firleddede og Mandiblerne med treleddede Palper. Første Par Fødder er omdannet til stærke Griberedskaber af en eiendommelig Bygning; femte Led eller Haanden er meget stor, opblæst, og fastet ved den indre Side til det foregaaende Led. Kloen er ikke som sædvanligt fastet til den nedre Vinkel, slaaende sig mod den bagre Rand med Spidsen opad, men er fastet til den bagre øvre Vinkel med Spidsen nedad; den stemmer saaledes i dette noget overeens med Krøyer's Slægt *Opis*. Det andet Par Fødder er dannet som hos Slægten *Anonyx*. Det tredie og fierde Par ere ulige; fierde Pars første og især tredie Led ere stærkt skieldformet udvidede, medens de hos tredie Par ere smallere. De tre følgende Par ere af den sædvanlige Bygning og tiltage efterhaanden i Længde. Halen er meget bred og stemmer i sin Form meget overeens med *Hyperidernes*, men de tre bagre Par Hale-beens Pedunkler ere kortere end hos disse. Andet Par Epimerer er særdeles stor, trekantet med Basis nedad og den afstumpede Spids opad og skiuler næsten det første Par.

"Dyret lignet saaledes *Hyperiderne* i Hovedets, Øinenes, Antennernes og Halens Bygning, tildeels ogsaa ved Maxillarføddernes ydre Plade, der er operculiform; men her findes Palper, som Hyperiderne mangler. I det Hele taget ere Munddelene hos dette Dyr eiendommelige, og synes at være bestemte til Sugning. Det nærmer sig i flere Henseender *Orchestiderne*, men har ogsaa meget tilfælles med Slægterne *Opis* og *Anonyx* blandt Gammariderne ved Antennernes og Føddernes Dannelse."

I have given the above in the original language, as the translation by Dallas is accessible in the Annals and Magazine for May, 1869, and the Latin description will be given further on.

The following remarks on the two species *Ædlicherus novi-zealandiæ*, Dana, and *Ædlicherus obtusus*, Bruzelius, supply all that is here given by way of definition for Boeck's new genus, *Aceros*; as distinguished from the other species of *Ædlicherus*, in these two, he says, the upper antennæ are elongate, the rostrum is wanting, the eyes have their ordinary lateral position. The point of the mandible is not dentate, and the second joint of its palp differs in form

from that in *Œdicerus saginatus*. The inner plate of the first maxilla is large and furnished with several strongly ciliated hairs. From regard to the marsupial plates and their relation to the branchiæ, he would place *Œdicerus* and *Aceros* rather with *Phoxus* and the like than near to *Gammarus*. In the form of the hands of the gnathopods he finds an approach to the subfamily of which *Leucothoë* is the type. Whether *Aceros* with a short penultimate syllable should be considered pre-occupied, because a genus of birds was called *Aceros*, with a long penult, is perhaps an open question.

For the new genus, *Iduna*, or at least for the two species which constitute it, he gives the following characters:—The accessory flagellum is especially long, while the principal flagellum of the upper antennæ is short. The lower antennæ are strong and almost subpediform. The molar tubercle of the mandibles is small; the inner plate of the first maxillæ is, as in *Eusirus*, oval and furnished with a single plumose seta; the biting-plates (Tyggeplader) of the maxillipeds are small and their palps much elongated. The first two pairs of legs are provided with strong clasping hands, their fourth joint sending out from the lower hinder angle a strong process, as in *Leucothoë*; the following pairs of legs are very thin and long, the last pair is very long; the uropods (Halefødderne) are long and the telson deeply cleft. The first side-plate (Epimer) is strong, larger than the next one. Thus they show great agreement with *Eusirus*, and differ much from the typical species of *Gammarus*. The marsupial plates, he says, in this genus are small, the branchiæ long and broad; the palp in the first maxillæ has the first joint short. Alike, he says, in *Eusirus* and *Iduna*, the inner plate of the first maxillæ is larger than [in] the other [members of the group], but in all furnished only with one bristle. In 1876, he says that this plate in *Lilljeborgia fissicornis* has one very long plumose seta and a smaller seta not plumose, and that in *Eusirus cuspidatus* it has two plumose setæ.

His genus *Epidesura*, he says, in many characters approaches *Dexamine*, Leach. The form of the antennæ is as in *Dexamine*; the mandibles, however, have a very thin, weak, triarticulate palp; the palp of the first maxillæ is bi-articulate, and the inner plate is furnished with six ciliated hairs; the biting-plates of the maxillipeds are large, the palps small, thin, with their fourth joint forming a small finger (Klo). The marsupial plates are especially large, furnished on the edges with close-set, long hairs; the branchiæ of the last thoracic legs are of the same peculiar form which is found in *Ichnopus*; the two last segments of the pleon are coalesced and the telson is divided; the body is strongly compressed.

The new genus *Amphithopsis* is instituted for those species (taken from *Paramphithoë*, Bruzelius, and united to two new ones), which have—an elongate, compressed body with moderate epimera and long antennæ; the inner plate of the first maxillæ furnished with four to five long, thick, plumose setæ; the inner plate of the second maxillæ with many simple setæ at the extremity, but several on the inner side very strong and plumose; the maxillipeds large, with palps of moderate length; the two first pairs of feet with hands of nearly the same size, small; the third and fourth pairs of legs with the fifth joint very long, longer than the third joint; the telson simple; the last uropods with the branches long, often unequal; the marsupial plates much larger than the branchiæ, closely margined with hairs.

In the new genus *Podoceropsis*, the body is somewhat depressed, the epimera small, the antennæ long and thin, the upper attached far in advance of the lower at the point of the projecting head. Their peduncle is very long, longer than the flagellum and without accessory flagellum. The mandibles are large, at the extremity divided and dentate, with long triarticulate palp. The palp of the first maxillæ is biarticulate, the inner plate small and thick. The maxillipeds are long, narrow, with the fourth joint of the palp divided into two joints, of which the last forms a pointed nail (Klo.). The two first ("sidste," last, by an obvious mistake for "første," first) pairs of feet having the fifth joint forming a clasping hand, which in the second pair is much larger than in the first, and not

of the same size in both sexes. The three hinder abdominal-feet are biramous, the rami conical, without spines. Telson small and thin.

Of *Hela*, he says:—"This remarkable new genus is characterized by a long, narrow, depressed body; small, nearly rudimentary epimera; very long legs, of which the first two pairs are furnished with strong clasping hands, the first larger than the second; the last three pairs have the first joint not at all dilated, but narrow and cylindrical like the following joints; the fingers long and conical. The tail is of the usual form, without any of its segments coalesced. Its first three pairs of feet are especially long and thin, the two following pairs biramous, and the last particularly thin, uniramous [grenet for cengrenet], the ramus longer than the peduncle. The mandibles have a divided, dentate point, a prominent molar tubercle, and a thin, triarticulate palp. In the first maxillæ the palp is long, thin, two-jointed, the inner plate small, furnished with a few bristles. The maxillipeds are very strong, with four-jointed palps. The branchial vesicles are found at the bases of the legs from the second to the sixth pair."

As to the new genus *Æginella* he gives his views in two passages; first he says, p. 670, under *Ægina*, Krøyer:—"Krøyer characterizes this genus by the triarticulate palp of the mandibles, and the biarticulate tail with two pairs of appendages, of which the first pair are biarticulate, the second uniarticulate. Dana refers to this genus some species, which differ from the type species *longicornis* by the structure of the tail, and he believes that this is of little systematic importance. But, as I have found two new species which completely agree with Krøyer's characters for *Ægina*, and besides, a species which is like these in that the mandibles have palps, but the tail of which is constructed as in the genus *Caprella*, I think that Dana's species must be transferred from *Ægina* to a new genus, of which this species of mine is the type. To this genus I have given the name *Æginella*." On p. 673, under *Æginella* mihi, he says, "This genus, which forms a link between the preceding genus [*Ægina*] and that which follows [*Caprella*], I have already characterized by its not having palps on the mandibles, and by the tail being, as in the genus *Caprella*, biarticulate, with unjointed appendages" ("ved at den mangler Palpe paa Mandiblerne, og ved at Halen er, som hos Slægten *Caprella*, toleddet med uleddede Appendices"). The discrepancy in the second statement is no doubt accidental, there remains, therefore, the single point in which *Æginella* differs from *Ægina*, namely, in having the abdominal feet unjointed. But Mayer points out, Caprelliden, p. 36, that Boeck is wrong in supposing the abdominal feet in *Caprella* to be unjointed. It is easy, therefore, to suppose that he may have made the same mistake in regard to the specimen which he names *Æginella*, in which case that genus will fall to *Ægina*, unless, since that is a preoccupied name, *Æginella* may be accepted as its substitute.

1860. LEYDIG, FRANZ.

Ueber Geruchs- und Gehörorgane der Krebse und Insekten. Archiv für Anat. und Physiol. Jahrgang 1860. pp. 265–314. Taf. VII.–IX.

See Note on Leydig, 1878.

1860. LÜTKEN, CHRISTIAN FREDERIK, born 4 October, 1827 (C. F. L.).

Bemærkninger om *Cyamus*, Forhandlinger paa Skandinav. Naturf. ottende Møde i Kjøbenhavn. 1860. pp. 590–592.

The preliminary object of these remarks was to show the error of the common supposition that there was only one species of *Cyamus* in the North Seas. Lütken here distinguishes six

species, leaving the name *Cyamus ceti*, Lin., to that parasitic on *Balaena mysticetus*, and giving the name *Cyamus nodosus*, Ltk., to that living on the Narval, figured in the *Zoologia Danica*, tab. 119.

1860. PHILIPPI, RUDOLPH AMANDUS, born 1808 (Hagen).

Reise durch die Wueste Atacama auf Befehl der chilenischen Regierung im Sommer 1853–54 unternommen und beschrieben von Docteur Rudolph Amandus Philippi. Halle, 1860.

Among the Crustacea Philippi describes one Amphipod, at page 170, thus:—“*Amphithoe andina* Ph.

“Die *obern Fühler* sind so lang wie der vierte Theil des Körpers; die drei Glieder des Stieles sind gleich lang, nehmen aber von der Basis an allmählig an Dicke ab; die einfache, vielgliedrige Geissel ist so lang wie der Stiel. Die *untern Fühler* sind etwas länger als die *oben*, etwa so lang wie der dritte Theil des Körpers, im übrigen sind sie denselben ähnlich [ähnlich]; das Grundglied des Stieles ist etwas kürzer als das zweite, welches so lang ist wie das dritte; die Geissel ist etwas länger wie der Stiel. Die *Augen* sind klein und eiförmig. Das *erste Fusspaar* ist sehr kurz, kaum so lang wie das erste Brustsegment; seine Glieder sind ziemlich gleich lang; das drittletzte und das vorletzte sind dreieckig, das letzte klauenartig gegen das vorletzte umgeschlagen und so lang, wie der Vorderrand desselben. Das *zweite Fusspaar* ist wenigstens doppelt so lang, gleichfalls zum Greifen eingerichtet; das drittletzte Glied ist viel breiter als lang und nach hinten in einen Lappen vorgezogen; das vorletzte ist gross und dreieckig; das Klauenglied ist ebenso lang wie der Vorderrand des vorletzten Gliedes. Das *dritte* und *vierte Fusspaar* sind so lang wie das zweite und haben cylindrische Glieder. Das fünfte, sechste und siebente Fusspaar sind bedeutend länger als die vorigen, zeigen aber sonst die gewöhnliche Bildung, dasselbe gilt von den Anhängseln des Schwanzes.—Die Farbe ist grau.

“*Bemerkung.* Diese Art weicht etwas von *Amphitoe* ab, indem die Hände dreieckig und nicht eiförmig, und die *oben* Fühler kürzer als die *untern* sind, doch scheint mir der Unterschied nicht erheblich genug, um eine generische Trennung zu rechtfertigen.

“Häufig in den Gewässern des hohen Theiles der Wüste: z. B. Cachinal de la Sierra, Agua de Profetas, Rio frio etc.”

The account of this species I have quoted in full, as I was neither able to find it mentioned in Mr. Spence Bate's Catalogue, nor to find Philippi's work in the British Museum. It may, I think, be presumed that the species belongs to the genus *Hyalella*, S. I. Smith, and may even be identified with the species *Hyalella inermis*, Smith; the name would be *Hyalella andina*. Philippi calculated the height of Cachinal de la Sierra by the quick-silver barometer at 7516 feet, by the Aneroid, in which he placed less trust, at 6200 feet, above the sea. Agua de Profetas, he says, lies 9180 feet above the sea, therefore, about at the height of Quito. At this place, he says, p. 50, “im Wasser waren Flohkrebse, *Amphithoe andina*, n. sp., *Elmis*, und kleine schwarze Blutegel, aber keine Schnecken, Mückenlarven etc. Auch sah ich sonst kein Insekt irgend einer Art.” At page 89 he says, “Der Lagerplatz von Rio frio liegt 10500 Fuss über dem Meere,” and at page 91, after describing “die Vegetation des Thales von Rio frio,” he says, “im Wasser waren die gewöhnlichen Flohkrebse und *Elmis*.”

Hyalella inermis, S. I. Smith, has been taken by Mr. Edward Whymper at heights still greater than those mentioned by Philippi for the habitat of his Amphipod.

1860. VOLLENHOVEN, SAMUEL CONSTANT SNELLEN, VAN.

Naturlijke Historie van Nederland. De dieren van Nederland. Overzigt der gelede dieren. Haarlem, 1860.

Under "de Amphipoden of vlookreeften," he mentions Roesel's species under the name "*Gammarus Roeselii* Gerv.," Pl. ii. fig. 1, distinguishing it from "*Gammarus Pulex* L." and *Gammarus puteanus* Koch. He mentions also *Talitrus saltator*, Edw., Pl. i. fig. 5; *Orchestia littorea*, Leach, Pl. i. fig. 6, of which he discusses the phosphorescence; "*Corophium longiorne* Desm.," Pl. i. fig. 7; "*Caprella lobata* Latr.," of the female of which he gives a woodcut; and lastly, "*Leptomera pedata* Latr.," Pl. ii. fig. 2, with a reference to Slabber, "Natuurk. Verlust. Plaat X, fig. 1, 2." The figure shows that *Proto ventricosa*, O. F. M., is in question, though the explanation of the plate calls it *Caprella linearis*, probably by an accidental slip.

1861. BATE, C. SPENCE.

On the Morphology of some Amphipoda of the division Hyperina. The Annals and Magazine of Natural History. 3 Ser. Vol. VIII. 1861. pp. 1-16. Pls. I.-II.

A new species, "*Vibilia Edwardsii*," is described, and the differences between the mother and the young taken from the incubatory pouch are given in detail. A new genus, *Platyscelus*, is thus defined:—"This genus agrees in every respect with Dana's genus *Dithyrus*, except that, after the basa in the third and fourth pairs of pereiopoda, the remaining joints are developed, whereas in *Dithyrus* they are wanting." In the Brit. Mus. Catal., p. 329, Spence Bate adds a note to his description of this genus, "it appears to me to be not improbable that *Platyscelus* may prove to be the female of *Typhis*, from which it differs only in the form of the superior and length of the inferior antennæ." With *Typhis ovoides*, Risso, Claus decisively identifies the species *Platyscelus serratus* here described as new. *Typhis* being preoccupied, Claus renames the genus *Eutyphis*, though on his own showing, *Dithyrus*, Dana, *Thyronus*, Dana, and *Platyscelus*, Spence Bate, have each, in the order named, a prior claim.

The new genus *Brachyscelus* is thus defined:—"Cephalon anteriorly rounded. Eyes occupying the lateral walls, which encroach upon the inferior margin. Pereion not distended, nearly as deep as the cephalon, and not wider. Pleon nearly as broad as the pereion; fourth and fifth segments fused together. Antennæ obsolete or very rudimentary. Oral appendages membranous and rudimentary. Gnathopoda completely subchelate. Pereiopoda having the basa of the three posterior pairs largely developed; fifth pair having the remaining joints not obsolete. Pleopoda biramous. Telson single." The type species is *Brachyscelus cruscum*, of which the female and young are described and figured.

Mr. Spence Bate remarks in regard to the young of the genera he has been discussing, that the adult form which approximates nearest to them is that of the genus *Oxycephalus*, "which bears so close a resemblance to the young of *Platyscelus*, that they might readily be accepted as belonging to one genus." Again, he says, M. Guérin-Méneville's "figure of the young of *Rhabdosoma* appeared to me to be a fair representation of an adult *Oxycephalus*." He thinks that the unimproved type in many genera of the Hyperina is to be found nearer to the young than to the adult form. Alluding to the dwelling of many Hyperina in the gill-cavities of Medusæ, he thinks we may assume that eyes, small in the type, have been monstrously increased in these creatures to make up for the depreciation of light that reaches them through the transparent animals they lodge in. To find out their nearest allies among the normal Amphipods, we must compare their young with the more aberrant forms, and

the link Mr. Bate considers is certainly to be found in *Phoxus* and other genera of the subfamily Phoxidae.

Claus, in 1879, identifies *Brachyscelus*, Spence Bate, 1861, with *Thamyris*, Spence Bate, 1862, and adopts the later *Thamyris* as the name of the genus, perhaps regarding *Brachyscelus* as pre-occupied, but the only earlier name like it in Scudder's nomenclator is *Brachyscelis*.

1861. BATE, C. SPENCE, and WESTWOOD, J. O.

A History of the British Sessile-eyed Crustacea. Part I., October 1, 1861. Part II., November 1. 1861. Part III., December 2. 1861. Pages 1-144. London. (The dates at which the Parts were published have been kindly supplied by Mr. John Van Voorst, the publisher.)

As this work, now complete in two volumes dated respectively 1863 and 1868, is now in the hands of every one who studies the Amphipoda in earnest, only such notes upon it will be given as are absolutely necessary to the plan of this Bibliography. In the first three parts no new species are included. A "tabular arrangement of the Amphipoda" is given, at page 10, in the following manner:—

Order.	Group.	Division.	Subdivision.	Tribe.	Family.	Subfamily.	Genus.
Amphipoda.				Saltatoria = Orchestiidae.			
	Normalia.	Gammariina.	Vaganina.			Stegocephalides, Lysianassides, . Ampeliscides, . Phoxides, .	Montaguia, Danaia. Lysianassa, Callisoma, Anonyx. Ampelisca. Phoxus, Sulcator, Kröyera, Westwoodilla, Grayia, Mouculodes, Ampphilochus, Darwinia, Urothoë, Liljeborgia, Phædra, Isaea, Iphimedia, Otus, Acanthonotus.
				Natatoria = Gammaridae		Gammarides, .	Gammarus, Dexamine, Atylus, Pherusa, Calliope, Eusirus, Leucothoë, Aora, Stimpsonia, Promedia, Bathyporeia, Niphargus, Crangonyx, Gammarella, Melita, Mora, Megamora, Eurystheus, Amathia, etc.
	Aber-	Hype-	Domicola.	Corophiidae		Podocerides, . Corophiides, .	Podocerus, Cyrtophium, Amphi-thoë, Sunamphithoë, Cerapus, Siphonocetus, etc.
rantia.		rima.		Cheluridae,		Corophium, Dryope, Cratippus.
				Hyperiidæ, Phronimidae,		Chelura.
				Dulichiidæ, Caprellidae, Cymadidæ,		Hyperia, Lestrigonus. Phronima.
						Dulichia. Proto?, Protella, Caprella.
						Cyamus.

1861. BENEDEN, P. J. VAN.

Recherches sur les Crustacés du littoral de Belgique. Mémoires de l'Académie Royale de Belgique. Tom. xxxiii, Bruxelles, 1861. pp. 1-174. Pl. i.-xxi. (Présenté à l' Académie le 6 mai 1860).

The same, as a separate extract, Bruxelles, 1861.

The part of this work relating especially to the Amphipoda extends from page 95 to page 99 and is devoted to "les Caprellidés." The five genera allotted to this family are called

Leptomera, *Naupredia*, *Cercops*, *Aegina*, and *Caprella*. *Cyamus* is spoken of as non-parasitic, and the *Cyamus* from *Balaena australis* is supposed to be identical with that from *Balaena mysticetus*. The genus *Naupredia*, Latreille, is upheld against those carcinologists who have supposed it to represent a mutilated *Leptomera*. A new species, *Naupredia tristis*, is figured and described, but it is very obvious that a young and mutilated specimen of *Proto ventricosa* is in question. Considering the habit of the Caprellidae of elinging to supports by their hind peraeopods, to have one of the family naturally destitute of these limbs would be most surprising. *Caprella obesa*, also described as new, is thought by Mayer to be possibly the young of *Caprella acutifrons*, Latreille. The specimen was only two millimetres in length.

1861. GRUBE, ADOLPH EDUARD, born 1812, died June 24, 1880 (Friedländer, Naturæ novitates).

Ein Ausflug nach Triest und dem Quarnero. Beiträge zur Kenntniss der Thierwelt dieses Gebietes. Berlin, 1861.

The following species are described as new, pp. 135–138, 1. *Lysianassa ciliata*, said by Grube to be “*L. humili* Cost. simillima,” by J. V. Carus, 1885, who quotes the description, thought to be possibly the same as *Lysianassa audouiniana*, Sp. Bate, but separated both from that species, and from the genus *Lysianassa* by the telson, see Note on Grube, 1866. 2. *Amphithoë brevitarsis*, which Grube in 1864, re-named *Dexamine brevitarsis*; 3. *Amphithoë (Hyale) istrica*, which he called *Nicea istrica* in 1864, and which may stand as *Hyale istrica*, or as *Hyale prevostii*, M.-Edw. (see Sp. Bate, 1865); 4. *Amphithoë (Amphitonotus) anisopus*, which in 1864 he called *Dexamine anisopus*, a species obviously founded on a malformed specimen of *Dexamine spiniventris*, Costa; 5. *Amphithoë (Amphitonotus) leptonyx*, in 1864 re-named *Dexamine leptonyx*, and separated by some not very striking marks of distinction from *Dexamine tenuicornis*, Rathke; 6. *Gammarus recurvus*, which in 1864 he named *Crangonyx recurvus*; 7. *Colomastix pusilla*, the type of a new genus thus defined:—

“Genus ad Podoerum aeedens, corpore depresso-rotundatum epimeribus humilibus. Antennæ breves, articulis paucis, flagellis distinctis nullis, nec tamen pediformes. Pedis pars 1mi styliformes, 2di subchelæformes, proximorum 5 ambulatorii.”

In the list headed, “Ausbeute von Triest, Fiume, Portoré und Cherso,” besides the species already mentioned, Grube records, p. 125, the capture of *Lysianassa longicornis*, Lucas; *Lysianassa spinicornis*, Costa; *Amphithoë picta*, Rathke; *Gammarus olivii*, M.-Edw.; *Gammarus locusta*, Linn.; *Leucothoë denticulata*, Costa. At page 24 he mentions *Podocerus pulchellus* in a sponge, and at page 73 “eine Gammarine,” taken among stones on the banks of the Wanasee, therefore no doubt the *Crangonyx recurvus*, already named.

1861. HELLER, CAMIL.

Synopsis der im rothen Meere vorkommenden Crustaceen. (Aus den Verhandlungen der k. k. zoologisch-botanischen Gesellschaft in Wien [Jahrgang 1861] besonders abgedruckt.) 30 pp.

Orchestiæ bottæ, M.-Edw., is the only Amphipod mentioned.

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

XXX 42

1861. HELLER, CAMIL.

Beiträge zur Crustaceen-Fauna des rothen Meeres. (Aus dem XLIV. Bande des Jahrganges 1861 der Sitzungsberichte der mathem.-naturw. Classe der kais. Akademie der Wissenschaften besonders abgedruckt.) II. Theil. Wien. 1861. (pp. 289–290, 294.)

The only Amphipod described in this work is *Orchestia inaequalis*, which is said to be strikingly distinguished from all other known species by the unequal development of the gnathopods of the second pair. The expression may be intended to refer only to other species of *Orchestia*, otherwise the *Melita palmata* which Spence Bate at one time established as a distinct species under the name *Gammarus inaequimanus*, and *Melita (Gammarus) fresnelii* of Savigny's Egypt would constitute other well-known species exhibiting the same unequal development. The fact that in Heller's specimen not only was the right gnathopod much larger than the left, but all the five peræopods on the right side showed a somewhat stronger development than those on the left, makes it highly probable that he had before him a monstrosity rather than a true species. Grube's *Dexamine anisopus* seems to be a parallel case.

1861. HELLER, CAMIL.

Vorläufiger Bericht über die während der Weltumsegelung der k. k. Fregatte Novara gesammelten Crustaceen. (Aus der Verh. der k. k. zool.-botan. Ges. in Wien [Jahrgang 1861] bes. abgedruckt.) 4 pp.

Reports Amphipoda collected from Madeira, 2 species; St. Paul 3; the Cape 1; Chili 2; a total of eight species.

1861. HERKLOTS, JANUS ADRIAN.

Symbolæ carcinologicæ. Études sur la classe des Crustacés. Leyden, 1861.

The introductory heading well expresses the contents of this pamphlet;—“Catalogue des crustacés qui ont servi de base au système carcinologique de M. W. de Haan, rédigé d'après la collection du Musée des Pays-Bas et les crustacés de la Faune du Japon.” “Ordo IV. *Tetraplecapoda* de Blainv.” has “Sectio 4. *Amphipoda* Latr.” and “Sectio 5. *Læmodipoda* Latr.” The latter wrongly includes “Gen. *Cecrops* Leach,” and under *Caprella* gives “*Modesta* Templ.” instead of *nolosa*. No new species are mentioned.

1861. HOGAN, A. R.

Notice of British Well Shrimps. Report of the thirtieth meeting of the British Association for the Advaneement of Science; held at Oxford in June and July 1860. London, 1861. pp. 116–117.

See Note on Hogan, 1859.

1861. KINAHAN, J. R.

Report of the Committee appointed to dredge Dublin Bay. Report of the thirtieth meeting of the British Association for the Advancement of Science; held at Oxford in June and July 1860. London, 1861. pp. 27–31.

At "the Cnook, a bank about seven miles from land in an easterly direction," he met with several species of Crustacea rare elsewhere, among which he mentions "*Tetromatus Bellianus*." In the "*List of Species obtained in Kingstown and Killiney Bays, and a few from Baldoyle*," the Amphipoda are "*Lysianassa longicornis*, *Anonyx denticulatus*, *Ampelisca typicus*, *Urothoe marinus*, *Urothoe elegans*, *Iphimedia obesa*, *Iphimedia Ebiana*, *Acanthonotus testudo*, *Dexamine spinosa*, *Gammarus locusta*, *Gammarus fluvialis*, *Gammarus palmatus*, *Gammarus Othonis*, *Gammarus longimanus*, *Amphithoe rubricata*, *Amphithoe littorina*, *Podocerus falcatus*, *Podocerus variegatus*, *Corophium longicorne*, *Chelura terebrans*, *Hyperia Galba*, *Caprella tuberculata*," without further information, except a notice that "detailed notes on the species will accompany the final Report."

1861. LOVÉN, SVEN, born 1809 (G. O. Sars).

Om några i Vettern och Venern funna Crustaceer. Öfvers. K. Vet.-Akad. Förhandl. [Föredrag den 10 October 1860]. 1861. pp. 285–314.

An account is given of a remarkable marine fauna found in the large fresh-water lakes of Southern Sweden, called on our English maps Wetter and Wener. The Amphipods mentioned are *Pontoporeia affinis*, Lindström, *Gammarus (Gammaracanthus) loricatus*, Sabine, and *Gammarus cancelloides*, Gerstfeldt. The inference from the whole fauna, of which these are a small portion, is that the lakes just mentioned were at one time part of the sea, but cut off from it, along with their inhabitants, by the rise of the land described in works on geology.

1862. BATE, C. SPENCE.

Catalogue of the specimens of Amphipodous Crustacea in the Collection of the British Museum. London. 1862. iv and 399 pages. Plates I.-LVIII. with Plate Ia. Plate XXI. has its lower half devoted to Plate XIVa.

This ambitious work, beyond the promise of its title, aims at bringing together, in systematic arrangement, all the Amphipoda then known to science. The preface explains that the arrangement of the species follows the classification proposed in the British Association Report for 1855, and adopted in the "British Sessile-eyed Crustacea" then in course of publication, but that observation during the progress of the Catalogue had "suggested a more natural arrangement by the absorption of the Orchestidae as a subfamily into the Gammaridae, establishing the Phoxides as a distinct family, and placing them between Corophiidae and Hyperidae."

The new species described and figured are, in Fam. 1. ORCHESTIDÆ:—*Talorchestia? Africana*, with the remark that "it may be the female of the *Orchestia* that Krauss supposed to be *O. Bottæ*;" "*Orchestia Aucklandiæ*," Hab. Auckland, as to which Mr. G. M. Thomson writes to me from New Zealand, expressing the opinion that Auckland Islands must be intended. *Orchestia Fuegensis*; "*Orchestia Novæ-Zealandiæ*," which along with *Orchestia tenuis*, Dana, G. M. Thomson unites under the common name *Orchestia sylvicola*, Dana; "*Orchestia Telluris*," of which G. M. Thomson remarks that it "is by no means a terrestrial species. It lives in burrows in the sand just above tide-marks;" *Orchestia megalophthalma* (*Orchestia megalophthalmus*, Leach MS., and White's Cat. Crust. B. M.); *Orchestia trigonochirus* (Leach MS. B. M.); "*Allorches Piedmontensis*"; "*Allorches Knickerbockeri*," a species which W. Faxou thinks may be synonymous with *Amphithoë aztecus*, Saussure, 1858, and the later *Hyalella dentata*, S. I. Smith, as Professor Smith had himself suggested, in which case the name would be *Hyalella azteca*; *Allorches carinatus*; "*Allorches Sayi*"; *Allorches microphthalmus* (*Gammarus microphthalmus*, MS. Brit. Mus.); "*Allorches Inca*," said to be perhaps a sex-form of *Allorches hirtipalma*, Dana; (for reference of species of *Allorches* to the genera *Hyale* and *Hyalella*, see Note on Rathke, 1837).

In Fam. 2. GAMMARIDÆ. Subfam. 1. STEGOCEPHALIDES:—*Montagu longimana*, perhaps only a variety of *Stenothoë monoculoides*; "*Montagu Guerinii*," which Spence Bate says bears a strong resemblance to *Stenothoë validus*, Dana.

In Subfam. 2. LYSIANASSIDES:—*Anonyx longicornis*, subsequently transferred by its author to the genus *Lepidepecreum*; *Anonyx obesus*, subsequently made the type of the genus *Acidostoma*, Lilljeborg; *Anonyx ampulloides*, Stimpson, MS.; *Anonyx punctatus*, Stimpson, MS.; *Anonyx annulatus*, Stimpson, MS.; *Anonyx longipes*, which with Bate's "*Anonyx ampulla*, Kröyer," Boeck renames *Tryphosa longipes*, as respectively female and male of one species; *Phlias rissoanus*.

In Subfam. 3. AMPELISCADES:—*Ampelisca ingens* (Pseudophthalmus ingens, Stimpson, MS.); "*Ampelisca Japonica*," (Ampelisca Japonica, Stimpson, MS.).

In Subfam. 4. PHOXIDES:—

Grayia, new genus, is thus defined:—"Cephalon produced, hood-shaped. Eyes two. Superior antennæ not appendiculate. Gnathopoda subchelate. Pereiopoda subequal, and terminating in a sharp-pointed curved dactylos. Posterior pleopoda biramous. Telson squamiform, entire? This genus differs from *Œdicerus* of Kröyer in having two eyes, and in the fifth pair of pereiopoda not being longer than the preceding."

To this genus two species are assigned, *Grayia imbricata*, n. s., which, in the opinion of A. M. Norman and myself, is the young of *Amathilla sabini*, and *Grayia pugettensis*, Dana, as to

which Spence Bate in a note, page 104, remarks that *Grayia pugettensis* may belong to the genus *Œdicerus*, certainly not to *Iphimedia*, in which Dana had placed it.

Westwoodilla hyalina, n. s., seems to me not distinguishable from *Westwoodilla cæcula*, Spence Bate; "Monoculodes Stimpsoni," I should have been inclined to unite with *Monoculodes carinatus*, Spence Bate, but that J. S. Schneider keeps them distinct. Spence Bate in his appendix sinks the name *Monoculodes stimpsoni* in favour of *Monoculodes affinis*, Bruzelius, Boeck makes *Monoculodes carinatus*, Spence Bate, = *Monoculodes affinis*, which G. O. Sars thinks very doubtful. Schneider accepts Spence Bate's second thoughts.

Amphilochus, new genus, is thus defined:—"Cephalon produced, anteriorly depressed. Eyes two, posterior to the superior antennæ. Superior antennæ not appendiculated. Gnathopoda subchelate; in both, the carpus is inferiorly produced. Pereiopoda subequal; coxae of the third pair not so deep as the preceding. Posterior pair of pleopoda double-branched (?). Telson single."

"This genus is distinguished from *Monoculodes* by having two eyes situated laterally, from *Krögera* by having the second pair of gnathopoda not chelate, and from both by the shortness of the posterior pair of pereiopoda."

Boeck accepts the name of this genus, but suggests that it ought to be changed as being preoccupied among the *Coleoptera*, but the name to which he refers is, according to Scudder, differently spelt, *Amphilocus*. The third uropods are in fact double-branched. The type species of the genus is *Amphilochus manudens*, n. s.

"*Urothoë Bairdii*, n. s." is a synonym of the earlier *Urothoë norvegica*, Boeck, 1860; *Urothoë brevicornis*, n. s., as suggested in the Brit. Sess. Crust. i. 198, is not distinct from *Urothoë marinus*, Spence Bate.

Liljeborgia, new genus, is thus defined:—"Cephalon not much produced. Pereion long, slender, and compressed. Inferior antennæ longer than the superior. Coxæ not deeper than their respective segments. Gnathopoda resembling each other in form; second pair larger than the first, subchelate; carpus continuous with the propodos, and produced anteriorly along its inferior margin. Pereiopoda having the dactyla styliform. Posterior pair of pleopoda biramous. Telson single, entire."

"This genus is distinguished from *Urothoë* by the large gnathopoda, small coxae, and the form of the telson."

The type of this genus is *Gammarus pallidus*, Spence Bate, 1855. Boeck established a genus *Iduna* in 1860, which is synonymous with *Liljeborgia*, but though prior yields to it, the name *Iduna* being preoccupied. It should be noted that the telson, described as entire, is in reality deeply cleft.

"*Phædra Kinahanii*, n. s." Boeck thinks may belong to the genus *Liljeborgia*. *Lysianassa spinifera* (Stimpson, Mar. Invert. Grand Manan, p. 49) is not mentioned in the index, but the description is quoted under the genus *Phædra*, with the remark that it "seems to be closely related to this genus, only differing from it, apparently, in the telson consisting of two long spines."

Otus, new genus, the name of which being triply preoccupied, was changed by Lilljeborg into *Odius*, is thus defined:—"Cephalon produced anteriorly. Percion distended. Pleon compressed. Antennæ simple, subequal. Mandibles having an appendage. Maxillipeds unguiculate. Ischium having a broad plate nearly as long as the four succeeding joints; basos furnished with a long narrow process. First pair of gnathopoda chelate; second subchelate. Pereiopoda short, robust, strong. Posterior pair of pleopoda biramous. Telson single, squamous."

"This genus differs from *Iphimedia* in the form of the maxillipeds, in the distinctly chelate character of the first pair of gnathopoda, and in the larger relative proportions of the second." The type species is *Otus carinatus*, n. s.

In Subfam. 5. GAMMARIDES:—

Brandtia, new genns, is thus defined:—"Cephalon not produced into a rostrum, but elevated into a crest. Antennæ subequal; the superior without a secondary appendage. Gnathopoda subequal, subchelate. Four anterior coxæ as deep as their respective segments of the pereion, not narrow or pointed. Three posterior pairs of pereiopoda short, subequal, having the base dilated at the upper posterior extremity, and narrowing with a concave sweep to the lower. Posterior pair of pleopoda biramous. Telson squamiform, divided." The type species, *Brandtia latissima*, is referred to "Gammarus latissimus, Brandt, Voyage de Mildendorff," the figures and descriptions having been "taken from specimens sent by Professor Brandt to the Museum at Paris," but, as already explained, that species was in reality instituted by Gerstfeldt, and is retained by Dybowski in the genus *Gammarus*.

"*Dexamine Blosserilliana* n. s.;" "*Dexamine Loughrimi*, n. s.," in the appendix held to be a variety of *Atylus swammerdami*; "*Atylus Huxleyanus* n. s.," probably belonging to Boeck's genus *Halirages*; *Atylus villosus*, n. s.; *Atylus gibbosus*, n. s., called *Tritata gibbosa*, in Boeck's arrangement; *Atylus austrinus*, n. s.; *Pherusa cirrus*, u. s., identified by Boeck with *Amphithoë bicuspis*, Kroyer, which G. O. Sars places in the genus *Paramphithoë*, Bruzelius; "*Pherusa Barretti*, n. s.; *Calliope Ossiumi*, n. s.," united by Boeck to *Amphithopsis latipes*, M. Sars, 1858; *Calliope grandoculis*, n. s., a variety of *Calliopius laviusculus*, Kr.; "*Eusirus Helvetiae*, n. s.," which Boeck assigns to his own *Eusirus longipes*, 1860.

The genus *Seba* is thus defined:—"Slender, smooth. Antennæ long, subequal. Coxæ small, four anterior deeper than the three posterior. Gnathopoda uniform, subequal, chelate." The type species is *Seba innoxinata*. For both genus and species the authority is hesitatingly given as "A. Costa, Pochi Crost. di Messina." Professor A. Milne-Edwards has kindly searched for the paper referred to, but without success. The genns is not mentioned in de Natale's letter to Costa, 1850 (see Appendix). See also Note on Seba, 1758–1760, p. 18.

Gossea, new genus, is thus defined:—"Slender, compressed. Superior antennæ without a secondary appendage, and having the joints of the peduncle short and subequal. Gnathopoda subchelate; first pair larger than the second. Posterior pair of pleopoda biramous; rami longer than the peduncle and extending considerably beyond the telson. Telson single, squamiform."

"The animals of this genns are very likely, upon a superficial examination, to be confounded with those of *Microdentopus*; but the differences in the superior antennæ, posterior pair of pleopoda, and telson, are considerable and important." The type species is *Gossea microdentopa*, of which the spelling was afterwards corrected to *microdeutopa*; both here and in the "British Sessile-eyed Crustacea" it is figured from a defective specimen, only $\frac{3}{10}$ ths of an inch long, and bears a suspicious resemblance to a young *Calliopius laviusculus*. M. Chevreux mentions a specimen in his list, 1883, but this he afterwards identified as *Calliopius norvegicus*, Rathke, as he himself informed me.

Stimpsonia, new genus, is thus defined:—"Slender; the inferior pair of antennæ considerably longer than the superior. First pair of gnathopoda larger than the second; carpus broader and longer than the propodos; second pair imperfectly chelate, having the carpus much longer than the propodos. Posterior pereiopoda long. Posterior pleopoda biramous. Telson tubular." The type species is *Stimpsonia chelifera*, n. s. Since the generic name is preoccupied among Vermes, this species may well be placed under Costa's genus *Microdeutopus*.

Protomediea hirsutimanus, n. s., description subsequently completed by A. M. Norman, 1868; "*Protomediea Whitei* n. s.," = *Claeirocratus sundevalli*, ♀, Rathke, according to Norman and Boeck. "*Bathyporeia Robertsoni*, n. s.;" both this and Spence Bate's other species, *Bathyporeia pelagica*, are in my opinion synonymous of *Bathyporeia pilosa*, Lindström. G. O. Sars in his *Oversigt*, 1882, speaks of having convinced himself that *Bathyporeia*

robertsoni is a distinct species, though very near to *Bathyporeia pilosa*. He does not give his reasons. Henri Blanc, 1884, accepts my view. *Melita proxima*, n. s., according to Norman, *Melita obtusata*, ♂; *Melita gladiosa*, n. s. The genus *Mæra*, Leach, is given as *Mæra*; the new species assigned to it are *Mæra truncatipes* (*Amphitoë truncatipes*, *Spinola*, MS. B. M. White, Cat. of Crust. in B. M. 1847); "*Mæra Blanchardi*"; *Mæra pocillimanus*; *Mæra pectenierus*. *Eurystheus bispinimanus*, n. s., an obscure species founded on a single imperfect specimen, is perhaps the female of the preceding species in the same genus, named *erythrophthalmus*. *Amathia dentata* is given as the name of a species from Pondicherry, with the synonym "*Gammarus dentatus*, Catalogue of the Crustacea in the Museum of the Jardin des Plantes." It is neither described nor figured, but said to resemble closely *Amathia sabinii* and *Amathia carinata*: the genus *Eurystheus* falls to the earlier *Gammaropsis*, Liljeborg, 1854.

Pallasea, new genus, is thus defined:—"Superior antennæ longer than the inferior, and furnished with a secondary appendage. Inferior antennæ subpediform, having the peduncle considerably longer than the flagellum; the flagellum short and stout. Mandibles having an appendage. Maxillipeds subpediform, having a small squamiform plate to the ischium only. Gnathopoda uniform, moderately large. Pereiopoda subequal. Posterior pleopoda biramous. Telson single, cleft."

"This genus is very nearly allied to *Amathia*, from which it differs more in the general aspect of the animal than in structural details. The form of the inferior antennæ, together with the altered condition of the maxillipeds, are appreciable characters that distinguish the genera from each other." The type species is *Oniscus cancellus*, Pallas, from which *Pallasea cancelloides*, Gerstfeldt, differs apparently in a very slight degree, according to the Appendix, p. 380. The name *Pallasea*, according to Boeck, is preoccupied for a Dipterous insect, but the insect's name in Scudder is given as *Pallasia*.

Gammaracanthus, new genus, is thus defined:—"Dorsal margin carinated, and having the posterior central margin with one or more segments produced posteriorly. Pleon without fasciculi of spines. Superior antennæ having a secondary appendage. Inferior antennæ longer than the superior. Mandibles with an appendage. Maxillipeds subpediform, unguiculate, having the squamiform internal processes but slightly developed. Gnathopoda subchelate and subequal, having the carpus inferiorly produced. Coxæ of the third pair of pereiopoda not so deep as the fourth. Posterior pair of pleopoda biramous; rami foliaceous. Telson double."

"This genus is selected from that of *Gammarus* of authors generally, comprising the Division AA. of M.-Edwards, and +1a of Liljeborg." Boeck remarks that it is not the inner, but the outer, plates of the maxillipeds that are little developed. The type species is *Gammarus loricatus*, Sabine.

Upon *Gammarus semicarinatus*, n. s., the remarks are added that "this may be the *Gammarus mucronatus* of Say," and that "the species is of considerable interest, as associating the genera *Amathia* and *Gammaracanthus* with *Gammarus*." Sp. Bate knew of no other distinctly carinated species carrying the dorso-caudal fasciculi of spines. Previously, on p. 203, he gives Say's species as *Gammaracanthus mucronatus*. *Gammarus subcarinatus* (*Gammarus subcarinatus*, Stimpson, MS.) comes from Behring's Straits. *Gammarus multifasciatus* (*Gammarus multifasciatus*, Stimpson, MS.) is from Grand Manan. *Gammarus Redmanni* (*Gammarus Redmanni*, Leach, MS. B. M., *Gammarus ornatus*, White, Cat. Crust. B. M. 1847 (not Edwards)) is from Jamaica. *Gammarus tenuimanus*, n. s., is probably an accidental variety of *Gammarus locusta*, as indeed is hinted in the Brit. Sess. Crust. vol. i. p. 384.

Megamæra, new genus (answering to *Gammarus*, Div. A.aa. M.-Edwards and *Gammarus*, Div. +2, Liljeborg), is thus defined:—"Dorsal segments of the pleon without fasciculi of spines.

Eyes round. Superior antennæ long; inferior about half the length of the superior. Gnathopoda subchelate, the second pair being the larger. Posterior pair of pleopoda biramous. Telson double."

"This genus is distinguished from *Mæra* by the relative size of the second pair of gnathopoda, by the greater size of the coxae, and by the more compact form of the animal generally; and from *Gammarus* by the absence of the fasciculi of spines upon the dorsal surface of the caudal segments and the shortness of the inferior antennæ. It is included by most authors in the genus *Gammarus*, but distinguished as a group by itself." In the Brit. Sess. Crust. p. 400, it is said to be distinguished from *Mæra*, as well by the coxae and second gnathopods, as "generally by the greater length of the posterior pair of caudal appendages." Heller and Boeck make it a synonym of *Mæra*. The new species assigned to it are *Megamæra serrata*, n. s., which is no doubt a synonym of *Mæra rubromaculata*, Stimpson; *Megamæra semiserrata*, n. s.; "*Megamæra Alderi*, n. s." which in the Brit. Sess. Crust., vol. i. p. 407, occurs as *Megamæra ? alderi*, with the rather singular observation that "the character of this animal appears to justify its admission as a species in the present genus, but we desire to express our conviction that it will ultimately be ascertained to be the female of a species of *Melita*, probably *Melita proxima*." This conviction is confirmed by A. M. Norman, who considers *Megamæra alderi* the ♀ and *Melita proxima* the ♂ of *Melita obtusata*.

Fam. 3. Corophiidae. Subfamily 1. Podocerides, receives "Amphithoe Falklandi, n. s.;" "Amphithoe Australiensis, n. s.;" "Amphithoe Desmarestii, n. s.," identified by Catta, 1876, with *Amphithoe penicillata*, Costa, but which is more probably a synonym of *Amphithoe vaillantii*, Lucas, 1849; *Podocerus ocius*, n. s.; "Cerapus Hunteri, n. s.," entered by S. I. Smith as a synonym of *Erichthonius difformis*, M.-Edwards.

Nænia, new genus, is thus defined:—Antennæ subequal; superior without a secondary appendage; inferior arising posteriorly to the superior. Gnathopoda subchelate; second pair very large. Pereiopoda strong, subequal. Posterior pair of pleopoda biramous, rami styliform. Telson tubular, tipped with one or two rudimentary denticles.

"This genus differs from *Eurystheus* chiefly in the absence of the secondary appendage to the superior antennæ and in the larger size of the second pair of gnathopoda." The type species is *Nænia tuberculosa*, n. s., which Boeck considers a synonym of his *Podoceropsis sophiae*; *Nænia rimapalma*, n. s., is changed to *Nænia rimapalmata*, in the Brit. Sess. Crust., p. 474. *Nænia excavata*, n. s., is doubtfully distinct from the preceding; *Nænia undata*, n. s., may perhaps belong to some other genus.

Cratippus, new genus, is thus defined:—"Body long. Antennæ short; flagella rudimentary; superior pair without any secondary appendage. Coxæ not so deep as the pereion. Gnathopoda subchelate; second pair having the propodos much larger than that of the first. Pereiopoda subequal. Three posterior pairs of pleopoda having short rami. Telson squamiform (?)." "The rudimentary character of the flagella of the antennæ, the absence of the secondary appendage, and the shortness of the coxae are characters that separate this genus from *Podocerus*; the size and form of the second pair of gnathopoda distinguish it from *Corophium*; and the shortness of the antennæ and relative proportions of the gnathopoda separate it from *Dryope* and *Unciola*." The type species is *Cratippus tenuipes*, n. s., but both genus and species have been anticipated by *Colomastix pusilla*, Grube, 1861. Grube (and subsequently Norman in his also synonymous *Exunguia stilipes*), shows that the first gnathopods, instead of being subchelate or "scarcely subchelate," are exungues, without a finger.

Dryope, new genus (answering to *Unciola*, Gosse, Marine Zool. i. p. 141, not Say) is thus defined:—"Animal long and slender. Superior antennæ without a secondary appendage; inferior antennæ not longer than the superior. Coxæ not so deep as the pereion. First pair of gnathopoda larger than the second, subchelate; second pair small, imperfectly chelate.

Posterior pair of pereiopoda longer than the others. Posterior pair of pleopoda short, almost rudimentary, double-branched. Telson single, squamiform."

"This genus differs from *Unciola* of Say in the absence of a secondary appendage to the superior antennæ, in the form of the second pair of gnathopoda, in the shortness of the posterior pair of pleopoda, and in the character of the telson." The type species is *Unciola irrorata*, Gosse (not Say). *Dryope crenatipalma*, n. s., re-named *crenatipalmata* in the Brit. Sess. Crust., seems to me to be only a variety of *Dryope irrorata*. The secondary appendage, though very small, is not wholly wanting to the upper antennæ.

Corophium spinicorne, n. s., is considered by Boeck a synonym of *Corophium crassicorne*, Bruzelius, 1859. The name too was preoccupied by Stimpson in 1856.

Division HYPERINA. Fam. 1. HYPERIDÆ. "*Lestrigonus Kinahani*, n. s.," is held by Boeck to be a synonym of *Hyperia medusarum*, Müller, which Meincrt rejects, considering Müller's description too indefinite, and therefore adopting the name *Hyperia galba*, Montagu. Streets would keep *Lestrigonus* distinct from *Hyperia*. "*Vibilia Edwardsii*," though here given as new, had been already published in the Annals and Magazine of Nat. Hist., 1861. *Vibilia affinis* (*Vibilia affinis*, MS. Cat. Musée Jardin des Plantes) is from Java. "*Cyllopus Lucasii*, n. s.," is from "the Powel [Powell] Islands," now known as the S. Orkneys; "*Cyllopus Danæ*, n. s.," from "near the Powel Islands," is probably a younger form of *Cyllopus lucasii*. "*Themisto Guérini*ii, n. s.," "Hab. (In the Atlantic?) Latitude of La Plata (MS. label)," is said to resemble closely the much larger *Themisto antarctica*, Dana.

Fam. 2. PHRONIMIDÆ. Subfam. 1. PHRONIMIDES. "*Phronima Bornensis*, n. s." (*Phronima Atlantica*, White, Cat. Crust. B. M. 1850) is no doubt, as Spence Bate himself suggests, to be identified with *Phronima sedentaria*, Forskål. Subfam. 2. PHROSONIDES. *Phrosina longispina*, n. s., is doubtfully distinct from *Phrosina semilunata*, Risso, with which Sp. Bate is inclined to unite *Phrosina nicetensis*, M.-Edwards. *Anchylomera antipodes*, n. s., was taken "near the Antipodes."

Fam. 3. PLATYSCELIDÆ. *Platyscelus*, here given as a new genus, though already described in the Ann. and Mag. of Nat. Hist., July 1861, is a synonym of *Dithyrus*, Dana. Of the species "*Platyscelus Rissoinæ*, n. s.," and *Platyscelus serratus*, n. s., the latter is united by Claus to *Typhis ovoides*, Risso, and he inclines to treat the former in the same manner.

Brachyscelus is here given as a new genus, but the description of it and of the type species, *Brachyscelus crusculum*, appeared in the Ann. and Mag. of Nat. Hist. for July 1861.

Thamyris, new genus, is thus defined:—"Superior antennæ short, three-jointed. Inferior antennæ obsolete. Posterior pair of pereiopoda represented by a basos in the form of a membranous scale only."

"In all other respects this genus so nearly corresponds with *Brachyscelus*, that future research will probably demonstrate their closer connection." The type species is *Thamyris antipodes*, u. s. Claus decides that *Thamyris* is the male of *Brachyscelus*. His own genus *Schnehagenia* he recognises as an additional synonym, and names the genus *Thamyris*, but *Brachyscelus* has the priority. *Brachyscelus* in turn must yield to *Dairilia*, Dana, if the suggestion of Bovallius be accepted, that *Dairilia* is identical with *Thamyris*.

Amphipronoë, new genus, is thus defined:—"Cephalon round, anteriorly oblique. Pereion not broader than the cephalon. Pleon having the fourth and fifth segments fused into one. Superior antennæ having the peduncle three-jointed; third joint large, inferiorly convex and anteriorly produced, having the superior margin subapically excavated to receive the short flagellum. Inferior antennæ five-jointed. First pair of gnathopoda complexly subchelate; second pair not subchelate. Third and fourth pairs of pereiopoda largely dilated, having the remaining joints as long as the basa; fifth pair rudimentary. Posterior

pair of pleopoda biramous, foliaceous. Telson nearly as broad at the base as the preceding segment of the pleon."

"This genus is very closely allied to *Pronoë*, but differs in the form of the superior antennæ and of the gnathopoda, and in the fusion of the fourth and fifth segments of the pleon into one." The type species is *Amphipronoë cuspidata*, n. s. Claus gives up this genus as not defined with sufficient accuracy. On the supposition that the first and second gnathopods have been interchanged in the description, he thinks it might be the same as his own genus *Parapronoë*. In any case the distinction drawn between *Amphipronoë* and *Pronoë* grounded on the fusion of the fourth and fifth segments into one, seems untenable, the rule in the Hyperina being that the fifth and sixth segments, not the fourth and fifth, of the pleon, coalesce.

In Fam. 5. OXYCEPHALIDÆ, "Subfam. 1. SYNOPIADES" is certainly out of place. In Subfam. 2. OXYCEPHALIDÆ, *Oxycephalus tuberculatus*, n. s., is, according to Claus, a synonym of *Oxycephalus piscator*, M.-Edwards; "*Rhabdosoma Whitei*, n. s.," according to Claus, is the male of *Rhabdosoma armatum*, M.-Edwards.

Group Aberrantia. Fam. 2. CAPRELLIDÆ. *Caprella calva*, n. s., is recognised in the Brit. Sess. Crust. as = *Caprella acanthifera*, Leach; *Caprella ultima*, n. s., according to Mayer = ?? *Caprella aequilibra*, Say.

1862. BATE, C. SPENCE.

Note on the supposed "Discovery of an extremely minute Vertebrate Lower Jaw in mud dredged at St. Helena, by Dr. Wallich, F.L.S." The Annals and Magazine of Natural History. 3 Ser. Vol. X. December 1862. pp. 440-441.

The supposed jaw in Mr. Spence Bate's opinion may be the dactylos or last joint of a leg of a small Hyperine Crustacean. He figures a leg of *Phrosina longispina* for comparison, and supposes that Dr. Wallich may have been misled by seeing a second row of marginal armature within the external one, such as appears in Crustacea near the period of moulting.

1862. CLAUS, C.

Bemerkungen über *Phronima sedentaria* Forsk. und *elongata* n. sp. Abdruck aus der Zeitschr. f. wissensch. Zoologie. Bd. XII. Hft. 2. 1862. pp. 189-196. Mit Tafel XIX.

In the heart of *Phronima sedentaria*, "the three pairs of lateral openings, which serve as venous Ostia for the reception of the blood flowing back from the body to the heart, are found in the second, third, and fourth thoracal-segments." From the point of the heart an arterial vessel, constituting the abdominal Aorta, stretches from the middle of the sixth peraeon-segment almost to the middle of the third pleon-segment. The Aorta cephalica is also mentioned. Claus also here speaks of two fine strings in the third and fourth peraeon-segments running "von der ventralen Fläche des Herzens aus schräg nach oben und vorn zum Magen," which he supposes may serve for fastening, although at first inclined to regard them as arteries. In his later work on the Phronimidae 1879, he finds that these are really lateral arteries, constant in the genera of the Phronimidae, and in *Paraphronima* and several other Hyperina supplemented by a third pair. He says that Pagenstecher has attributed

to the thorax a ganglion-pair too many, and in the last peraeon-segment figured a ganglion in a place, where none such exists. The habitation which the female *Phronima sedentaria* occupies is discussed.

Phronima elongata, n. s., Taf. xix. Figs. 2, 3, 7, is described. This subsequently became the type for a new genus as *Phronimella elongata*.

Phronima sedentaria, Taf. xix. Figs. 1, 4, 5, 6, is described, and the suggestion made that *Phronima atlantica* of Guérin and M.-Edwards (*Phronima custos*, Risso) is the not completely adult form of *Phronima sedentaria*. With reference to the sort of metamorphosis which Pagenstecher had shown that this species undergoes as it advances in age, Claus states that he has noticed similar facts in regard to *Phronima elongata*, in which, he says, the most interesting peculiarity is "die Anwesenheit zweier einfacher stummelförmiger Fühlhörner unterhalb der grösseren 2gliedrigen Antennen (Fig. 7.). Die junge Ph. elongata hat also wie die ächten Hyperinen zwei Antennenpaare und es ist das obere Paar, welches in der späteren Zuständen persistirt."

1862. CLAUS, C.

Ueber *Phronima elongata* Cls. Hierzu Tafel VI. (Fig. 6-11). Würzburger naturwissenschaftliche Zeitschrift. III. Band. 1862.

Claus gives a further description, believing that he has found the male form. This in 1872 he decided to be "das noch junge Männchen vor Eintritt der Geschlechtreife und vor der Entfaltung sämmtlicher Antennenglieder." He corrects an oversight in the previous account, where the fourth pair of feet, instead of the third, was stated to be the longest. Of the second uropods, he says, "das mittlere Paar der 3 Springfüsse sehen wir an dem ausgebildeten Weibchen vollständig hinwegfallen, bei dem Männchen dagegen entwickelt sich dasselbe jederseits zu einem engen und kurzen Schlauche, der an seiner Spitze einfach bleibt und kann über das letzte Leibes-segment hinaus ragen. Die hakenförmige Anlage dieser Extremität, wie wir sie in den 4-5 Mm. langen Jugend-stadien antreffen, würde demnach in beiden Geschlechtern eine verschiedene Veränderung im Laufe des weiteren Wachsthums erleiden." He figures and describes the mouth-organs.

1862. COSTA, ACHILLE.

Osservazione sul genere *Lysianassa* e descrizione di una novella specie. Annuario del Museo zoologico della R. Università di Napoli per Achille Costa. Anno 1. Napoli, 1862. pp. 79-82.

In a species discovered by Costa the lower antennæ are furnished with a slender flagellum as long as the body. This seemed to him a difference of almost generic value, but the rest of the organization was so perfectly identical with that of *Lysianassa* that he was content to let it rank as a specific distinction. It is now known to be only a sexual character of the adult male. He names the species *Lysianassa filicornis*. The Latin description of it is:— "L. antennis superioribus corporis quarto brevioribus, pedunculi articulo primo valde incrassato, infra spina acuta terminata; inferioribus seta gracillima corporis longitudinem equante; pedibus primi paris manu elongato-conica, unguiculo valvulisculo praedita, secundi paris longioribus, gracilioribus, manu ovato-rotundata, setis terminata; pedibus spuriis abdominalibus aequa terminatis. Longit. corp. millim. 10." Tav. II, fig. 18-23.

1862. COSTA, ACHILLE.

Annuario del Museo Zoologico della R. Universita di Napoli per Achille Costa.
Anno I. Napoli, 1862.

Articolo 10°. *Osservazioni sulla Diphya quadrivalvis e su' Crostacei che si sviluppano entro i bottoni delle appendie urticanti.* pp. 90-94.

While watching some specimens of *Diphya (Galeolaria) quadrivalvis*, Costa noticed some movements in the urticating apparatus which surprised him. He found them due to a little Crustacean encased in the "bottoni," which stand at the extremity of the secondary filaments. "Entro que' bottoni, come entro di un sacco cistico, era un piccolo Crostaceo, nello stato quasi embrionale, co' piedi toracici ripiegati contro il petto ed immobili, e con i falsi piedi addominali in continuo movimento. L'abito generale dell' animale ci porterebbe a vedervi qualche affinità con le *Phrosine*; però la struttura de' piedi non presenta nulla de' caratteri proprii de' Crostacei di tal genere; siccome non ci è permesso vedervi con esattezza alcuno de' generi già noti nello stato adulto. Laonde, salvo sempre a ben fissarne le note caratteristiche, noi le chiameremo *Diphyicola rubens*." He proceeds to ask, whence come the eggs of the Crustaceans, in what way do they penetrate into the appendages of the *Diphya*, when do they leave this receptacle, etc.? The observation is most interesting, but it seems rash to have constituted a new genus, with practically no characters. Figures 5, 6, are given on pl. iii., of the animal in a very embryonic condition in its involucrum, and "figura 7, Il Crostaceo osservato in altro bottone più sviluppato, ed avente già tutte le parti ben determinate. Esso rimaneva avvolto da una semplice membrana, la quale come per un funicello era attaccata al filamento accessorio indicata."

1862. BATE and WESTWOOD.

A History of the British Sessile-eyed Crustacea. Part IV., January 1, 1862.
Part V., February 1, 1862. Part. VI., April 1, 1862. Part VII., May 1, 1862.
Part VIII., July 1, 1862. Part IX., November 1, 1862. Part X., December 1, 1862. pp. 145-480, each Part in this work containing 48 pages. London.

At page 161 *Ædiliceros parvimanus*, n. s., is figured and described, on which the authors remark that "Kroyer in his generic description states that both pairs of hands are very large," whereas in their species "neither of the hands can be described as being large, and the second is decidedly smaller than the first." In vol. ii. p. 528, 1868, the authors mention specimens which they think must be the male form. "They differ from that described in having the upper antennæ but little longer than the peduncle of the lower, the lower antennæ as long as the entire animal, and the gnathopoda with hands somewhat larger, but scarcely equal to the 'very large' hands as described by Kroyer in his description of the genus."

At page 177 *Kroyera altamarina*, n. s., is figured and described. By J. Sparre Schneider, 1885, this is made a synonym of *Pontocrates norregicus*, Boeck. See Note on Schneider, 1885.

At page 206 *Liljeborgia shetlandica*, n. s., is figured and described. This appears to be a synonym of *Cheirocratus sundevalli*, Rathke, 1843.

At page 226 is given the new genus *Pereionotus*, thus defined:—

"Cephalon short. Pereion distended. Pleon compressed. Antennæ very short. Superior longer and more robust. Gnathopoda subchelate, subequal. Pereiopoda short, robust.

Antepenultimate pair of pleopoda having the peduncle very short, rami long, subfoliaeeous. Penultimate pair having the peduncle long, rami styliform. Ultimate pair short, unibranched. Telson single." The authors remark further, "this genus bears a near relationship to that of *Phlias* of Gnérin. The only distinction of importance which we are enabled to discover exists in the form of the posterior pair of caudal appendages; these are biramous in the description and figure of *Phlias*, as given by the author in the 'Magasin de Zoologie' for 1836." Of *Phlias rissouanus* the authors had a specimen at command, but they say "the specimen being small, we were not able to make out the form of the last pair of caudal appendages without dissection, and we felt unwilling to destroy our only specimen," by this means saving their specimen and destroying its use. Such economy was particularly undesirable in the present instance. The genus *Pereionotus* was instituted to receive the *Oniscus testudo* of Montagu, which was preserved in the British Museum, and had been supposed by Adam White to belong to the genus *Acanthonotus*, Owen. See Note on Montagu, 1808. It is only by a minute comparison of the figures as well as the descriptions given by the various authors, respectively, of *Phlias serratus* by Guérin, 1836, of *Pereionotus testudo* by Bate and Westwood, and of *Iridium fuscum* by Grube (1863) 1864, that the close connection between these three forms can be appreciated. When also the minuteness of the specimens is borne in mind, the possibility of error in one or more of the descriptions will be taken into account.

At page 242 *Dexamine vellomensis*, n. s., is figured and described. This is named *Atyhus vellomensis*, by Boeck.

Culliope singalli, n. s., figured and described at page 263, may possibly, the authors say, "be only an exaggerated variety of *C. Ossiani*." By Boeck both of these species are considered to be synonyms of *Amphithopsis latipes*, M. Sars, 1858.

At page 333 *Gammarella normanni*, n. s., is figured and described, with the remark that "this animal bears so close a resemblance to the preceding that we are inclined to think that it may only be the female of that species," i.e., *Gammarella brevicaudata*, M.-Edw. The specimen described has the flagella of the upper antennæ longer than those observed in *Gammarella brevicaudata*, though in other respects agreeing with the female of that species. It is possibly a young male.

The genus *Amathia*, Rathke, is here (p. 359) renamed *Amathilla*, *Amathia* being pre-occupied among Polyps, Decapod Crustacea, and Moths.

At page 411 is introduced the new genus *Eiscladus*, thus defined:—

"Slightly compressed. Eyes on a prominently-advanced lobe between the superior and inferior antennæ. Superior antennæ without a secondary appendage. Gnathopoda subchelate. Coxæ of the third pair of pereiopoda having the anterior lobe as deep as the coxæ of the second. Posterior pair of pleopoda biramous, rami unequal. Telson squamiform, single." This genus has since been recognised as a synonym of *Photis*, Kröyer, 1842. The type species, *Eiscladus longicaudatus*, figured and described as new at page 412, is by Boeck considered a synonym of "*Photis Reinhardi*," Kröyer, with which it agrees in the excavate and dentate palm of the second gnathopods.

1862. GERSTAECKER, CARL EDUARD ADOLPH, born 1828 (Hagen).

Bericht über die wissenschaftlichen Leistungen im Gebiete der Entomologie während des Jahres 1861. Archiv für Naturgeschichte. Berlin, 1862. Crustaceen. pp. 528–571.

The Articulata by Gerstaecker (Hagen).

1862. HOEVEN, J. VAN DER.

Determinatio Ieonum Slabberi. Verslagen en mededeelingen der Kon. Akademie van Wetenschappen XIV, 1862. pag. 270 sqq.

I take the notice of this work from R. T. Maitland, 1876. See Note on Maitland, under that date, for the information affecting the Amphipoda.

1862. LOVÉN, SV.

Till frågan om Ishafssfaunans fordna utsträckning öfver en del af Nordens fastland. Öfvers. af K. Vet.-Akad. Förh. 1862. N:o 8. pp. 463–468.

This paper gives further particulars of the distribution of the three species of Amphipods mentioned in the author's previous paper (see Note on Lovén, 1861), and compares the shape and size of various specimens of the fresh-water *Gammarus loricatus*, with a specimen from Spitzbergen.

1862. MEYER, H. ADOLPH, und MÖBIUS, KARL.

Kurzer Ueberblick der in der Kieler Bucht von uns beobachteten wirbellosen Thiere, als Vorläufer einer Fauna derselben. Archiv für Naturgeschichte. Acht und zwanzigster Jahrgang. Erster Band. Berlin, 1862. pp. 229–237.

Of Amphipoda they mention *Gammarus locusta*, Montagu, " *Gammarus Sabinei*," Leach, two species of " *Amphitoë*," "*Leptomera pedata*, Müll.," and "*Caprella linearis*, Hbst."

1862. MILNE-EDWARDS, ALPHONSE.

Notes sur l'île de la Réunion, par L. Maillard. Faune carcinologique par M. Alph. Milne-Edwards. Annexe F.

It may save trouble to future enquirers to quote the negative observation in this work; " il est aussi à noter que, dans les collections que nous avons pu consulter, il ne se trouve aucun Amphipode." Milne-Edwards suggests that new researches might well be undertaken to fill up this and other lacunæ.

1863. GERSTAECKER, A.

Bericht über die wissenschaftlichen Leistungen im Gebiete der Entomologie während des Jahres 1862. Archiv für Naturgeschichte. Berlin, 1863. Crustaceen. pp. 566–598.

1863. BATE and WESTWOOD.

A history of the British Sessile-eyed Crustacea. Part XI., April 1, 1863. Part XII., August 1863. pp. 481–507, and (Vol. II.) pages 1–64. London.

At page 490, the species *Dryope crenatipalma*, Spence Bate, is renamed *Dryope crenatipalmata*.

At page 497, a species is given as *Corophium bonellii*, Milne-Edwards, which Norman regards as unquestionably the female of *Corophium crassicornis*, Bruzelius. To the *Corophium bonellii* here figured and described, *Corophium spinicorne*, Sp. Bate, is made a synonym. *Chelura terebrans* is misprinted as *Chelura terebans*, and the figures of the gnathopods are wrongly lettered.

At page 51 (Vol. II.) the genera *Podalirius* and *Aeyina* of Krøyer are rejected, but on insufficient grounds, so that for *Caprella typica* (page 75), *Podalirius typicus*, Krøyer, must be reinstated.

Cyamus erraticus, Roussel de Vauzème, is, at page 86, regarded as a synonym of *Cyamus ceti*, Linnaeus, but erroneously in the opinion of Lütken, who also considers it rash to include *Cyamus oralis* and *Cyamus gracilis*, as is here done, in the British Fauna. (N.B.—Part XIII. containing pages 65–112 was published July 2, 1866. The Amphipoda end at page 98. For the Appendix see under 1868. The intervening parts containing the Isopoda were published—Part XIV., October 1, 1866. Part XV., December 2, 1866. Part XVI., May 1, 1867. Part XVII., June 1, 1867. Part XVIII., August 1, 1867. Part XIX., October 1, 1867. Part XX., April 1, 1868. Part XXI., August 1868.)

1863. CARUS and GERSTAECKER.

Handbuch der Zoologie. 1863.

Mayer notes the erroneous statement, vol. ii. p. 363, that the mandibular palp is wanting in all the Caprellidae.

1863. CLAPARÈDE, JEAN LOUIS RENÉ ANTOINE EDOUARD, born 1832 (Hagen).

Beobachtungen über Anatomie und Entwicklungsgeschichte wirbelloser Thiere an der Küste von Normandie angestellt von Dr A. René Edouard Claparède. Mit 18 Kupfertafeln. Leipzig, 1863.

Pages 101–102 contain the section “Ueber die Blutbahnen bei den Caprellen,” illustrated by Taf. xvi. Fig. 17–18.” He says that in all the Caprellæ he examined the arterial current of the blood took its course along the side of the foot occupied by the flexor muscles, and the venous current along the extensor side; he points out that Frey and Leuekart were in error in saying that the whole arterial stream ran to the end of the leg, there to bend round into the venous stream. “Am peripherischen Ende jedes Fussgliedes (vgl. Fig. 17) spaltet sich nämlich die arterielle Blutströmung in zwei Zweige, wovon einer als arterieller Strom in das folgende Glied dringt, während der andere sofort umbiegt und auf der Streckseite in den venösen Strom übergeht.” The arterial and venous currents are kept separate, he says, in the long legs by a very transparent membrane, in which he detected an elongate sharply defined opening, just where one part of the blood-corpuscles passed over from the arterial into the venous stream. On this subject Delage, p. 130, says in 1881, “dans les pattes, les vaisseaux afférents sont placés du côté de l’extension. Ils suivent donc le bord supérieur dans les deux premiers paires de pattes, et l’inférieur dans les trois dernières paires. Chacun

se continue au sommet de l'appendice avec le vaisseau différent correspondant qui suit le bord opposé, et communique avec lui en plusieurs points de son trajet par de petites échappées qui s'ouvrent dans les lacunes du membre." Mayer observes that in the hind legs of *Caprella* the back-currents are not nearly so frequent as Claparède might lead one to suppose, since many blood-corpuscles, which disappear between muscles and seem to pass over into the venous division, circle round one muscle or another, and win their way back into the arterial main stream.

1863. KINAHAN, JOHN ROBERT.

Notes on the Marine Fauna of the Coast of Clare. (Read before the Natural History Society of Dublin, June 21, 1861). The Dublin Quarterly Journal of Science, No. IX. January, 1863. London. pp. 7-11.

"The only Amphipod I could meet in this [the littoral] zone," the writer says, "after much research, was *Orchestia littorea*, although *O. Mediterranea* occurs abundantly in Dublin and Plymouth. In the other zones were met, along with a multitude of others, *Caprella tuberculosa*, *Neara bicuspisata*, *Amphiooe rubricata* and *littorina*, *Lestrigonus falcatus*; but I met with no specimen of *Gammarus palmatus*, although this latter occurs at Dublin."

1863. LORENZ, JOS. ROM.

Physicalische Verhältnisse und Vertheilung der Organismen im Quarnerischen Golfe. Wien. 1863.

Twelve species of Amphipods are named as distributed in the Quarnero, from the surface down to 45 fathoms. See pp. 288, 293-295, 303-326, 349.

1863. PACKARD, ALPHEUS SPRING, JR., born February 10, 1839 (S. I. Smith).

A list of Animals dredged near Caribou Island, Southern Labrador, during July and August, 1860. The Canadian Naturalist and Geologist. December, 1863. Vol. VIII. No. 6. pp. 401-429.

At page 419 he mentions " *Unciola irrorata* Say. *Anonyx* sp. In 15 feet gravel. *Anonyx* sp. *Ampeliscus pelagica* Stm. *A. Eschrichtii* Kr. *Gammarus purpuratus* Stm. In 10 feet mud and sand. *G. mutatus*, Liljeborge, (G. pulex). Occurs as in Maine."

At page 425, in "a List of the Invertebrata collected at Anticosti and Mingan Islands, by Messrs A. E. Verrill, A. Hyatt, and N. S. Shaler, in 1861," he mentions " *Gammarus mutatus* Leily. Low water, abundant." "*Caprella*. Two species, 20 feet, common. *Calliope lavinscula*. Magdalen Isles. Abundant at the surface of the water in the caverns under eroded cliffs. *Themisto* sp. Anticosti, common."

In regard to the typographical errors, see Note on Packard, 1867. The lists, he says (of course with no special reference to the Amphipoda), " seem to afford very satisfactory evidences that there are three distinct assemblages of marine invertebrates intermingled on the coast of Southern Labrador." See also Note on S. I. Smith, 1883.

1863. SARS, M.

Zoologiske Notitser fra Christiansund og Bejan. Nyt Magazin for Naturvidenskaberne. Tolvte Binds tredie Hefte. Christiania, 1863.

At page 290 he records "*Aeyinella spinosa* A. Boeck. Ikke sjeldent mellem Sertulariner paa 30-40 F. D. ved Bejan. Det levende Dyr Farve er hvidagtig og staerk marmorert eller plettet med rustbruunt, Øjnene minierede."

1863. SARS, GEORG OSSIAN, born 1837 (G. O. Sars).

Beretning om en i Sommeren 1862 foretagen zoologisk Reise i Christianias og Trondhjems Stifter. Nyt Magazin for Naturvidenskaberne. Tolvte Binds tredie Hefte. Christiania, 1863. pp. 193-252.

Pages 205-212 relate especially to the fresh-water Amphipoda observed on this journey. First Sars discusses *Pontoporeia femorata*, Krøyer, Var., to which he strongly inclines to make *Pontoporeia afinis*, Lindström, a synonym. Secondly, he gives a full description of a species under the following heading, "*Gammarus pulex* De Geer, an a specie vulgo hoc nomine descripta diversus?" As to its *habitat* he says, "har jeg altid kun truffet vor Gammarus in større stillestaaende Vande, aldrig i Elve." If it should prove a distinct species, he proposes to name it in correspondence with its habitat *Gammarus lacustris*, a name which he afterwards changed to *Gammarus neglectus*. Thirdly, he describes "*Gammarus cancelloides* Gerstfeldt, Var. (?)." This form, he says, had been already described by A. Boeck as a new species, uuder the name *Gammarus quadrispinosus*. It is rather in deference to Lovén's opinion, than upon his own judgment, that he hesitates to accept Boeck's view.

1863. STIMPSON, WILLIAM.

Synopsis of the Marine Invertebrata collected by the late Arctic Expedition under Dr. J. J. Hayes. From Proceedings of the Academy of Natural Sciences of Philadelphia, May, 1863.

The Amphipods recorded are *Anonyx ampulla*, Krøyer, which is a synonym to *Anonyx nugar*, Phipps; *Pherusa tricuspis*, n. s., which is identified by Boeck with *Amphithoë fulvocincta*, M. Sars, 1858, under the name *Halirages fulvocinctus*; *Gammarus locusta*, J. C. Fabr. and *Themisto arctica*, Krøyer? *Gammarus pulex*, Stimpson, from Grand Manan, is here placed as a synonym to *Gammarus locusta*, Fabr.

1864. BATE, C. SPENCE.

Characters of New Species of Crustaceans discovered by J. K. Lord on the coast of Vancouver Island. [From the Proceedings of the Zoological Society of London. December 13, 1864.] pp. 662-668.

A new species "*Möera fusca*," is thus described:—"The body is long and slender; the superior antennæ are about half the length of the animal, the peduncle being scarcely longer than (ZOOL. CHALL. EXP.—PART LXVII.—1887.)

the flagellum; the secondary appendage being half the length of the primary, the second joint of the peduncle being about the same length as the first. Second pair of gnathopoda having the propodos large; palm without teeth, and defined by a small pointed process. Posterior pair of pereiopoda having the posterior margin of the base smooth.

"In its general appearance this species bears a near affinity to *Mera grossimana*, as well as to *M. tenella*, from the Feejee Islands, the only appreciable distinctions being in the shorter length of the second joint of the antennæ, the absence of teeth from the palm of the hand in the second pair of gnathopoda, and in the even margin of the last (the only remaining) pair of pereiopoda, and perhaps also in the shortness of the peduncle of the ultimate pair of pleopoda." Habitat, a sponge in Esquimalt Harbour.

Tanais loricatus, n. s., is also described in this paper.

1864. COSTA, ACHILLE.

Di due nuove specie di Crostacei Amfipodi del golfo di Napoli. Annuario del Museo zoologico della R. Università di Napoli per Achille Costa. Anno II. 1862. Napoli, 1864. pp. 153-157.

He first describes "Ampelisca rubella, nob. Tav. II. fig. 7. *A. saturata rosea*; antennis capite thoraceque parum longioribus, subæqualibus; scapo in superioribus vix quartum, in inferioribus tertium totius antennæ formante: pedibus primi et secundi paris subcylindraceis, longe pilosis (secundi gracilioribus paullumque longioribus), ungue arcuato, infra dentato; tertii et quarti articulo secundo et quarto brevissimis, ungue recto acutissimo; quinti et sexti articulo primo valde dilatato, orbiculari-cordato, ungue minutissimo retrum verso; septimi coeteris brevioribus, articulo primo minus elato, inferius lobato-producto, articulis 2-5 brevibus subæqualibus, ungue spurio, obtuso; lamina caudali ovato-elliptica, postice profunde scissa.—Long. mill. 7." He says that from *Araneops diadema* and *Araneops longicornis*, the two species of *Ampelisca* which he had previously described from the Gulf of Naples, the present species differs sensibly, in colour, smaller size and other more important organic characters. He gives a fuller description in Italian.

He next describes "Protomedea fasciata, nob. Tav. II, fig. 8. *P. albida*, fasciis fuscis nigro punctatis, antennis subæqualibus, scapo superiorum illo inferiorum breviore; pedibus thoracici quinti, sexti et septimi paris articulo primo margine integro.—Long. mill. 7-8." It has, he says, great affinity with *Protomedea hirsutimana*, Bate and Westwood, but differs in having the first joint of the fifth pair of feet not serrate, in the distribution of the hairs (peluria) of the feet of the second pair and in the antennæ. It keeps its colour in alcohol.

1864. COSTA, ACHILLE.

Di alcuni crostacei e di un distomideo parassito degli acalefi. Rendiconto della R. Accademia delle Scienze Fisiche e Matematiche di Napoli. Fascicolo 4°—Aprile 1864.

Costa here notices that in 1850 Natale had placed Cocco's *Orio ornithoramphus* in a new genus, as "*Ornithoramphus Coccoi*." With this Costa himself proposes to arrange three new species in two new genera, forming a little natural group, the ORNITORAMFINI. The genus *Natalius* is thus defined:—

"Corpus elongatum, dorso rotundatum. Caput antrorsum ad rostri instar conice productum, rostro infra canaliculato. Antennæ duo, infra rostrum in canaliculo insertæ, minutæ. Oculi elongati, subreniformes. Palpi maxillares duo, corporis dimidiā longitudinem

superantes, gracillimi, trigeniculati. Pedes primi et secundi paris minuti, validiusculi, subprehensiles;—tertii et quarti coeteris longiores, gracillimi, filiformes—quinti, sexti et septimi normales. Pedes spurii primi, secundi et tertii segmenti abdominalis biremes, remis setosis, setis utrinque fimbriatis—quarti, quinti et sexti stylis biarticulatis." The type species, *Natalius candidissimus*, A. Costa, is defined as follows:—" *N. albus, immaculatus, oculis tantum rubris, antennis sex-articulatis, articulo primo valde incrassato, setoso; pedibus primi et secundi paris carpo elongato, infra in spinam validam anterius producto; manu cylindracea, ungue parum arenata; tertii paris illis quarti paullo longioribus; illis quinti, sexti et septimi longitudine decrescentibus, margine antico minutissime serrulatis; articulo primo parum dilatato; pedibus spuriiis quarti, quinti et sexti segmenti abdominalis æque terminatis. Longit. millim. 13.*"

The genus *Natalius* may perhaps be identical with *Oxycephalus*, M.-Edw., with which Carus doubtfully unites it, citing the *palpi maxillares duo* as "[? *antennæ II.*]," but that they are the lower *anteunæ* is beyond question. The genus might be distinguished from *Oxycephalus* on the ground of its subprehensile gnathopods, did not the description of the type species indicate that they are in fact complexly chelate. The species *Natalius candidissimus*, Carus gives doubtfully as a synonym of *Oxycephalus similis*, Claus, 1879; but except that the specimens were taken in the same waters, the authors do not happen to take any common characters, on which a comparison can be founded, unless the slenderess of the first and second *peræopods* be considered such. It is strange that Costa makes no reference to *Oxycephalus*, and stranger still that he does not refer to *Erpetorampus costæ*, described by de Natale, 1850, in a letter to Costa, beginning "Carissimo Achille."

The genus *Carcinornis*, A. Costa, is thus defined:—

Corpus elongatum, compressum, dorso subcarinatum. Caput anterius ad rostri instar conice productum, rostro infra canaliculato. Antennæ duo, infra rostrum in canicula insertæ, minutæ. Oculi ovato-reniformes. Palpi maxillares minutissimi, quadriarticulati, haud fructi. Pedes primi et secundi paris minuti, validiusculi, prehensiles—tertii et quarti filiformes—quinti, sexti et septimi normales. Pedes spurii primi, secundi et tertii segmenti abdominalis biremes, remis setosis, setis fimbriatis—quarti, quinti et sexti stylis biarticulatis." The type species, *Carcinornis acutirostris*, A. Costa, is described as follows:—" *C. albus, utrinque vitta lata purpurea per totum fere corpus cœcurrente notatus; capite cum rostro tertiam fere totius corporis partem formante, rostro acuminato; antennis setaceis; pedibus tertii et quarti paris subæqualibus—quinti, sexti et septimi longitudine decrescentibus, margine antico minutissime serrulatis, articulo primo modice dilatato; pedibus spuriiis quarti, quinti et sexti segmenti abdominalis fere æque terminatis. Longit. millim. 5–6.*" The second species, *Carcinornis inflaticeps*, A. Costa, is very briefly described in this way:—" *C. capite inflato, cum rostro minus acuminato quartum totius corporis partem formante; cœterum præcedenti similis. Longit. millim. 5–6.*"

The genus *Carcinornis*, if really distinct, may eventually be identified by the coloration assigned to the type species. *Carcinornis inflaticeps* is suggestive of *Oxycephalus typhoides*, Claus, from the harbour of Messina, which has been already mentioned (p. 241) for comparison with *Ornithoramphus coccoi*, de Natale.

1864. GRUBE, A. E.

Beschreibungen einiger Amphipoden der istrischen Fauna. Archiv für Naturgeschichte. XXX. Jahrgang. I. Bd. 1864. pp. 195–213. Taf. V.

He here renames several of the species described by him in 1861; see Note on Grube, 1861.

He says that the Amphipod, which Spence Bate treats as Rathke's *Dexamine tenuicornis*,

differs from it in several respects. He figures as a new species *Iphimedia multispinis*, and describes it in great detail. It seems closely to resemble *Iphimedia eblanæ*, Spence Bate, which is itself probably a form of *Iphimedia obesa*, Rathke.

The genus *Colomastix*, Grube, 1861, is here more fully defined:—

“*Corpus* subteres, depresso, postice attenuatum, coxis humilibus. *Antennæ* breves, fortes flagellis maxime obsoletis vel nullis, *superiores* inferioribus vix longiores, flagello secundario nullo. *Pedes maxillares* exungues. *Pedes paris* 1mi tenues, exungues, 2di fortiores, subchelati. *Pedes spurii* omnes biramei, spinulis nullis, ramo paris 3ii exteriore neque uncinato, neque uncinis armato. *Telson simplex*, laminare.” The species *Colomastix pusilla* is partly figured.

The new genus *Iceridium* is thus defined:—

“*Corpus* depresso ex ovali oblongum, postice elongatum. *Antennæ* breves, articulis paucis, *inferiores* superioribus breviores, tenuiores. *Caput* (deorsum visum) quadrangulum, angulis anterioribus prominentibus, oculos ferentibus. *Pedes omnes* ambulatorii, longitudine sensim crescentes. *Postabdomen* ex segmentis 5 compositum, *appendices anteriorum* 4 birameæ, setigeræ, *segmenti* 5ti brevissimæ, simplices esetes. *Telson* nullum.” The type species, *Iceridium fuscum*, Grube “(Sitzungsberichte der Schles. Gesellsch. vom 18ten Februar 1863),” is described and figured. The specimen, 3·5 mm. in length, a female with young in the brood-pouch, was taken at Neresine on the Island of Lussin. Compare the Notes on Montagu, 1808, Guérin, 1836, Spence Bate, 1865, for the affinity of this genus with *Oniscus testudo*, Montagu, and *Phlias*, Guérin.

1864. GRUBE, ADOLPH EDUARD.

Dic Insel Lussin und ihre Meeresfauna. Nach einen sechswöchentlichen Aufenthalte geschildert von Dr. Adolph Eduard Grube. Breslau, 1864.

A list of the Amphipoda observed is given on pages 72 to 75.

A new species is described as follows:—“*Kroyeria* Sp. B. ? *Kr. haplocheles* Gr. n. sp.? Hat den Habitus einer *Kroyeria*, würde sich aber von den anderen Arten dieser Gattung dadurch unterscheiden, dass der Carpus des zweiten Fusspaars in keinen unteren Fortsatz ausläuft, die schmale Scheere also einfach ist, auch durch die beiden stachelartigen Zacken des Telson; allein das 7. Fusspaar ist abgebrochen, und es bleibt daher unsicher, ob dies Thier überhaupt zur Gattung *Haplocheles* [*Kroyeria*] gehört; Lussin.” In this passage *Haplocheles* is evidently a slip of the pen, *Kroyeria* is a mis-spelling of *Kroyera*; for the position of *Kroyera* itself see Note on Spence Bate, 1858. Under “*Megamoera* Sp. Bate,” he places *Ceradocus orchestipes*, A. Costa, of which “die Antennen sind roth, der Hinterrand der 6 letzten mit Extremitäten versehenen Segmente läuft in einen Rückendorn, am zehnten auch seitlich in Zähnchen aus.” The observation is added that, “Die Gattung *Ceradocus* von A. Costa lässt sich nach den von ihm aufgestellten Charakteren nicht halten und es liegt keine Nothwendigkeit vor, sie neu zu begründen; wenn man bei ähnlicher Beschaffenheit der Antennen und der Hand des zweiten Fusspaars wie billig, das Hauptgewicht auf die Beschaffenheit des dritten Paars des Springfusses legt, so lässt sich dieser Amphipode der Gattung *Megamocra* unterordnen, deren bei Spence Bate abgebildete Arten allerdings sämtlich keinen Rückendorn auf den hinteren Segmenten besitzen, sich aber durch den gezähnelten Hinterrand an dem Seiten- oder Hüfttheil des zehnten Segmentes auszeichnen. Die Gattung *Melita*, deren hintere Segmente bei mehreren Species Rückendornen tragen, zeichnet sich durch die ungleiche Grösse der Aeste des letzten Springfusspaars aus, und die Einordnung des in Rede stehenden Amphipoden in diese Gattung würde die Umänderung eines sonst durchgreifenden Gattungscharakters erfordern; ich muss hierin Herrn Professor Heller beistimmen.”

Under *Cerapus* Say, he thus describes " *C. latimanus* Gr. n. sp. Jahresbericht d. Schles. Gesellsch. für 1863. Zeigt grosse Uebereinstimmung mit dem Männchen von *C. abditus* Templet. (Spence Bate Brit. Sessil-eyed Crust. I. p. 455. Fig.), aber die Hand des zweiten Fusspaars ist über halb so breit als das vorhergehende Glied, ihr Unterrand nur mit 1 zwischen die beiden vorderen Zacken desselben eingreifenden Vorsprünge versehen, sonst glatt und die flach sichelförmig gestaltete Klaue vom Grunde an allmälig verjüngt zulaufend. Die Länge von *C. abditus* wird auf etwa 1½ Lin. angegeben, unser Cerapus misst 5 mill.; bei Neresino gefunden." Under *Caprella* Lam., he describes " *C. inermis* Gr. n. sp. ohne alle Rückenstacheln und Höcker, der oben gewölbte Kopf mit dem ersten Segment zusammen beinahe ebenso lang als das zweite, die oberen Antennen etwa nur $\frac{1}{5}$ kurzer als der Körper; ähnelt der *C. robusta* Dana, doch ist der Unterrand der länglich ovalen Hand des zweiten Fusspaars zahnlos; die ähnlich gestaltete Hand des ersten ist wenig kleiner, das letzte Fusspaar war nicht erhalten. Länge etwas über 3 mill.; Lussin piccolo." Mayer thinks that this may just possibly be the young of *Caprella acutifrons*, Latreille.

1864. LEYDIG, FRANZ.

Vom Bau des thierischen Körpers. Handbuch der vergleichenden Anatomie.
Tübingen, 1864.

On plumose hairs, p. 35, n. 2; on olfactory tubes and calcareous tubes, pp. 98, 99, n. 4; on the brain of the Arthropoda, p. 185.

1864. MÜLLER, FRITZ.

Für Darwin. Leipzig, 1864. 8 maj. m. 67 Holtzschn.
Facts and arguments for Darwin, by Fritz Müller. With additions by the Author. Translated from the German by W. S. Dallas, F.L.S., &c., with illustrations. London; Murray, 1869.

In this translation of the celebrated work, Für Darwin, are figured *Melita exilii*, n. sp., " *Orchestia Darwinii*," n. sp., two forms of the chelæ of the male of this species, portions of the penultimate peræopods of " *Melita Messalina*" and " *Melita insatiabilis*," an embryo of a *Corophium*, portions of the legs of " *Hyperia Martinezii*," n. sp., and the second gnathopod of the male and of the female of " *Orchestia Tucuratinga*," while mention is made of *Corophium dentatum*, n. sp., without either figures or description, and of " *Orchestia Tucurauna*," n. sp., which is apparently the same as " *Orchestia Tucuratinga*."

A protest may be entered against the inconvenient course of publishing new species at various points of a highly argumentative essay, especially when the descriptions are almost of necessity confined to those isolated characters with which the argument happens to be concerned.

Fritz Müller has found the secondary flagellum on the upper antennæ " in species of the genera *Leucothoë*, *Cyrtophium*, and *Amphilochus*, in which genera it was missed by Savigny, Dana, and Spence Bate." " A species proved by the form of the epimera (coxae Sp. Bate) of the caudal feet (*uropoda* Westw.), etc., to be a true *Amphithoë* possesses it." " In many species of *Cerapus* it is reduced to a scarcely perceptible rudiment." " It is sometimes present in youth and disappears (although perhaps not without leaving some trace) at maturity, as was found by Spence Bate to be the case in *Acanthonotus Owenii* and *Atylus carinatus*, and I

can affirm with regard to an *Atylus* of these [Brazilian] seas, remarkable for its plumose branchiae."

He regards the telson as a sequent, notwithstanding its want of appendages. In favour of this view he says, "we have the relation of the intestine, which usually opens in this piece, and sometimes even traverses its whole length, as in *Microdeutopus* and some other Amphipoda. In *Microdeutopus*, as Spence Bate has already pointed out, one is even led to regard small processes of this tubular caudal piece as rudimentary members." He speaks of the appendages of the first three pleon-segments as being "reproduced in wearisome uniformity throughout the entire order" of Amphipoda. This remark is not very applicable to *Cerapus* (see S. I. Smith, 1880), and has a disadvantageous tendency to discourage the examination of these organs in other genera.

In "Orchestia Darwinii," n. s., he figures two forms of the powerful chelæ of the second pair of feet in the male, "two forms united by no intermediate terms." Faxon, on *Dimorphism in the Genus Cambarus*, 1884, thinks that possibly "these are to be explained in the same way as the two forms of the male *Cambarus*, which appear to be "alternating periods in the life of the individual," the one form assumed during the pairing seasons, the other in the intervals.

In *Melita Messalina*, u. s., and *Melita insatiabilis*, n. s., in the case of the females "the coxal lamellæ of the penultimate pair of feet are produced into hook-like processes, of which the male lays hold with the hands of the first pair of feet."

He remarks that generally throughout the Amphipoda the heart "extends in the form of a long tube through the six segments following the head, and has three pairs of fissures, furnished with valves, for the entrance of the blood, situated in the second, third, and fourth of these segments," as found by La Valette in *Niphargus* and by Claus in *Phronima*. Only in *Brachyscelus* he found the first pair of fissures wanting to the shortened heart.

"The Amphipoda," he says, "are distinguishable from the Isopoda at an early period in the egg by the different position of the embryo, the hinder extremity of which is bent downwards. In all the animals of this order which have been examined for it, a peculiar structure makes its appearance very early on the anterior part of the back, by which the embryo is attached to the 'inner egg-membrane,' and which has been called the 'micropylar apparatus,' but improperly as it seems to me." To this statement he appends a note, "Little as a name may actually affect the facts, we ought certainly to confine the name 'micropyle' to canals of the egg-membrane, which serve for the entrance of the semen. But the outer egg-membrane passes over the 'micropylar apparatus' of the Amphipoda without any perforation, according to Meissner's and La Valette's own statements; it appears never to be present before fecundation, attains its greatest development at a subsequent period of the ovarian life, and the delicate canals which penetrate it do not even seem to be always present, indeed it seems to belong to the embryo rather than to the egg-membrane. I have never been able to convince myself that the so-called 'inner egg-membrane' is really of this nature, and not perhaps the earliest larva skin, not formed till after impregnation, as might be supposed with reference to *Ligia*, *Cassidina*, and *Philoscia*."

"The young animal, whilst still in the egg, acquires the full number of the segments and limbs." In the Hyperinæ, indeed, "the young and adults often have a remarkably different appearance; but even in these there is no new formation of body segments, and limbs, but only a gradual transformation of these parts." The sexual differences in the Amphipoda are also discussed.

1864. NORMAN, ALFRED MERLE, born August 29, 1831 (A. M. N.).

Report of Dredging Operations on the Coasts of Northumberland and Durham, in July and August, 1863. Edited by George S. Brady. Report on the Crustacea, by the Rev. Alfred Merle Norman, M.A. Transactions of the Tyneside Naturalist's Field Club, 1863-64. Vol. VI. Newcastle-upon-Tyne, 1864. pp. 183-187.

No new Amphipoda are included in the list of Crustacea. *Otus carcinatus*, Bate, is recorded among those taken.

1864. SARS, G. O.

Beretning om en i Sommeren 1863 foretagen zoologisk Reise i Christiania Stift. Nyt Magazin for Naturvidenskaberne. Trettende Binds tredie Hefte. Christiania, 1864. pp. 225-260.

At page 231 he mentions, *Gammarus cancelloides*, Lov., as occurring in various localities, and his own *Gammarus lacustris* as a characteristic form for their Alpine regions, in still waters. He is confirmed in the view that it is distinct from *Gammarus pulex*.

1864. STIMPSON, WILLIAM.

Descriptions of new species of Marine Invertebrata from Puget Sound, collected by the Naturalists of the North West Boundary Commission, A. H. Campbell, Esq., Commissioner. Proc. Acad. Nat. Sci. Philadelphia. June 1864.

A note is prefixed saying—"The following descriptions are extracted, by permission, from the Zoological Report of the Boundary Commission. They were written in the year 1860, and accompanied by illustrative drawings of all the species, which, it may be hoped, will soon be published." Whether the hope has been gratified I am unable to say.

The first Amphipod described is "*Caprella Kennerlyi*," which Mayer considers indeterminate. *Amphithoë humeralis*, more than an inch long, a little resembles *Amphithoë falklandi*, Spence Bate, from the Falkland Islands, in the dilated first joints of the first and second pereiopods. Of *Anonyx filiger* I give the description for convenience of comparison with the Challenger species:—"Head with a strong triangular process on each side beneath the base of the superior antennæ; extremity of this process not acute. Superior antennæ very short, about as long as the head, with a long thick pencil of hair on the inner side of each; basal joint large, with a strong protuberance above, forming a prominent angle at its anterior extremity; flagellum seven-jointed, the first joint constituting one-third of its length; accessory flagellum tri-articulate. Inferior antennæ longer than the body; the peduncle, however, constitutes but a small part of their length, being but little larger than the superior antennæ; the very slender filiform flagellum appears as if serrated above, but is not provided with calceolæ. The first pair of feet in our single specimen appear to be pointed and simple, the dactylus not being retracted against the manus, which has no palm. Second pair with a minute truncate hand, supporting a small tuft of hair at the base of the dactylus. The dorsum in this species is sharp, or carinated, but not dentated, being entire and smooth in outline for the greater part of its length, and similar in the thoracic and first three abdominal segments. There

is, however, a deep, triangular sinus between the third and fourth abdominal segments, the latter being strongly protuberant, projecting over the very small fifth segment. The second abdominal segment is subtruncate below, and has a deep semicircular sinus on the anterior lateral margin, near its lower extremity. Rami of the last pair of caudal stylets shorter than those of the second pair, and telson rather elongated and slit in two down the middle. Length about one-third of an inch. It resembles an English species of which a figure has been privately circulated by C. Spence Bate, Esq., under the name of *Lysianassa chausica*, M.-Edw. Dredged in deep water by Lieut. White."

The *Lysianassa chausica* here referred to was afterwards identified by Spence Bate with *Lysianassa longicornis*, Lucas, as to which see Note on G. O. Sars, 1882.

Gammarus subtenuis has the "first, second and third joints of the abdomen armed above with a sharp central spine on the posterior margin, and with four or five minute spines, or sharp comb-like teeth on each side of the middle spine, the margin bearing these latter spines being a little concave. At the corresponding part of the fourth and fifth abdominal segments, there are also two or three spines similar to the central spine of the other segments though not quite so large." Stimpson thinks it no doubt closely allied to *Gammarus longicauda*, Brandt, a species which Spence Bate renames *Megamæra longicauda*, and inclines to identify with *Gammarus dentatus*, Krøyer. *Amphithonotus septemdentatus* is "strongly compressed and carinated, like *A. carinata*." *Amphithonotus occidentalis* is "closely allied to the Arctic *A. panopla*, Kr., and the east coast species, *A. cataphractus*, Stm., but differing from both in being more elongated, having less height and breadth." The generic name *Amphithonotus*, as already observed, is inadmissible, having lapsed as a synonym of *Dexamine* before it was adopted by Stimpson. Of the species which Stimpson here mentions for the sake of comparison, *Amphithoë carinata*, Krøyer, is now called *Atylus carinatus*, Fabr.; *Amphithoë panopla*, Krøyer, is called *Pleustes panoplus*, and *Amphithonotus cataphractus*, Stimpson, is called *Rhachotropis cataphracta*. In *Ampelisca pugetica* "the last three joints of the abdomen are separated from the preceding ones by a deep notch, and project into two sharp teeth."

1864. ZADDACH, ERNST GUSTAV, born 1817, died 1881.

Ein Amphipode im Bernstein, entdeckt durch Herrn Pfarrer von Duisburg und beschrieben von G. Zaddach. Taf. 1. 12 pages. Schriften der königlichen physikalisch-ökonomischen Gesellschaft. 5. Jahrg. Königsberg. 1864.

To the existing fauna of the neighbourhood in which this fossil was found Zaddach ascribes seven species of Amphipods, viz., the fresh-water "*Gammarus fluviatilis*, Raj," four species which he dredged in the Bay of Dantzig, at some distance from the coast, and only two, he says, which live near the coast, *Gammarus locusta*, Mont., and *Talitrus saltator*, Klein. Of these he says that they frequently let themselves be thrown by the waves on to the strand, where, by help of their styliform uropods, they make powerful leaps, or with great dexterity bury themselves in the wet sand in order to be washed back into the water by the next wave, or gather round the remains of a dead fish for a meal, but never go beyond the narrow selvage of shore which is regularly washed to a greater or smaller extent by the waves. In these remarks Zaddach can scarcely be accurate. The sand-hopper, *Talitrus (saltator) locusta*, lives at the edge of high water-mark, and may follow down the ebb and retreat before the flow of the tide, but does not surely play with the waves in the manner described. The dexterous delving in the sand seems also more appropriate to species of *Urothoë*, *Lepidactylis* and *Eurydice* than to the slithering *Gammarus locusta*.

Zaddach supposes his species to be the first fossil Amphipod discovered, since, he says, the genus *Gampsonyx* Jord. from the carboniferous period, which Bronn mentions in his *Lethaea geognostica*, 1856, is remote from the present Amphipods, and represents a special order of Crustaceans intermediate between Amphipods, Stomatopods and Decapods, or rather antecedent to them all and belonging to a time when their several characters were not yet separated. He is apparently unaware of the Permian fossil, called *Palaeocrangon problematicus* by Schaueroth in 1854, and *Prosponiscus problematicus* by Kirkby in 1857.

After a careful and detailed description of the fossil, Zaddach establishes for its reception a new genus, *Palaeogammarus*, which he thus defines:—"Caput altius quam longius. Antennæ et superiores et inferiores validæ, scapis triarticulatis, longitudine subæqualibus, illæ flagello appendiculari ornatae. Epimera longa, duo anteriora angustissima, primo cingulo dorsali subjecta, quartum maximum, apice duplo latius quam basi. Postabdominis segmenta anteriora propriis laminis lateralibus instructa. Pedes quarti paris infirmi, ad ambulandum apti, quinti et sexti paris coxis permagnis in laminas ovales mutatis, ceteris articulis gracilibus, unguibus minimis rectis." For this genus he would find a place among the genera *Gammarus*, *Pontoporeia* and *Tulitrus*. In 1878, however, he recognises that the characters on which he had relied for separating it from *Gammarus* were probably only due to the accidental condition of the specimen. He speaks of the peduncles of the lower antennæ as triarticulate, but they are from his figures clearly of the ordinary structure, though the composite basal joint is not visible. The amber being found on the coast of Samland, he names the species *Palaeogammarus sambiensis*, with this definition:—"antennis superioribus inferiores longitudine superantibus, inferiorum flagello ex octo articulis composito, segmenti undecimi et duodecimi margine dorsali spinis obsito, pedibus spuriis longitudine æqualibus, appendicibus in abdominis apice nullis." The absence of the terminal appendages, as he afterwards noticed, should not have been included in the specific character, that being almost certainly due only to the defectiveness of the specimen.

To the question how this broken Amphipod got into the amber, the answer is suggested that the amber-producing woods probably came down in former ages close to the sea-shore, and that the creature with the sand attached to it may there have been introduced into a mass of resin. In 1878, he says with regard to it, "die Uebereinstimmung zwischen der tertiären Art und einer jetzt lebenden lässt sich nicht nachweisen, aber wahrscheinlich ist jene den Arten *Gammarus marinus*, *locusta*, *Edwardsii* sehr ähnlich gewesen. Der Stammbaum unseres gemeinen Flohkrebss reicht also bis in jene längst vergangene Zeit hinauf, in der sich die oligocänen Schichten ablagerten." The fresh-water *Gammarus pulex* might well have been added to the list of species compared.

1865. BATE, C. SPENCE.

Crustacea. The Record of Zoological Literature. 1864. Volume First.
London, MDCCCLXV. pp. 257–311. Amphipoda, pp. 287–289.

Grube's *Nicea istrica* is considered identical with *Nicea prevostii*, M.-Edw. *Anonyx filiger*, Stimpson, is said to be closely allied to *Lysianassa longicornis*, Lucas, "or *L. chausica* (Spence Bate), not *Alibrotus chausicus* (Milne-Edwards)." "The female of the genus *Gammarella* approximates so nearly in form to *Crangonyx*, only having the eye coloured with black pigment, that we have little doubt," Spence Bate says, "of the near relationship of Professor Grube's *Gammarus recurvus* to *Gammarella normani*, which is probably the female of *G. brevicaudata*." *Iphimedia multispinis*, Grube, which Grube himself likens to *I. nodosa*, Dana, shows, in Spence Bate's opinion, "a closer approximation to *I. eblana*, the dorsal teeth being less strong (probably a sexual distinction)." The difference

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

Xxx 45

of *Colomastix pusilla* ♀, Grube, "from *Cratippus tenuipes* consists in the form of the first pair of gnathopoda, which in 'Colomastix' terminate in several curved spines, whereas in *Cratippus* it is scarcely subchelate." Even this distinction as suggested by Prof. Grube, may be only of sexual importance; and we think it insufficient to warrant the formation of a new genus." It may be observed that *Colomastix* was not instituted in 1864, but in 1861, and therefore takes precedence of Spence Bate's *Cratippus*.

On *Iridium fuscum*, Grube, Spence Bate observes:—"There is a slight discrepancy between Prof. Grube's excellent figures and the description. First, the telson is undoubtedly present; and since the ante- and penultimate pairs of pleopoda are attached to one somite, we must rather consider that the two somites are fused into one than that one is wanting. We therefore perceive that one, instead of two somites, only is wanting; but it is contrary to previous observation that this deterioration takes place in the anterior portion of the pleon instead of the posterior; for undoubtedly one of the anterior pairs of pleopoda is the missing pair."

1865. COSTA, ACHILLE.

Sopra una specie mediterranea del genere *Lestrigonus*. (*letta nella tornata del di 14 febbrajo 1865*). Rendiconto dell' Accademia delle scienze fisiche e matematiche. Anno IV. Napoli, 1865. p. 34.

He mentions "*Lestrigonus Fabricii*" (Milne-Edwards) (no doubt meaning *Lestrigonus Fabreii*), from the Indian Ocean, *Lestrigonus rubescens* (Dana), from the Pacific, *Lestrigonus exulans*, from Chili, as the earliest known members of the genus, followed by "*Lestrigonus Kinaliani*," Spence Bate, from the British waters. To this he considers a form recently taken in the Gulf of Naples upon a *Medusa* to be closely allied. The distinguishing characters he takes from the proportions of the upper compared with the lower antennæ, and from the form of the uropods. He thus describes the species:—"Lestrigonus mediterraneus, nob.:—*L. antennis superis inferioribus paullum brevioribus; pedibus spuriis quarti et quinti segmenti abdominalis stylis lanceolatis, externo parum longiore, in margine interno toto minute dentato-serrato; in margine externo integro; stylo interno margine utroque integerrimo; fusco-rufus, antennis, pedibus (articulo primo excepto) caudaque albidis. Longit. millim. 5.*"

1865. GOËS, AXEL THEODOR, born 1835 (Hj. Thécl).

Crustacea amphipoda maris Spetsbergiam alluentis, cum speciebus aliis arcticis enumerat A. Goës. Tab. XXXVI.—XLI. [Acad. Scient. Sueciæ propos. die XI. Octobris 1865]. Öfversigt. af K. Vet. Akademiens Förhandlingar. 1865. pp. 1–20 (517–536).

From this brief but learned work notes will be quoted under the numbers which Goës attaches to most of the species he mentions.

He begins with the Gammaridæ:

1. *Pontoporeia femorata*, Kröyer. "Forma minor, depauperata = *P. furcigera*, BRUZEL." *Opis typica*, Kröyer, Nat. Tidsskr. 2. R. II, 46, " = *Opis Eschrichti*, KRÖY., Nat. Tidsskr. I. R. IV, 149." This is now called *Opisa eschrichti*.

- Lysianassa gryllus*, Mandt. fig. 1, "Eurytenes Magellanicus, LILLJEBORG." Why he rejects Lilljeborg's genus is not explained.
2. "Lysianassa Vahli," Kröyer, "in itinerariis articis cum sequente omnino confusa, sub nomine Talitro nugace (Ross, PARRY's attempt to reach the North Pole, 205), sive Gammaro nugace (SABINE, Append. to PARRY's First Voy., 229) edita.—Var. segmenti abdominalis tertii angulo postico rotundato, neque truncato nec emarginato, statura minore."
 3. *Lysianassa lagenaria*, Kröyer, "=Cancer nugax, PHIPPS." Of these, between three fathoms and sixty, there is "copia stupenda, eo ut, si perite ac prudenter in captura versaris, hos pelagi voracissimos vespillones molibus milliariis cadavere avium vel phocarum brevi e fundo elicere potes."
 4. *Lysianassa tumida* (*Anonyx*), Kröyer, "=An. tumidus, BRUZEL." "In spongiis et sacco branchiali ascidiarum vitam saepe degens."
 5. "Lysianassa Martensi," n. s., fig. 2, which Boeck transfers to *Anonyx*.
 6. *Lysianassa crispata*, n. s., fig. 3, considered by Boeck to be a synonym of his *Orchomene serratus*.
 7. *Lysianassa producta*. n. s., fig. 4, identified by Boeck with the earlier *Anonyx pumilus* Lilljeborg, 1865, to which Goës himself says it is "proxima et vix distineta."
 - Lysianassa alyssi*, n. s., fig. 5, called by Boeck *Hippomedon abyssi*.
 8. *Lysianassa holbölli* (*Anonyx*), Kröyer. 9. *Lysianassa minutula* (*Anonyx*), Kröyer, "vix An. minutns, Sp. BATE. Cat. of Amphip." 10. *Lysianassa gulosa* (*Anonyx*), Kröyer.
 11. *Lysianassa umbo*, n. s., fig. 6, by Boeck referred to his own genus *Orchomene*, by Sars, 1882, to *Lepidepecreum*, Bate and Westwood. A comparison of the description and figures of *Lepidepecreum carinatum*, Bate and Westwood, with those of *Lysianassa umbo*, Goës, excites the strong suspicion that they are the same species, and that the English authors have not noticed the boss (umbo) on the fifth side-plates, while the little two- to three-jointed accessory flagellum has been accidentally wanting in their specimens. The definition of *Lepidepecreum* will in that case need some alteration. The type species would still be *Lepidepecreum longicorne*, Sp. Bate, 1862, with *carinatum* and *umbo* for synonyms.
 12. "Lysianassa Edwardsi" (*Anonyx*), Kröyer, "Nat. Tidsskr. 2 R. II. 1; Voy. en Seaudin. t. 16 f. 1 (icone vix fida); non Sp. BATE, Brit. Sessile-eyed Crust. II. 94, nec Catalogue of Amphip. in Brit. Mus. 73, t. 11, f. 5."
 13. *Lysianassa plauta* (*Anonyx*), Kröyer. 14. *Lysianassa litoralis* (*Anonyx*), Kröyer, "=Alibrotus litoralis, Sp. BATE."
 15. *Lysianassa? cymba*, n. s., fig. 7. "Medium tenet inter Lysianassas et Stegocephalos." On this Boeck observes, "Whether this form belongs to *Lysianassa* or is an intermediate form between that and *Stegocephalus* I cannot decide as I have not seen the animal. Among the *Lysianassinae* we have a form in which the back is carinate, *Orchomene umbo*, while I do not know of any with carinate back belonging to the *Stegocephalinæ*. The hand of the second gnathopods also refers this form to the *Lysianassinae*, but the very elongate hand of the first gnathopods shows that it cannot belong to the genus *Orchomene*, which it otherwise resembles by its deep side-plates. Before it can be placed in a new genus of the *Lysianassinae* fresh investigation is required."
 16. *Stegocephalus ampulla* (*Cancer*), Phipps, "=Gammarus ampulla, Ross," "=Steg. inflatus, KRÖY.," "=Stegocephalus ampulla, BELL." "Formæ duæ occurunt:—Altera epimero quarto æquale fere alto ac lato, articulo pedum sexti et septimi parvis primo dilatato, angulo infero postico subrecto aut acento.—Fig. 8. Altera epim. quarto latiore quam altiore, articulo pedis sexti primo angusto, angulo infero postico lobulo rotundato determinato, pedes septimi articulo eodem dilatato margine infero postico rotundato nec angulato.—Fig. 9. An differentia sexualis?"

17. "Montagua Alderi," Sp. Bate, called *Metopa Alderii* by Boeck.
18. *Montagua clypeata* (*Leucothoë*) Kröyer, called *Metopa clypeata* by Boeck.
19. "Montagua Bruzelii," n. s., fig. 10, " = *Leucothoe clypeata*, BRUZ." See Note on Bruzelius, 1859.
20. *Montagua glacialis* (*Leucothoë*), Kröyer, called *Metopa glacialis* by Boeck.
21. *Otus carinatus*, Sp. Bate.
22. *Vertumnus cristatus*, Owen, "Acanthouotus, nomen geueris piscium anno 1801 editum."
23. *Vertumnus serratus* (*Oniscus*), Fabr., " = *Amph. serra* KRÖY.," " = *Acanthonotus serra* BRUZ."
24. *Vertumnus inflatus* (*Acanthonotus*), Kröyer, fig. 11.
" *Paramphithoë*, BRUZ. A. Epimera quarta dilatata (*Pleustes*, SP. BATE)."
25. *Paramphithoë exigua*, n. s., fig. 12, identified by Boeck with his *Amphithopsis glaber*, 1860, which he afterwards called *Pleustes glaber*.
26. *Paramphithoë media*, n. s., fig. 13, by Boeck called *Pleustes mediuss*.
27. *Paramphithoë panopla* (*Amphithoë*), Kröyer, " = *Paramph. pauopla* BRUZ.;" " = *Pleustes tuberculatus* S. BATE," called *Pleustes panoplus* by Boeck, 1876.
" B. Epimera quarta non dilatata.
" a. Caudæ appendix fissa aut incisa (*Atylus*, LEACH—S. BATE)."
28. *Paramphithoë carinata* (*Gammarus*), Fabr., " = *Atylus carinatus*, LEACH;" = *Amphithoë carinata*, KRÖY.; now accepted as *Atylus carinatus*.
29. *Paramphithoë Smitti*, n. s., fig. 14, by Boeck called "*Atylus Smitti*."
Paramphithoë inermis (*Amphithoë*), Kröyer, is mentioned.
30. *Paramphithoë fragilis*, n. s., fig. 16, "Forma *Amphithonotis propinquus*." In accordance with this suggestion Boeck calls it *Tritropis fragilis*, which will now become *Rhachotropis fragilis*.
" b. Caudæ appendix indivisa vel obsolete incisa [*Calliope*, *Pherusa*, LEACH, et *Paramphithoë*, S. Bate]."
31. *Paramphithoë laeviuscula* (*Amphithoë*), Kröyer, " = *Amphithoë serraticornis*, SARS, 1858; = *Paramph. laeviuscula*, BRUZEL.;" " = *Calliope laeviuscula*, S. Bate."
32. *Paramphithoë bicuspis* (*Amphithoë*), Kröyer. See Note on Bruzelius, 1859.
Paramphithoë tricuspis (*Acanthonotus*), Kröyer.
Paramphithoë tridentata, Bruzelius. "An = *Amphithoë macrocephala*, SARS ?" 1858.
33. *Paramphithoë fulvoincta* (*Amphithoë*), Sars, 1858, fig. 15; " = *Pherusa tricuspis*, STIMPS.," 1863. 34. *Paramphithoë pulchella* (*Amphithoë*), Kröyer. 35. *Paramphithoë hystrix* (*Acanthosoma*), Owen.
36. *Amphithonotus aculeatus* (*Oniscus*), Lepechin, " = *Talitrus Edwardsi*," SAB., " = *Amphithoë Edwardsi* OWEN."
37. " *Amphithonotus Malmgreni*," n. s., fig. 17. This in 1870 was made the type of a new genus, *Acanthostephia*, by Boeck in the subfamily Oedicrinæ.
38. *Oediceros saginatus*, Kröyer, fig. 18. 39. *Oediceros propinquus*, n. s., fig. 19, by Boeck made a synonym of *Oediceros lynceus*, M. Sars, 1858.
40. *Oediceros longirostris*, n. s., fig. 20, called *Monoculodes longirostris* by Boeck.
41. *Oediceros affinis*, Bruzelius, Amphip. Gamm., "93, f. 18 (non rite delineata) secundus articulus pedunculi antennar. sup. apice interdum dilatato; rostrum variat, nunc leviter curvatum, nunc fere geniculatum; segmenta abdominis quatuor antica dorso interdum carinato.—Fig. 21 et 21." Boeck refers *Oediceros affinis*, Goës (non Bruzelius), partly to *Monoculodes norvegicus*, Boeck, 1860, and partly to *Monoculodes borealis*, Boeck, 1870, with which J. Sp. Schneider, 1883, agrees, but "non sine dubio," the geniculate rostrum represented in Goës' fig. 21¹ being the attribute of *Monoculodes borealis*.
42. *Oediceros brevicalcar*, n. s., Fig. 22, by Boeck named *Hahimedon brevicalcar*.
43. *Oediceros latimanus*, n. s., Fig. 23, by Boeck called *Monoculodes latimanus*.
44. *Oediceros obtusus*, Bruz., Amph. Gamm. " p. 92, f. 17. Alia forma etiam occurrit: secundo

antennar. supern. pedunculi articulo valde abbreviato, pedes ordinis tertii et quarti articulo quarto valde dilatato, unguis pedum 3, 4 et 5 obtusus, foliaceus, angustus elongatus.—Fig. 24 et 24'." See Note on Bruzelius.

The new genus *Syrrhoë* is thus described:—

"Frons producta, oculi oedicerorum, antennæ supernæ flagello appendiculari instructæ, mandibula palpo triarticulato."

45. *Syrrhoë crenulata*, n. s., Fig. 25.

Syrrhoë bicuspis, n. s., Fig. 26. This is identified by Boeck with the earlier *Tiron acanthurus*, Lilljeborg, 1865; Boeck calls attention to the fact that Lilljeborg's work is referred to by Goës, and must therefore have priority, though both authors published in 1865.

46. *Phoxus plumosus*, Kröyer. He also mentions *Phoxus Holbölli*, Kröyer, and *Bathyporeia pilosa*, Lindström, 1855, for this giving also a reference to "LOVÉN, Öfvers. af K. Vet. Akad. Forhandl. 1861?"

47. *Haploops lubricola*, Lilljeborg. "Ex abyso ad Aukpadlartok Groenlandiae copiam magnam retulit TORELL speciminum valde robustorum et oculis quatuor, duobus in vertice, duobus in angulo infero laterali antico capitis insignium,—ceterum cum nostra plane congruentium." Boeck refers to this statement by Goës as to the eyes, without being able to confirm it from his own experience, so that in his generic account of *Haploops* he writes "Oculi duo (qvatuor?)"; but he considers that the genus is distinguished from *Ampelisca* by other characters, especially the peculiar form of the last peræopods.

48. " *Ampelisca Eschrichii*," Kröyer, " = A. macrocephala LILLJEB." These two species are however, kept apart both by Boeck and J. Sp. Schueider.

49. " *Ampelisca Gaimardi*," Kröyer. 50. *Pardalisca cuspidata*, Kröyer. 51. *Eusirus cuspidatus*, Kröyer.

52. *Gammarus pallidus (Lilljeborgia)* Sp. Bate, " = G. fissicornis SARS," 1858; " = G. brevicornis BRUZEL;" —Fig. 27. "ad Spetsbergiam in sinu Storfjord paucos fundo argill. org. 5 prof. prehendit MALMGREN 1864, validiores quam nostros quadruplo statura, fere pollicares, spinis segmentorum abdominis 4:ti et 5:ti sat longis surrectis, pedibus septimi ordinis valde incrassatis, oculis indistinctis." Boeck separates *Lilljeborgia pallida*, Sp. Bate, 1855, and *Lilljeborgia fissicornis*, M. Sars, 1858, but the distinctions are tolerably subtle. He assigns *Gammarus pallidus*, Goës, fig. 27, to the latter species.

53. " *Gammarus Loreni*," Bruzelius, by Bate called *Mæra loveni*. " *Gammarus Torelli*," n. s., Fig. 28, by Boeck called *Mæra torelli*.

54. *Gammarus dentatus*, Kröyer, " = G. Kröyeri BELL;" " = Megamæra dentata S. BATE." "Formæ duæ occurunt paullum diversæ; vide Fig. 29 et 29'." By Boeck called *Melita dentata*.

55. *Gammarus spinosus*, n. s., Fig. 30, by Boeck called *Melpliidippa spinosa*.

56. *Gammarus locusta (Cancer)* Linn., in the synonymy of which he mentions *Gammarus boreus*, Sabine; *Gammarus arcticus*, Scoresby; *Oniscus pulex*, Fabr., Fn. Gr. 1780; and says that it scarcely differs from *Gammarus silchensis*, Brandt. He gives notes on its distribution, and remarks "Oculorum forma variat, nunc oblongo-reniformis, nunc angustissime linearis, nunc evanescentes."

57. *Gammarus loricatus*, Sabine, " = Gammaracanthus loric. S. BATE."

58. " *Gammarus Sabini*," Leach, " = Anathia Sabini S. Bate;" " = Cancer macrourus articulatis, dorso earinato serrato, spinis caudæ bifidis STRÖM."

59. *Gammarus pinguis*, Kröyer.

60. *Autonoë macronyx (Gammarus)*, Lilljeborg, "Forma arctica, elatior, manus ♂ secundi pedum ordinis subquadrata, margine postico crenis 5–6 obsoletis (nec tuberculis) spina angulari interdum evanescute, ungue crassiore atque breviore; antennæ pedesque omniuo longiores. —Fig. 31." This is identified by Boeck with *Protomedæia fasciata*, Kröyer.

61. *Autonoë depressa*, n. s., Fig. 32, transferred by Boeck in 1870 to a new genus *Goësia*, near to *Leptocheirus*.

At this point Goës passes from the Gammaridæ to the Corophidæ.

Amphithoë reinhardi (*Photis*), Kröyer, “= Amph. pygmæa LILLJEB.” Boeck restores the name *Photis reinhardi*, Kröyer.

62. *Podoceros anguipes* (*Ischyrocerus*), Kröyer. “Statura corporis atque forma antennarum valde variat.”

63. *Erichthonius difformis*, M.-Edw. “= *Podocerus Leachii* Kröy.;” “= *Cerapus difformis* S. BATE, Brit. Sess.-eyed Crust. II, 457.—*Validus*, quam nostras duplo-triplo elatior.”

Siphonæctes typicus, Kröyer.

64. *Glaucouome leucopis*, Kröyer, “= *Unciola leucopis* S. BATE.”

In the Hyperidæ he gives

65. *Themisto libellula* (*Gammarus*), Mandt, “= *Th. arctica* Kröy.;” “= *Th. crassicornis* Kröy.;” “Antennæ interdum elongatæ, multiarticulato flagello.—Fig. 33, 33’.” Among the places of capture he names “Finmarkiam (MALMGREN), ubi alia etiam forma occurrit a typica paullum discrepans: pedes tertii et quarti articulo 4:to angustiore, art. quinto longiore; pedes quinti septimis paullo breviores aut inter se longitudine æquales.”

Themisto compressa, n. s., Fig. 34, 34’, referred by Boeck to his new genus *Parathemisto*.

66. *Hyperia exulans* (*Lestrigonus*), Kröyer, “= *Lestrig. exulans* Sp. BATE, Brit. Sess.-Ey. Crust. I. [II]. 5; = *L. Kinahani* ibidem p. 8; ♀ = *Hyp. oblivia* KRÖY. Grönl. Amphip., D. Vid. Selsk. Afh. 298, t. iv, f. 19 (non Sp. BATE et Westwood, Brit. Sess.-ey. Crust. II. p. 16) = *H. medusarum* Sp. BATE, Catal. of Amph. in Brit. Mus. 295, t. 49, f. 1.—An *Hyp. galba* MONT., Trausact. of Liu. Soc. XI. 4 2, f. 2 et Sp. BATE et WESTWOOD Brit. Sess-eyed Crust. I. [II]. 12?”

“Ad nostras oras alia etiam forma occurrit paullum diversa, pedum primi ordinis articulo quinto fere cylindrico uudique setoso, ungue minuto.” This variety Boeck identifies with his own *Hyperia spinipes*, 1860; the *Hyperia exulans* with *Hyperia medusarum*, O. F. Müller.

67. *Hyperia medusarum* (*Metoecus*), Kröyer, “=? *Cancer medusarum* MÜLL.,” 1776; “? *Oniscus medusarum* FABR., F. Groenl. 1780 p. 257; Ieo prototypica ab his relata STRÖMI (Om Söudmör etc. I, t. 1, f. 12) non sat distincta.” “♂ auteuius longissimiis multiarticulatis.”

Goës notes of this and the preceding species, that they are found free as well as on Medusæ.

In the Dulichidæ, he mentions 68. *Dulichia spinosissima*, Kröyer.

In the Caprellidæ, he mentions 69. *Caprella septentrionalis*, Kröyer, “= *Squilla lobata* FABR., Faun. grönl. 1780, p. 248 (non MULLER); = *Capr. cercopoides* WHITE, Append. to SOUTHERLAND’s Journ. 203 f. 1 et p. 207; nunc tuberculatus nuuc fere lœvis.”

70. *Caprella spinifera*, Bell, Append. to BELCHER’s list of Arct. Voy., p. 407. t. 35. f. 2.

1865. GOSSE, P. H.

A Year at the Shore. London, 1865.

Pages 151–154 discuss some Amphipods. The habits of *Gammarus locusta*, “the common Locust Screw,” and *Gammarus pulex* are mentioned, and some of Lovén’s remarks are reproduced, in regard to the discovery of *Gammaracanthus loricatus*, Sabine, *Pontoporeia affinis*, Lindström, and *Gammarus cancelloides*, Gerstfeldt, in Lakes Wetter and Wener in Sweden.

1865. HELLER, CAMIL.

Kleine Beiträge zur Kenntniss der Süßwasser-Ampipoden. Mit 1 Tafel : (Taf. 17.) (Aus den Verhandlungen d. k. k. zoologisch-botanischer Gesellschaft in Wien [Jahrgang 1865] besonders abgedruckt.)

The new species *Orchestia cavimana* is here described and figured. It was taken on Mount Olympus in Cyprus, at a height of 4000 feet by Dr. Kotschy. The new species, "Gammarus Veneris" was also taken by Dr. Kotschy in Cyprus, 50 feet above the sea. This species is said by Heller to be intermediate between *Gammarus marinus* and *Gammarus pulex*. In "a review of the hitherto known South European fresh-water amphipods," he says that "they all belong to the genus *Gammarus* Fabric." He arranges them as follows:—

"A. First gnathopod somewhat larger than the second, telson simple, undivided; third uropod with a single ramus. (Subg. *Crangonyx*, Sp. Bate.)

"1. *G. recurvus*.

"AA. First gnathopod not larger than the second, telson deeply split, or double; third uropod with two rami:—

"a. First gnathopod almost as large as the second, eyes rudimentary, the three last segments of the pleon without bundles of spines, the outer ramus of the third uropod bi-articulate. (Subg. *Niphargus*, Sch.).

"2. *G. puteanus*.

"b. First gnathopod smaller than the second, eyes well developed. The three last pleon-segments with bundles of spines, the outer ramus of the third uropod uni-articulate. (Subg. *Gammarus*, Sp. Bate).

"a. The three first pleon-segments prolonged backwards to a pointed spine-tooth.

"3. *G. Roeselii*.

"β. The three first pleon-segments straight behind, without spine-tooth.

"† The outer ramus of the last uropod only a little longer than the inner.

"4. *G. pulex*.

"†† The outer ramus of the last uropod much longer than the inner.

"5. *G. pungens*."

These divisions are founded on 1. *Crangonyx recurvus*, Grube; 2. *Niphargus* (*Gammarus*) *puteanus*, Caspary, with which Heller unites *Niphargus stygius*, Schiödte, and *Niphargus aquilex*, Sp. Bate; 3. *Gammarus roeselii*, Gervais, identified with *Squilla fluvialis*, Rösel, and *Gammarellus pulex*, Herbst; 4. *Gammarus pulex*, Desmarest, identified with *Gammarus fluvialis*, M.-Edwards, and 5. *Gammarus pungens*, M.-Edwards. Of this last he says that it closely agrees with his own new species *Gammarus veneris*, only that, according to M.-Edwards' short description, *Gammarus pungens* appears to have the inner ramus of the last uropod quite rudimentary. Of *Gammarus veneris* itself, Heller thus describes the last uropod, "ramus interior pedum sexti paris postabdominis exteriore multo brevior, ramis hirsutissimis." *Gammarus roeselii*, he says, "lebt in tiefen stehenden oder schwach fliessenden Gewässern. Ich kenne ihn aus der Umgebung von Salzburg, Wien und Ofen, in Tirol habe ich ihn noch nicht angetroffen."

1865. LILLJEBORG, W.

Bidrag till kännedomen om underfamiljen *Lysianassina* inom underordningen *Amphipoda* bland kräftdjuren.

On the *Lysianassa magellanica* H. Milne Edwards, and on the Crustacea of the suborder *Amphipoda* and subfamily *Lysianassina* found on the coast of Sweden and Norway. By William Lilljeborg. With 5 Plates. Upsala, MDCCCLXV. (Nova Acta Reg. Societ. Scient. Upsal. III^e Série.)

The two papers, written in different languages by the same author, are essentially the same. In the suborder Amphipoda Lilljeborg mentions as common to both the arctic and autarctic zones the genera *Orchestia*, Leach, *Anonyx*, Kröyer, *Iphimedea*, Rathke, *Atylus*, Leach, *Amphithoë*, Leach, *Hyperia*, Latreille, *Themisto*, Guérin-Méneville, *Cyamus*, Lamarck (properly Latreille). He speaks of *Themisto* and *Anonyx* as peculiar to the zones in question, but immediately after qualifies this statement. *Lysianassa magellanica*, he makes the type of a new genus *Eurytenes*, which he thus defines:—

“Corporis forma crassa et robusta, epimeris magnis et pedibus breribus. Antennæ superiores flagello appendiculari præditæ, pedunculo crasso et ejus segmentis 2:do et 3:to brevibus, et flagelli segmento 1:mo longo. Antennæ inferiores segmento pedunculi 1:mo magno et inflato et extus visibili. Mandibulæ palpigeræ acie laevi et tuberculo molari magno instructæ, Maxillæ 1:mi paris palpo biarticulato angusto, apice duas vel tres setas vel aculeos minores mobiles gerente, et earum ramus interior latus et brevis et setis multis ciliatis instructus. Maxillipedum lamina truncæ segmenti 2:di, sive lamina exterior margine interiore tenuissime noduloso, et eorum palpus quadriarticulatus et unguiferus. Pedes truncæ sive thoracici 1:mi et 2:di paris subcheliformes, illi validi et breves, ungue bene evoluto, li longiores et graciliores, ungue minutissimo. Reliqui pedes truncæ forma solita, robusti. Laminæ branchiales simplices minimeque pectinatim plicatae. Pedes caudales ultimi paris ramis lamellosis. Segmentum 7:mum sive ultimum caudæ profunde bifidum, laciniis acuminatis ad apicem vero non spiniferis.—Tantummodo una species:—*Eurytenes magellanicus* (H. Milne Edwards).” The definition inserted in the Swedish paper adds to the account of the mandibulæ, “processu accessorio vero minimo et simplice,” which in the English paper appears in the description of the species. The species is now known as *Eurytenes gryllus*, having been identified by Boeck with *Gammarus gryllus*, Mandt, (rather Lichtenstein in Maudt), 1822. A full and interesting account of the species is here given, with good figures, Plates I., II., III., figs. 19–22. Lilljeborg agrees with Spence Bate in numbering the limb-joints, not from the first free joint, but from the true first joint, “to which the gill-sack and lamina for covering the eggs are attached.

A tabular view of the families of the Amphipoda gives them in two groups; those in which “Pedum caudalium omnia paria adsunt—*Normalia*, S. Bate,” are 1. Gammaridæ, Dana. 2. Orchestidæ, Dana. 3. Corophidæ, Daua. 4. Cheluridæ, Allmau. 5. Hyperidæ, Dana. Those in which “Pedum caudalium unum vel pluria paria absunt—*Aberrantia*, S. Bate,” are 6. Dulichidæ, Dana. 7. Caprellidæ, Dana. 8. Cyamidæ, Dana. The Hyperidae are distinguished from the four preceding families by having the “maxillipes imperfecti et palpo carentes.” The Cheluridæ are separated from the three preceding by having the “Segmenta caudalia posteriora coalita;” but since the establishment of the genus *Goplana*, Wrześniowski, this character has lost some of its definiteness.

In a tabular view of the genera of the Gammaridæ, Lilljeborg introduces *Microplax* as a new name for *Iduna*, Boeck, *Iduna* being preoccupied, but *Liljeborgia*, Spence Bate, 1862, has the priority. *Odius* is substituted for *Otus* preoccupied, and *Calliopius* for *Calliope*

preoccupied. The genus *Tiron* is "typified" in a new species called *Tiron acanthurus*, and thus defined:—

"Forma capitidis ex parte cum eadem gen. *Oediceri* congruit, antennae superiores vero flagello appendiculari longo sunt præditæ, et pedes trunci 7:mi paris longitudine pedes anteriores æquant, et breves, crassi et nngniferi sunt. Pedes trunci 1:mi et 2:di paris graciles, ungue tamen non flexibili instructi. Segmenta caudalia superne in medio longitudinaliter carinata, carina ad marginem posteriorem segmentorum in aculeum, qui in segmentis 4:to et 5:to magnus est, et adhuc in segmento 6:to observatur, excurrente. Antennæ superiores longitudine pedunculo antennarum inferiorum æquales. Frons aliquanto producta, basin antennarum superiorum obtegens, rostro brevi sed acuto. Oculi rubri. Longitudo circ. 10 millim."

The new genus *Oediceropsis* is also typified by a new species, which, because the upper antennæ are particularly short, is called *Oediceropsis brevicornis*, with this definition:—

"Forma corporis eidem gen. *Oediceri* valde similis, caput tamen rostro caret, et pedes trunci 7:mi paris, qui longum et rectum anguem habent, et longi et graciles sunt, tamen pedibus anterioribus 6:ti paris non duplo—circ. sesqui—longiores sunt. Antennæ superiores non finem articuli penultimi pedunculi antennarum inferiorum assequuntur, et flagello appendiculari carent. Antennæ inferiores magnæ, fere pediformes, articulo penultimo pedunculi ceteris majore et ad apicem infra setam magnam gerente. Oris partes appendiculares et hujus et anterioris speciei structura solita. Pedes trunci 1:mi et 2:di paris forma inter se similes manu subcheliformi, ovali, carpo postice aliquantum producto. Pedes trunci 3:ti et 4:ti paris parvi et graciles. Segmentum caudale 7:mum integrum et parvum sed laminare. Pedes caudales ultimi ramis dnobus angustis, fere aequalibus. Color flavescentis; oculi rubescentes, sed parum visibles. Longitudo cir. 8 millim."

In the subfamily Lysianassina Lilljeborg gives five genera, which correspond to thirteen out of the seventeen which Boeck has assigned to it.

Lysianassa, Milne-Edwards, he defines as follows:—

"*Pedes trunci s. thoracici 1:mi paris manu subcheliformi carentes, ungue non flexibili, segmento 6:to sive manu apicem versus attenuato ibidemque basi unguis vix crassiore. Mandibulae tuberculo molari minimo. Laminæ exteriore maxillipedum margine interiore noduloso vel læviuscuso.*" Within this he distinguishes three species thns:—

" <i>Lysianassa.</i>	Segmentum 7:mmm caudæ . . .	{ fissum. Laminæ branchiales . . .	{ pectinatim plicatæ . . . 1. <i>spinicornis</i> (A. Boeck).
			{ non plicatæ . . . 2. <i>Vahli</i> (Kröyer).
			{ non fissum, margine posteriore convexo . . . 3. <i>Costæ</i> , M. Edwards."

Of these the first is *Ichnopus spinicornis*, Boeck, 1860, the second was called "*Socarnes Valli*" by Boeck in 1870, the third is the original type species of *Lysianassa*.

The second genus, *Eurytenes*, has been already described. The third genus, *Anonyx*, Kröyer, is thus defined:—

"*Pedes trunci (thoracici) 1:mi paris manu subcheliformi armati, ungue flexibili, margine inferiore manus plus vel minus definito. Mandibulae tuberculo molari mediocris vel magno. Laminæ exteriore pedum maxillarium margine interiore plerumque noduloso, raro dentato vel aculeato.*" To this he assigns the following fifteen species, 1. *Anonyx ampulla* (Phipps); Kröyer, Pl. iv. fig. 52, which is rather to be called *Anonyx nugax*, Phipps; 2. *Anonyx longipes*, Sp. Bate, Pl. iii. figs. 23–31, called *Tryphosa longipes* by Boeck, 1870; 3. *Anonyx gulosus*, Kröyer, including his own *Anonyx norvegicus*, 1851, and the *Anonyx holboelli* of Bate and Westwood; 4. *Anonyx nanoides*, n. s., Pl. iii. fig. 32–34, called

Tryphosa nanoides by Boeck, 1870; 5. *Anonyx pumilus*, n. s., Pl. iv. fig. 35-41; 6. *Anonyx brachycercus*, n. s., Pl. iv. fig. 42-49, called *Menigrates brachycercus* by Boeck in 1870; 7. " *Anonyx Bruzelii*," Boeck, which is recognised as standing near *Anonyx gulosus*, and was subsequently regarded by Boeck himself as a variety only of that species, see the table of errata and addenda to De Skand. og Arkt. Amph.; 8. *Anonyx nanus*, Kröyer, by Boeck in 1870 called *Tryphosa nanus*; 9. *Anonyx pinguis*, Boeck, later called *Orchomene pinguis* by Boeck; 10. *Anonyx serratus*, Boeck, Pl. iv. fig. 50, afterwards called *Orchomene serratus* by Boeck; it is here identified with *Anonyx Edwardsii* (Spence Bate), but wrongly according to Sars; 11. " *Anonyx Edwardsii*," Kröyer, afterwards called *Onesimus edwardsii* by Boeck; 12. *Anonyx litoralis*, Kröyer, called *Onesimus litoralis* by Boeck; 13. " *Anonyx Holbölli*," Kröyer, called *Hippomedon holbölli* by Boeck; *Anonyx denticulatus*, Spence Bate, is here said to be the male of this species; 14. *Anonyx obtusifrons*, Boeck, which was afterwards called *Menigrates obtusifrons* by Boeck; 15. *Anonyx tumidus*, Kröyer, Pl. iv. fig. 51, which Boeck calls *Aristias tumidus*. Boeck, it will be observed, requires seven genera for these fifteen, or perhaps thirteen, species. *Anonyx bruzelii* falls to *Anonyx gulosus* (*cicada*), and *Anonyx brachycercus* is considered by Boeck, in 1876, to be a synonym of *Anonyx (Menigrates) obtusifrons*. In Lilljeborg's synoptic table *Anonyx brachycercus* is separated from *Anonyx obtusifrons* by the maxillipeds. In *brachycercus* these have the outer plates large, "ultra medium articuli 3:ti palpi exteusæ, ad marginem interiorem tantummodo apicem propius nodulosæ, nodulis discretis 4, et ad marginem exteriorem setam unam et pilos minimos gereutes," while in *obtusifrons* he finds from Boeck's description that these plates "have some few scattered coarse teeth on the inner margin." These delicate characters seem little suited for important subdivisions. I am inclined to think that the teeth on the inner margins of the outer maxilliped-plates are very liable to accident, so that their absence cannot always be depended on as characteristic.

The fourth genus, *Callisoma*, Costa, has the species *Callisoma kröyeri*, Bruzelius.

The fifth genus, *Acidostoma*, which is new, is thus defined:—

" *Forma corporis et antennarum cum genere Anonycis congruit, oris partes appendiculares tamen plane diversæ. Labii rami laterales angusti. Mandibulæ processu accessorio, maxillæ 1:mi paris palpo, et palpus maxillipedum ungue carentes, et hæ partes oris conjunctim acumen productum præbent. Pedes trunci 1:mi paris robusti, manu prehensili. Pedes 2:di paris graciles, ungue carentes.*" To this genus, as the type species, is referred *Anonyx obesus*, Sp. Bate, which is described and figured, Pl. v.

1865. MÜLLER, FRITZ.

Description of a new genus of Amphipod Crustacea. The Annals and Magazine of Natural History. Series 3. Vol. XV. 1865. pp. 276, 277. Pl. X.

The new genus, *Batea*, is thus defined:—"Antennæ simple. Coxa of the first pair of gnathopoda rudimentary, those of the second pair of gnathopoda and the first two pairs of pereiopoda largely developed. Coxa of the second pair of pereiopoda deeply excavated upon the upper part of the posterior margin. First pair of gnathopoda rudimentary, consisting of coxa and basis only; second pair of gnathopoda subchelate. Mandibles having an articulated appendage. Maxillipeds having a squamiform plate on both the basis and ischium joints. Fourth and fifth pairs of pleopoda with styliform rami, sixth pair with subfoliaceous rami. Telson single, deeply cleft."

"Species *Batea Catharinensis*, F. M."

Fritz Müller dates from Desterro, Brazil. He gives figures of the male, and notes in his

description several differences presented by the female. Among other points he mentions that "the first pair of gnathopoda are shorter in the male, with but few hairs near the top; they are as long as the basis of the second pair of gnathopoda in the female, slender, flexible, with long hairs on the anterior margin, and shorter curved hairs at the distal extremity."

1866. BATE, C. SPENCE.

Crustacea. The Record of Zoological Literature. 1865. Volume Second. London. MDCCCLXVI. pp. 306–366.

In reviewing Lilljeborg's work on the Lysianassina, Spence Bate remarks, "the closest inspection of specimens of *Caprella aequilibra* from the United States of America has not enabled us to distinguish it from specimens found at Hong Kong and England by so much as a variation that could be tortured into being of specific value. This, moreover, appears to be true of forms that we find described as specifically distinct; but as yet no forms have been determined by competent zoologists as specifically identical in both extreme zones, there being no intermediate locality in which they are known to exist." He thinks "the carcinologist may have confidence that the figure in the British Museum Catalogue fairly and faithfully represents the general form of the type specimen of *Lysianassa magellanica*." Part of the inferior antennæ "may have been hypothetically inserted." He draws the conclusion that Lilljeborg's identification cannot be maintained between his *Eurythenes magellanica* and the *Lysianassa magellanica* of Milne-Edwards. He compares the *Anonyx ampulla* of the British Sessile-eyed Crustacea with Kroyer's figure in Voy. Scand., pl. xiii. fig. 2, with which he thinks it identical.

Spence Bate objects to the placing of his *Anonyx obesus* in the new genus *Acidostoma* "as all the distinguishing conditions are changes in degree only."

1866. COSTA, ACHILLE.

Descrizione di una specie di *Cyamus* parassita de' Delfini. Annuario del Museo zoologico della R. Università di Napoli pel Cav. Achille Costa. Anno III.—1863. Napoli, 1866. pp. 82–83.

He notices that Guérin, in the Icon. Regn. Anim., figures a species of *Cyamus* parasitic on a species of *Delphinus*, which he calls *Cyamus delphini*, and which differs from the parasites on species of *Balaena* in important characters, and that Gervais and Van Beneden have proposed for it a separate genus *Isocyamus*, without however formulating the generic characters. As he has himself found a *Cyamus* differing apparently from Guérin's, he concludes that there must be more than one species parasitic on the *Delphini*. He describes and figures (pl. iv. fig. 2) the new species as *Cyamus chelipes*, remarking, "Ne possediamo un solo individuo femmina rinvenuto sopra un Delfino comune pescatosi nel golfo di Napoli. Osservazioni. Se la figura data dal Guérin del *Cyamus Delphini* è esatta, la nostra specie ne differisce per le antenne interne men lunghe, pe' piedi del primo pajo a mano prensile, per quelli del secondo proporzionalmente meno grossi e per una diversa forma delle mani de' medesimi, pel primo articolo de' piedi del quinto sesto e settimo pajo non fortemente intaccato nel margine posteriore." Lütken gives no opinion upon this species, probably not having met with the account of it.

1866. DOHRN, ANTON, born December 29, 1840 (Paul Mayer).

Zur Naturgeschichte der Caprellen. Mit. Taf. XIII. B. Zeitschrift für wissenschaftliche Zoologie. Bd. XVI. 1. Heft. 1866. pp. 245–251.

Dohrn remarks, as Gosse had done before him, that Caprellæ can upon occasion swim with activity. In his account of the nervous system, he says that “the brain mass consists of two large, differently-formed swellings, of which the upper is considerably larger than the lower. The former shows three distinct sections, a larger upper, a central giving off the optic nerves, and a small anterior one. The upper mass is pierced by the two branches of the aorta, the lower by the oesophagus; behind this the broad oesophageal commissures pass obliquely backwards, entering the first mass of the ventral chain, which likewise consists of two coalescent ganglia. The hinder smaller ganglion belongs to the coalescent first pereon-segment and is considerably smaller than the anterior, properly suboesophagean ganglion.” Mayer observes that the coalescence here spoken of is true of the genus *Proto*, but in most genera and species of the Caprellidæ, the ganglia in question come together without actually coalescing. Dohrn cannot agree with Frey and Leuckart in the view that the ganglion of the second pereon-segment is more powerfully developed than any other, although he thinks that no doubt the importance of the ganglia depends on the extent of the regions they have to supply. He studied the nerves in the young animal, but as a matter of fact in some adult Caprellæ the second pair of limbs are so greatly developed that the statement by Frey and Leuckart is just in accord with the general principle which Dohrn accepts. Dohrn found that the last pereon-segment and the rudimentary pleon, at any rate in the young animal, were without nerve-masses, but on the other hand he discovered that the last ganglion, in the sixth pereon-segment, corresponded not merely to two coalescent nerve-masses, but rather to five, some of which he naturally supposed were derived from the pleon. Mayer, investigating young animals of *Caprella* and *Protella*, has since seen “behind and between the two strong nerves that run from the seventh pereon-ganglion to the corresponding pair of legs, *no less than seven ganglia*, three pairs and an odd one. The second and third pairs rapidly unite into a single mass, and do not appear to give off any nerves. The last odd one shows traces of coalescence out of an original pair. It is the largest of the pleon-ganglia, and no doubt, as Mayer says, corresponds to the single ganglion which provides in the normal Amphipoda for the three segments preceding the telson.

Dohrn finds only two liver tubes in the Caprellidæ, and therefore concludes that when Speeck Bate speaks of the liver in the Amphipoda as consisting of four tubes, it is an error of observation. The number, however, varies in different genera.

In treating of the circulation, Dohrn attributes to the heart five pairs of fissures instead of three. The first, he says, is in the cephalic segment, where the aorta parts from the dorsal vessel; the second, third and fourth lie in the middle of the corresponding segments. The fifth lies in the middle of the fifth segment at the end of the dorsal vessel. The fourth is by far the largest.

In regard to the sexual organs, Dohrn supposes, but erroneously, that there are two pairs of testes in *Caprella*, though in the other Amphipoda he is aware from concurrent testimony that there is but one pair.

1866. GRUBE, A. E.

Beiträge zur Kenntniss der istrischen Amphipodenfauna. Archiv für Naturgeschichte. Zwei und dreissigster Jahrgang. Erster Band. Berlin. 1866. pp. 377-417. Taf. ix. x.

Grube explains, to begin with, that he names the seven joints of the leg numerically according to their position, except the seventh, which for brevity he calls the finger (die Klaue). On the first joint his remark is that he reckons "das Basalstück, an welchem die Kieme und das zum Tragen der Eier bestimmte borstenrandige Blatt befestigt ist, und das zwar von der Epimeralplatte aussen überwachsen aber doch von dieser unterscheidbar ist, als 1tes Glied oder Hüftglied." He defines the Amphipoda genuina, the Gammarina, and the two families, Orchestidae and Gammaridae.

After discussing "*Orchestia littorea*," and "*Orchestia Montagui*, Aud.," Taf. ix. fig. 1, with some of their synonyms, Grube gives a definition of *Allorchestes*, Dana, including "Telson simplex vel bipartitum." To this genus he assigns 1. "*Orchestia Perieri*, Lueas," Taf. ix. fig. 2; 2. a new species, "*Allorchestes Helleri*," Taf. ix. fig. 3, which he had previously classed as "*Allorchestes imbricatus*, Spence Bate? juv.," but which is probably *Hyale nilsonii*, Rathke; and 3. a new species, *Allorchestes stylifer*, Taf. ix. fig. 4, "carpo . . satis lato, postice in proeessum styliformem curvatum exeunte," a peculiarity which, with some other slighter distinctions, separates it, he says, from *Amphithoë (Allorchestes) prevosti*, Milne-Edwards. He then gives a definitio of *Nicea*, Nicolet, including "Telson profunde divisum," and, depending apparently only on comparative lengths of the antennæ for the generic distinction, he assigns his *Amphithoë (Hyale) istrica* to this genus as *Nicea istrica* ♂, Taf. ix. fig. 5. He describes a new species, *Nicea longicornis*, from a single female specimen, 4 mm. in length, having "antennæ superiores inferioribus paulo longiores et fortiores, usque ad segmentum 5tum pertinentes, articulis 14, 2^{do} longitudine 1^{mi}, dupla 3ⁱⁱ." It reminds him of *Calliope*, but for the last uropods, while *Gammarella* and *Crangonyx* are excluded on other accounts. The character of the antennæ at any rate seems little to accord with *Nicea (Hyale)*, and, as no figure is given, it might be rash to suggest *Pherusa fucicola*, Leach, for this species, on the presumption of some error in Grube's desription.

In defining the genus *Lysianassa*, Grube gives "Telson squamiforme integrum vel fissum," and in it describes, 1. *Lysianassa spinicornis*, A. Costa, Taf. ix. fig. 6; 2. ? *Lysianassa loricata*, A. Costa; 3. his own *Lysianassa ciliata*, Taf. ix. fig. 7, which has the "telson oblongum longitudine appendium pedes bistyl 3ⁱⁱ, usque ultra medium fissum," and is thereby excluded from the genus *Lysianassa* as generally defined, and from identity with *Lysianassa audouiniana*, Sp. Bate, as proposed by Heller; 4. *Lysianassa humilis*, A. Costa, which in Heller's opinion is probably the same as *Lysianassa costa*, M.-Edw.; 5. *Lysianassa longicornis*, Lucas, Taf. ix. fig. 8, with remarks on the differences between the two sexes, extending not only to the size and shape and armature of the antennæ, but also to the form of the first gnathopods and of the telson. "Das Telson, dessen Form als charakteristisch für die Species gilt, war hier bei Männchen und Weibchen verschieden gestaltet, bei beiden zwar länglich, oben etwas verschmälert mit geraden Seitenräudern, aber bei jenen ganzründig und abgerundet bei diesen hingegen länger und scharf und tief eingeschnitten, daher zweispitzig, jede Spitze mit einem Stachelchen besetzt." Though he had specimens with eggs well advanced in development, Grube states that he had sought in vain for the marsupial plates. On the whole I incline to infer that, while assuming to describe the female of *Lysianassa longicornis*, Lueas, he has had before him not only a distinct speies, but the species of a distiuct genus, probably *Ichnopus taurus*, A. Costa. He figures and describes (seemingly

from the female only), what he calls "gefiederte Kieme," the branchiae not simple, but carrying symmetrically arranged supplementary vesicles, an arrangement now known to exist in several species, and already described by Costa in *Ichnopus*. He also draws discriminating characters from the mouth-organs of the three species *longicornis*, (probably the ♀ so-called), *spinicornis* and *ciliata*.

Grube makes *Leptocheirus*, Zaddach, and *Ptilocheirus*, Stimpson, synonyms of *Protomedieia*, Kröyer, in agreement with Spence Bate and other writers, but Boeck places *Leptocheirus*, with *Ptilocheirus* for a synonym, in his subfamily Leptocheirinae, and *Protomedieia* in the subfamily Microdeutopinæ, the differences being in the maxillipeds, the side-plates, the second gnathopods, and the last uropods. In the Leptocheirinae, moreover, it is noted that the first joint of the mandibular palp is elongate. Grube describes "*Protomedieia hirsutimana*, Sp. Bate? Taf. x. fig. 2," but in the description of "Taf. x. fig. 2," he calls it "*Protomedieia pilosa* (Zadd.)." having apparently convinced himself of the identity of his own specimen with Zaddach's species. His new species, *Protomedieia guttata*, Taf. x. fig. 3, as well as the old one, must evidently be placed in the genus *Leptocheirus*.

He figures his species *Crangonyx recurvus*, Taf. x. fig. 1, and describes it anew.

Being unacquainted with *Gammarus marinus*, Leach, Grube refers a species, which he had previously called *Gammarus olivii*, M.-Edw., to *Gammarus paeциurus*, Rathke. He describes *Gammarus gracilis*, Rathke, recognising that it may be only a variety of *Gammarus paeциurus*. All these *Gammari* are by Boeck accepted under the name *Gammarus marinus*, Leach. Grube concludes this paper with a description of *Gammarus locusta*, Linn.

1866. HELLER, CAMIL.

Beiträge zur näheren Kenntniss der Amphipoden des Adriatischen Meeres.
Wien. 1866 in 4to. 62 pp. u. 4 Kpfr. Denkschriften der k. Akad. d. Wissensch. Mathem. naturw. Cl. B. 26. 2 Abth. pp. 1-62. (Vorgelegt in der Sitzung am 3 Nov. 1865).

Orchestia montagui, Audouin, is given as a distinct species from *Orchestia littorea*, Leach, but *Orchestia constricta*, Costa, is made synonymous with *Orchestia montagui*. The new species described and figured are *Nicea plumicornis*; *Nicea fasciculata*; "*Nicea Buccichi*"; *Nicea nudicornis*; *Nicea macronyx*, which will be *Hyale prevostii*, if Catta is right in identifying it with *Amphithoe prevostii*, M.-Edw.; *Nicea camptonyx*; "*Nicea Schmidtii*"; *Nicea rufa*; *Nicea crassipes*; *Probolium megacheles*, which being without mandibular palp must be transferred to Dana's genus *Stenothea*, and, for the species, is identified by Catta, 1876, with Costa's *Probolium polyprion*; *Lysianassa pilicornis*; *Ichnopus aſinīs*; *Ichnopus calceolatus*, identified by Boeck with his own *Ichnopus spinicornis*, 1860; "*Anonyx Schmarda*," in Boeck's opinion, perhaps, together with the next species, belonging to his genus *Ambasia*; *Anonyx filicornis*; "*Anonyx Nardonis*" (at p. 59 by a misprint assigned to Kröyer), said to differ little from *Anonyx nanus*, and by Boeck referred to his genus *Tryphosa*; *Iphimedia carinata*, not figured, and not in my opinion specifically distinct from *Iphimedia obesa*, Rathke, which includes two other synonyms or varieties, *Iphimedia eblana*, Sp. Bate, and *Iphimedia multispinis*, Grube; *Eusirus bidens*, already described by Boeck as *Eusirus longipes*; "*Melita Coroninii*"; *Mæra integrimana*; "*Mæra Donatoi*," which, like *Mæra grossimanus*, Montagu, and *Mæra Lovéni*, Bruzelius, has the finger of the second gnathopods fringed with hairs on the outer margin; *Amphithoe bicuspis*, a name preoccupied by Kröyer, and the species identical with *Sunamphithoe conformata*, Sp. Bate; from *Sunamphithoe hamulus* Heller himself observes that it is distinguished only by the greater

length of the upper antennæ and by the presence of two terminal hooks on the telson; "*Amphithoë Brusinae*;" *Podocerus monodon*, identified by Boeck with *Podocerus falcatus*, Montagu; Heller himself distinguishes it from *Podocerus variegatus*, "especially by the presence of a simple hook on the outer branch of the third uropods," (compare *Amphithoides*, Kossmann, 1880); *Podocerus largimanus*, with forty joints to the flagellum of the upper antennæ, yet given by Boeck as a synonym of *Podocerus anguipes*, Kröyer, which has that flagellum of six to eight joints; *Podocerus longicornis*, said by Heller to approach *Amphithoë crassicornis*, Costa, and by J. V. Carus, 1885 (probably on Nebeski's authority) entered together with the preceding species in the genus *Amphithoë*, without special notice of the secondary flagellum in each of these species; "*Microdeutopus Titii*," *Cyrtophium lare*, probably the same as *Cyrtophium darwinii*, Sp. Bate, Dr. Heller having apparently taken the account of the transverse ridge to mean a longitudinal carina; *Cratippus crassimanus*, without much doubt to be united with *Cratippus tenuipes*, Sp. Bate, and *Exunguia stilipes*, Norman, under the common name *Colomastix pusilla*, Grube; *Caprella obtusa*, which Boeck identifies with *Caprella septentrionalis*, Kröyer, and Mayer with *Caprella acutifrons*, Latreille, ♂ juv.; *Caprella monacantha*, which again according to Boeck is *Caprella esmarkii*, Boeck, but according to Mayer, *Caprella xequilibra*, Say, ♂ juv.; *Caprella aspera* = *Caprella acanthifera*, Leach; *Caprella leptonyx* = *Caprella acanthifera* juv.; and *Caprella armata*, according to Mayer another synonym of *Caprella acanthifera*, Leach. Costa's *Lysianassa filicornis* is said to be a synonym of *Lysianassa longicornis*, Lucas; *Lysianassa humilis*, Costa, possibly of *Lysianassa costae*, Milne-Edwards, and *Lysianassa ciliata*, Grube, of *Lysianassa audouiniana*, Sp. Bate. Boeck regards Grube's *ciliata* and possibly Costa's *humilis* as belonging to his genus *Aristias*, of which he makes *Anonyx tumidus*, Kröyer, the type, with *Lysianassa audouiniana*, Sp. Bate, (wrongly given) as a synonym. *Amphithonotus spiniventris*, Costa, is renamed *Dexamine spiniventris*, *Amphithonotus*, Costa, being synonymous with Leach's genus *Dexamine*. Under the name of "*Atylus Costae*" are united Costa's two species *Nototropis spinulicauda* and *Nototropis guttatus*, though surely *guttatus*, in right of priority, should have been retained. The close agreement between *Leucothoë articulosa*, Leach, and *Leucothoë denticulata*, Costa, is pointed out. Both these species are united by Boeck under the older name *Leucothoë spinicarpa*, Abildgaard. Three species described by Costa under the names *Gammarus punctimanus*, *Gammarus obtusunguis*, *Amphithoë semicarinata*, are all referred, the two former as males, the last as female, to *Gammarella brevicaudata*, Sp. Bate. *Ceratlocus orchesiipes*, Costa, which Sp. Bate transferred to *Melita*, here becomes *Mæra orchesiipes*. It is in all probability the *Gammarus fasciatus* of O. G. Costa. Attention is called to points of agreement between *Mæra grossimana*, Leach, *Mæra scissimana*, Costa, and *Mæra integrimana*, Heller's own species. *Megamæra brevicaudata*, Sp. Bate, is transferred to the genus *Mæra*. A species supposed to be *Eurystheus erythrophthalmus*, Sp. Bate, but with cleft telson, receives the name *Mæra erythrophthalma*. Since, however, Spence Bate's species is the same as *Gammaropsis erythrophthalmus*, Liljeborg, Heller's species, with the cleft telson, must not be confounded with it. The similarity of *Amphithoë penicillata*, Costa, to *Amphithoë albomaculata*, Kröyer, is noticed. It is pretty certainly the same as *Amphithoë vaillantii*, Lucas, 1849, if it may not be carried still further back to *Amphithoë rubricata*, Montagu. *Erichthonius bidens*, Costa, is said to be identical with *Cerapus abditus*, Templeton. *Corophium crassicornis*, Bruzelius, is identified with the earlier named *Corophium acherusicum*, Costa, an identification which Boeck accepts with a? *Caprella tabida*, Lucas, is made a synonym of *Caprella acutifrons*, Latreille.

A table is added of all the Amphipods found in the Adriatic up to the date of this work. Valuable descriptions and figures are given of several of the previously known species, as well as of the species discovered by Heller himself.

1866. SCHIGDTE, J. C.

Krebsdyrenes Sugemund. Naturhistorisk Tidsskrift. 3. Raekke. 4. Bind.
Kjøbenhavn, 1866. pp. 169–206. Tab. X og XI.

This paper deals principally with the mouth-organs of the Isopoda. Of the biting Isopoda the mouth is said to present three principal types, and the first type is said to comprise *Onisci*, *Aselli*, *Idotheæ* and *Sphæromata*, and to be essentially the same as the type met with in the majority of the Amphipoda.

This paper is translated in "The Annals and Magazine of Natural History," ser. 4, vol. i. No. 1, January 1868, pp. 1–25. Plate 1.

1867. BATE, C. SPENCE.

Crustacea. The Record of Zoological Literature. 1866. Volume Third.
London, MDCCCLXVII. pp. 216–250.

Spence Bate demurs to Grube's view that "*Allorchestes imbricatus* (Sp. B.), is but the young of *A. helleri*." He "suggests to continental carcinologists to determine whether or not there be two freshwater species [of *Gammarus*], viz., *G. pulex* and *G. fluvialis*, as, from the great confusion of the two names by various authors, he is inclined to think that they, and also the figures, are but the result of imperfect drawings and descriptions of one and the same species." *Gammarus torelli*, sp. n., Goës, he says, "evidently belongs to the genus *Megamœra* of the Brit. Sessile-eyed Crustacea." In the "Naturalist in Vancouver Island and British Columbia, by J. Keast Lord. London, 1866," vol. ii., ch. xiii., pp. 262–284, with a plate, a description is given by Spence Bate of the "Vancouver Island Crabs." In this chapter, he mentions from Esquimalt Harbour, *Allorchestes verticillatus*, Dana; *Allorchestes brevicornis*, Dana; *Mœra fusca*, Sp. Bate; *Amphithoë peregrina*, Dana; *Amphithoë orientalis*, Dana; *Amphithoë filicornis*, Dana.

1867. COSTA, ACHILLE.

Saggio della collezione de' Crostacei del Mediterraneo Del Museo Zoologico della Università di Napoli spedito alla Esposizione di Parigi del 1867. Annuario del Museo Zoologico della R. Università di Napoli. Anno IV., 1864. Napoli, 1867. pp. 38–46. Pl. III.

It mentions 72 species of Crustacea, the principal object being to show the specialities of the Italian waters, as discovered by Cocco, De Natale, O. G. Costa, Hope, and A. Costa himself. The numbers 32–59 refer to the Amphipoda. 35 is *Orchestia crassicornis*, n. s., near to *Orchestia littorea*, "but differing in the proportions and robustness of the lower antennæ, especially of the male. They are shorter and more robust than in the three allied species, *littorea*, *mediterranea*, and *constricta*." On 37, *Orchestia deshayesii*, Audouin, it is remarked that the hand of the second gnathopod varies greatly. 40, *Lysianassa filicornis*, A. Costa, "by the length and tenuity of the lower antennæ approaches *L. longicornis*, Lucas, from which it is distinguished chiefly by the proportions of the upper antennæ, those of the abdominal false feet and other characters. Nevertheless, the two species in question, on account of the extreme length of the lower antennæ, may very well constitute a distinct group or subgenus, for which we have proposed the

name of *Lysianassina*." On 45, *Epimeria tricristata*, A. Costa, the observation is made that it is very close to *Acanthonotus owenii*, Bate and Westwood, so that at first sight they might be thought the same, but that specifically they differ much in the length of the antennae and the hands of the second gnathopods. Nor does Costa admit the propriety of placing the species in the genus *Acanthonotus*. Boeck, who has not apparently seen this paper, makes both names synonyms to *Epimeria cornigera*, Fabricius. As to 47, *Gammarus longicaudatus*, A. Costa, and 48, *Gammarus montanus*, A. Costa, it is recognised that these two fresh-water species, of which the first is identified by Bate and Westwood with *Niphargus aquilex*, Schiödte, may be only varieties of one and the same species. 49. *Guerinia niceensis*, A. Costa, is figured. In regard to 51, *Microdeutopus gryllotalpa*, A. Costa, the form of the carpus of the first gnathopods is said not to be accurately given in the figure of the species by Bate and Westwood. As a matter of fact, their figure probably represents a different species. Costa further observes that the carpus of his species is found to vary in regard to the number and proportions of teeth on its lower margin. 59 is *Caprella gigas*, A. Costa, from the Bay of Naples, undescribed. 54 is *Orio zanclerus*, Prest. 55, *Cheiropristis messanensis*, Cocco. 56, *Ornithorhamphus coccoides*, De Nat. 57, *Carcinococcus costæ*, De Nat. (not an Amphipod).

1867. GERSTAECKER, A.

Bericht über die wissenschaftlichen Leistungen im Gebiete der Entomologie während der Jahre 1865–66. Archiv für Naturgeschichte. Drei und dreissigster Jahrgang. Zweiter Band. Berlin, 1867.

The works on Amphipoda are described in pages 487–495.]

1867. MARCUSEN, JOH.

Zur Fauna des schwarzen Meeres. Vorläufige Mittheilung. Archiv für Naturgeschichte. Drei und dreissigster Jahrgang. Erster Band. Berlin, 1867. pp. 357–363. (Also in the Transactions of the first meeting of Russian Naturalists at St. Petersburg, 1868. pp. 176–179. In Russian.)

The list of the Amphipods which Dr. Marcusen had obtained is given as follows:—"Talitrus locusta Linn. Orchestia littorea Montagu. Orchestia mediterranea Costa. Montaguia pontica mihi—ähnlich der M. marina Sp. B. Bathyporeia pontica mihi—ähnlich der B. Robertsonii Sp. Bate, mit calceola am unteren Fühler, aber auch einer calceola am oberen. Ampelina Gaimardii Sp. Bate. Dexamine pontica mihi—mit gefiedertem Kiemenplättchen. Calliope grandoculis. Microdentopus gryllotalpa Sp. Bate. Microdentopus nov. spec. Microdentopus nov. spec. Gammarus glacialis Rathke. Gammarus locusta Linn. pilosus var. mihi. Amphitoë picta Rathke. Podocerus pulchellus M.-Edw. Podocerus ähnlich dem falcatus Sp. Bate. Podocerus ähnlich dem pelagicus S. Bate, Cerapus ponticus mihi. Siphonæcetes n. sp. Corophium Bonelli M.-Edw. Corophium bidentatum mihi. Corophium ähnlich dem crassicornis." The description of the new species, with figures, is promised for a later opportunity. The question is discussed whether the Black Sea should be reckoned as part of the Mediterranean, a question which C. Heller answers in the affirmative. Of Amphipoda, it is said that there are in the Black Sea representatives of almost all families, among them species not as yet found in

(Zool. Chall. Exp.—Part LXVII.—1887).

Xxx 47

the Mediterranean, as *Bathyporeia pontica*; there are several nest-builders, as species of *Podocerus*, *Cerapus* and *Siphonæcetes*. The resemblance of its Crustacean fauna to that of the northern seas is illustrated by the presence, among others, of species of *Bathyporeia*, *Podocerus* and *Siphonæcetes*.

1867. NORMAN, ALFRED MERLE.

Reports of Deep Sea Dredging on the Coasts of Northumberland and Durham, 1862-4. Edited by George S. Brady. Report on the Crustacea, by the Rev. Alfred Merle Norman, M.A. Natural History Transactions of Northumberland and Durham : 1865-67. London, 1867. pp. 12-29.

The new genus *Cheirocratus*, assigned to Fam. GAMMARIDÆ, Norman. (Subfam. Gammarides B. & W.) is thus defined:—"Superior antennæ shorter than inferior, having a secondary appendage. First gnathopods not subchelate. Second gnathopods subchelate, very large. Telson double. Last pair of pereiopods very long." The type species, *Cheirocratus mantis*, here fully described as new, is identified by Boeck with *Gammarus assimilis*, Lilljeborg, 1851.

In the family Corophiidae, Bate and Westwood, the genus *Unciola*, Say, is described as having the "last uropods double-branched," which is not in accordance with Say's own account. In the description of the new species, *Unciola planipes*, we also read, "uropods of last pair two-branched, small, scarcely reaching beyond telson, or the basal joint of preceding pair; outer branch tipped with long simple hairs; inner branch terminating in a single spine." The figure (G. S. Brady del.) gives only a single branch, and a prolongation of the peduncle tipped with a spine. Boeck gives the species as a synonym ? of his *Glaucome kröyeri*, 1870. The Museum Normaniannm, 1886, gives "Unciola planipes, Norman, = Unciola leucopis, B. & W. (non Kröyer)."

1867. NORMAN, A. M.

Report of the Committee appointed for the purpose of exploring the coasts of the Hebrides by means of the dredge. Part II. On the crustacea, echinodermata, polyzoa, actinozoa, and hydrozoa. (From the Report of the British Association, for 1866.) pp. 193-206. 1867.

Eight Amphipods are added to the British Fauna. Among these are the new species *Anonyx melanophthalmus*, the new genus, *Euonyx*, "differing from *Anonyx* in having the first gnathopods chelate, and the second stronger than the first, subchelate, nail large and strong. Posterior uropods two-branched. Telson cleft," with its new species *Euonyx chelatus*, "dredged parasitic on *Echinus esculentus*, L.;" and the new genus *Microprotopus*, "allied to *Microdeuteropus*," but with differences shown in the italicized part of the following definition:—"Antennæ with secondary appendage. First gnathopods subchelate. Second gnathopods larger than first, subchelate, greatly developed in ♂, much smaller in ♀. Uropods terminating in simple spines, those of last pair with a single ramus. Telson tubular." The new species for which this genus was formed is named *Microprotopus maculatus*.

1867. PACKARD, A. S., JR.

View of the recent Invertebrate Fauna of Labrador. Memoirs read before the Boston Society of Natural History; being a new series of the Boston Journal of Natural History. Volume I. Part. II. Boston, 1867. (Read October 4, 1865. pp. 262-303. Pl. VIII.

Packard's article on the marine invertebrates found at Caribou Island, Straits of Belle Isle, which was published in the Canadian Naturalist and Geologist for December 1863, is, he says, embodied in the present article, with typographical corrections. "Valuable information regarding the identification of several species of Amphipoda has been kindly communicated through Dr. Lütken by Mr. A. Boeck." The Amphipoda occupy pages 297-301.

"*Monoculodes nubitalus* nov. sp. [Pl. VIII., fig., 4.]" is thus described:—'Female. Cephalic ring produced into an obtuse, tumid rostrum, smaller than in *M. carinatus* Bate, of the British shores; the segments of the thorax and abdomen are not carinated above as in that species, being nearly smooth, while the abdominal segments are slightly sinuated just behind each suture. Eyes small, round, situated just above and opposite the insertion of the superior antennæ; not colored in the adult, but black in the young. Superior antennæ a little longer than the peduncle of the inferior pair; inferior antennæ reaching to the hind edge of the fourth thoracic, including the cephalic, ring; the penultimate and last joint of the peduncle equal in length; flagellum about half the length of the whole antenna. Both pairs of gnathopoda very equal in size, the propodos being long, ovate; anterior pair slenderer than in *M. carinatus*, palm very oblique, with minute hairs; dactylos two thirds the length of the propodos; carpos minute, not prominently produced as in *M. carinatus*, but rather continuous with the propodos. The second pair are much stouter and more ovate than in *M. carinatus*, according in this respect more with that of *M. demissus*, Stimp. In form it closely repeats that of the anterior pair; carpus with a long, slender, spine-like prolongation from the palm, forming a thumb closely appressed to the propodos, but not extending to the middle. Palm of the propodos on the anterior half fringed with hairs. Dactylos one-half as long as the propodos. Anterior pair of thoracic legs subequal; posterior pair of thoracic legs twice as long and much larger than the anterior, coxae regularly short, pyriform. Abdominal legs large, equal in size, reaching nearly to the tip of the caudal stylets, which are lanceolate, very slender, acute; the first pair being a very little longer than the third. Color pale, mottled with slate. Length, .50 inch.

"It differs from *M. demissus* of Grand Menan, in its color, and the very unequal antennæ. From *M. carinatus* of the British Isles it may be readily distinguished by the very equal gnathopoda and non-carinated segments, the slenderer antennæ, and the smaller, round eyes.

"Caribou Island, eight fathoms, sand." See also Note on S. I. Smith, 1883.

1867. SARS, GEORG OSSIAN.

Histoire Naturelle des Crustacés d'eau douce de Norvège. 1^e livraison. Les Malacostracés. Avec 10 Planches. Christiania. 1867. pp. III + 146. (Amphipoda, pp. 41-90. Pl. IV., V., VI., VII., VIII. fig. 1-5.)

In this masterpiece Professor Sars has taken the opportunity to describe, with great fulness of detail and a clearness that leaves nothing to be desired, the whole structure of an Amphipod, illustrating the description by figures which are not only elaborate and artistic but possess the further virtues of being in the most satisfactory manner explanatory and intelligible. In the period of active investigation since this work was published, one or two of its statements

have been called in question. In a note to p. 41 Professor Sars says that in some males of the genus *Tanaïs* the eyes are not only pedunculate (pédicellés) but even mobile. This statement, to say the least, requires confirmation. In regard to the apparatus for the circulation of the blood, Delage observes that, while Sars is the first who clearly pointed out the existence of a posterior aorta with definite walls, he reproduces the old mistake of attributing to the heart six, instead of three, pairs of lateral slits (valvules); nor does he recognise the delicate walls which more or less confine the currents of the blood. In regard to the species *Gammarus neglectus*, which Sars describes with so much valuable detail, Fr. Meinert inclines to believe that it should not be separated from *Gammarus pulex*, auctorum, the differences being at best minute, and these capable of being bridged over by intermediate examples. If the species stands, Meinert thinks it should retain the name *Gammarus lacustris*, which Sars gave it in 1863. For altering this Sars gives the insufficient reason that he had met with a casual reference in Nilssou's "Skandinavisk Fauna," tome 4, page 420, to a species named in parenthesis "(*Gammarus neglectus* Lilljeborg)," on which the trout, var. *Salmo punctatus*, fatten in the Scandinavian mountain-tarns. It is certainly an error to suppose, as Sars appears to do on the authority of Hosius, that *Gammarus pulex* is only found in very rapid rivers.

On page 59, under the heading *Organes excréteurs*, Sars observes "Comme organes exeréteurs et avant tout urinaires, correspondant aux vaisseaux de Malpighi des insectes, on doit indubitablement considérer les 2 minces appendices cylindriques (pl. 5, fig. 25 p.), qui débouchent en haut dans l'intestin à la naissance du rectum. Placés l'un tout contre l'autre et contre la face dorsale de l'intestin, ces appendices pénètrent profondément, chez les individus adultes, avec leurs bouts obtusément arrondis dans le dernier segment thoracique. . . . On doit sans doute encore faire entrer dans cette catégorie un caudal flexueux en forme de fronde, de structure glanduleuse, qui se trouve dans le premier article fortement tuméfié des antennes inférieures et débouche sur la pointe du proœd conique que le 2^e article envoie en bas, la soi-disant épine olfactoire." The reader therefore must not be led astray by the references to the "olfactory spines" on page 48, and in the descriptions of pl. iv. fig. 21 and pl. vi. fig. 27. A further safeguard is supplied on page 62, where Professor Sars says, "Le sens *olfactif* ou le sens qui chez les crustacés semble s'en rapprocher le plus, est, comme chez le genre *Mysis*, restreint à la tige extérieure des antennes supérieures; chacune de ses articulations porte généralement au bout, dans le bord supérieur, un appendice cylindrique très petit, correspondant exactement dans sa structure aux papilles appelées olfactoires des céphalopodes." As to the analogy of the urinary organs first mentioned with the Malpighian tubes of insects, see Note on Spence, 1885.

Of the pleopods Sars figures and describes the peculiar spines and special setæ (à bout bifurqué), which have either escaped the notice of authors in general or not been thought worthy of attention.

The other Amphipods described in this work are *Pallasea cancelloides*, Gerstfeldt, var. *quadrispinosa*, Esmark; *Gammaracanthus loricatus*, Sabine, var. *lacustris*; *Pontoporeia affinis*, Lindström, said to come very close to *Pontoporeia femorata*, Krøyer.

1868. BATE and WESTWOOD.

A history of the British Sessile-eyed Crustacea, Part XXII. and Part XXIII.
December 31, 1868. pp. 497–536, and Introduction, signed (C. S. B.), pp. iii.–lvi.
London.

The gnathopods of *Orchestia brevidigitata*, n. s., from Banff are figured and described. The length is given as about eight-twentieths of an inch, the colour a light olive-green. It is

said to bear a close resemblance to *Orchestia euchore*, Müller. As Boeck identifies the latter with *Orchestia gammarellus*, this species also may be a variety of the same.

A short account is given, and the second gnathopod figured, of Kröyer's *Leucothoë clypeata*, under the name *Montagua clypeata*, with the suggestion that *Montagua pollexiana*, Spence Bate, may be the male of Kröyer's species; in that case it would become a synonym of *Metopa clypeata*, Kröyer. The second gnathopod of *Montagua norvegica* is figured and described, with a reference to *Leucoluoë norvegica*, Liljeborg, 1850, and to the Brit. Mus. Catal., p. 370, where Spence Bate expresses the opinion that this species is most probably a synonym of *Montagua clypeata*. Boeck agrees with this view, naming it therefore *Metopa clypeata*, Kröyer (but see Note on Liljeborg, 1850).

At page 501, *Opis leptochela*, n. s., is figured and described. Of this Norman, Last Report, etc., p. 335, 1868, says, "this I find to be the species described by me under the name *Euonyx chelatus* (Brit. Assoc. Report 1866 (1867), p. 202). My specimen differs from that described by B. and W. in having the second gnathopods larger and stronger than the first, and the hand furnished with a strong nail. This difference is perhaps one of sex. The species cannot, I think, be placed in the genus *Opis*." Boeck, apparently unaware of Norman's genus, says of *Opis leptochela*, that it cannot belong to *Opis*, "as the first gnathopod has a very elongate wrist and an elongate chelate hand, thereby resembling the genus *Krögeria*, which belongs to the subfamily Edicerinæ. It ought therefore to become the type of a new genus, which might be called *Leptochela*."

At page 503, *Opis quadrimana*, n. s., is described, and the first gnathopod figured. On the ground that this does not agree with *Opis* either in the mouth-organs or the structure of the first gnathopods, Boeck, in 1870, makes it the type of a new genus, under the name *Normania quadrimana*, Bate and Westwood.

A species is partly figured and described as probably belonging to *Ampelisca larvata*, Lilljeborg, but by Norman and Boeck the form in question is said to be *Ampelisca tenuicornis*, Lilljeborg. *Haploops tubicola*, Lilljeborg, is figured and described, and said to have been taken by Mr. Norman "in the Shetlands," where "Hebrides" should be read instead of "Shetlands."

At page 507, *Monoculodes longimanus*, n. s., from Banff, "length about one-fifth of an inch," is briefly described, and the first and secoud gnathopods are figured. "Specific character. Dorsal surface slightly carinated. First pair of gnathopoda long and narrow, resembling the second pair."

At page 508, *Kroyera brevicarpa*, n. s., is described. The gnathopods are figured. This is identified by Boeck with *Krögeria haplochela*, Grube, 1864, and therefore named *Pontocrates haplochela*.

At page 509 the new genus *Lepidepecreum* is defined as follows:—"Cephalon having the orbital or intra-antennal process considerably developed and produced. Percion well-developed. Pleon having the last four segments very short. Eyes not made out; supposed to occupy the intra-antennal process;—superior antennæ having the upper surface of the first two joints of the peduncle considerably produced anteriorly, having no secondary appendage. Inferior antennæ posterior to the superior. Mandibles furnished with a biarticulate appendage. First pair of gnathopoda moderately robust, subchelate. Second pair feeble and chelate or subchelate. Posterior pair of pleopoda short, biramous. Telson—?" The type is figured and described as *Lepidepecreum carinatum*, n. s. It was "taken at Banff by Mr. Edward, associated with *Anonyx longicornis*, with which it is very closely allied, being perhaps a young female." There seems little, I think, to justify the establishment of a new species, and the name for the two forms should therefore stand as *Lepidepecreum longicorne*. In the description of *Anonyx longicornis*, the telson was given as "very long and deeply cleft," so that "telson cleft" may be presumed to be properly part of the generic

character. G. O. Sars, 1882, mentions the capture at Lodshavn of a single specimen (♀) of “*Lepidepecreum carinatum*, Sp. Bate,” but does not describe the telson. In a specimen which I owe to the kindness of Mr. David Robertson of Glasgow, I find the telson very narrow, cleft almost to the base, each tip having two small spines. Sars thinks that *Lysianassa umbo* of Goës should be included in this genus, and not in Boeck’s *Orchomene*. See Note on Goës, 1865.

Nicippe tumida, Bruzelius, is figured and described.

Cheirocratus mantis, Norman, is figured and described, but with some variations in the generic character, which need correction. The upper antennæ are much shorter than the lower, not subequal, and the third uropods are not unibranched, but biramous. The species is identified by Boeck with the earlier *Cheirocratus assimilis*, Liljeborg.

At page 515, *Megamæra multidentata* (Norman, MSS.), from Guernsey, is figured and described.

This is “*Mæra Batei*,” Norman, published in the Annals and Magazine of Natural History for December 1868, and therefore taking precedence by a few days of the name *Megamæra multidentata*. This is indicated at page 530 by the citation, “*Mæra Batei* Norm. (See our Vol. ii. p. 515),” but no notice is there taken of some slight discrepancies between the two accounts, which were no doubt drawn up from different specimens.

On pages 517–518, Norman’s *Unciola planipes* is figured and described as *Unciola leucopes*, Krøyer, Krøyer’s genus *Glauconome* being identified with *Unciola*, Say. Norman, Last Report, etc. 1868, says, “*Unciola leucopes*, Krøyer. B. and W. consider my *U. planipes* as ‘probably identical’ with this species. It may be so, but there are points of difference which make me think it wiser to keep them apart until the examination of Greenland specimens should settle the question definitely.” Krøyer’s species, it should be observed, was named *leucopis* from “λευκός, albus, et οψ, oculus.” Boeck gives “? *Unciola planipes*, Norman,” as a synonym to his own *Glauconome krøyeri*, 1870. Sars in 1882 accepts *Glauconome leucopis*, Krøyer, as identical with *Unciola irrorata*, Say.

Hyperia tauriformis, n. s., from Banff, briefly described and partly figured on page 519, is identified by Norman with *Metoecus medusarum*, Krøyer, which Boeck names *Tauria medusarum*, O. Fabr., 1780, but Bovallius, 1885, points out that Bate and Westwood, and Boeck likewise, have misunderstood Dana’s account of his genus *Tauria*, so that neither the name *Hyperia tauriformis* nor *Tauria medusarum* is admissible. The name will perhaps become *Hyperia abyssorum*, Boeck.

On page 520, *Hyperia prehensilis*, n. s., from Banff, is figured and described. “*Specific character.* Superior antennæ about the length of the head. Both pairs of gnathopoda with the carpus and propodus simple. Three hind pairs of pereiopoda subprehensile at the tips.” Length, three-twentieths of an inch.

On page 521, *Hyperia cyanex*, Sabine, is described. “It looks like a young *H. Galba*, with rudimentary antennæ, but one of the specimens sent to us had the incubatory pouch of the adult female fully developed, so that we cannot mistake it for a young animal.” By Boeck Sabine’s species is identified with *Hyperia medusarum*, O. F. Müller.

Themisto crassicornis, Krøyer, is next figured and described, a species which Boeck identifies as *Themisto libellula*, Mandt.

On pages 534–535, *Vibilia borealis*, u. s., from Banff, is figured and described, a letter from Thomas Edward, on its habits and colouring, being quoted.

In the Supplemental Notes, among other matters of interest, the names are mentioned of the genera and species of which A. M. Norman had published descriptions in December 1868.

The Introduction, signed C. S. B., is a general account of the structure, functions and distribution of the Amphipoda.

1868. BRADY, GEORGE STEWARDSON, born April 18, 1832 (G. S. B.).

Notes on the Crustacean Fauna of the English Lakes. Intellectual Observer, XII. 1868. pp. 110–130, with plate.

“*Gammarus* and *Asellus* are scarcely to be found in” the British lakes, according to this observer; “marine forms of Amphipoda, analogous to those of the large lakes of Sweden, have not been found.” (Zool. Record, 1869.)

1868. CZERNIAVSKI (or TSCHERNJAFSKI), WOLDEMAR.

Materialia ad Zoographiam Ponticam comparatam. Studiosi universitatis charcoviensis Voldemari Czerniavski.

At page 78 is given “Ordo VI. Arthrostraca Cls. s. Edriophthalmata. Subordo. a. Isopoda.” At page 90, “Subordo. b. Læmodipoda,” contains Fam. 24. Caprellidæ. Gen. 41. *Protella*, Dana. 51. *Protella typica*, n. s., (juv.?), Tab. vi. fig. 7–10; 52. *Protella intermedia*, n. s., Tab. vi. fig. 11–13. Gen. 42. *Caprella*, Lamarck. 53. *Caprella protelloides*, n. s., Tab. vi. fig. 14; 54. *Caprella ferox*, Tab. vi. fig. 15–20; 55. “*Caprella Danilevskii*,” n. s., Tab. vi. fig. 21–34. Of these, the two species of *Protella*, both less than 4 mm. in length, are considered by Mayer to be certainly young, possibly female, forms, with nothing to show whether they belong to *Protella* or *Caprella*. *Caprella protelloides* is in much the same indefinite situation. *Caprella danilevskii* he considers to be either identical with or extremely like *Caprella inermis*, Haswell, but he leaves the names undisturbed, while he makes *Caprella ferox* definitely a synonym of *Caprella acanthifera*, Leach. From a comparison of specimens brought by the Challenger from the Bermudas with a specimen of *Caprella inermis* sent me by Mr. Haswell from Australia, and a further comparison of these specimens with Czerniavski’s figures, it becomes, I think, quite clear that we have in *Caprella danilevskii* to deal with a species of very wide range, and that the name *danilevskii* must take precedence of *inermis*, which is moreover preoccupied.

At page 93, “Subordo. c. Amphipoda. Divisio. Gammarina, Kröyer, Subdivisio. I. Domicala,” contains Fam. 25. Cheluridæ Allman. “Gen. 43. *Chelura* (Philippi), emend.” To this is assigned *Chelura pontica*, n. s., Tab. vii. fig. 1–18. But the figures and long description do not seem to distinguish it from *Chelura terebrans*, Philippi.

“Fam. 26. Corophiidæ Sp. Bate and W.,” contains “a. Subfam. Corophiides Sp. Bate and W. Gen. 44. *Corophium* Latr.;” “57. *Coroplium Bonelli* Edw.,” on which he says, “Additio. Articuli pedunculi antennarum inferiorum 3-ius et 4-tus margine interiore spinis fortibus insiti, art. 5-tus spinis duabus armatus et unguibus duobus terminatus;” “b. Subfam. Podocerides Sp. Bate and W.,” Gen. 45. *Dercothoe* (*Cerapus* ♀) Dana; 58. *Dercothoe* (*Cerapus* ♀) *punctatus*, Edw.; Gen. 46. *Cerapus*, Say, with *Erichtonius*, Edwards and Bruzelius, *Cerapodina*, Edwards, *Podocerus* (pars) Kröyer, and *Pyctilus*, Dana, as synonyms; 59. *Cerapus macrodactylus* (Dana), with *Pyctilus macrodactylus*, Dana, for a synonym, followed by a quotation of the description, and “*Varietas pontica* mihi,” thus described:—

“Mas. *Antennæ inferiores* articulo 3-io breviore quam 4-to, flagello multo breviore quam basis, sed multo longiore quam art. 4-tus. Manus 2-da fere parallelogramo-forma, digito immobili basi incrassato, manu ultra hujus digitus [basin] abbreviate-producta, digito paulo longiore quam manus, articulo ejus 1-mo paulo longiore, incrassato, 2-do curvo, paulatim attenuato, apice obtuso setis obsito. Articulo 5-ti *paris* 2-do (art. 1-mus Dana) postice obtuso. Additio. *Oculi rubri. Antennæ inferiores* flagello 7-articulato. Articulus 2-dus *pedum*

- 3-ii-7-mi paris* latus. Long. corp. usque ad 5 mm. Colore griseo cum maculis parvis nigris. Femina feminæ *C. difformi* similis."
60. *Cerapus pugnax* (Dana), is followed by a quotation of the description, and "Var. *Pontica* m. *Antennæ superiores* flagello longitudine variabili, plus minusve breviore quam pedunculum. *Pedes 2-di paris* digito minus elongato, articulo ejus 1-mo crasso, 2-do margine posteriore incrassato, apice obtuso setis nonnullis obsito. *Oculi* rubri. Long. corp. usque ad 3·8 mm. Color ut in præcedente." The quotations which I have omitted in regard to this and the preceding species are given in V. Carus, prodr. Faun. Medit., p. 393, but Czerniavski's own descriptions of his varieties are omitted by Carus.
- "61. *Cerapus bidens*, nov. sp. *Varietati ponticæ Cerapi macrodactyli* simillimus, nisi *pedes paris 2-di* digito immobili paulo curvato et in apice bidentato, articulo 5-to intus maxime erroso, tuberculo subbasali valde forti. Long. corp. usque ad 5·2 mm." These differences, from a species confessedly variable, are but of doubtful specific value. The species is not noticed by Victor Carus, Faun. Medit., except in so far as he intimates that the name is preoccupied, by giving "*C. bidens*, V. Crs. (nee Czern.)" to take the place of Costa's *Ericthonius bidens*.
- Gen. 47. *Podocerus*, Leach, is given with the synonyms, *Ischyrocerus*, Kröyer, *Cerapus* (pars), Milne-Edwards, *Jassa* Leach, Milne-Edwards, *Gammarus* (pars), Rathke, *Cratophium*, Dana. "62. *Podocerus Ocius*, Sp. Bate;" 63. *Podocerus dentex*, n. s., Tab. vi. fig. 35, is thus described:—"Mas. Frons obtusa. *Antennæ superiores* inferioribus paulo breviores et multo debiliores, flagello 3-articulato, articulo præcedente non multo longiore, articulis valde decrescentibus, filis olfactoriis tenuioribus in margine inferiore instructo, flagello secundario rudimentario; a. *inferiores* incrassatae, flagello 3-articulato, articulis valde decrescentibus, sub apice spinis unguiformibus duabus armato. Ambo paria antennarum margine inferiore sat setoso. *Pedes paris 1-mi* manu pyriformi, triplum majore quam carpo, palma setulosa et spinulis nonnullis (3) subbasalibus armata, ungue forti, curvato, margine posteriore paulo dentato; p. 2-di manu magna, elongata, palma excavata, dentibus duobus posterioribus magnis et duobus vel tribus subapicalibus multo minoribus terminata setis plumosis dense obsita, ungue curvato, margine posteriore incrassato; p. 3-ii et 4-ti breviores ungue minore, vix curvato. Long. corp. usque ad 4·3 mm. Color flavescente-brunescens, maculis nigris. *Oculi nigri.*"
- "Gen. 48. *Sunamphithoë* (Sp. Bate), emend., is thus defined:—
- "Ut *Amphithoë*. Telson crassum et vel uno hamulo vel duobus terminatum. *Pedes paris* 5-ti, 6-ti, 7-mi tarso (articulus 6-tus Sp. Bate) ad apicem dilatato." In the synonymy Czerniavski refers to *Amphithoë podoceroides*, Rathke, and *Amphithoë bicuspis*, Heller. He also assigns to this genus, "64. *Sunamphithoë valida* nov. sp., Tab. vi. fig. 36," thus described:—"Mas. *Oculi* ovales. *Antennæ superiores* segmentum 6-tum thoracis attingentes, inferioribus paulo longiores, pedunculo apice articulum 3-iun inferiorum æquante, flagello filiformi duplo longiore quam pedunculus, 12-15 articulato (articulis in apice filo olfactorio instructis); a. *inferiores* validiores, pedunculo longissimo (flagello superiorum æquali), flagello brevissimo, fere triplum breviore quam pedunculus (3/4 articuli 4-ti æquante), articulis 7-9 valde decrescentibus. Ambo paria antennarum setulis paucis perbrevibus instructa. *Pedes paris* 1-mi et 2-di maxime inæquales, p. 1-mi carpo sat magno, triangulari, manu subpyriformi, palma obliqua, denticulo spiniformi postice terminata, ungue in margine posteriore leviter dentato; p. 2-di manu valida semi-ovali, palma transversa, concava, postice dentem (fere indicem) validum, rotundatum exhibente, ungue maxime curvo, postice dentato. *Pedes ceteri* ut in *S. humulo* Sp. Bate conformati, p. 7-mi tarso ad apicem maxime dilatato. Telson crassum, retrorsum paulo angustatum, marginibus lateralibus rectis, hamulis duobus fortibus terminatis. Flavescens, cum maculis nonnullis parvis fuscis. Femina. *Pedes paris* 2-di 1-mo non majores,

manu simili, nisi abbreviata et dilatata, carpo multo minore postice in processum elongatum, obtusum egresso. *Laminæ fotoriæ ellipticæ*, margine longe-cirrato. *Ova ovalia*, flavescentia, long. 0·36 mm. Long. corp. ♂ usque 6·3 mm., ♀ usque 6 $\frac{1}{2}$ mm." The fig. 36, referring to the ♀ of this species, only represents "corpuscula setigera sensitiva," not therefore greatly contributing to the understanding of the species itself.

"Gen. 49. *Amphithoë* Leach. 65. *Amphithoë Vaillantii* Lucas." In the synonymy to this species he gives, "(An *Cymadusa* Sav.=*Amphithoe flosa* Aud.)," and then describes "*Varietas pontica* mihi. Tab. vii. fig. 19–27. Mas. *Antennæ superiores* inferioribus longiores, reversæ usque ad abdomen pertinentes, pedunculo articulum 3-iūm inferiorum non superante, dimidium flagelli aequante, articulo 1-mo incrassato, breviore quam caput, vix longiore quam 2-do, 3-io trientem 1-mi aequante, flagello filiformi, articulis circ. 30, in apice filo olfactorio muuitis. *Antennæ inferiores* incrassatae, setosæ, pedunculo longo, articulo 1-mo (brevissimo) et 2-do junctis 3-io brevioribus, 4-to longiore, flagello brevi, non multo longiore quam articulus præcedens, articulis 18 (apicalibus exceptis) brevibus. *Oculi* parvi, rotundati. *Pedes paris* 1-mi et 2-di longissimi, fortiores, unguibus fortibus, in margine posteriore denticulatis, p. 1-mi paulo minores, articulis 2-do et 3-io (art. 1-mus et 2-dus Luc.) in apice antrorum spatuliforme fortissime productis, carpo et manu maxime elongatis, carpo in margine posteriore piloso, margine inferiore recte truncato, manu longiore et fortiore, pilosa, palma brevissima, leviter excavata, p. 2-di articulo 2-do (art. 1-mus Luc.) angustiore quam in primis, in apice late spatuliforme fortissime producto, carpo elongato, triangulare, manu maxime elongata, dilatata, in apice antrorum maxime producta et rotundata, palma breviore, profunde excavata, postice dente forti obtuso terminata. *Pedes paris* 3-ii, 4-ii et 5-ii breves, p. 6-ii et 7-mi valde elongati, sed anterioribus breviores. *Pedes spurii* p. postremi ramis brevissimis, externo hamulis duobus fortibus armato. *Telson* triangulare, angulis obtusatis. Corpus sordide-flavescens, maculis fuscis aggregatis. Long. corp. 9·46 mm. Femina. *Pedes paris* 1-mi articulo 3-io in apice haud producto, carpo abbreviato, margine inferiore curvo, palma haud convexa, p. 2-di carpo haud elongato, latiore, postice in processum rotundatum producto, manu haud elongata nec in apice producta. Long. corp. usque ad 8·73 mm.

Gen. 50. *Grubia*, nov. gen., is thus defined:—

"*Antennæ superiores* filiformes, pedunculo longo, tribus articulis, 1-mo incrassato, 2-do et 3-io maxime attenuatis, paulisper in flagellum longissimum multiarticulatum exeuntibus, flagello secundario uniarticulato, rudimentario; a. inferiores iis breviores, sed pedunculo longissimo, articulis 4 composito. *Pedes paris* 1-mi et 2-di subchelati, 2-di multo majores, fortissimi. *Pedes spurii paris* postremi biramei, sed ramis ambobus minutissimis, rudimentariis, antecedentibus paris 2-di aequales, paris 1-mi paulo prominentes. Segmenta 11-mum et 12-mum spiculis binis subter armata, 13-mum inerme. *Telson* squamiforme integrum." This contains one species, "66. *Grubia taurica* nov. sp., Tab. viii. fig. 1–10 [11]. *Antennæ* pilis tenuibus sparsis instructæ, superiores reversæ usque ad segmentum 7-mum vel multo longius pertinentes, articulis 29 ad 45, pedunculo dupla fere capitilis longitudine et quarta flagelli principalis, articulo 1-mo vix breviore quam caput et vix longiore quam 2-do, 3-io trienti 2-di aequale, flagello principali filis olfact. tenuioribus instructo, flagello secundario uniarticulato, minutissimo; a. inferiores $\frac{2}{3}$ superiorum aequales, articulis 29 ad 31, 1-mo (breviore) et 2-do junctis 3-io pæne aequalibus, 4-to vix longiore quam 3io, $\frac{3}{4}$ sua longitudinis pedunculum superiorum superante. *Oculi* suborbicularis, rubri. *Pedes* pilis sat longis, tenuibus instructi; p. paris 1-mi carpo elongato postice in processum obtusum piligerum exeunte, manu subovali, aequa longa et lata ac carpo, palma pilosa, ungue forti curvato, margine posteriore mollissime dentato. *Pedes* 3-ii, 4-ii et 5-ii validi, articulo 2-do maxime dilatato, 4-to et 5-to dilatatis, ungue curvo, paris 5-ii multo

minores, nngue parvo, minus curvato, *p. 6-ti et 7-mi* multo longiores, longitudine 2-di paris, articulo 2-do dilatato, 6-to (tarsns) teuni et multo longiore quam in antecedente, ungue tenui cnrvo. *Pedes spuri* paris 1-mi et 2-di fortis, spinulis multis armati, pedunculo maxime dilatato, ramis longis, *paris 1-mi* multo majores, spina magna inter ramos posita, *paris postremi* pedunculo maxime incrassato, margine apieis externo-iuferiore piloso, ramis brevissimis—ramo interno vix longiore—in apice spinulis et pilis parvis armatis. *Telson* basi lata, fere recta, lateribus maxime convexis in apieem obtusum convenientibus, dorsaliter postice earina laevi in dentieulum parvum antrorsum producta, subtus fascieulum minnatum spinarum gereus. Color lucide-brunneus vel subgriseo-flavus. Mas. *Pedes paris 2-di* 1-mo majores, fortissimi, carpo brevi triangnlari, manu valida oblonga, pene alterum tantum longiore quam lata, margine anteriore eonvexa, nngue fortissimo curvo, $\frac{1}{2}$ artieuli proximi aequante. Femina. *Pedes paris 2-di* 1-mo simillimi. *Laminae fotoriae* longae, ad apieem paulo latiores, eirris longis mollibus deuse marginatae. *Ova* ovalia, flavescentia, long. 0,54 mm. Long. ♂ usque ad 12 mm., ♀ 8,7 mm."

"Subdivisio. II. Vagantia Sp. Bate and W. Tribus. A. Natatoria Sp. Bate and W. Fam. 27. Gammaridae Sp. Bate and W.," contains "Subfam. a. Gammarides Sp. Bate and W. Gen. 51. *Gammarus*, Fabr." 67. *Gammarus paecilurus*, Rathke, Tab. vii. fig. 28–36, with *Gammarus gracilis*, Rathke, and "*Gammarus Kröyeri*," Rathke, for synonyms, followed by a deserption and this "Additio," "Nonnulla exemplarium sinns Tahanrohensis aberrantia: alia de, *pedes spuri paris postremi* spinis tantum armati, setis destituti (characteres essentiales *Gammari Kröyeri* Rathke), alia de, *p. spuri paris postremi* ramo majore setis plumatis densis oruato, spinis tantum duabus lateralibus et spina magna apicali nulla; praeter ea, nonnulli ♂♂ aberrantes de, *antennæ inferiores* pilis longis crispis densissimis, permultis pedibus 1-mi—4-ti paris, ornatae." By Bocch Rathke's three species here mentioned are regarded as synonyms of *Gammarus marinus*, Leach.

Gen. 52. *Melita*, Leach. 68. *Melita palmata* (Montagu) Leach, with "*Gammarus Dugesii* (= ♀). M.-Edwards," among the synouyms, followed by a long description.

Gen. 53. *Niphargus*, Schiöldte. 69. *Niphargus ponticus*, n. s., Tab. viii. fig. 12–14. "Capit segmentis tribus insequentibus junctis paulo brevius. Segmentorum abdominalium quodque in dorso postice setulam spiniformem gerens. *Antennæ superiores* abbreviatæ, reversæ segmentum 4-tum attingentes, paulo setosæ, pedunculo paulo breviore quam caput, artieulo 1-mo oblongo, erasso, 2-do dimidium 1-mi vix excedente, paulo longiore quam 3-io, flagello 4-artienlato, longitudine pedunculuui aequante, artieulis longis, deereseentibns, flagello secundario bi-articulato, æqne longo ae art. 3-iis. pedunculi. *Antennæ inferiores* pedunenlo hand iucassato, articulo 1-mo (brevissimo) et 2-do (paulo longiore) junetis 3-io brevioribus, 3-io elongato, longiore quam art. 2-dus superiorum, 4-to *Oculi* subovales, sat magni. *Pedes paris 1-mi et 2-di* carpo elongato, subtus dilatato, latiore et longiore quam manus, manu quadrangulare-elongata angulis rotundatis, palma transversa, convexa, postice setulis spiuiformibus armata, ungue curvato acuto, in basi dilatato et in margine posteriore setulas 3 eniittente, *p. 3-ii et 4-ti* artienlo 2-do lato, 4-to antrorsum dilatato subtus latiore, 5-to paulo dilatato, ungue brevi basi incrassato, vix curvato; *p. posteriores* 3 validiores, spinis nonnullis armati, articulo 2-do latissimo subtus angustato, nngue majore. *Pedes spuri paris postremi* pedunculo crasso, ramo iuteriore miuutissime-tuberculiformi, vix distineto, exteriore magno, erasso, longe-conieo, segmentis tribus postieis junetis longiore, articulo 1-mo fere duplo longiore qnam pedunculus et in apice spinis 3-4 armato, 2-do dimidium fere primi aequante, in apiee bisetoso; *p. parium antecedentium* fere æqne (nsque ad basin ramoruui ultimi) prominentes. *Telson* lateraliter oblongum attenuatum pedunculo pedis postremi longius, apice bi-spinuloso. Color brunneens. 1 exempl. long. corp. 2,1 mm.; ant. sup. 0,73 mm.; pes caudalis 0,31 mm."

Gen. 54. *Pherusa*, Leach, with *Amphithoë* (pars), M.-Edwards (nec Dana); *Pherusa*, Sp. Bate

and Westwood, Grube, Heller; and *Paramphithloë* (pars), Bruzelius, in the synonymy, receives
70. *Pherusa pontica*, n. s. Tab. viii. fig. 15, thus described:—

“*Atylo bispinoso* Sp. B. permuto similis.

“Caput rostro acutissimo, leviter curvato, $\frac{2}{3}$ articuli 1-mi antennæ sup. aequante. Segmenta abdominis 1-mum et 2-dum dorso (eujusque) in deutem posticum acutissimum excurrente, segmenta tria anteriora augulis infero-posterioribus retrorsum acute productis, 3-iunctorum margine posteriore in lateribus excavato, infra 3-dentato supra unidentato. *Antennæ superiores* inferioribus longissimis multo breviore, reversæ segmentum 5-tum attingentes, pedunculo breviore quam caput, articulo 1-mo incrassato ambobus ceteris junctis longitudine, flagello filiformi, articulis 17 elongatis, paribus vel imparibus, quoque in apice paulo latiore et filo olfactorio setulisque minutissimis iuncto, ceteris levibus. *A. inferiores* reversæ abdomen attingentes, superioribus duplo longiores, pedunculo incrassato, duplo longiore quam pedunculus superiorum, articulis 1-mo et 2-do brevibus, junctis 3-io aequantibus, 3-io et 4-to aequo oblongis, flagello articulis 37–40, primo elongato, ceteris initio brevibus ad apicem crescentibus. *Oculi magni*, ovales. *Pedes paris* 1-mi et 2-di mediocres, similes, carpo elongate-triangulares, sed multo breviore quam manus, p. 1-mi vix fortiores quam 2-di. *Pedes ceteri* fortes, crescentes, ungue magno forti curvo, p. ultimorum 3 spinosi, articulo 2-do ovali, postice serrato et infra rotundate-producto. *Pedes spurii* similes, ramis styliformibus spinulosis, in apice rugue vix curvato instructis, p. 1-mi et 2-di pedunculo gracili, ramo exteriore breviore, 1-mi 2-dum prominentes, usque ad basin ramorum ultimi pertinentes, p. postremi (3-ii) pedunculo segmentorum 12-mi et 13-mi junctorum longitudine, incrassato ramis fere aequo longis, pedunculo longioribus, praeter spinulis setisque plumatis ornatis. *Telson* e latere visum acute acumiuatum, supero visum ovato-laucoelatum, acuminatum.

“Mas. *Pedes paris* 1-mi et 2-di manu carpoque sat fortibus, multo latioribus quam articuli ceteri, manu saepissime elongate-pyriformi ad apicem angustiore, palma obliqua, convexa, spinuloso debilibus dense obsita, ungue longiore quam palma, paulo curvato, debili; rarissime manus (adulti) forma ut in femina.

“Femina. *Pedes paris* 1-mi et 2-di manu carpoque minoribus, uero latioribus quam articuli ceteri, manu subquadrangula longiore quam lata, in medio marginis anterioris fasciculo setularum ornata, palma oblique-convexa, tenuiter spiculosa, rugue in margine posteriore setulis nonnullis tenuioribus ornata. *Sacculus oviferus* [oviger] maximus; *laminæ fotoriae* permaximæ, elongate-ovales, epineras permuto excedentes, margine longe-cirrate.

“Junior. Deutibus centrodorsalibus segmentorum 1-mi et 2-di abdominis vix exeuntibus, obtusissimis.

“Long. corp. ♂ et ♀ usque ad 5 mm.

“Color variabilis; griseo-flavescens, saepe rubro tenuiter maculatum; rarer in parte anteriore vel omne rubro fuscissime pigmentatum, aspectu nigrum.

“Ova late ovalia, flavescentia, long. 0,4 mm.”

“71. *Pherusa* sp.? an nova? (*inermis* m.).” Only the *habitaculum* is mentioned.

Gen. 55. *Dexamine*, Leach, receives, under 72. *Dexamine spiniventris* (Costa) Grube, “*Varietas pontica* unih. Tab. viii. fig. 16. Caput marginibus ante-ocularibus dentiforme acute productis. Segmenta abdominis tria anteriora in margine posteriore dorsi denticulis lateralibus carentia, 3-iunctorum et 4-tum denticulis anterioribus nullis, 6-tum dentibus tribus posticis fortibus. *Antennæ superiores* articulis 23–24, a. pedunculi 1-mo $\frac{1}{2}$ longitudinis 2-di longiore, infra in tuberculum obtusum fortem exeunte, articulis flagelli anterioribus filum olfactoriū gerentibus; a. *inferiores* illis duplo breviore et tenuiores, articulis 16–17, 1-mo et 2-do brevibus, 2-do (articulus 1-mus Hell.) supra in denticulum exeunte. *Pedes paris* 7-mi tarso paulo breviore quam tibia. *Laminæ fotoriae* feminæ elongatissimæ, in dimidio basali angustæ, dimidio apicali oblongo, cirris paucis marginatae. Cetera ut a Hellerio observata. Long. corp. ♂ usque ad 6 mm., ♀ usque ad 7 mm. Ova ovalia, flavescentia,

long. 0,53 mm. Variatio. *A. Antennæ inferiores* superioribus paulo breviores, articulis 18-23. Variatio. *B. Antennæ inferiores* superiores longiores et fortiores, articulis 28 valde crescentibus, 1-mo infra in tubulum acutum (organ. audit.), 2-do supra producto, margine superiore ut 3-ii dense piloso; transitionem ad *D. spinosam* faciens."

"Subfam b. Stegocephalides, Sp. Bate and W.," contains Gen. 56. *Probolium*, Costa, Czerniavski not recognising that this had been anticipated by Dana's *Stenothoë*. He gives 73. *Probolium ponticum*, n. s., Tab. viii. fig. 17-23. "Proximum *Probolio* (*Montagua*) *monoculoidi* (Mont., Sp. B.), epimeris utriusque speciei simillimus.

"Caput rostro brevissimo, obtuso. *Oculi* rotundi. *Antennæ superiores* usque ad dimidium segmenti 4-ti pertinentes, 10-articulatae, pedunculo incrassato dimidio flagelli paulo longiore, articulis decrescentibus, flagello ad apicem sensim attenuato, articulis in apice filum olfact. gerentibus; *a. inferiores* breviores et multo debiliores, pedunculo æque longo ac superiorum, articulo 1-mo et 2-do brevissimis, junctis 3-io haud longioribus, 4-to paulo longiore quam 3-iis, flagello æque longo ac pedunculo, 5-articulato. *Pedes paris* 1-mi et 2-di fere similes, carpo triangulari, manu subquadrangula antice leviter convexa, palma obliqua leviter convexa, spinulis minutissimis obsita, *p. 1-mi* palma æque longa ac margo posterior, postice spinulam minutam gerente, ungue crasso paulo curvato, *p. 2-di* multo majores et validiores, carpo postice anguste-producto, manu subtus latiore, palma multo longiore quam margo posterior, postice leviter excavata et denticulis spiniformibus 4 armata, ungue elongato leviter curvato. *Pedes ceteri* longitudine crescentes, tarse curvato subtus latiore, ungue forti, *p. 3-ii* et 4-ti articulo 2-do (*basis* Sp. B.) haud multo dilatato, fere æque lato, 3-io antrorsum dilatato et in apice producto, *p. 5-ii*, *6-ii*, *7-mi* articulo 2-do retrorsum maxime dilatato et in apice rotundate producto, margine posteriore levi, 3-io retrorsum dilatato et in apice producto, ungue curvo. *Pedes spurii* elongati, *p. 1-mi* et 2-di ramis styliformibus leviter curvatis, æque longis ac pedunculus, inæqualibus, *p. 2-di* $\frac{2}{3}$ primi longitudine, *p. postremi* simplices, 3-articulati, articulis æque longis, 1-mo et 2-do spinis singulis (2-4) armati. *Telson* oblongum, leve, postice rotundatum, marginibus lateralibus rectis. Long. corp. usque ad $2\frac{1}{2}$ mm. Color flavescent. Oculi rubri."

"Tribus B. *Saltatoria* Sp. B. and W.," contains Fam. 28. Orchestidae Dana. In this he places Genus 57. *Nicea*, Nicolet, with *Hyale*, Rathke, *Amphithoe* (pars), M.-Edwards, Rathke, Grube, *Orchestia* (pars) Lucas, *Allorchestes* (pars), Dana, Bruzelius, Grube, in the synonymy. In the genus *Nicea* he gives 74. *Nicea istrica*, Grube, Tab. viii. fig. 24-25, which he describes, and "75. *Nicea Perieri* (Luc.) mihi. Tab. viii. fig. 26-27," with the synonymy, "*Orchestia Perieri*," Lucas, and "*Allorchestes Perieri*," Grube, describing "A. *Varietas pontica* m. Maxime proxima varietati maris Adriatici. Mas. *Antennæ superiores* segmentum 4-tum attingentes, articulis 12-16, *inferiores* usque ad segmentum 6-tum pertinentes, articulis 23-33. *Oculi* ovales vel suborbicularis. *Pedes paris* 2-di articulo 2-do antrorsum fortiter dilatato et in apice paulo subtus producto, 3-io antrorsum maxime rotundate-producto; *pedes posteriores* 3 articulo 4-to retrorsum dilatato. Femina: ut in varietate adriatica. *Laminæ fotoriae* oblongæ, sat longe cirratae. Long. corp. ♂ usque ad 6 mm., ♀ usque 5 mm. Color ut in precedente [sordide flavescent, saepe dorso rubrescente-flave scente]."

"B. *Varietas brevicornis* m. Mas. Præcedenti simillimus; sed antennæ abbreviatae, paulo crassiores, *superiores* segmentum 3-iun pâne attingentes, articulis 11-12, *inferiores* usque ad segmentum 4-tum pertinentes, 14-articulatae. *Oculi* ovales. *Pedes paris* 2-di articulo 2-do et 3-io ut in varietate Adriatica haud dilatatis. Long. corp. usque 6,6 mm. Color sordide-flavescent."

"Genus 58. *Orchestia* (+ *Talitrus*) Leach," receives "76. *Orchestia Bottæ*, Edw.," Tab. viii. fig. 28-32, with "*O. constricta*, Cost.," "*O. littorea*, Grube," "*O. Montagui* (pars), Rathke," in the synonymy. A description of the species is followed by the description of a variety, "*Varietas feminaformis* mihi. Tab. viii. fig. 33. *O. Bottæ* simillima, nisi *pedes* 2-di *paris* articulo 2-do oblonge-ovato, carpo haud abbreviato, longiore quam lato, in margine auteriore

convexo, manu subquadrangula, marginibus anteriore et posteriore parallelibus, palma vix obliqua, ferc transversa, brevi, leviter convexa, spinosa, ungue leviter curvato, obtuso. 1 exempl. long. corp. 8,1 mm.; long. manus 2-de 0,66 mm."

"77. *Orchestia Montagui*, Aud. Tab. viii. fig. 34-39," has in the synonymy "*O. littorea*, Rathke," *Talitrus saltator*, M.-Edwards, Zaddach, Lucas, "*Talitrus locusta*, L., Sp. Bate and Westwood, *British Sessile-eyed Crustacea*, p. 16-23 (♀ et ♂ secund.?), fig." Czerniavski remarks, "Species maxime variabilis, transitionibus gradatis cum *O. Bottae* omnino juncta. Long. corp. ♂ usque ad 19,1 mm., long. manus 2-dæ usque ad 2,8 mm.; long. ♀ usque ad 18 mm., long. manus 2-dæ usque ad 0,8 mm." Whether the attendant remarks in Russian would throw any light upon the novel identification of *Talitrus* with *Orchestia* in this synonymy, I am unable to say.

The remaining species given are 78. *Orchestia mediterranea*, Costa, Tab. viii. fig. 40-41.

79. *Orchestia littorea*, Leach. "80. *Talitrus (locusta L.) saltator*, Edw. Tab. viii. fig. 42-44. Vide apud *O. Montagui et mediterranea*."

In the Appendix at page 130, under Amphipoda are given, 91. *Gammarus locusta* (L.). Gen. 66. *Amathilla* Sp. Bate and W. "92. *Amathilla carinata* (Rathke) Sp. Bate and W.," a species in the opinion of those authors doubtfully distinct from *Amathilla sabini*.

A remark in Russian is here made upon *Nicea pontica* and "*Nicea Perieri*."

"93. *Orchestia Deshayesii* Aud.," has a "Variatio localis. Tab. viii. fig. 52-53. Antennæ superiores capite paulo longiores, dimidium articuli 3-ii inferiorum superantes, usque ad articulum 4-tum pertinentes, 8-articulatae, inferiores dimidio corporis magis minus breviores, articulis 18, 1-mo et 2-do brevissimis, 3-io iis junctis duplo longiore, dimidia longitudine 4-ti, flagello æquæ longo ac art. 4-tus vel illo breviore. Oculi suborbicularis. Pedes paris 1-mi spinulosi, carpo postice tuberculiforme producto, manu subtus dilatata, ungue curvato, acuto. Pedes ceteri spinulosi, posteriores 3 articulo 2-do subquadrato rotundato, art. 4-to subtus dilatato, p. 5-ti paulo longiores quam p. 4-ti, multo breviores quam p. 6-ti; p. 7-mi proximis paulo longiores. Telson triangulare rotundatum, fere æquilaterum. Color sordide flavescent. Mas. Pedes paris 2-di manu permagna subpyriformi, ad apicem maxime angustata, palma concava dimidium marginis posterioris occupante, dente subbasali valido acutoque, subtrorsum producto, apicem manus attingente, ungue valido curvato, cum dente quasi chelam formante, prædita. Femina. Pedes paris 2-di manu breviore quam dimidium manus maris, latissime subrhombæ, palma transversa (per prolongationem subtrorsum laminis duabus ferme approximatis, a margine posteriore medio exhibitis, anteriore subquadrata, posteriore multo longiore angusta, plicata), profundissime bilobata, lobis ambobus inter se ferme approximatis (posteriore magis prolongato), apice rotundatis et molle spinulosis, ungue abbreviato, crasso, curvato, obtuso. Long. corp ♂ millim., ♀ 8 millim." The length of the male accidentally omitted.

As already hinted, in order to derive the full advantage offered by this work, the carcinologist who knows not Russian, must either find leisure to learn it, or venture on the perhaps more difficult task of finding an interpreter.

1868. EDWARD, THOMAS, born Dec. 25, 1814 (Smiles), died Apr. 27, 1886 (Pall Mall Gazette).

Stray Notes on some of the smaller Crustaceans. Note I. On the Habits &c. of the *Hyperiidæ*. pp. 143-147. (Read June 21, 1866). Note II. pp. 165-170. (Read December 6, 1866.) The Journal of the Linnean Society. Zoology. Vol. IX. London, 1868.

This acute and ardent naturalist is able, from personal observation, to deny that the *Hyperiidæ* "exist only in the gill cavities of the medusæ." He maintains that they exist far more

commonly swimming freely. In regard to the species which had been established, he says, "I consider the genus *Lestrigonus* of Milne-Edwards and subsequent writers to be nothing more nor less than the male of *Hyperia*. I am led to this conclusion from the remarkable similitude which exists among them, and from the fact that in all the species (*five in number*) which I have met with, the sexes have always been associated, except in the case of *Lestrigonus Kinahani*." *Lestrigonus exulans* he positively identifies as the male of *Hyperia galba*. He has found the males, not yet described, of *Hyperia oblivia* and *Hyperia medusarum*, and of a new species, which he provisionally names *Hyperia minuta*.

Although *Lestrigonus kinahani* "may be, and is occasionally, found in company with *H. galba*, the one is easily distinguishable from the other. They are nothing alike, either in form or colour; not to speak of the long and slender antennæ of the one in comparison with those of the other. *H. Kinahani* is longish, more shrimp-like, especially behind, and not so round and dumpy as *H. galba*, and the colour is always much darker. The eyes too are dark instead of being of a light green." [Compare Note on Montagu, 1813]. He further says of *Lestrigonus kinahani*, "there appears to be little or no difference between the young and the old. They are both slender, and of a dark lead colour, and both have the remarkable long and hair-like antennæ."

In his second note Edward says that of *Hyperia oblivia* he has seen "thousands, nay, millions, or countless hordes." He has never found them parasitic on fish, but in examining the stomachs of herrings on two successive days, he found them all full of this Amphipod. "From one," he says, "I took 59, from another 47, and from a third 33; and all the others were more or less well crammed." As contrasted with "the vast legions which occasionally appear" of *Hyperia oblivia*, he says, "I have only taken *H. medusarum* on three or four occasions, and but a few each time. This species is decidedly the gem of the whole. It is partially pellucid, being beautifully banded, alternately, with rings of a crystal hue and others of a deep red. As regards *H. minuta*, I have only taken it twice, and even in fewer numbers than the last." Of the species just mentioned, he adds, "in their general manners all three resemble each other, their restlessness and activity being one of their most remarkable traits, and beyond the power of description. But if I were to particularise any of them as being more lively and more restless than the rest, I certainly should give *H. minuta* the character, as being the most active species which, so far as I remember, I have as yet seen. All three seem to me far more active in their whole movements than either of their congeners, *L. Kinahani* or *H. galba*, and they do much better in confinement."

"*Lestrigonus Kinahani* and *Hyperia galba* generally appear here [at Banff] about the beginning of July, and disappear again towards the end of September; *H. oblivia* usually about August, and continues till spring; *H. medusarum* in December, and remains till March (on one occasion I took two of this species as late as the month of May); and the time I found *H. minuta* was from October to December. During these periods, too, I have never failed to find the females of all, save the first, to contain, in some cases eggs, in others well-developed young. With reference to *H. oblivia*, I not unfrequently find females of this species with young from September to January, thus extending over a period of five months."

Recognising *Lestrigonus* as applying only to male forms of *Hyperia*, Edward retains the name only provisionally for "*Lestrigonus Kinahani*," to which he had not definitely been able to assign a female. He does not give authorities for the specific names he adopts, but there is good reason to believe that he uses the nomenclature of "The British Sessile-eyed Crustacea."

1868. HELLER, CAMIL.

Reise der österreichischen Fregatte Novara um die Erde in den Jahren 1857–58–59 unter den Befehlen des Commodore B. von Wällerstorf-Urbair. Zool. Theil. 2. Bd. 3. Abth. Crustaceen. Mit 25 Tafeln. Wien. 1868. Amphipoda, pp. 128–9. Pl. XI. Fig. 4. 5, 5a–c. (Tanaïs. pp. 133–4. Pl. XI. Fig. 3.)

The new species of Amphipoda described and figured are, 1. “*Allorchestes Paulensis*,” which is stated to be rather like *Allorchestes verticillata*, Dana, apparently belonging to the genus *Hyale*; 2. “*Anonyx Chilensis*,” said to approach the genus *Callisoma* in the almost cheliform structure of the second gnathopod, but appearing to correspond more nearly, so far as described, with Boeck’s genus *Orchomene*.

As only two or three pages referring to the Amphipoda are embalmed in this handsome and expensive work, for the benefit of students who may not be able to consult it, I here append the Latin descriptions of the new species:—

Allorchestes paulensis, “antennæ secundæ primis fere duplo longiores, pedunculo et flagello fere æque longis, articulo pedunculi secundo tertio breviore, flagello 12-articulato, articulis oblongis, setis brevibus dense verticillatis. Antennæ primæ nudiusculæ, flagello pedunculum paulo superante, 11-articulato. Pedes primi parvuli, secundi sat fortes, manu subovata palma inferiore rectiuscula pubescente, dactylo longo; antibrachio infra producto. Pedes quinti, sexti septimique subæqui, brevcs, setis paucis sparsis instructi. Abdominiis segmentum ultimum latum, postice arcuatum. Longitudo 12 millim.”

Anonyx chilensis, “Oculi reniformes. Antennæ primæ secundis plus duplo breviores, pedunculi articulis duobus ultimis brevissimis, flagello pedunculo longiore 11–12-articulato. Antennæ secundæ fere dimidiam corporis longitudinem æquantes, pedunculo dimidium flagelli antennularum superiorum attingente, supra ciliato, flagello 24–25-articulato, parce setoso. Pedes antici subcheliformes breves; secundi elongati, graciles, cheliformes. Abdominis segmentum ultimum acutum, medio divisum. Longitudo 7 millim.”

1868. HESSE, EUGÈNE.

Observations sur des Crustacés rares ou nouveaux des côtes de France. 15^{me} art. Description d’un nouveau Crustacé appartenant au genre *Limnoria*. Annales des Sciences Naturelles. 5^{ème} sér. Zool. et Paléont. X. Paris, 1868. pp. 101–120. Pl. 9.

Under the name *Limnoria xylophaga*, as though the species were new, *Chelura terebrans*, Philippi, is elaborately described and figured. Hesse considers that the function of respiration is discharged not only by the “vésicules branchiales” at the base of the pereopods, but also by the “fausses pattes branchiales flabelliformes” (*i.e.*, the anterior pleopoda). The heart, he says, is a longitudinal, cylindrical vessel, reaching from the base of the head with a gradual contraction to end in a point at the extremity of the seventh pereon-segment. The stomach and digestive tube have very solid walls, suitable to the ligneous diet of the animal. Of the “pattes thoraciques” he says there are seven pairs, which all have four or five joints. [As a matter of fact they have the usual number]. Of the eyes he states that they are not, as usual, “recouverts d’une cornée simple dans laquelle sont encastrées des cornéules, qui forment un ensemble collectif; ces cornéules paraissent, au contraire, composées de lames plates et squameuses, indépendantes, fixées verticalement par la base et

groupées circulairement autour d'un centre vers lequel elles convergent et s'inclinent ou se redressent, suivant l'occurrence de manière à augmenter ou à diminuer les saillies et conséquemment à éviter les dangers du contact." This seems to want confirmation.

1868. JARSCHINSKI, F. (? IARZYNSKY, TH.)

[On the Leydigian organs at the antennæ of the Crustacea Amphipoda. Transactions of the first meeting of Russian naturalists at St Petersburg, 1868, 4to, pp. 176-179 (written in Russian).]

"The so-called Leydigian organs on the first pair of antennæ, first observed by La Valette in *Gammarus puteanus*, and afterwards accurately described and stated to be sensitive organs by Leydig, are the subject of a paper by F. Jarschinski (*l. c.*), who has observed them in various genera of Amphipoda." (Dr. von Martens, Zool. Record for 1870.)

1868. JOSEPH, GUSTAV.

Jahresbericht der schlesischen Gesellschaft für vaterländische Kultur. Jahrgang 1868.

Fries refers to a paper in the above Transactions, and another in "Amtl. Bericht der Münchener Naturforscher-Versammlung, 1877 (p. 172)," in which G. Joseph records the occurrence of a blind Gammarid (*Niphargus oreinus*, n. s.) in the brooks of the hill-grottoes of Carniola, which probably from these reaches the lake of Zirlenitz, where it can be freely gathered. It comes to the surface after sunset in calm weather.

1868. MARTENS, EDUARD VON, born 1831.

Crustacea. The Record of Zoological Literature. 1867. Volume Fourth. London, MDCCCLXVIII. pp. 611-622.

Packard's new species, *Monoculodes nubilatus*, mentioned on p. 613, is called *Monoculodes nubeculatas* on p. 617. It is stated that "the genus *Pontoporeia* is reunited with *Lysianassa*" by G. O. Sars in his Hist. Nat. des. Crust. d'eau douce de Norvège, p. 82, note. But Sars only says, "il vaudrait peut-être mieux les réduire, en attendant, à un seul genre." In the text he retains the name *Pontoporeia*.

1868. MARTENS, EDUARD VON.

Über einige ostasiatische Süßwasserthiere. Archiv für Naturgeschichte. Vier und dreissigster Jahrgang. Erster Band. Berlin, 1868. pp. 1-64.

At page 56, under the heading "Tetradecapoden," Martens notices the continental and terrestrial habits of some members of the genera *Gammarus*, *Talitrus* and *Orchestia*. In Madeira he had met with a *Gammarus*, which was more frequently to be found on the banks of the brooks than under water; in Japan an *Orchestia* presented itself "am Waldrande, zwischen abgefallenem feuchtem Laube, aber doch nicht im Wasser." After referring to Dana's *Orchestia sylvicola* from New Zealand and *Orchestia tahitensis* from Tahiti, and Heller's *Orchestia cavimana* from Cyprus, he describes the Japanese species as *Orchestia humicola*,

with the description :—“ Die vier vordern Epimeralstücke verhältnissmäßig gross, gerundet, das fünfte etwas kürzer und viel schmäler als das vierte. Die oberen Fühler nicht länger als das erste Basalglied der untern. Diese halb so lang als der Körper, die Geissel ungefähr eben so lang als der Stiel. Glieder der Geissel kurz. Zweites Fusspaar fast doppelt so lang wie das erste mit einer kleuen, flachen, länglich-elliptischen Hand, deren Daumen kaum zu erkennen ist. Drittes und viertes Fusspaar um weniges länger, aber dünner, mit einfachem spitzigem Endgliede, wie die folgenden ; das fünfte wiederum etwas länger, sonst gleich. Das sechste und siebente unter sich gleich, sehr lang und kräftig. Afterfüsse mit mehreren kurzen Endborsten, aber an den Seiten obne Borstcu.” The genus *Amphitoë*, without the accessory flagellum that distinguishes *Gammarus*, is not, he remarks, found in the fresh waters of Europe, although in Eastern Siberia “ *Amphitoë muricata* Pall. sp.” is found in the Angara (Jenisei), and in North America *Amphitoe dentata*, Say, in the fresh-water marshes of South Carolia. Corophiun, the Hyperina, and the Læmodipoda, have, so far as he knows, no fresh-water representatives. It is not, I should think, by any means certain that Say’s “ *Ampithoe dentata* ” really belongs to the genus *Amphitoe* as now accepted, while the *Oniscus muricatus* of Pallas is clearly excluded from it by having an accessory flagellum.

1868. MILNE-EDWARDS, ALPHONSE.

Description de quelques Crustacés nouveaux provenant des voyages de M. Alfred Grandidier à Zanzibar et à Madagascar. Nouvelles archives du Muséum d’histoire naturelle de Paris. Tome Quatrième. Paris, 1868. pp. 69–92.

Caprella megacephala, n. s., from Cape Sainte-Marie, where it was dredged up from a rocky bottom at a considerable depth, is described on pages 89–91, and figured pl. 20, figs. 12, 13. The chief character relied on seems to be the head, of which Milne-Edwards says, “ chez le mâle, la tête, légèrement renflée, est arrondie en avant, et ne porte ni pointe ni tubercule ; elle se rétrécit un peu postérieurement, mais on n’aperçoit cependant pas le sillon qui la sépare du premier anneau thoracique, avec lequel elle est complètement confondue. La pièce, ainsi constituée, est remarquablement allongée.” After further description, the remark is made, “ la *Caprella scaura* (Temp.) provient de la même localité ; elle se rapproche davantage de notre espèce, à raison de la longueur du premier segment, mais la tête est surmontée d’une pointe conique et les pattes de la deuxième paire sont pourvues d’une main tridentée en dessous.” The corresponding hand in this species is described as “ très-longue, cintrée en dessus ou en avant, pourvue sur son bord postérieur de deux denticules très-éloignées l’une de l’autre. Le doigt terminal est robuste, très-arqué, et offre, près de sa base sur son bord supérieur, une petite échancreure ou encoche.” In *Caprella januarii*, Dana, from Rio Janeiro, the hand is more elongate “ et pourvue de trois denticulations en dessous.” Mayer thinks that Milne-Edwards’ species may just possibly be *Caprella aquilibra*, Say.

1868. NORMAN, A. M.

On Crustacea Amphipoda new to Science or to Britain. The Annals and Magazine of Natural History. Series 4, Vol. ii. December, 1868. London, 1868. Plates XXI., XXII., XXIII. figs. 1–11.

This paper gives the definition of the genus *Haploops*, Lilljeborg, which includes the character “ eyes two, simple,” but the British specimens of *Haploops tubicola*, Lilljeborg, are described
(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

as agreeing with those found by Torell off the coast of Greenland, in having *four* simple eyes. "The number of eyes, therefore, would not seem to be constant." Compare Note on Goës, 1865.

A new genus, *Tessarops*, is thus defined:—"Eyes four—two (large, compound) situated above the origin of the superior antennæ, and two (nearly simple) below the others, at the base of the superior antennæ. Superior antennæ furnished with a very slender secondary appendage. Both pairs of gnathopods simple, not subchelate. Last pereiopods short, stout. Pleon having dorsal margins of segments toothed. Telson squamiform. Last uropods two-branched." To the description of the species *Tessarops hastata* are prefixed as possible synonyms, *?Tiron acanthurus*, Lilljeborg, 1865, and *?Syrrhoe bicuspis*, Goës, 1865. Boeck has decided that the three species named are in fact but one, and that *Tiron acanthurus* has priority.

A new species, "*Mæra Batei*," is described and figured. Attention is called to the difference in size and structure of the second gnathopod in the two sexes of this genus. *Megamæra othonis* is assigned as female to *Megamæra longimana*, *Megamæra alderi* as female to *Melita obtusata*, to which *Melita proxima* is united "as another and the more usual form of the male."

The genus *Megamæra*, Bate, is thought to be in effect not distinct from *Mæra*.

The new genus *Helleria* is thus defined:—"Eyes compound. Superior antennæ slender, much shorter than inferior, with[out] secondary appendage. Both gnathopods subchelate. Last pereiopods rather short, furnished with long plumose setæ. Fifth and sixth segments of pleon coalesced into one. Last uropods two-branched. Telson squamiform, cleft almost to the base." The new species is named *Helleria coalita*. But the name *Helleria* must be changed, being preoccupied among Isopoda.

1868. NORMAN, A. M.

Preliminary Report on the Crustacea, Molluseoidea, Echinodermata, and Cœlenterata, procured by the Shetland Dredging Committee in 1867. Report of the Thirty-seventh Meeting of the British Association for the Advancement of Science; held at Dundee in September 1867. London, 1868. pp. 437–441.

"As a rule," Mr. Norman observes, "those Amphipods which occur also on the British coast attain a much greater development within the Arctic circle." He notices, without naming, new species of *Atylus*, *Cyrtophium*, *Corophium*, *Pleustes?*, and one "allied apparently to *Calliopius*," with "a new genus allied in general characters of eyes, of gnathopods, and pereiopods, especially in the broadly flattened meros and carpus of the last pair, to *Haploops*, but having the antennæ furnished with an appendage."

1868. PLATEAU, FÉLIX.

Recherches sur les Crustacés d'eau douce de Belgique. 1^e Partie. Genres *Gammarus*, *Linceus* et *Cypris*. Mémoires Couronnés Acad. Roy. de Belgique, XXXIV. 1868. 1 Pl.

The Annals and Magazine of Natural History, Ser. 4, Vol. iii. p. 12.

"*Gammarus puteanus* (Koch) is not blind, but sensible to light." (Zool Record, 1870.)

1868. SARS, MICHAEL.

Fortsatte Bemærkninger over det dyriske Livs Udbredning i Havets Dybder.
(Særskilt aftrykt af Vidensk.-Selsk. Forhandlinger for 1868.) pp. 246-275.

On p. 260 twenty species of Amphipods are mentioned as occurring at depths between 250 and 300 fathoms. For one of them, "*Lysianassa magellonica*, Lilljeborg, vix M.-Edwards," the depth is given, 300 to 400?

1868. WAGNER, NICOL.

[*Hyalosoma dux*, a new form of Amphipod Crustacea. Transactions of the first meeting of Russian Naturalists at St. Petersburg, 1868. pp. 218-238, 4 pls.]. Zool. Record for 1870.

Of this paper, which I have not seen, Messrs Friedländer assure me that the exact title in German is:—"Hyalosoma dux, eine neue Form aus der Gruppe der Daphniden," so that the attribution of *Hyalosoma* to the Amphipoda is no doubt accidental.

1869. BESSELS, EMIL.

Einige Worte über Entwicklungsgeschichte und morphologischen Werth des kugelförmigen Organes der Amphipoden. Jenaische Zeitschrift für Medicin und Naturwissenschaft. Bd. V. Jena, 1869. pp. 91-101.

"E. Bessels has given a *résumé* of his researches into the development of these Crustaceans [Amphipoda], the detailed description having been unfortunately lost during his journey." (Zool. Record, 1870).

1869. CAJANDER, ALFRED HENRIK, born 1843, died 1868 (Note to his Contribution).

Bidrag till kännedomen om sydvestra Finlands krustaceer. Notiser ur Sällskapets pro Fauna et Flora fenniae förhandlingar. Tionde häftet. Ny serie. Sjunde häftet. Helsingfors, 1869. pp. 371-376.

He remarks that the Crustacea of Finland were all but uninvestigated up to that time. In the list which he here gives only one Amphipod is included, thus mentioned:—"Corophium longicorne Latr. Ålands och Åbo skärgård h. o. d." The notes say, "h. o. d. = här och där," and "När en art uppgiftes för skärgården menas dermed, att den förekommer i havvet." The author's early death precluded him from advancing the subject.

1869. DALLAS, WILLIAM SWEETLAND, born January 31, 1824 (W. S. D.).

Observations on the Amphipoda occurring on the Norwegian Coasts. By Axel Boeck. Translated from the Forhandlinger ved de Skandinaviske Naturforskernes, Ottende Möde, 1860, pp. 631-677, by W. S. Dallas, F.L.S., etc. The Annals and Magazine of Natural History, Ser. 4, Vol. iii. May and June, 1869.

1869. FOREL, F. A.

Introduction à l'étude de la faune profonde du lac Léman. Bulletin de la Société Vaudoise d'Histoire Naturelle. Tome X. No. 62. 1869. pp. 220–224.

"One species of *Gammarus*, two of *Cyclops*, two of *Daphnia*, two or three of *Cypris*, have been found at a depth of 75 meters, about 250 feet, in the *Lake of Geneva*; at 300 meters one species of the order Amphipoda, one *Cypris*, one *Cyclops*." (Zool. Record, 1870.)

1869. GRUBE, A. E.

Mittheilungen über St. Vaast-la-Hougue und seine Meeres-, besonders seine Annelidenfauna. Verhandlungen der schlesischen Gesellschaft für vaterländische Kultur. 1869. pp. 1–39. Taf. 2.

In this paper Grube describes and figures "Urothoë marinus Sp. Bate. ? var. pectinatus Gr.," in which the third pereopod appears not only very much broader and flatter than either of the following pairs, but has the hand and two preceding joints in their whole breadth on the lower rim, the hand and wrist also in the centre, armed with a comb of spines. The telson is split only to the centre, and is much longer than broad. Other differences concern the last uropods and the eyes. At page 35 a list is given of the Amphipods, eight species, which Grube obtained at St. Vaast.

1869. HELLER, CAMIL.

Zur näheren Kenntniss der in den süßen Gewässern des südlichen Europa vorkommenden Meeres-erustaceen. Zeitschrift für wissenschaftl. Zool. XIX. Bd. 1. Heft. Leipzig, 1869. pp. 156–162.

Of "Gammarus Veneris, Heller," he says, we have in this species obviously a *Gammarus marinus*, cut off from the sea and forced to live in fresh water, becoming changed accordingly to suit its new conditions of life. His *Orchestia cavimana* he considers in like manner derived from "*Orchestia Montagui*."

1869. HILGENDORF, FRANZ.

Von der Deeken's Reisen in Ost-Afrika in den Jahren 1859 bis 1865. 3 Bd. 1 Abth. Zoologie. Crustaceen. Bearbeitet von Franz Hilgendorf. Mit fünf lithographirten Tafeln. Leipzig, 1869.

In the "Uebersicht der ostafrikanischen Crustaceen," pp. 103–115, he names the following Amphipoda, "Talitrus Cloquetii, Aud.," "Orchestia Bottae, M. E.," "Orchestia inaequalis, Hell.," "Orchestia Deshayesii, Aud.," "Amphithoë filosa, Sav.," "Amphithoë costata, M. E.," "Amphithoë Fresnelii, Aud.," "Leucothoë furina, Sav.," and under the head of Laemodipoda he gives "Caprella scaura, Templet," and "Caprella nodosa, Templet."

1869. MARTENS, EDUARD VON.

Crustacea. The Record of Zoological Literature. 1868. Volume Fifth. London, MDCCCLXIX. pp. 510–533.

Martens notes *Tessarops hastata*, n. g. et s. "to be compared with *Tiron acanthurus* (Lilljeb.) and *Syrrhoë bicuspis* (Göes)." Boeck places the three together under the name *Tiron*

acanthurus. On the new genus, *Helleria*, Norman, in the Annals and Magazine, 1868, Martens observes that "the paper is published in the December part, therefore later than *Helleria* of Erber," Verhandl. zool.-bot. Gesellsch. Wien, xviii. 1868, pp. 95-114, pl. 1.

1869. MÜNTER, JULIUS, died February 2, 1885 (Friedländer, Naturæ novitates), and BUCHHOLZ, RUDOLPH, died April 17, 1876 (Taschenberg).

Ueber *Balanus improvisus* Darw. var. *gryphicus* Münter. Beitrag zur carcinologischen Fauna Deutschlands. Mittheil. a. d. naturwissensch. Verein v. Neu-Vorpommern u. Rügen. I. 1869. pp. 1-40.

In the Crustacean Fauna of their district, the authors say, "aus der Ordnung der Amphipoden sind bis jetzt nachgewiesen:—*Gammarus Locusta* Fabr., *G. fluviatilis* Edw. (*pulex* L.) und *G. ambulans* Fr. Müller; ferner *Corophium longicorne* Latr., *Talitrus saltator* Milne Edw., *Orchestia Euchore* Fr. Müller, *O. Gryphus* Fr. Müller und *Leptocheirus pilosus* Zaddach."

1869. NARDO, GIOVANNI DOMENICO.

Annotazioni illustranti cinquantaquattro specie di crostacei Podottalmi, Endottalmi [Edriottalmi] e Succhiatori del mare Adriatico, alcune delle quali nuove o male conosciute, accompagnate da trentatre figure litografate, e precedute dalla storia della carcinologia Adriatica antica e recente. (Presentata il 27 dicembre 1868.) Memorie del R. Istituto Veneto. Vol. XIV. Venezia, 1869. pp. 217-343. Tav. XII.-XV.

The Bibliography extends from the year 1524 to the year 1868, occupying the first part of the work. The second part, pages 283 to the end, is concerned with the fifty-four species mentioned in the title. The "Edriottalmi amphipodi" are described on pages 330-332. First Nardo gives "Sp. 46.) ORCHESTIA LITTOREA? Leach. *Cancer locusta*, L., Chier., sp. 58, fig. 74.—Volg. *Saletto de fosso*," with a note to the effect that, since his work in 1847, he had noticed characters which seemed to distinguish this species from *Orchestia littorea*. Fig. 9, on pl. xv., purporting to be copied from Chiereghin, negatives all idea of an *Orchestia*, the upper antennæ, though shorter than the lower, being far too long for that genus. The proportions of the antennæ, coupled with the large rami of the third uropods, would point rather to some genus like *Cheirocratus*, Norman.

Nardo next gives "Sp. 47.) LYSIANASSA? *Cancer salectus*, Chier., sp. 59, fig. 75.—Volg. *Saletto de mar*." He repeats the Latin description quoted in 1847, and adds an Italian quotation, "L'esterna superficie di tutto il corpo, aggiunge, rilevasi liscia e tutta seminata di piccole macchiette di color rosso sopra un fondo biancastro, ed ha sul margine superiore tanto del quinto che del sesto pezzo delle articolazioni del tronco caudale, un paro per cadaun pezzo di lunghetti, sottili ed avvicinati pungiglioni, rivolti verso la parte posteriore. Abita il nostro golfo ne'siti fangosi. Non serve ad aleun uso per essere minutissimo, ed è difficile raccoglierne in qualche numero." The extreme minuteness of the specimen leads Nardo to suspect that it had not attained its full development. Chiereghin's figure is reproduced, pl. xv. fig. 8, with a line a tenth of an inch long to show the natural size. The upper antennæ are much shorter than the lower, but filiform,

quite unlike those of *Lysianassa*. Five short filiform legs are represented, followed by two very long ones, with the first joint in each dilated, the rest slender. The pleon is elongate.

"*Genere LUSYTA*, Nardo," follows, containing

"Sp. 48. *LUSYTA ALGENSIS*, Nardo; *Sinon. moderna cit. Cancer algensis*, Chier., sp. 60, fig. 76-79. *Podoceros Leach.; Annot. aut. all'opera ms. del Chiereghin.*" Nardo says that Leach wrote with his own hand at the foot of the page containing the figure given by Chiereghin, the generic name *Podoceros*, without indicating the species. Nardo himself considers it to differ from *Podoceros* and also from *Cerapus* and *Cerapodina*, though like the two last, especially from its habit of living in a case. As the genus is not separately defined, its characters must be derived from those which are said to be the essential ones of the species:—"Estremità della testa un poco prolungantesi in rostro; occhi posti lateralmente alla base di tal rostro, alquanto peduncolati; due lunghe antennae sorgono dal dissotto del rostro terminate in punta; hanno ciascuna nove articolazioni, e lungo il loro lato inferiore dei lunghi sottilissimi peli; al dissotto ne sorgono altre due più corte, di sole sei articolazioni, pelose anch'esse come le prime.

"I primi due piedi sono grossetti, eguali, di cinque articolazioni, aventi il quarto pezzo più grosso degli altri, e su di questo nasce un dito incurvato verso l'ingiù, terminante in punta ed attò a piegarsi sul lato inferiore del detto quarto pezzo.

"Seguono cinque altri piedi per ogni lato. I tre primi paja sono sottili, composti di sei pezzi, l'ultimo de' quali termina in una punta rivolta un poco verso l'ingiù. Gli altri due paja sono un poco più grossi e più lunghi coll'ultimo pezzo che è più ingrossato e parimenti terminante in punta alquanto più aguzza. Altri due paja di piedi analoghi, sono posti sotto l'ottavo pezzo. Nel quinto, sesto e settimo nascono invece che piedi delle appendici membranose e filamentose.

"La superficie del corpo è liscia e di color bianco candido."

Its dwelling is said, on Chiereghin's authority to be on the leaves of the *Zoslera marina* in tubes shaped like a *Cornucopia*, formed of very fine threads agglutinated together, out of which it thrusts its upper half, when seeking food, and by rapidly waving its arms and antennæ puts the water into movement to draw small animals towards its mouth. The original Latin definition is quoted, without the improvements upon the Latinity given in 1847, thus:—"Cancer algensis, macrourus, thorace rosato, manibus adactylis, pedibus decem, termine caudæ triphylo." The figures 7, 7b, on plate xv., show the shape of the tube, slightly curved, narrow at one end, widening gently to the mouth at the other extremity; figures 7a, 7c, portray the animal very indistinctly, but with the upper antenna decidedly longer than the lower, which is unsuitable to *Podocerus*. The description of "i primi piedi," i.e., evidently the second gnathopods, suits the genus *Cerapus*, but in the well-ascertained species of that genus the tubes are straight, and open at both ends. J. V. Carus 1885, gives *Lusyta*, Nardo, as a synonym of *Podocerus*, Leach, but without explanation and without mention of the species *algensis*.

The "Edriottalmi lamedipodi" are described on pages 323-324. In this division Nardo gives "Sp. 49.) *CAPRELLA LINEARIS*, Milne Edw. *Cancer linearis*, L., Chier. sp. 61, fig. 80. — — Olivi; Zool. Adr. *Oniscus Linearis*, Latr., Martens; *Reise nach Venedig*, p. 497." He says that in 1847 he erroneously marked it as "*Caprellæ nova species?*" He finds that it differs from *Caprella monocantha* [*monacantha*], Heller, by not having the spine at the base of the second pair of feet, and some other trivial characters. Heller's species is identified by Haller and Mayer with *Caprella æquilibra*, Say; Mayer gives up Nardo's species as undecipherable. The fig. 4, on plate xv., however, will fairly suit *Caprella æquilibra*, in which the spine above-mentioned has escaped the notice even of good observers.

He next mentions "Sp. 50.) CAPRELLA FABRIS, Nardo. *Cancer linearis*, L., *varietas*, Chier., sp. 61, fig. 81-82. *Caprellæ nova species?* Nardo; *Sinon. mod. citata*." The specific name, he says, was omitted in the "sinonimia" by a typographical error. He finds it very near to, if not the same as, *Caprella armata*, Heller. Both are by Mayer made synonyms of *Caprella acanthifera*, Leach. It is figured on pl. xv. figs. 5, 5a, the magnified figure leaving no doubt of its identity.

The last species is "Sp. 51.) CAPRELLA CORNALIA, Nardo," not derived from Chiereghini's work. Nardo recognises its likeness to *Caprella acutifrons*, Heller [Latreille], with which the description and figure, pl. xv. fig. 6, justify Mayer in identifying it beyond doubt.

1869. NORMAN, A. M.

Notes of a Week's Dredging in the West of Ireland. By George Stewardson Brady, C.M.Z.S., and David Robertson. The Annals and Magazine of Natural History. May, 1869. Ser. 4. Vol. III. London, 1869. pp. 353-373. Pls. 21, 22. (The Amphipoda and Isopoda by the Rev. A. M. Norman.)

Numerous species of Amphipoda are recorded, with occasional notes on the nomenclature. The genus *Exunguia* is thus defined:—"Antennæ short and strong; flagella rudimentary, upper pair without a secondary appendage. Body wide; coxae shallow. First gnathopods long, slender, filiform; dactylos obsolete. Second gnathopods subchelate, slender, but yet much stouter than the very delicate first pair. Perciopods rather short, subequal; propodos longer than carpus. Uropods all two-branched; branches short, simple. Telson squamiform.

"This genus seems to be most nearly allied to *Cratippus*, from which it is distinguished by the remarkable character of the first gnathopods." The type species, *Exunguia stilipes*, is also fully described, and partly figured, pl. xxii. figs. 7-12.

The genus is, like *Cratippus*, Sp. Bate, a synonym of *Colomastix*, Grube, 1861. The species is no doubt the same as *Cratippus tenuipes*, and probably also the same as *Colomastix pusilla*, Grube.

1869. SAENGER, N.

[Preliminary account of an exploration of the Fauna of the Baltic] in [Communications of the Imp. Society of Nat. Sc., Anthropol. and Ethnol. of the Univers. of Moscow] vol. viii. 1869, pp. 22-34.

"The journal and paper are written in the Russian language." "At Reval . . . occur . . . species of *Crangon*, *Mysis*, *Gammarus*, and *Corophium longicorne* (Fabr.) at about 40 feet." (Zool. Record, 1870.)

1870. BENEDEK, ÉDOUARD VAN.

Recherches sur la Composition et la Signification de l'Œuf, basées sur l'Étude de son Mode de Formation et des premières Phénomènes embryonnaires (Mammifères, Oiseaux, Crustacés, Vers). *Mém. couronnés et Mém. des savants étrangers publiés par l'Académie Royale de Belgique*. Vol. XXXIV. 1870. 283 pp., 12 pl. (Crustacea, pp. 107-143, Pl. VII.-X.).

1870. BENEDEEN, ÉDOUARD VAN, et BESSELS, ÉMILE.

Mémoire sur la Formation du Blastoderme chez les Amphipodes, les Lernéens et les Copépodes. Mém. cour. Acad. Roy. de Belgique. Vol. XXXIV. 1870. 59 pp. 5 pl.

"The development of the ovum of various orders of Crustacea is the subject of several papers by Ed. van Beneden. . . . It is very remarkable that there is a difference between the fresh-water and marine species of *Gammarus*; in the latter the separation of deutoplasm and protoplasm occurs immediately after the complete cleaving of the yolk, as in *Chondracanthus* and the Copepods; in the fresh-water species, on the contrary, the deutoplasm is not included in the multiplication of the egg-cells. An abstract of these papers will also be found in the Quart. Journ. Microsc. Scienc., January 1870, pp. 81-84." (Zool Record., 1870.) Compare Note on Claus, 1884. For *Dermophilus lophii*, see Note on Huxley, 1877.

1870. BENEDEEN, PIERRE JOSEPH VAN.

Les Cétacés, leurs commensaux et leurs parasites. Bulletins de l'Académie royale des sciences, des lettres et des beaux-arts de Belgique. Trente-neuvième année.—2^{me} Série, T. XXIX. Bruxelles, 1870. pp. 347-368.

Van Beneden says at the outset, "Nous ferons suivre le nom des cétacés de l'énumération des commensaux et des parasites qu'ils hébergent." He then gives "*Balaena mysticetus*. *Cyamus ceti* Linn.—*Cyamus ovalis*. Ce crustacé, commensal comme les Cirripèdes, vit sur la peau et a été signalé par la plupart des baleiniers qui ont fait la pêche au Nord." Lütken objects to the synonymy here given, and also to classing the parasitic *Cyamus* with animals that are merely *commensaux*. The next entry referring to the Amphipoda is "*Balaena biscayensis*, Eschr. *Cyamus biscayensis*. Le docteur Monedero a publié la figure qui représente la jeune baleine qui a été capturée en 1854 sur la plage de Saint-Sébastien, dans le golfe de Gascogne, et à côté de la baleine il a donné le dessin d'un Cyame qui a été probablement trouvé sur elle. Malheureusement on n'en a pas conservé pour les comparer." Under these circumstances it is a rather strong measure, as Lütken thinks, to establish a new species.

Under *Balaena australis*, is mentioned *Cyamus erraticus*, Roussel de Vauzème, and two figures are given, with the remarks that Roussel de Vauzème "admet trois espèces sous les noms de *Cyamus ovalis*, *Erraticus*, et *Gracilis*. Nous avons tout lieu de croire, comme le pensaient Audouin et Milne-Edwards, que ce naturaliste n'a pas tenu assez compte des modifications que l'âge apporte dans la forme. Nous avons trouvé de jeunes animaux au milieu d'adultes auxquels les caractères du *Gracilis* convenaient fort bien. Nous reproduisons la forme d'un de ces jeunes individus." Lütken upholds all the three species as distinct. Van Beneden refers also under this heading to Latreille's three species of *Cyamus*, two brought by De Lalande from the Cape of Good Hope, the other coming from some eastern Cetacean.

Under *Physeter macrocephalus*, he mentions "Oniscus. L'espèce n'est pas indiquée; occasionnally adhère to the skin, dit F. Debell Bennet." "Proc. Zool. Soc., 1837 April, p. 30."

Under *Hyperoodon (rostratum) butzkopf*, he mentions "Cyamus (Platyeyamus) Thompsoni (Gosse). Ce Lœmodipode vit également sur la peau mais sans s'y fixer."

Under *Globiceps melas* he mentions, "Cyamus globicipitis, Lutk. Comme les autres Cyames, on l'a trouvé à la surface de la peau."

Under *Monodon monoceros* he mentions "Cyamus monodontis et C. nodosus Lutk. Ces Cyames sont signalés sur ce cétacé par M. Lutken."

In the concluding observations he says, "Parmi les commensaux libres se trouvent les Cyames qui se cramponnent à la peau des Mysticètes et sur plusieurs Cétodoutes. C'est le seul commensal de la baleine du Groënland."

1870. BOECK, AXEL.

(Appendix by Lütken).

Crustacea amphipoda borealia et arctica. (Særskilt aftrykt af Vidensk.-Selsk. Forhandlinger for 1870.) 200 + viii. pages.

In this prodromus to his greater work, Boeck accepts only two divisions of the Amphipoda, which he calls "Hyperidæ Dana 1852," and "Gammaridæ Dana 1849," although in point of fact, the names which Dana employed for his subtribes of the Amphipoda in 1849 were Gammaracea and Hyperiacea, and in 1852 were Caprellidea, Gammaridea and Hyperidea.

In the division *Hyperidæ* Boeck includes two families, *Hyperidæ* and *Tryphanidæ*. Among the former he describes *Meteocus abyssorum*, n. s., which he afterwards called *Tauria abyssorum*, by G. O. Sars identified with *Tauria (Oniscus) Medusarum*, O. Fabr., 1780, for which see Note on Bovallius, 1885. In a new genus, *Parathemisto*, he includes *Themisto compressa*, Goës, and *Parathemisto abyssorum*, n. s., synonymous, according to G. O. Sars, with *Hyperia oblivia*, Sp. Bate (non Krøyer), so that the name will be *Parathemisto oblivia*. To *Themisto*, Guérin, he assigns *Gammarus libellula*, Maudt, and *Themisto bispinosa*, n. s. In his family *Tryphanidæ*, he places the new genus and species, "*Tryphana Malmii*," but according to G. O. Sars, the genus *Tryphana* is a synonym of *Lycæa*, Dana, in the family *Typhidæ*, as limited by Claus.

In the division *Gammaridæ* he places:—

Family I. Prostomatæ, containing only *Trischizostoma raschii*, Esmark and Boeck.

Family II. Orchestidæ, with three genera, *Orchestia*, *Talitrus*, and *Hyale*.

Family III. Gammaridæ, with twenty-two subfamilies, as follows:—Subfam. I. *Lysinassina* (æ), Dana, 1849, comprising, together with species not new, *Lysianassa plumosa*, n. s., which, according to G. O. Sars, is the male of *Lysianassa costæ*, Milne-Edwards; "*Ambasia Danielssenii*," n. g. et s.; *Ichnopus minutus*, n. s.; *Socarnes*, a new genus doubtfully identified with *Epliippiphora*, White, 1848; *Callisoma*, Costa, 1851; *Hippomedon*, a new genus to include *Anonyx holbølli*, Krøyer, and *Lysianassa abyssi*, Goës; *Cyphocaris anonyx*, n. g. et s., named by Lütken, but described by Boeck; *Eurytenes*, Lilljeborg; *Aristias*, a new genus to receive *Anonyx tumidus*, Krøyer; *Anonyx*, Krøyer, with a new species, "*Anonyx Lilljeborgii*"; *Onisimus*, afterwards corrected to *Onesimus*, n. g., doubtfully identified with *Alibrotus*, Milne-Edwards, 1840, but not including any new species; *Menigrates*, a new genus to receive Boeck's own species, *Anonyx obtusifrons*; *Orchomene*, a new genus embracing *Anonyx pinguis*, Boeck, *Anonyx serratus*, Boeck, *Anonyx minutus*, Krøyer, *Lysianassa umbo*, Goës, which Sars refers to *Lepidecreum*, Sp. Bate, and *Orchomene Goësii*, n. s.; *Tryphosa*, n. g., with four species, of which only "*Tryphosa Høringii*" is new; *Normania*, a new genus to receive *Opis quadrimana*, Spence Bate et Westwood, 1868; *Opis*, Krøyer, afterwards altered to *Opisa*; *Acidostoma*, Lilljeborg. Of the new names, *Tryphosa* is inconveniently near to *Triphosa* among Lepidoptera.

Subfam. II. (by mistake printed III.), "Pontoporeinæ. Dana 1852," contains *Pontoporeia*, Krøyer, with the species *Pontoporeia femorata*, Kr., *Pontoporeia furcigera*, Bruzelius, according to Sars not distinct from *femorata*, and *Pontoporeia affinis*, Lindström; *Priscilla armata*, described here as a new genus and species, but in the later work accompanied by the synonym *Pontoporeia armata*, Boeck, 1860; *Argissa typica*, n. g. et s.; *Bathyporeia*,

Lindström, including *Thersites guilliamsoniana*, Sp. Bate, and *Thersites pelagica*, Sp. Bate, as synonyms, female and male respectively, of *Bathyphoreia pilosa*, Lindström.

Subfam. III. "Stegocephalinæ, Dana 1852," contains *Stegocephalus*, Krøyer, with the species *Stegocephalus ampulla*, Phipps, and "Stegocephalus Christianensis," n. s.; *Andania*, n. g., with the new species, *Andania abyssi*, and *Andania nordlandica*.

Subfam. IV. *Amphilochinæ*, contains *Amphilochus*, Sp. Bate, including, besides the type species, *Amphilochus manuidens* (more correctly *manudens*), *Amphilochus odontonyx*, n. s., *Amphilochus bispinosa*, n. s., *Amphilochus tenuimanus*, n. s.; *Gitana*, n. g., with "Gitana Sarsi," n. s., and *Gitana rostrata*, n. s.; *Astyra abyssi*, n. g. et s.

Subfam. V. "Phoxinæ, Spence Bate 1857," embraces *Phoxus*, Krøyer, with the species *Phoxus holbølli*, Kr., and *Phoxus simplex*, Spence Bate, 1857, the latter in Sars' opinion being a wrong identification, so that he names Boeck's species *Phoxus falcatus* on account of the peculiar rostrum; *Harpina* (a preoccupied name afterwards changed to *Harpinia*), a new genus to receive *Phoxus plomosus*, Krøyer, and *Harpina crenulata*, n. s.; *Sulcator arenarius*, rather to be called *Haustorius arenarius*, Slabber; *Urothoë*, Dana.

Subfam. VI. *Stenothoninæ*, new, includes *Stenothonoë*, Dana, Boeck's own *Stenothonoë danai*, being here recognised as a synonym of *Montagua marina*, Sp. Bate, with the name *Stenothonoë marina*; *Metopa*, a new genus to receive *Leucothoë clypeata* and *Leucothoë glacialis* of Krøyer, *Montagua alderii*, Sp. Bate, *Montagua bruzelii*, Goës (as to which, Sars, in 1882, points out that Boeck's species is distinct from that of Goës, and he therefore names it *Metopa borealis*), *Metopa affinis*, n. s., *Metopa longicornis*, n. s., *Metopa megacheir*, n. s., *Metopa longimana*, n. s., and *Metopa nasuta*, n. s.; *Cressa*, a new genus with the new species, "Cressa Schiødtei" and *Cressa minuta*. If the species *Schiødtei* be, as G. O. Sars considers it, a synonym of *Danaia dubia*, Spence Bate, the genus *Cressa* will become a synonym of *Danaia*, in which Boeck's species *minuta*, is very doubtfully distinct from its congener. The difficulty with regard to the mandibular palp has been already mentioned.

Subfam. VII. *Syrrhoinæ*, new, receives *Syrrhoë*, Goës, with the species *Syrrhoë crenulata*, Goës, and *Syrrhoë levii*, n. s.; *Tiron acanthurus*, Lilljeborg; *Bruzelia typica*, new genus and species.

Subfam. VIII. *Pardaliscinæ*, new, has *Pardalisca*, Krøyer, with the species *Pardalisca cuspidata*, Krøyer, *Pardalisca boeckii*, Malm, and *Pardalisca abyssi*, n. s.; the new genus *Halice*, with the new species *Halice abyssi* and *Halice grandicornis*, the latter, according to G. O. Sars, Ov. Norg. Crust. p. 106, being undoubtedly the male of the former; *Nicippe tumida*, Bruzelius.

Subfam. IX. "Leucothoninæ, Dana 1852," includes *Lilljeborgia pallida*, Sp. Bate, and *Lilljeborgia fissicornis*, M. Sars, the latter doubtfully distinct from the former; *Eusirus cuspidatus*, Krøyer, and *Eusirus longipes*, Boeck; *Leucothoë spinicarpa*, Abildgaard; the new genus *Tritropis* (a preoccupied name), for the species *aculeata*, Lepechin, "Helleri," n. s., and *fragilis*, Goës, of which the first two should perhaps be called *Rhachotropis aculeatus*, and the third *Rhachotropis fragilis*.

Subfam. X. "Oedicerinæ, Lilljeborg 1865," contains *Oediceros*, Krøyer, with the species *saginatus*, Kr., *lynceus*, M. Sars, *borealis*, n. s.; *Acanthostephia*, a new genus to receive "Amphilithonotus Malmgreni," Goës; *Monoculodes*, Stimpson, to receive the species *Oediceros affinis*, Bruzelius, *Oediceros norvegicus*, Boeck, "Monoculodes Grubei," n. s., *Monoculodes longicornis*, n. s., which in the opinion of J. S. Schneider is very near the preceding *Monoculodes grubei*, "Monoculodes Krøyeri," n. s., "Monoculodes Packardi," n. s., *Monoculodes tenuirostratus*, n. s., *Monoculodes tuberculatus*, n. s., *Monoculodes borealis*, n. s., both this and *Monoculodes norvegicus* in Boeck's later work receiving the same synonym, "Oediceros affinis", Goës, Crust. Amphip. maris Spetsb. p. 11. fig. 21 (non Bruzelius); *Oediceros latimanus*, Goës; *Halimedon*, a new genus, with the species, "Halimedon Mölleri," n. s. (afterwards spelt Müller), "Halimedon Saussurei," n. s. (criticised by J. S. Schneider), *Halimedon longimanus*,

n. s., and *Halimedon brevicalcar*, altered from *Oediceross brevicalcar*, Goës; *Pontocrates* a new genus, with *Oediceross norvegicus*, Boeck, 1860, for the type, a species which was named *Krögera* (or *Krogera*) *arenaria*, by Sp. Bate, and Hancock, in 1858 (see Notes under that date); *Pontocrates haplocheles*, Grmbe, 1864; *Aceros*, Boeck, with the species *Aceros phyllonyx*, M. Sars; *Halicreion longicaudatus*, new genus and species; *Oediceropsis brevicornis*, Lilljeborg; *Paramphithoë*, Brñzelius, 1859, to receive the species *Amphithopsis glaber*, Boeck, *Paramphithoë media*, Goës, *Amphithoë panopla*, Krøyer, *Paramphithoë parva*, n. s., *Amphithoë pulchella*, Krøyer, *Amphithoë bicuspis*, Krøyer, all of which in the later work are transferred to *Pleustes*, Sp. Bate, 1858.

Subfam. XI. Iphimedinæ, new, contains *Vertumnus*, White, 1847, altered in the later work to *Acanthonotozoma*, here receiving the species *Acanthonotus cristatus*, Owen, *Oniscus serratus*, O. Fabricius, and *Acanthonotus inflatus*, Krøyer; *Iphimedia obesa*, Rathke; *Odius*, Lilljeborg, 1865, to receive *Otus carinatus*, Sp. Bate; *Laphystius sturionis*, Krøyer, the original spelling *Lafystius* being subsequently recognised.

Subfam. XII. Epimerinæ, new, has "Acanthozone n. g. (Acanthosoma, Owen)," for *Oniscus cuspidatus*, Lepechin; and *Epimeria*, Costa, for *Gammarus corniger*, Fabricius.

Subfam. XIII. Dexamininæ, new, receives *Dexamine spinosa*, Montagn, *Dexamine thea*, Boeck, "Dexamine Heibergi," n. s.; and *Lampra*, new genus, afterwards named *Tritaeta*, for the single species *Atylus gibbosus*, Sp. Bate.

Subfam. XIV. "Atylinae. Lilljeborg 1866," has, in the genns *Atylus*, Leach, 1817, the species *Gammarus carinatus*, Fabr., *Paramphithoë smitti*, Goës, *Amphithoë swammerdamii*; M.-Edwards, *Dexamine vedlomensis*, Bate and Westwood, "Atylus Nordlandicus," n. s.; *Pontogeneia*, a new genus to receive *Amphithoë inermis*, Krøyer; *Halirages*, a new genus for *Dexamine lispinosus*, Sp. Bate, *Halirages borealis*, n. s., *Paramphithoë tridentata*, Brñz., *Amphithoë fulvocincta*, M. Sars; *Calliopus*, Lilljeborg, 1865, for *Amphithoë leviuscula*, Krøyer, and *Amphithoë norvegica*, Rathke; *Amphithopsis*, Boeck, 1860, with "Amphithopsis Malmgreni," n. s., *Amphithopsis longicaudata*, Boeck, *Amphithopsis longimana*, n. s., and *Amphithoë latipes*, M. Sars; *Cleippides*, a new genus for *Acanthonotus tricuspis*, Krøyer; "Laothoës Meinerti," new genus and species.

Subfam. XV. "Gammarinæ. Dana 1849," contains *Gammarus*, Fabricius, 1776, with the species *locusta*, Linné, 1867, *marinus*, Leach, 1815, *pulex*, Pennant, 1777, and *neglectus* (Lilljeborg), G. O. Sars, 1867, in all of which the synonymy given demands attention; *Pallasia*, Spence Bate, 1862, in the later work spelt correctly *Pallasea*, with the single species *Pallasia quadrispinosa* (Esmark), G. O. Sars, 1867; *Mæra*, Leach, for the species *Gammarus lovéni*, Brñzelius, *Gammarus torelli*, Goës, and *Gammarus longimanus*, Thompson; *Melita*, Leach, for the species *obtusata* and *palmata* of Montagn, and for *Gammarus dentatus*, Krøyer; *Elasmopus*, Costa, 1856, for *Elasmopus latipes*, n. s.; *Cheirocratus*, Norman, 1865, for "Gammarus Sundewalli," Rathke, and *Gammarus assimilis*, Lilljeborg; *Gammaracanthus loricatus*, Sabine; *Niphargus*, Schiødte, 1851, for *Eriopis elongata*, Bruzelius; *Amathilla*, Bate and Westwood, for *Gammarus sabini*, Leach, *Gammarus angulosus*, Rathke, and *Gammarus pinguis*, Krøyer; *Melphidippa*, a new genus to receive *Gammarus spinosus*, Goës, and the new species *longipes* and *borealis*.

Subfam. XVI. "Ampeliscinae. Spence Bate 1857," includes under *Ampelisca*, Krøyer, 1842, the species *tenuicornis*, Lilljeborg, *assimilis*, n. s., *typica*, Sp. Bate (according to G. O. Sars, Ov. Norg. Crust., p. 107, 1882, undoubtedly the male of *tenuicornis*), *aquicornis*, Bruzelius, *spinipes*, Boeck, *dubia*, n. s., *eschrichtii*, Krøyer, *macrocephala*, Lilljeborg, *propinqua*, n. s., *lævigata*, Lilljeborg, a group of species which no doubt stands in need of some revision; under *Haploops*, Lilljeborg, 1855, *tubicola*, Lilljeborg, *carinata*, Lilljeborg, and *setosa*, n. s.; under *Byblis*, a new genus, the single species *Ampelisca gaimardi*, Krøyer, "1846?"

Subfam. XVI. Leptocheirinæ, new, contains *Leptocheirus pilosus*, Zaddach, and the new genus *Goësia*, for *Autonoë depressa*, Goës.

Subfam. XVII. Photinæ, new, said by a slip, which is repeated in the larger work, to have "Pedes 7 mi paris breviores quam 6ti paris," receives *Photis reinhardi*, Krøyer, "Photis Lütkeni," n. s., which Norman identifies with the earlier *Eiscladus longicaudatus*, Bate and Westwood, while Boeck makes *longicaudatus* a synonym of *Reinhardi*; *Microprotopus maculatus*, Norman; "*Xenoclea Batei*," a new genus and species, which is so like the earlier *Nænia rimopalma* of Spence Bate, that I do not think they should be kept distinct, although Boeck says that the apex of the telson in his species is cleft or sinuate. On the other hand the genus *Nænia*, 1862, must yield to *Podoceropsis*, 1860.

Subfam. XVIII. Microdentopinæ, new, contains *Microdentopus*, Costa, 1853, for the species *Microdentopus gryllotalpa*, Costa, and *Gammarus anomalus*, Rathke; *Aora gracilis*, Sp. Bate; *Autonoë*, Bruzelius, 1859, for *Gammarus longipes*, Lilljeborg, and *Autonoë plumosa*, n. s.; *Protomedea fasciata*, Krøyer, and *Protomedea longimana*, n. s.; *Gammaropsis erythrocephalus*, Lilljeborg, the species described by Boeck being, according to G. O. Sars, Ov. Norg. Crust., p. 111, quite distinct from Lilljeborg's, on which account he renames it *Gammaropsis melanops*, although it must be observed that in this work the eyes are said to be "rubri," an expression omitted from the later work, where no colour for the eyes is mentioned; *Podoceropsis sophiae*, Boeck.

Subfam. XIX. Amphithoinæ, new, contains *Amphithioë podoceroides*, Rathke, *Amphithioë grandimana*, Boeck; *Sunamphithioë hamulus*, Sp. Bate, *Sunamphithioë longicornis*, n. s.

Subfam. XX. Podocerinæ, new, includes *Podocerus*, Leach, to receive *Ischyrocerus latipes*, Krøyer, *Podocerus megacheir*, n. s., *Ischyrocerus anguipes*, Krøyer, *Cancer (Gammarus) falcatus*, Montagu; *Janassa*, a new genus for *Podocerus variegatus*, Leach, which is probably only a form of *Podocerus falcatus*, while the name *Janassa* is preoccupied among fossil fish; *Cerapus*, Say, 1817, to receive *Cerapus abditus*, Templeton, *Cerapus difformis*, Milne-Edwards, *Cerapus longimanus*, n. s., and *Cerapus hunteri*, Sp. Bate, the last three of which S. I. Smith places in the genus *Erichthonius*, Milne-Edwards, making the species *hunteri* synonymous with *difformis*.

Subfam. XXI. "Chelurinae. Allman 1837," has only *Chelura terebrans*, Philippi.

Subfam. XXII. "Corophinæ. Dana 1849," contains *Corophium*, Latreille, 1807, to receive *Cancer grossipes*, Linné, *Corophium crassicornis*, Bruzelius, 1859, with "? *Corophium acherusicum*, Costa," 1856, and "? *Corophium crassicornis* (Bruzelius), Spence Bate and Westwood," 1863, given in the synonymy, *Corophium affine*, Bruzelius, with "? *Corophium Bonellii*, Milne-Edwards," ♀, 1830, in the synonymy, this last being, according to G. O. Sars, Ov. Norg. Crust., p. 112, distinct from *Corophium crassicornis*, Bruzelius, to which Boeck in his later work doubtfully makes it a synonym, withdrawing it from *Corophium affine*; *Siphonæcetus*, afterwards corrected to *Siphonæcetes*, Krøyer, 1845, to receive *Siphonæcetes typicus*, Krøyer, "*Siphonæcetes Colletti*," n. s.; *Glauconome*, Krøyer, 1845, a preoccupied name, which must yield, as pointed out by S. I. Smith, to *Unciola*, Say, but here used for the three species, *leucopis*, Krøyer, which Smith identifies with *Unciola irrorata*, Say, "*Krøyeri*," n. s., and "*Steenstrupi*," n. s.; and lastly *Hela* (now *Neohela*) *monstrosa*, Boeck.

Fam. IV. "Dulichidae. Dana 1849," comprises *Dulidilia*, Krøyer, 1845, with six species, *spinosissima*, Krøyer, *falcata*, Sp. Bate, "*Nordlandica*," n. s., *tuberculata*, n. s., *curticaula*, n. s., *orrecta*, Sp. Bate; *Paradulichia typica*, new genus and species; *Læmatophilus*, Bruzelius, 1859, with the species *tuberculatus*, Bruzelius, and *spinosissimus*, n. s.; "*Xenodice Frauenfeldti*," new genus and species.

Fam. V. "Caprellidae. Leach 1815," has two subfamilies:—

Subfam I. Caprellinæ, new, contains *Proto goodsirii*, Sp. Bate, which is now made a synonym of the following species, *Proto ventricosa*, Müller; *Cercops holbølli*, Krøyer; *Ægina*, Krøyer,

1843, for the species *Aegina longicornis*, Krøyer, *Cancer phasma*, Montagu, which properly belongs to *Protella*, Dana, *Aegina echinata*, Boeck, and *Aegina larvis*, Boeck, which Mayer unites to *Aegina longicornis*, Krøyer; *Aeginella spinosa*, Boeck; *Caprella*, Lamarek, 1818, with the species *linearis*, Linné, *laticornis*, Boeck, *longicornis*, n. s., *esmarkii*, Boeck, "Lovéni," n. s., *septentrionalis*, Krøyer, *punctata*, Boeck, *lystrix*, Krøyer, of which Mayer makes *laticornis* and *esmarkii* synonyms of *Caprella aquilibra*, Say, and queries whether *longicornis*, *lovéni* and *punctata* be not synonyms of *Caprella septentrionalis*, Krøyer; *Podalirius typicus*, Krøyer.

Subfam. II. "Cyaminæ. Krøyer 1843," in a "Conspetus Cyamidarum borealium hujusque [hueusque] eognitarum. Auctore Chr. Lütken," contains *Platycyamus*, Ltk., new genus for *Cyamus thompsoni*, Gosse; and *Cyamus*, Latreille.

The latter genus has the species "Cyamus *Mysticeti* Ltk.," with the "Synonymia: *Oniscus ceti* Pall., *Squilla Balæni* de Gcr, *Cyamus ceti* Auct. plerumqve. (*Oniscus ceti* Linn. indeterminabilis?);" "Cyamus *Monodontis* Ltk.;" "Cyamus *Boopis* Ltk.," with "Syn. *Oniscus ceti* Fabr. Faun. Grønl. 330.;" "Cyamus *nodosus*, Ltk., with "Syn. *Oniscus ceti* Zool. Dan. iii. tab. exix. f. 13-17.;" "Cyamus *Globicipitis* Ltk.," with "Syn. *Cyamus* sp. n. Stp." It may be, and has been questioned, whether Lütken is justified in superseding the old name *Cyamus ceti* for the species parasitic on the Greenland whale.

The new genera are described as follows:—

Div. I. Fam. I. Hyperidae. Gen. III. *Parathemisto*. "Corpus sat compressum; dorso carinato. Mandibulæ in apice perlatae, serratae, æque ut mala interna; tubereulo molari latissimo, in margine erenato; palpo longissimo. Maxillæ 1mi paris dentibus quatuor perlóngis et firmis armatae. Pedes 2di paris (non pedis 1mi paris) carpo in angulo inferiore posteriore valde produeto; manu cheliformi. Pedes 3tii 4tiqve paris articulo 4to subdilatato. Pedes trium parium ultimorum subæqvales."

Fam. II. Tryphanidae. Gen. I. *Tryphana*. "Truneus segmentis septem perangustis. Postabdomen segmentis tribus anterioribus perlatis. Caput permagnum antie obtusum. Pedes 1mi 2diqve paris sat parvi; articulo 5to non subcheliformi. Pedes 3tii et 4ti paris magnitudine et forma æqvales. Pedes trium parium ultimorum gradatim magnitudine valde decrescentes; pedes 5ti paris pedibus 7mi paris plus duplo maiores."

Div. II. Fam. III. Gammaridae. Subfam. I. Lysianassinae. Gen. II. *Ambasia*. "Hypostomum valde gibbosum, prominens. Mandibulæ palpo elongato et tenui, profundius quam tubereulo molari parvo affixo. Maxillæ 1mi paris lamina interiore minima, ovata. Maxillæ 2di paris breves, non lati. Pedes maxillares laminis exterioribus permagnis, ovatis, vix in margine interiore nodulosis; palpo brevi; articulo 4to tubereuliformi. Antennæ inferiores articulo 3tio prælongato. Pedes 1mi paris graciles, manu subcheliformi destituti. Pedes saltatorii ultimi paris breves; ramo interiore multo breviore quam exteriore. Appendix caudalis brevis, fissa."

Gen. IV. *Socarnes*. "Labium superius prælongatum, prominens, aerrinum, eum hypostomi apieae acuto coniunctum. Mandibulæ medioeriter elongatae; palpo multo profundius quam tubereulo molari prominenti affixo. Maxillæ 1mi paris dentibus perlatis; lamina interiore prælongata, angusta et in apice duobus setis plumosis instructa. Maxillæ 2di paris laminis angustis, elongatis. Pedes maxillares laminis exterioribus ovatis, in margine interno nodulos parvulos gerentibus; lamina interiore prælongata; articulo palpi 2do elongato; articulo 4to ungviformi. Antennæ breves. Pedes 1mi paris breves; manu apicem versus attenuata et haud subcheliformi. Appendix caudalis longitudine medioeri, usqvo ad medium fissa."

Gen. VI. *Hippomedon*. Mandibulæ breves; mala exteriore angusta; in sinistra dente parvulo accessorio instruetæ; palpo in eadem altitudine ac tubereulo molari permagno affixo. Maxillæ 1mi paris palpo in apieae multis, brevibus, latis, parum serratis dentibus instrueto; lamina interiore sat brevi, in apice duabus setis plumosis instrueta. Maxillæ 2di paris

laminis brevibus. Pedes maxillares breves, lati; lamina exteriore ultra articulum palpi 2dum porrecta, in margine interno dentibus crebris, validis armata; lamiua interiore brevi. Antennæ elongatæ; auteunæ inferiores articulo 5to multo longiore qvam 4to. Pedes 1mi paris sat elongati; imprimis articulus 4tus; manu invalida, subcheliformi. Appendix caudalis elongata, profunde fissa, ultra pedunculum pedium saltatoriorum paris ultimi porrecta."

Gen. VII. *Cyphocaris*, Lütken, n. g. "Mandibulæ brevissimæ; palpo longo et latissimo, in eadem altitudine ac tuberculo molari robusto affixo. Maxillæ 1mi paris palpo apicem versus dentibus paucis sed validis et una seta prælongata plumosa armato; lamina interiore elongata, et in margine interno setis multis plumosis instructa. Pedes maxillares lamina exteriore brevissima, in margine interno dentibus paucis sed validis armata; palpo prælongato; articulo 1mo et 2do eadem longitudine; articulo 4to cylindrico, non ungviformi, seta robusta plumosa instructo. Antennæ inferiores articulo 1mo ab integumentis capitis nou tecto, sed extus visibili, in incisura eorundem sito. Pedes 1mi paris parvi; manu apicem versus acuta, vix subcheliformi. Pedes 2di paris elongati, ungvæ destituti. Appendix caudalis profunde fissa, longe ultra articulum basalem pedium saltatoriorum paris ultimi porrecta. Segmentum trunci 1mum valde gibbosum; caput sub anulo situm, ex parte tectum; epimerum 1mum nullum, 2dum parvulum; 3tum et 4tum coalita, magna."

Gen. IX. *Aristias*. "Maudibulæ elongatae, angustæ, in apice vero latae, sine dente accessorio; tuberculo molari prominenti, acuto, palpo in eadem altitudine infixo. Maxillæ 1mi paris perlatae; in margine crebras setas plumosas gerentes; lamina interiore etiam brevi, ovata, in apice crebris setis plumosis instructa; at palpo angusto, in apice paucis spinis instructo. Maxillæ 2di paris item laminis latissimis, in margine setis multis instructis; lamina exteriore angustiore qvam interiore. Pedes maxillares lamina exteriore permagna, in margine setis paucis modo armata et ferme ad finem articuli palpi 3tii porrecta; articulo palpi 3tio brevi et gracili; 4to ungviformi; lamina interiore brevisaima, triangulare, ad basiu lata, et in apice uno dente et setis pluribus plumosis armata. Antennæ superiores peduueculo elongato, angusto. Pedes 1mi paris manu apicem versus angustiore. Pedes 2di paris elongati; manu sat angusta. Pedes saltatorii paris ultimi ramo interiore paulo breviore qvam exteriore; ramo interiore in margine externo et interno serrulato, exteriore in margine interno modo. Appendix caudalis brevissima, non ad fiuem pedunculi pedum saltatoriorum ultimi paris porrecta, usqve ad basin fissa."

Gen. XI. *Onisinus*. "Hypostomum prominens. Mandibulæ palpo in eadem altitudine ac tuberculo molari mediocri affixo; in apice dente firmo et dente accessorio angusto instructæ. Labium inferius laciniis in apice spina una armatis. Maxillæ 1mi paris lamina interiore parva, ovata, in apice setas duas plumosas gerenti; palpo in apice 5–6 spinis instructo. Maxillæ 2di paris laminis brevissimis; exteriore duplo fere longiore qvam interiore. Pedes maxillares laminis exterioribus parvis, non ad finem articuli palpi 2di porrectis; in margine interno nodis paucis et in apice dente una instructis. Epimera qvatuor anteriora angusta; epimerum 4tum subcurvatum. Angulus inferior posticus segmenti postabdominis 3tii acutus. Anteunæ plus minusve prælongatae. Antennæ inferiores articulo 5to breviore qvam 4to. Pedes 1mi paris brevissimi, robusti; manu quadrangulari, in acie oblique truncata. Pedes saltatorii ultimi paris ramis brevibus. Appendix caudalis sat brevis, non ad finem pedunculi pedum saltatoriorum ultimi paris porrecta."

Gen. XII. *Menigrates*. "Mandibulæ brevissimæ; palpo brevi, profuudius qvam tuberculo molari robusto affixo. Maxillæ 1mi paris lamina iuteriore ovata, in apice setis duabus plumosis instructa; palpo in apice paucas spinas gerenti. Maxillæ 2di paris laminis medio criter elongatis. Pedes maxillares latissimi, breves; lamina exteriore ultra finem articuli palpi 2di porrecta, paucis spinis gracilibus et nodis et in apice spina una valida armata; articulis palpi brevissimis et latis; articulo 4to processum brevem, obtusum, tuberculiformem

formanti. Corpus peraltum et crassum. Antennæ sat breves. Pedes 1mi paris robustissimi; manu vix subcheliformi. Pedes saltatorii brevissimi et crassi."

Gen. XIII. *Orehomene*. "Hypostomum prominens, cassiforme. Mandibulæ longæ, angustæ; palpo profundius quam tuberculo molari prominenti affixo. Maxillæ 1mi paris lamina interiore prælongata, augusta, infra in apice setas duas plumosas gerenti; palpo in apice dentibus multis, minutis instructo. Maxillæ 2di paris laminis perlóngis et perangustis; exteriore paulo longiore et angustiore quam interiore. Pedes maxillares lamina exteriore ultra finem articuli palpi 2di porrecta; articulo palpi 1mo magno. Corpus sat altum. Epimerum 5tum altius quam latius. Angulus inferior posticus lateralis segmenti post-abdominis 3tii non sursum productus et curvatus. Antennæ inferiores articulo pedunculi 3tio prælongato, angusto. Pedes 1mi paris brevissimi, robusti; manu quadrangulari, longitudinem carpi triangularis superanti. Pedes 2di paris manu in angulo inferiore postice producta. Appendix caudalis brevissima, in apice parum fissa, non ad finem pedunculi pedum saltatoriorum ultimorum porrecta."

Gen. XIV. *Tryphosa*. "Hypostomum plus minusve prominens. Mandibulæ palpo gracili fere in eadem altitudine ac tuberculo molari affixo; articulo palpi 3tio brevi. Maxillæ 1mi paris lamina interiore ovata, in apice setas duas plumosas gerenti; palpo in apice dentibus nonnullis obtusis instructo. Maxillæ 2di paris laminis haud valde prælongatis. Pedes maxillares lamina exteriore lata, ovata, in margine interiore nodis multis, in apice spinis duobus armata, ultra finem articuli palpi 2di porrecta. Pedes 1mi paris elongati. Appendix caudalis prælongata, ultra finem articuli ultimi pedum saltatoriorum porrecta."

Genus XV. *Normania*. "Mandibulæ palpo gracillimo, elongato. Maxillæ 1mi paris palpo latissimo, ovato; lamina interiore angusta, non vero prælongata, setas duas plumosas gerenti. Maxillæ 2di paris laminis angustis, non vero longis. Pedes maxillares lamina exteriore latissima, in margine spinis paucis gracilibus instructa; lamina interiore prælongata, angusta; palpo multo breviore quam lamina exteriore, triarticulato; articulo palpi 4to absenti. Antennæ superiores breves, non crassi. Antennæ inferiores breves; segmento pedunculi 1mo inflato et extus visibili. Pedes 1mi paris manu magnopere inflata, lata, valde subcheliformi. Pedes 2di paris elongati. Pedes saltatorii elongati. Appendix caudalis perbrevis, lata, non fissa."

Subfam. II. Pontoporeinæ. Gen. II. *Priscilla*. "Epimera anteriora quatuor rigida, longa, attenuata, in apice setis longis plumosis instructa. Pedes 1mi et 2di paris inter se eadem fere forma; manu parva, subcheliformi instructi. Pedes 3tii et 4ti paris robusti; articulo ultimo serie setarum validarum instructo. Pedes 5ti et 6ti paris articulo 1mo perrigido, parum dilatato, in angulo superiore producto. Pedes 7mi paris articulo 1mo valido, clipeoformi, dilatato; articulo 5to in apice spinis multis, rigidis armato. Pedes saltatorii ultimi paris ramo interiore parvulo. Appendix caudalis latissima, insinuata modo, non fissa."

Gen. III. *Argissa*. Antennæ superiores inferioribus multo breviore. Epimerum 1mum magnum, in margine inferiore rotundatum. Epimera cætera magnitudine valde decrescentia; epimerum 3tium parvulum, sed 4tum pergrande, clipeoformis. Pedes 1mi et 2di paris inter se eadem forma, sed infirmi; manu subcheliformi. Pedes 3tii et 4ti paris ungvem minimo. Pedes 5ti et 6ti paris articulo 1mo postice sat dilatato; ungibus parvulis. Pedes 7mi paris articulo 1mo pergrandi, clipeoformi; ungvem parvo. Pedes saltatorii ultimi paris ramis universis inter se fere eadem longitudine. Appendix caudalis elongata, usque ad basin fissa."

Subfam. III. Stegocephalinæ. Gen. II. *Andania*. "Mandibulæ in apice non aut minime modo dentatae; mala interiore mandibulæ sinistram item minima. Maxillæ 1mi paris palpo elongato, lato, 2articulato. Maxillæ 2di paris lamina exteriore multo breviore quam interiore et parum modo angustiore quam longa. Appendix caudalis integra, minimæ."

- Subfam. IV. *Amphilochinæ*. Gen. II. *Citana*. "Mandibulæ articulo palpi 3to breviore quam 2do. Maxillæ 1mi paris palpo uniarticulato, in apice angusto. Pedes 1mi et 2di paris manibus angustis, vix subcheliformibus. Pedes maxillares palpis perangustis, elongatis; articulo 3to in extremo margine interiore producto."
- Gen. III. *Astyra*. "Mandibulæ in apice dilatatae et deutatae; tuberculo molari prominenti sed tenui, apicem versus angustiore; articulo 3to palpi breviore quam 2do. Maxillæ 1mi paris lamina iuterua latiore, setis multis instructa. Maxilla 2di paris lamina interna perbrevi sed lata. Pedes maxillares lamina externa permagna, in margine interiore dentibus multis armata; palpo brevi. Antennæ broves; superiores inferioribus breviores; flagello accessorio parvo; pedunculo brevi, sed crasso. Pedes 1mi et 2di paris vix subcheliformes. Pedes trium parium ultimorum articulo 1mo uou perdilatato. Pedes saltatorii ultimi paris ramo interiore breviore quam exteriore. Appendix caudalis brevis, iu apice iucisa."
- Subfam. V. *Phoxinæ*. Gen. II. *Harpina*. "Maxillæ 1mi paris palpo 2articulato. Pedes 5ti paris articulo 1mo nou dilatato. Cæteroqviv ferme ut apud genus *Phoxus*."
- Subfam. VI. *Stenothoinæ*. Geu. II. *Metopa*. "Mandibulæ palpo brevi, 3articulato; articulo 3to fere obsoleto. Maxillæ 1mi paris palpo 1articulato. Reliqva cum genere Stenothoë ferme conveniunt."
- Gen. III. *Cressa*. "Mandibulæ palpo elongato, 3articulato. Antennæ superiores inferioribus multo crassiores et longiores. Epimera non permagna; 4um in supremo margine postico profunde incisum. Pedes trium parium ultimorum articulo 1mo postice valde dilatato. Reliqva cum genere Stenothoë fermo conveniunt."
- Subfam. III. *Syrrhoïnæ*. Gen. III. *Bruzelia*. "Mandibulæ crassissimæ, latæ, pyramidales, iu apice insiuuatæ, non dentatae. Maxillæ 1mi paris palpo angusto. Corpus subdepressum; epimeris perrigidis, prominentibus, magnitudinis mediocris; epimero 4to maximo. Pedes 1mi et 2di paris manu parva, subcheliformi. Pedes 3tii et 4ti paris perangusti, elongati; articulo 3to perbrevi. Pedes trium parium ultimorum elongati; articulo 1mo parum dilatato. Pedes saltatorii 1mi paris ramo exteriore breviore quam interiore; 2di paris ramo interiore latissimo, exteriore parvo. Appendix caudalis longa, non fissa."
- Subfam. VIII. *Pardaliscinæ*. Gen. II. *Halice*. "Instrumenta cibaria æqve ut apud genus *Pardalisca*. Caput parvum, non inflatum; rostrum frontale elongatum. Antennæ inferiores pedunculo prælongato, angusto. Pedes 1mi ot 2di paris carpo angusto; manu elongata; ungve gracili. Pedes trium parium ultimorum sat prælongati."
- Subfam. IX. *Leucothoinæ*. Geu. IV. *Tritropis*. Antennæ superiores inferioribus breviores. Epimera parva; 1mum in angulo inferiore antico productum. Pedes 1mi et 2di paris manu sat magua, ovata; ungve longo; carpo brevi, in angulo inferiore postico producto. Pedes 3tii et 4ti paris perlongi, graciles; articulo 3to brevi. Pedes trium parium ultimorum gracillimi et longissimi; articulo 1mo dilatato. Appendix caudalis prælongata, in apice fissa."
- Subfam. X. *Oedicerinæ*. Gen. II. *Acanthostephia*. "Pedes maxillares lamina externa parvula, non ad medium articulum palpi 2dum porrecta; lamina interna etiam parvula. Antennæ prælongatae, tenues; superiores inferioribus paulo breviores. Corpus valde carinatum; segmentis trunci posterioribus et segmentis postabdominis postice in processus longos et deutiformes exeuntibus; epimeris posterioribus valde acuminatis; capite antice in rostrum longissimum producto. Cæteroqvin ferme ut apud genus *Œdiceros*."
- Gen. IV. *Halimedon*. "Mandibulæ in apice parum modo deutatae et crassæ; palpo prælongato et angusto. Pedes 1mi paris carpo tam longo aut multo longiore quam manu ovata et in angulo inferiore postico parum dilatato. Pedes 2di paris carpo prælongato, angusto, calce parvula prædicto aut destituto; manu tam longa aut breviore quam carpo."
- Gen. V. *Pontocrates*. "Pedes 1mi paris pervalidi; manu magna, lata; calce carpi eadem longitudine ac margine manus posteriore. Pedes 2di paris manu prælongata, cheliformi; calce carpi prælongata aut abseuti. Cæteroqvin ferme ut apud *Œdiceros*."

Gen. VII. *Halicereion*. "Pedes maxillares lamina utraque minima; palpo praelongato. Antennae elongatae; superiores articulis pedunculi longitudine parum modo decrescentibus et apud mare minimis; articulis flagelli anterioribus maris coalitis. Pedes 7mi paris pedibus 5ti et 6ti paris paulo, non multo, longiores. Pedes saltatorii 1mi et 2di paris postice ad apicem pedunculi ultimi paris porrecti. Pedes saltatorii ultimi paris praelongati. Cæteroquin ferme ut apud genns CEdiceros."

Subfam. XII. Epimerinæ. Gen. I. *Acanthozone*. "Segmenta trunci et postabdominis seriebus pluribus dentium armata. Epimera qvatuor anteriora non pernagna sed rigida, in apice acuminata. Pedes trium parium ultimorum articulo 1mo valde dilatato et spinis armato. Pedes saltatorii ultimi paris ramis lanceolatis."

Subfam. XIII. Dexamininæ. Gen. II. *Lampra*. "Pedes maxillares laminis exterioribus angustioribus, valde curvatis et modo in summo dimidio spinis paucis sed validis armatis; laminis interioribus latioribus et longioribus quam apud genus Dexamine, spinis multis curvatis et gracilibus armatis. Epimera minima; epimera qvatuor anteriora 5to non altiora, in margine inferiore armata. Pedes qvinqve parium ultimorum articulo 4to et 5to perbrevibus; ungve parvo."

Subfam. XIV. Atylinæ. Gen. II. *Pontogeneia*. "Mandibulæ palpo valido; articulo 3tio multo breviore quam 2do. Maxillæ 1mi paris lamina interua paucis (3-6) setis plumosis instructa. Pedes maxillares lamina externa et interna spinis (non dentibus) elongatis instructis; palpo brevi; articulo ejusdem 3tio in fine marginis exterioris producto. Antennæ superiores inferioribus paulo longiores. Pedes saltatorii 1mi et 2di paris ramis exterioribus brevioribus quam inferioribus. Pedes saltatorii 3tii paris pedunculo perbrevi, breviore quam appendice caudali. Appendix caudalis duplex. Corpus levc, non carinatum; epimeris parvis; epimera 4to altiore quam 5to."

Gen. III. *Halirages*. Mandibulæ palpo elongato; articulo 3tio breviore quam 2do. Maxillæ 1mi paris lamina interiore ovata, in margine interiore setis panceis plumosis (3-6) instructa. Pedes maxillares lamina exteriore magnitudinis mediocris, non ad finem articuli palpi 2di porrecta et in margine interiore spinis tenuibus armata. Corpus non valde compressum; dorso rotundato, non carinato; segmentis trunci nltimis et postabdominis anterioribus plerisque in medio margine posteriore in dentes retroversos desinentibus; epimeris magnitudinis mediocris vel parvis. Antennæ pedunculis brevibus sed flagellis praelongatis, multiarticulatis; superiores inferioribus multo breviores. Pedes 1mi et 2di paris elongati, angusti; manibus parvis. Pedes saltatorii 1mi 2diqve paris ramis exterioribus brevioribus quam inferioribus; pedes saltatorii ultimi paris pedunculo longiore quam appendice caudali. Appendix caudalis parva et integra."

Gen. VI. *Cleippides*. "Mandibulæ articulo palpi 3tio perlato et brevi. Maxillæ 1mi paris lamina interiore elongata, in margine interiore setis multis plumosis instructa. Pedes maxillares lamina exteriore spinis elongatis plumosis armata; palpis brevibus, latis. Epimera qvatnor anteriora parva. Antennæ flagellis elongatis, multiarticulatis; superiores inferioribus longiores. Pedes 1mi et 2di paris manu parva. Pedes trium parium ultimorum articulo 1mo non multo dilatato. Pedes saltatorii ultimi paris pedunculo elongato. Appendix caudalis integra."

Gen. VII. *Laothoës*. "Mandibulæ articulo palpi 3tio perlato, dimidiæ longitudinem articuli 2di ferme æqvanti. Maxillæ 1mi paris lamina interna parva, ovali, in margine setis plumosis panceis instructa; palpo unarticulato, parvo. Maxillæ 2di paris laminis angustis. Pedes maxillares lamina interna longitudinis mediocris, in apice dentibus tribus armata; lamina externa permagna, in margine interiore dentibus multis, parvis sed firmis, apicem versus paulo majoribus, armata; palpo parvo, parum modo longiore quam lamina externa; articulo palpi ultimo ungviformi. Corpus elongatum, angustum, non carinatum; capite inflato; epimeris parvis; epimero 4to altiore sed breviore quam 5to. Antennæ pedunculis brevibus;

flagellis praelongatis, multiarticulatis; superiores inferioribus longiores. Pedes 1mi 2diqve paris graciles, longitudine et forma fere æqvales. Appendix caudalis *integra*."

Subfam. XV. Gammarinæ. Gen. X. *Melphidippa*. "Mandibulae palpo brevi atqve perangusto; articulo palpi 3tio breviore qvam 2do. Maxillæ 1mi paris lamina interiore sat lata, non vero longa, in margine interiore setis compluribus plumosis instructa. Pedes maxillares palpis angustis, elongatis; lamina exteriore brevi, lata, in margine interiore dentibus paucis, parvis armata. Corpus elongatum, maxime postabdomen. Segmenta postabdominis in margine posteriore dentibus majoribus aut minoribus armata. Epimera sat parvula. Antennæ elongatae, graciles; superiores et inferiores longitudine fere æqvales. Pedes angusti, elongati; pedes 1mi et 2di paris manu subcheliformi, parva; pedes trium parium ultimorum articulo 1mo parum modo dilatato. Pedes saltatorii ultimi paris ultra finem eorundem 1mi et 2di paris longe producti. Appendix caudalis elongata, plus minusve fissa."

Subfam. XVI. Ampeliscinæ. Gen. III. *Byblis*. "Oculi qvatuor. Mandibulae articulo palpi 3tio multo breviore qvam articulo 2do angusto. Pedes maxillares articulo palpi 3tio vix dilatato. Epimera minora qvam apud genera præcedentia [Ampelisca and Haploops]. Antennæ inferiores articulo pedunculi 1mo et 2do extus visibilibus, in incisura capitis sitis. Pedes 7mi paris articulo 1mo deorsum et postice perdilatato; articulo 3tio brevi; articulo 4to et 5to elongatis. Pedes saltatorii ultimi paris perbreves. Appendix caudalis brevis, lata, parum fissa."

Subfam. XVII. Leptocbeirinæ. Geu. II. *Goësia*. "Corpus subdepressum; epimeris uon altis; epimero 2do minore qvam apud genus Leptocheirus. Antennæ superiores flagello accessorio fere obsoleto. Pedes 2di paris iisdem 1mi paris validiores, sed non multo longiores, in margine anteriore setis longis plumosis instructi; manu magna, subcheliformi; carpo nou prælongato. Cæteroqvin ferme ut apud genus Leptocheirus."

Subfam. XVIII. Photinæ. Gen. III. *Xenoclea*. "Antennæ superiores articulo pedunculi 3tio elongato; flagello accessorio absenti. Pedes 1mi paris carpo elongato. Pedes 3tii et 4ti paris articulo 1mo latissimo. Pedes saltatorii ultimi paris biramei; ramis invicem longitudine fere æqvalibus. Appendix caudalis in apice insinuata."

Subfam. XXI. Podocerinæ. Gen. II. *Janassa*. "Mandibulae palpo perlato, non vero longo; articulo palpi 3tio obovato. Antennæ robustæ, setis densis instructæ; superiores flagello perbrevis, ex articulis paucis (3) constanti; articulo ejusdem 1mo perlongo; flagello accessorio fere obsoleto. Antennæ inferiores superioribus multo longiores et crassiores; flagello ex articulis paucis constanti; articulo ejusdem 1mo permagno, prælongato. Corpus subdepressum; epimeris parvis. Reliqva cum genere Podocerus ferme conveniunt."

Fam. IV. Dulichidæ. Gen. II. *Paradulichia*. "Antennæ multo breviores qvam apud genus Dulichia. Pedes saltatorii ultimi paris 1ramosi; ramo minimo. Reliqva cum genere præcedenti conveniunt."

Gen. IV. *Xenodice*. "Pedes maxillares 2di paris lamina interiore magnitudinis mediocris, in margine interiore setis pluribus (7) instructa. Antennæ superiores et inferiores longitudine fere æqvales; flagellis multiarticulatis sed multo brevioribus qvam pedunculo. Antennæ superiores flagello accessorio instructæ. Pedes 1mi 2diqve paris magnitudine et forma fere æqvales; manu parva, subcheliformi. Pedes 3tii et 4ti paris ejusdem magnitudinis, elongati. Pedes trium parium posteriorum longitudine gradatim crescentes, filiformes. Pedes saltatorii 1mi 2diqve paris elongati, biramei."

Fam. V. Caprellidæ. Subfam. II. Cyaminæ. Geu. I. *Platycyamus* (Liitken), "distinguitur a *Cyamus* propriis annulo primo corporis a capite sejunctb, pedibusqve primi paris pedes secundi paris fere æqvantibus hisceque antepositis."

It may be proper to observe that the generic characters above quoted are more or less dependent

on the characters of the families and subfamilies, which Boeck describes at great length. Occasionally there are discrepancies between the one set of characters and the other, which is excusable in so comprehensive a work. For instance, the character of *Platycyamus* does not suit the words "segmento truncis lmo cum capite coalito" included in the definition of the family Caprellidæ. Several of the subfamilies have been by some accident wrongly numbered in the original.

1870. BRADY, GEORGE STEWARDSON.

On the Crustacean Fauna of the Salt-marshes of Northumberland and Durham. Nat. Hist. Trans. of Northumberland and Durham, Vol. III., pp. 120-136. Pl. IV. V. London, 1870.

Mr. Brady says, "The higher orders of Crustacea are almost always represented in salt-marsh pools by *Carcinus mænas*, *Palæmon varians*, *Crangon vulgaris*, *Mysis vulgaris*, *Gammarus locusta*, *Corophium longicorne*, and *Sphaeroma rugicauda*; in Hylton Dene I met also with *Orchestia littorea*, and at Seaton Sluice with *Oniscus asellus*." In the "debateable ground" between fresh and brackish water at Hylton Dene he found *Corophium longicorne* along with *Palæmon varians* and *Mysis vulgaris*.

1870. DOHRN, ANTON.

Die Ueberreste des Zœa-Stadiums in der ontogenetischen Entwicklung der verschiedenen Crustaceen-Familien. Jenaische Zeitschrift für Medicin und Naturwissenschaften. Bd. V. pp. 471-491.

"He regards the dorsal spine as a very essential character of *Zœa*, and thinks that the dorsal accumulations of cells in the embryos of some Isopods and Amphipods, the so-called micropyle-apparatus in the Amphipods, the dorsal sucker of the larvæ of *Limnadia* and the *Cladocera*, the frontal fixing apparatus of *Caligus* and *Chalimus*, and the peduncle of the Cirripeds are to be regarded as transformations of the dorsal spine of *Zœa*" (Dr. von Martens in Zoological Record for 1870).

1870. LARZYNISKY, TH.

Praemissus catalogus Crustaceorum amphipodum, inventorum in mari albo et in mari glaciali ad litus murmanicum anno 1869 et 1870. S. Petersburg, L. Universität. Zool. Museum. Tome i. Pt. ii. pp. 315-316. St. Petersburg, 1870.

In all, fifty-two species are named in this catalogue, but, as usual in such lists, some deduction must be made from the total, on the score of synonyms entered as separate species. Notice is given, without any description, of *Montagua variegata*, n. sp., " *Lysianassa Gœlesi*," n. sp., " *Ampelisca Koreni*," n. sp., " *Oediceros Brandtii*," n. sp., *Uruios*, n. gen., *Uruios viridis*, n. sp., with the remarks "similis Gammaro longicaudæ Brandt (mari Ochotico). Hab. mari glaciali ad litus murmanicum (ad insulas Gavrilenses)," and " *Dulichia Malmgreni*," n. sp.

It is not easy to see what object is served by publishing names of undescribed species and genera, which neither convey any information of importance, nor can reasonably establish any claim to priority of discovery.

1870. MALM, August Wilhelm, born 1821, died March 4, 1882 (Hj. Théel).

Om två för vetenskapen nya Amfipod-species från Bohuslän, af hvilka det ena är typ för ett nytt genus inom Pontoporeinernas grupp. Öfversigt af Kongl. Vetenskaps Förfhandlingar, 1870. No: 6. Stockholm. pp. 543–548. Tafl. v.

This short paper describes a new genus, *Boeckia*, which is said to come close to *Pontoporeia*, Kröyer; *Boeckia typica*, n. sp., in which the second gnathopod has a very long wrist and a very short hand, with the side-plate covering that of the first gnathopod and exceeding in size each of those that follow it. There is further a description of "*Pardalisca Boeckii*," n. sp., and figures of both species.

The new genus *Boeckia* is thus described:—"Epimera primi paris ab iis secundi paris occulta, haec omnium maxima. Carpus pedum secundi paris valde elongatus; manus perbrevis, vix prehensilis. Pedes quinti, sexti, septimi paris longitudine sensim accrescentes; articulus primus paris septimi parum dilatatus. Pedes saltatorii perbreves, aculeis validis armati. Appendix caudalis perbrevis, postice leviter emarginata, non vero fissa. Lamina interior maxillæ primi paris elongata, perparum lata, extremitato setis nonnullis prædita. Pedes maxillares elongati; lamina exterior angusta, margine interiore dentibus elongatis instructo; articuli palpi graciles." The genus is named in honour of Axel Boeck, who mentions *Pardalisca Boeckii* both in 1870 and in his later work, but in neither takes any notice of the genus *Boeckia*. Yet the description which Boeck himself gives of *Leptocheirus pilosus*, Zaddach, tallies so completely with Malm's figures of *Boeckia typica*, as to leave no doubt that they refer to the same species. Since, however, Malm's name is not included in Boeck's list of authors, and his name only, without the title of his work, is cited as authority for *Pardalisca Boeckii*, it is possible or even probable that the work itself for some reason never came into Boeck's hands.

1870. MARTENS, EDUARD VON.

Crustacea. The Record of Zoological Literature. 1869. Volume Sixth. London, MDCCCLXX. pp. 598–623.

1871. CUNNINGHAM, ROBERT OLIVER, born March 27, 1841 (R. O. C.).

Notes on the Reptiles, Amphibia, Fishes, Mollusea, and Crustacea obtained during the Voyage of H.M.S. "Nassau" in the years 1866–69 (Plates LVIII., LIX.). Read June 16th, 1870. The Transactions of the Linnean Society of London. Vol. XXVII. London, MDCCCLXXI. pp. 465–502.

Under Amphipoda, page 497, he mentions the following species:—"61. *Orchestoidea tuberculata*, Nic. Common on the sandy beach of San Carlos de Ancud, Chiloe." "62. *Allorchestes patagonicus*, n. sp. (Pl. LIX. fig. 14). A single specimen of an *Allorchestes*, apparently undescribed, was taken by me in a freshwater stream in the neighbourhood of the Chilian settlement of Punta Arenas (Sandy Point) in the Strait of Magellan. Unfortunately it is considerably injured; so I abstain from describing it, and content myself with bestowing upon it the above provisional name." It may be presumed that this is some species of *Hyalella*. The figure appears to give nine pereon-segments with ten side-plates attached to them. "63. *Atylus?* *Batei*, n. sp. (Pl. LIX. fig. 9). Cephalon not produced into a rostrum. Eyes oblique. A mesial dorsal carina. Last segment of pereion, and first four of pleon, produced into dentiform processes." "A single specimen from Possession Bay, Strait of

Magellan." In the figure the last segment of the peraeon, the first two and the fourth of the pleon, are produced into dentiform processes. It is likely enough that it is identical with, or at most a variety of the species next mentioned. "64. *Atylus Huxleyanus*, Bate. Taken in the Strait of Magellan." "65. *Themisto antarctica*, Dana. Taken in numbers in the towing-net between the river Plate and the Strait of Magellan, during a calm which succeeded a violent gale, in November 1867." "66. *Iphimedia Normanii*, n. sp. (Pl. LIX. fig. 7). Cophalou produced into a sharp-pointed rostrum. First three segments of pleon having a sharp-pointed tooth on each lateral margin. Eyes subreniform. Superior and inferior antennae of nearly equal length. Colour purplish. Length 4 lines. One specimen of this species, named in honour of the Rev. A. M. Norman, was dredged off Elizabeth Island in February 1867." The figure shows a peraeon of six segments with only five side-plates! Neither figure nor description is adequate for the determination of a species. "67. *Caprella dilatata*, Dana. Taken in numbers on the screw of H.M.S. 'Nassau' in August 1867." Daua's species is considered by Mayer to be the same as *Caprella acutifrons*, Latreille.

1871. BRANDT, ALEXANDER.

Ueber die Haut der nordischen Seekuh (*Rhytina borealis* Illig.). Mémoires de l'Académie impériale des sciences de St. Pétersbourg. Sér. VII. t. XVII. No. 7.

1871. pp. 17-23, fig. 17-19.

Dr. Brandt supposes a piece of whale-skin beset with *Cyami* which he found in the St. Petersburg Museum to be the skin of the extinct *Rhytina borealis* bearing the parasite for which J. F. Brandt proposed the genus *Sirenocystamus*. He notices the great similarity between the specimens thus found and *Cyamus ovalis*, Roussel de Vauzème, and Lütken subsequently came to the conclusion that the supposed "*Cyamus Rhytinæ*" was actually *Cyamus ovalis*, attached to the skin, not of *Rhytina borealis*, but of *Balaena japonica*.

1871. BUCHHOLZ, RUDOLPH.

Erlebnisse der Mannschaft des Schiffes Hansa. Königsberg, 1871.

"*Gammarus arcticus* and *Themisto borealis* occur in large swarms in the Arctic Sea, and form the principal food of many marine animals, probably also of the Right Whale." pp. 3-5.

1871. CLAUS, C.

Untersuchungen über den Bau und die Verwandtschaft der Hyperiden. Nachrichten von der K. Gesellschaft der Wissenschaften und der Georg-Augusts-Universität aus dem Jahre 1871. pp. 149-157. Göttingen, 1871.

This paper describes the discovery of an organ of hearing in the Oxycephalidae, and many other details of great interest; alludes to *Phronima elongata* under the new name *Phronimella*

elongata; brings *Oxycephalus oceanicus*, Guérin, as a male not fully developed, under *Oxycephalus piscator*, Edw.; assigns *Rhabdosoma whitei*, Sp. Bate, as the male form, to *Rhabdosoma armatum*, Edw.; describes *Oxycephalus tenuirostris*, n. sp.; *Simorhynchus*, n. g.; *Simorhynchus antennarius*, n. sp.; *Schnehagenia*, n. g., afterwards recognised as = *Thamyris*, Sp. Bate; *Schnehagenia rapax*, n. sp.; and in conclusio remarks that the genus *Synopia*, Dana, belongs not to the Oxycephalidae, but to the Gammaridae.

For the descriptions of the geuera, etc., see Notes on Claus, 1879.

1871. COPE, EDWARD DRINKER, born July 28, 1840 (S. I. Smith).

Life in the Wyandotte Cave. The Annals and Magazine of Natural History. No. 47, for November 1871. Vol. VIII. Fourth Series. London, 1871. pp. 368–370.

This accouut, borrowed from "Indianapolis Journal, Sept. 5, 1871," refers to a Gammaroid Crustacean, not found in the Wyandotte Cave, but in the waters of the Mammoth Cave. Cope afterwards called it *Stygobromus vitreus*. See Note on Cope, 1872.

1871. DARWIN, CHARLES, born February 11, 1809, died April 19, 1882.

The Descent of Man, and Selection in relation to sex. Second edition. 1885. (First Edition, 1871.)

Remarks bearing on the Amphipoda are made in "Chapter VIII. Principles of Sexual Selection," and "Chapter IX. Secondary Sexual Characters in the Lower Classes of the Animal Kingdom." See pages 209, 233, 237, and especially 265–271, in which Fritz Müller's "Facts and Arguments for Darwin" are utilized, together with information received from Mr. Spence Bate.

On page 485, note 39, these observations are made, "Fritz Müller has shewn ('Facts and Arguments for Darwin,' Eng. Trans. 1869, p. 79) that the males of several Amphipod Crustaceans become sexually mature whilst young; and I infer that this is a case of premature breeding, because they have not as yet acquired their fully developed claspers. All such facts are highly interesting, as bearing on one means by which species may undergo great modifications of character."

On page 568 Darwin says, "an ear to be capable of discriminating noises—and the high importance of this power to all animals is admitted by every one—must be sensitive to musical notes. We have evidence of this capacity even low down in the animal scale; thus Crustaceans are provided with auditory hairs of different lengths, which have been seen to vibrate when the proper musical notes are struck. (Helmholtz, Théorie Phys. de la Musique, 1868, p. 187)."

Geschichte des Krebstammes, nach embryologischen, anatomischen und palaeontologischen Quellen. Jenaische Zeitschrift für Medicin und Naturwissenschaften Bd. VI. pp. 95–156.

An account of this paper is given in the Zoological Record for 1870, by Dr. von Martens.

1871. GRUBE, A. ED.

Mittheilungen über St Malo und Roscoff, und der dortigen Meeres-, besonders Annelidenfauna. Abhdl. d. Schles. Ges. f. vaterl. Cultur, (1870-72), 1872.

According to Dr. von Martens, in the Zool. Record for 1871, he enumerates sixty-two species of Crustacea, observed in the neighbourhood mentioned, and describes "*Urothoe marinus*," Sp. Bate, p. 55, pl. ii. fig. 4.

1871. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1870; being volume seventh of the Record of Zoological literature. London, M.DCCC.LXXI. pp. 188-206.

1871. METZGER, AD.

Die wirbellosen Meeresthiere der ostfriesischen Küste. Jahresbericht der naturforschenden Gesellschaft zu Hannover. No. XX. for 1869-70. pp. 31-33. Abstract, Archiv f. d. gesammt. Naturwiss. xxxvi. Bd., 1870, pp. 523-526.

According to Dr. von Martens, in the Zool. Record for 1870, he gives a list of Crustacea observed hitherto on the coast of East Friesland (between the mouths of the rivers Ems and Jade), containing nineteen Amphipoda, including two Læmodipoda. He describes "*Orchestia*, sp., from the strand of East Friesland, allied to *A. [O.] mediterranea*, and supposed to be perhaps a second male form of *O. littorea*, Leach." "*Bathyporeia*, sp., dredged and found in the stomach of haddocks," is shortly indicated; so also, "*Podocerus*, sp., frequent between Sertulariae in the Estuaries." The number was not obtainable at the British Museum Library.

1871. METZGER, AD.

Die wirbellosen Meeresthiere der ostfriesischen Küste. Zweiter Beitrag. Ergebnisse der im Sommer 1871 unternommenen Exeursionen. Einundzwanzigster Jahresbericht der Naturhistorischen Gesellschaft zu Hannover, von Michaelis 1870 bis dahin 1871. Hannover, 1871.

The Amphipoda are referred to on pages 28-32. *Atylus falcatus*, n. s., is thus described:—
"♀. Carina segmenti postabdominis 4ti dentes duos, anteriorem minorem quam posteriorem, formans. Oculi ovales nigri. Rostrum frontale parvum, subrectum. Antennæ inferiores superioribus longiores, longitudinem animalis dimidiam fere æquantes, articulo quinto longiore quam quarto.

"Pedes 2di paris longiores et parum angustiores quam 1mi paris, manu ferme eadem longitudine ac carpo.

"Pedes 3tii paris articulo quarto perbrevi, multo breviore quam quinto; articulo utroque conjunctis longitudinem tertii vix æquantibus; articulo quinto subcurvato, in margine interiore basin versus spinis validis et obtusis armato; ungue pervalido, incurvato (falcato).

"Pedes 4ti paris articulo quarto perbrevi, articulis quarto et quinto conjunctis multo brevioribus quam tertio; articulo quinto subrecto, ungue parvo.

"Pedes 5, 6 et 7mi paris articulo quarto eadem ferme longitudine ac tertio, longitudinem quinti multo superanti.

"Appendix caudalis duplo longior quam ad basin lata, fere usque ad radicem fissa; laciua utraque in apice spinis singulis armata.

"Longitudo animalis 10 mm."

It can be recognised at the first glance, Metzger says, by the great sickle-shaped finger of the first pereopod. The upper antennae are somewhat shorter than the lower. The hinder edges of the three first pleon-segments are slightly crenulate, their lower angles are almost rectangular, and only a little drawn out posteriorly. (The species described under the name *Atylus uncinatus* by G. O. Sars, in 1882, seems to be identical with Metzger's *Atylus falcatus*. It must, I should think, belong to the genus *Tritaea*, Boeck, but, as unfortunately neither description takes note of the mandibles, the generic position is left a little uncertain.)

The male of *Bathyporeia pilosa*, Lindström (*Bathyporeia pelagica*, Bate) is not rare, he says, "im flachen Wasser am Straude der Inseln und selbst im Wattenmeere (Osterems, Memmertsbalge)," but with the female he has never happened to meet. (On British coasts, *in the sand, uncovered by the tide*, I may notice that the female is far more frequent than the male.)

He confirms the supposition that "Megamoera Alderi," Bate, is the female of *Melita proxima*, Bate.

Nænia excavata, Bate, is found along with *Nænia rimapalmata*, Bate, the latter the more rare.

Siphonocetes cuspidatus, n. s., is thus described:—"Rostrum frontale gracile, aculeiforme, paulo longius quam anguli laterales capitidis, oculos gerentes. Antennæ iuferiores longitudine animalis parum modo breviores.

"Pedes 1mi paris vix longiore quam carpo oblongo.

"Pedes 2di paris manu multo longiore quam carpo triangulari.

"Pedes 3 et 4ti paris articulo tertio paulo longiore quam lato; ungue longitudinem articuli quarti et quinti junctorum aequanti.

"Ramus exterior pedum saltatorins. 1mi paris in margine exteriore spinis brevibus circiter 8 instructus, in margine interiore inermis; ramus interior in margine exteriore spiculis 3 armatus, in margine interiore minutissime denticulatus.

"Pedes saltatorii ultimi paris ramo parvo rotundato, eadem fere latitudine ac longitudine.

"Appendix caudalis spatiis binis scabridis instructa. Longitudo animalis 6 mm.

In further description he says, among other things, "das erste Fusspaar zeigt einen ovalen, am Ende abgestutzten Carpus, dessen innere Vorderecke mit einem längern Dorn versehen ist; die Hand ist kaum so lang wie der Carpus, und der schräge Palmarrand mit zwei grösseren Dornen bewaffnet, zwischen welche der an der Innenseite sägeähnige Flieger einschlägt. Das zweite Fusspaar ist etwas kräftiger als das erste, der dreieckige Carpus kürzer als die Hand und an dem nach innen gerichteten Winkel mit einem kurzen aber kräftigen Dorn endet." At the first glance Metzger took it for a species of *Corophium*.

1871. SARS, G. O.

Beskrivelse af de paa Fregatten Josephines expedition funde Cumæeer. K. Svenska Vetenskaps-Akademiens Handlingar. IX. no. 13. 1871.

"G. O. Sars states that in several genera of *Crustacea* there are two sorts of males, one nearly resembling, the other very different from, the females; the former is much more common and may be found all the year round, the other only in one season; the latter may be the fully developed and the former the incomplete stage of the male. This has been observed in *Diastylis*, *Pontoporia*, *Apseudes*, and *Philomedes*, and exists therefore in very different orders." (Dr. von Martens in Zool. Record for 1872.)

Compare Note on Faxon, 1884, and Note on Chilton, 1885.

1871. SMITH, SIDNEY IRVING, born February 18, 1843 (S. I. S.).

Dredging in Lake Superior under the direction of the U. S. Lake Survey.
pp. 373-374. Number XI.

Notice of the Invertebrata dredged in Lake Superior in 1871, by the U. S. Lake Survey, under the direction of Gen. C. B. Comstock, S. I. Smith, naturalist,
by S. I. SMITH and A. E. VERRILL. pp. 448-454. Number XII. *The American Journal of Science and Arts.* New Haven, 1871.

Along with *Mysis relicta*, Lovén, *Pontoporeia affinis*, Lindström, "was found at every haul from the shallowest to the deepest." *Crangonyx gracilis*, Smith, n. s., was also taken, and is here described, with the remark that "the incubatory lamellæ of the female are very large, projecting much beyond the coxae of the anterior legs, as in *C. recurvatus*, Grube, which our species much resembles in the form of the antennulae, antennæ, gnathopoda, etc., while it differs much in the ultimate pleopoda and in the form of the telson." *Gammarus lacustris*, Smith, n. s., length 15 to 20 mm., is also here described. It was afterwards named *Gammarus limnæus*.

1871. TROSCHEL, FRANZ HERMANN, born October 10, 1810, died November 6, 1882
(P. Bertkau).

Handbuch der Zoologie. 7th Ed. 1871.

Mayer notices the inaccurate supposition, page 515, that the pleon is *entirely* wanting in the Caprellidæ.

1871. WOODWARD, HENRY, born November 24, 1832 (H. W.).

On *NECROGAMMARUS SALWEYI* (H. Woodward) an Amphipodous Crustacean from the Lower Ludlow of Leintwardine. (February 23, 1871.) *Transactions of the Woolhope Naturalists' Field Club.* 1870. Hereford, MDCCCLXXI. pp. 271, 272, and Plate.

It is explained that the Crustacean fragment, on which this new genus and species were founded "was noticed and figured in Messrs. Huxley and Salter's important work on the Eurypteridæ (Memoirs of the Geological Survey, Monograph I., 1859, p. 25, pl. XIII., Fig. 7). Professor Huxley observes, 'The fossil figured is evidently Crustacean, but it exhibits no character by which it can be identified as a part of a *Pterygotus*.' (See Fossil Sketches, No. 11, Fig. 2.)"

"It presents us with the side-view or profile, of what appear to be three laterally-compressed and thin-crusted somites or body-rings." The feet "are articulated along the border" of the somites. From the dorsal line to the border these somites are said to measure between $1\frac{3}{4}$ and $2\frac{1}{4}$ inches, while from front to back they measure 10 or 11 lines.

"The third segment (*c*) is 10 lines broad and measures 2 inches from the dorsal line to the sharply-pointed epimeral border; from the posterior side of this the limb (*c* 3) is given off of which six joints are visible, the first or basal joint not being seen. Joint (2) is broadly rounded, joint (3) is narrower and more elongated; joint (4) is hollowed out to receive joint (5) which is larger but similar in form to (4) and also to joint (6) which is, however, the smallest of the three [;] joints 4, 5, and 6 have each their distal borders sharply pointed. The 7th and terminal joint is a simple claw, not chelate. The total length of this entire appendage is 2 inches."

It is referred "to the order Amphipoda—Normalia and to the division *Gammaridæ* among some of the natatorial forms of which occur limbs not unlike the fossil before us." It is therefore named "*Necrogammarus Salweyi*, after its discoverer." What forms among the *Gammaridæ* are here intended it is not easy to guess. The appendage as figured is more suggestive of an antenna or limb of an Isopod than of any form with which I am acquainted among the limbs of the *Gammaridæ* or any other division of the Amphipoda *Gammarina*. The combination of a transverse first "(2)" joint with a second "(3)," of great relative size, articulated to the middle of it, is, I should say, quite unknown in the group, and almost impossible as an ancestral character.

1872. BOECK, AXEL.

Bidrag til Californiens Amphipodefauna. Særskilt Aftryk af Forhandlinger i Videnskabs-Selskabet i Christiania Aar 1871. Christiania 1872. pp. 32–51.

The species described are *Caprella californica*, Stimpson = ?? *Caprella linearis*, see Mayer, Caprelliden, p. 79; *Caprella verrucosa*, A. Boeck = ? *Caprella acanthifera*, Leach, juv., see Mayer, Capr., p. 82; *Erichthonius rapax*, Stimpson, which Boeck transfers (erroneously) to the genus *Cerapus*; *Podocerus californicus*, A. Boeck; "Amphilhoe Stimpsoni," A. Boeck; "Paramphilhoe Bairdi," A. Boeck, and "Metopa Esmarki," A. Boeck. An explicatio tabulæ concludes the paper, but unfortunately the plate to which the explanation refers never appeared. The report of the Society's meetings during 1871 states, under March 10th, p. 532, that "A. Boeck indleverede Tegninger af 6 nye Arter Amphipoder, som Esmark havde sendt ham fra Californien, og fremsatte nogle Bemerkninger om Amphipodernes Udbredelse og Udseende i de forskjellige Egne af Jorden." If the drawings are still in existence, it is very desirable that they should be published.

1872. BOECK, AXEL.

De Skandinaviske og Arktiske Amphipoder, beskrevne af Axel Boeck. Förste Hefte. (Méd 7 Kobberstukne Tavler.) Christiania, 1872. pp. 1–160.

This, and the succeeding volume published in 1876, constitute a work of vast labour and research, of foremost importance to the student of the Amphipoda. The introductory part contains, first, a general account of the bodily structure in this group, dealing chiefly with the mouth-organs, on which Axel Boeck laid special systematic weight; secondly, an alphabetical list of nearly three hundred authors with the titles of their works relating to the Amphipoda, down to the year 1870; and thirdly, a chronological review of the development of this branch of natural history from Aristotle down to the year 1855. It winds up with an article on the geographical distribution of the Amphipoda, and an account of various systems, including the author's own, which have been proposed for the classification of this group.

It is to be regretted that this ingenious author should have in some cases thought it necessary to ground generic distinctions on very minute differences; and it sometimes detracts from the pleasure and facility of consulting his accurate plates, that many of the figures are exceedingly small, and that not unfrequently the parts of animals in different genera are represented in embarrassing confusion on the same plate. Most of all it is to be regretted that by his early death this author was prevented, not only from putting the last touches and corrections to his almost completed work, but from further pursuing a study in which there is so much still to be done, and in which he was so eminent a master.

To the following Table, drawn from Boeck's work, I have only added, for facility of reference, the numbers of the pages on which the several groups are described :—

Divisioner.	Familier.	Underfamilier.
<i>Amphipoda</i> <i>Hyperina</i> , p. 76.	{ Hyperidæ, p. 77. Tryphanidæ, p. 90.	
	{ Prostomatidæ, p. 95. Orchestidæ, p. 99.	
	Gammaridæ, p. 111.	{ Lysianassinæ, p. 112. Pontoporinæ, p. 194. Phoxinæ, p. 212. Œdicerinæ, p. 254. Epimerinæ, p. 227. Dexaminiæ, p. 310. Atylinæ, p. 320. Gammarinæ, p. 362.
<i>Amphipoda</i> <i>Gammarina</i> , p. 94.	Leucothoidæ, p. 418.	{ Stegocephalinæ, p. 419. Amphilochinæ, p. 430. Stenothoinæ, p. 445. Syrrhoïnæ, p. 470. Pardaliscinæ, p. 480. Leucothoinæ, p. 494. Iphimedinæ, p. 235.
	Ampeliscaidæ, p. 516.	
	Photidæ, p. 546.	{ Leptocheirinæ, p. 546. Photinae, p. 552. Microdeutopinæ, p. 563.
	Podoceridæ, p. 586.	{ Amphithoinæ, p. 586. Podocerinæ, p. 598.
	Corophidæ, p. 619.	{ Corophinæ, p. 621. Helainæ, p. 642.
	Cheluridæ, p. 645. Dulichidæ, p. 649.	
<i>Amphipoda</i> <i>Caprellina</i> , p. 668.	{ Caprellidæ, p. 669. Cyamidæ, p. 703.	

There are no new species described in this volume, but the descriptions of those already known and the attendant observations are of the highest value.

Of the family Prostomatidæ he gives the following definition :—" Instrumenta cibaria valde prominentia et conjuncta processum 3 fissum, tubiformem formantia. Labium superius prælongatum, angustum. Mandibulæ styliformes, acutæ, palpis longis triarticulatis instructæ. Maxillæ angustæ, elongatæ, in apice acuminatæ. Pedes maxillares laminis interioribus angustis, exterioribus brevibus et latioribus; articulo palpi 4to longo, non ungviformi. Corpus compressum, latum; epimeris latis. Antennæ superiores breves, flagellis accessoriis instructæ. Pedes 1mi paris manu pervalida subcheliformi. Pedes 2di paris elongati, angusti; manu subcheliformi, parva. Pedes saltatorii biramei; ramis latis. Appendix caudalis parvula."

The genus *Trischizostoma* is thus defined:—"Caput antice in rostrum frontale crassum, latum, in apice rotundatum, produncum. Antennae inferiores articulato 4to longitudinem 5ti superanti. Pedes 1mi paris manu permagna, inflata, ovata; ungues non in angulo inferiore anteriore, ut solito, sed in angulo inferiore posteriore inarticulato, antice verso. Pedes 4ti paris articulato 3to valde dilatato et latiore quam pedum 3ti paris. Epimerum 1mm parvum. Epimerum 2dum deorsum valde dilatatum, 1mum partim tegens. Oculi magni. Appendix caudalis lata." In regard to this genus see Note on Costa, 1853.

1872. BRANDT, ALEXANDER.

Bericht über die Cyamiden des zoologischen Museums der Kaiserlichen Akademie der Wissenschaften zu St Petersburg. 23 Mai
4 Juni 1872. Mélanges Biologiques tirés du Bulletin de l'Académie impériale des sciences de St.-Pétersbourg. Tome VIII. pp. 673-702. (Aus dem Bulletin, T. XVIII, pp. 113-133. Oct. 1872.)

A new species, "*Cyamus Kessleri*," is figured and described, with the following diagnosis, "Corpus maris pyriforme, feminæ obverso-pyriforme vel rhomboideum. Maris primi paris manus dente armatae, feminæ fere edentulae. In utroque sexu manus secundi paris duabus dentibus munitæ, quorum basalis multo major. Branchia simplicia, elongata, longitudine corporis fere æquantia. In mare appendicem branchialium sex paria inæqualia. Habitat in sinu Metshigensi Maris Beringii, in Balænus." Lütken considers that the accessory branchiae on the third and fourth segments are double, not triple, and that Brandt has confused with these appendages the postero-lateral angles of the segment which form a process bent downwards and forwards.

Cyamus ovalis, Ronssel de Vanzème, is recognised as including "*Cyamus Rhytinæ* (?)" which in 1871 Brandt supposed that he had re-discovered, though with notice of its great resemblance to *Cyamus ovalis*.

The name *Cyamus ceti*, anctorum, is upheld for *Oniscus ceti*, Lin., against the proposal of Lütken to institute the designation *Cyamus mysticeti*. For *Cyamus ceti*, Sp. Bate (Catal. Amph. Crust. p. 366, pl. lviii. fig. 2), a very narrow elongate form from Talcahnna, which has nothing in common with *Oniscus ceti*, Lin., he gives a name proposed by Lütken, *Cyamus pacificus*. Without absolutely deciding, Brandt seems inclined to regard *Cyamus monodontis*, Lütken, as a variety of *Cyamus ceti* (to which Lütken himself regards it as "valde affinis"), and to agree with Bate and Westwood (Brit. Sess. Crust. vol. ii. p. 86) in making *Cyamus erraticus*, Ronssel de Vanzème, a synonym of the same *Cyamus ceti*, which Lütken regards as a very decided error. Brandt notes that *Cyamus boopis*, Lütken, is recognised by its author as in close relationship to *Cyamus erraticus*, and this latter he is willing to regard as a link between *Cyamus ceti* and *Cyamus boopis*, leaving it perhaps an open question whether they may not all be one species. *Cyamus globicipitis*, Lütken, he thinks probably identical with "*Cyamus Delphini*," Guérin (Icon. dn Règne Anim. T. III. p. 25, pl. xxviii. fig. 5). Remarks are made on *Cyamus nodosus*, Lütken, and *Cyamus gracilis*, Ronss. de Vauzème. *Cyamus thompsoni*, Gosse, which Lütken transferred to a new genus, under the name of *Platyceyamus thompsoni*, Brandt would have been content to leave united to the other *Cyami*.

1872. CLAUS, C.

Zur Naturgeschichte der *Phronima sedentaria* Forsk. Mit Tafel xxvi. xxvii. Zeitschrift für wissenschaftliche Zoologie. Bd. XXII. pp. 331–338.

Claus here states his conviction that the cell inhabited by *Phronima* is derived exclusively from smaller or larger specimens of *Pyrosoma* eaten out for the purpose. He describes the differences presented by the male form of *Phronima sedentaria*. Guérin's *Phronima atlantica* he regards as nothing but "das noch jugendliche, kleine, aber doch schon fort-pflanzungsfähige Weibchen" of the same species, and thinks that Spence Bate did wrong in giving a separate specific name, "*Phronima Borneensis*," to White's variety of *Phronima atlantica* from Borneo. Compare Note on Streets, 1877.

Referring to his own earlier observation of rudiments of a second pair of antennæ on the head of the young *Phronimella elongata*, he says that he wrongly concluded that the Phronimidae in general might have both pairs of antennæ in rudiment to start with, the females eventually developing only the front pair. He found, however, that in the little, sexually indifferent, young ones of *Phronima sedentaria* there was no trace of the hinder pair; in individuals 4 mm. long sexual difference was shown in the front antennæ, and in larger forms the position of the coming second pair of antennæ was indicated. The sexual organs of the male are described and figured.

1872. COPE, E. D.

Descriptions of species from the Mammoth Cave. The American Naturalist. Vol. VI. July, 1872.—No. 7. Vol. VI. Salem, Mass. Peabody Academy of Science, 1872. pp. 421–422.

The new genus which Cope established for the Gammarid, which he found in the Mammoth Cave, is thus described:—

"*Stygobromus*, Cope, Gen. nov. *Gammaridarum*. Near *Gammarus*. The first antennæ with flagellum, and much shorter than the second. Two pairs of limbs chelate by the inflexion of the last claw-like segment; other limbs clawed. Terminal abdominal segment very short, spiniferous; the penultimate segment with a stout limb with two equal styles, the antepenultimate short, two-jointed and undivided. Eyes none."

"This genus is nearer to the true *Gammarus* than the allied genus described from the Austrian Caves, the *Niphargus* of Schiödte (Proc. Entom. Soc. London, 1851, p. 150). In the latter the first antennæ are the larger, and the body terminates in a very long style; the last abdominal limb is undivided like that which precedes it. In *Stygobromus* the penultimate limb is like that represented by Schiödte for *Niphargus*, though I am not certain whether it is homologically identical. The last limb is about equally divided, but the simple basis is long and stout."

"It is just possible that the antepenultimate limb represents the basis and one style only, for in that of one side a slight process appears at the extremity of the basal segment, though it is not visible on that of the other. The terminal limbs are recurved and appressed to the last abdominal segment, forming a fulcrum or prop. The animals of this genus are aquatic, and swim much as the common *Gammari*. The absence of eyes is another example of the adaptation to darkness."

The type species he describes thus:—" *Stygobromus vitreus*, Cope. 'Gammaroid Crustacean' Cope, Annu. Mag. Nat. Hist., Nov., 1871. Two last pairs of limbs appressed to last

abdominal bristles and of nearly equal length, forming a brush. Last segment of abdomen with two terminal bristles. Last segment of the limbs from the third to the seventh, with a long, straight claw directed forwards. Fringed limbs behind this point very small. Outer or second antennae half as long as the first, which embrace eleven segments, and are about as long as the last five abdominal segments. Total length of head and body 2·1 lines or .0045 m. There are few conspicuous hairs, the most so are those which stand at the extremity of the last joint of the limbs, rising from the base of the claw. Color translucent."

S. I. Smith, 1875, considers Cope's description very inadequate, but identifies the genus *Stygobromus* with the earlier *Crangonyx*.

1872-3. DALL, WILLIAM HEALEY, born August 21, 1845 (S. I. Smith).

Descriptions of three new species of Crustacea parasitic on the Cetacea of the N.W. Coast of America. The Annals and Magazine of Natural History. Number LXII. Vol. XI.—Fourth Series. London, 1873. pp. 157-158. (From Proceedings of the California Academy of Sciences, November 1872.)

He describes the three species as follows:—

“*Cyamus Scammoni*, n. sp.—Male. Body moderately depressed, of an egg-ovate form; segments slightly separated; third and fourth segments furnished with a branchia at each side; this, near its base, divides into two cylindrical filaments spirally coiled from right to left; at the base of each branchia are two slender accessory filaments not coiled, quite short, and situated one before and the other behind the base of the main branchia; second pair of hands kidney-shaped, with the carpal articulation halfway between the distal and proximal ends, and having two pointed tubercles on the inferior edge, before the carpal joint; third and fourth segments somewhat punctate above, all the others smooth, the sixth and seventh slightly serrate on the upper anterior edge, and without ventral spines. Colour yellowish-white. Long. .70, lat. .39 in., of largest specimen.

“Female similar to the male in all respects, except in being a little more slender, and in wanting the accessory appendages to the branchiae; the ovigerous sacs are four in number, overlapping each other.

“*Hab.* On the California grey whale (*Rhachianectes glaucus* of Cope) on the coast of California, very numerous.”

“*Cyamus suffusus*, n. sp.—Body flattened, elongate; segments subequal, outer edges widely separated; branchiae single, cylindrical, slender, with a very short papilliform appendage before and behind each branchia; superior antennae unusually long and stout; first pair of hands quadrant-shaped; second pair slightly punctate, arcuate, emarginate on the inferior edge, with a pointed tubercle on each side of the emargination; third joint of the posterior legs keeled above, with a prong below; pectoral extremely minute; segments all smooth; no ventral lines on the posterior segments. Colour yellowish-white, suffused with rose-purple, strongest on the antennae and branchiae. Length .41, breadth (of body) .25 in. All the specimens which have passed under my observation, some eight or ten in number, were males.

“*Hab.* On the ‘humpback’ whale (*Megaptera versabilis*, Cope), Monterey, California.”

“*Cyamus mysticeti*, n. sp.—Body flattened, subovate, segments adjacent; branchiae single, short, stout, pedunculated, a single papilliform appendage behind each; head short and wide; first pair of legs very small; hands all simple and smooth, fingers greatly recurved; carpal articulation in the second pair of hands halfway between the proximal

and distal ends of the hand; pleon very minute. Colour dark brownish-yellow. Length .33 in., breadth (of body) .16 in. Two female specimens.

"*Hab.* On the northern 'bowhead' whale (probably *Balaena mysticetus*, Linn.), near Behring Strait.

"This is the most compact of the three species, as well as the smallest. I find, in comparing large series of *C. Scammoni*, that a considerable variation in form obtains, so far as regards comparative length and breadth, even in adult specimens, and these differences are greater than those observed, in the same characters, between the sexes."

Lütken is of opinion that the *Cyamus mysticeti* here mentioned is the same as his own *Cyamus mysticeti*, 1870. A. Brandt, 1872, as already noticed, does not admit the propriety of giving up the old name, *Cyamus ceti*, for this species. Indeed, no names would be safe, if subsequent confusion of heterogeneous animals, under a name rightly established to begin with, were allowed to make such a name void. For "no ventral lines," in the description of *Cyamus suffusus*, Lütken thinks "no ventral spines" should be read. The species may, he supposes, be the same as his own *Cyamus pacificus*, which also lives on *Megaptera versabilis*, C.

1872-3. DALL, W. H.

On the Parasites of the Cetaceans of the N. W. Coast of America, with Descriptions of New Forms. The Annals and Magazine of Natural History. Number LXIII. Vol. XI.—Fourth Series. London, 1873, p. 238. (From Proceedings of the California Academy of Sciences, December 18, 1872.)

He here adds, in regard to *Cyamus suffusus*, "the females, which were unknown at the date of my description, now prove to resemble the male in every respect, except in regard to the sexual organs, and in being a trifle more slender in form." All the specimens came from the humpback (*Megaptera versabilis*, Cope). Dall favours "the hypothesis that each species of whale has its own peculiar parasites, and that there is rarely more than one species of *Cyamus* found upon one animal."

1872. FRIC (FRITSCH), ANTON.

Dic Krustenthiere Böhmens. Archiv für die naturwissenschaftliche Landesforschung von Böhmen. II. Prag, 1872. pp. 203-269.

Among the Crustacea which have been observed in Bohemia, and are here described, Dr. von Martens, Zool. Record for 1872, says that two Gammaridæ are included.

1872. HOY, P. R.

Deep-water Fauna of Lake Michigan. Transactions of the Wisconsin Academy of Sciences, Arts, and Letters, 1870-2. Madison, Wis., 1872. pp. 98-101. (Also in the Annals and Magazine of Natural History. Vol. XI.—Fourth Series. London, 1873. p. 320.)

He records from the stomachs of white-fish, and from dredgings at depths of 50 to 70 fathoms, three species of Amphipods determined by Dr. William Stimpson. Nothing, however, but

the names is given. They are styled "Gammarius Hoyi—Stimpson; Gammarius brevistilus—Stimpson; Gammarius filicornis—Stimpson." Gammarius is of course an accidental error for *Gammarus*. S. I. Smith, 1874, calls the first two of these species "Pontoporeia Hoyi," the third "*Pontoporeia filicornis*." See p. 433.

1872. MURIE, JAMES.

On the Skin &c. of the Rhytina, suggested by a recent Paper of Dr A. Brandt's. The Annals and Magazine of Natural History. Number LII. Vol. IX. Fourth Series. London, 1872. pp. 306–313. Pl. XIX.

Dr. Murie does not agree with some of Dr. Brandt's deductions in regard to the skin of the *Rhytina*. He quotes or refers to his remarks upon "*Cyamus Rhytinæ*," and reproduces Brandt's figures of it. But the paper was written before Lütken had criticised Brandt's supposed discovery.

1872. NICHOLSON, HENRY ALLEYNE.

Preliminary Report on Dredgings in Lake Ontario. The Annals and Magazine of Natural History. Number LVIII. Vol. X. Fourth Series. London, 1872. pp. 276–285.

Under Crustacea he enumerates two species of *Gammarus*, one of *Crangonyx* ?, and *Pontoporeia affinis*, Lindström. The specimens to which he applies the last name are, he says, "small Amphipods varying in length from $\frac{1}{10}$ up to $\frac{1}{4}$ inch, of nearly uniform flesh-colour. They are referable to the genus *Pontoporeia*; and though they have not yet been satisfactorily examined, I have little doubt as to their being identical with the *Pontoporeia affinis* of the Swedish lakes and of Lake Superior. They occur in great plenty in from 30 to 45 fathoms."

1872? PACKARD, A. S., JR.

Annual Report of the Trustees of the Peabody Academy of Arts and Sciences. V. p. 95.

In regard to his *Crangonyx vitreus*, see Note on S. I. Smith, 1875.

1872? ULJANIN, B.

Izvestia Imperatorskio Obshtshestva Ljubiteloi Testestvasnaniya (Trans. Imp. Soc. Nat. Sci. Moscow). IX. pp. 68–79.

Thirty-eight species of Amphipoda are enumerated as inhabitants of the Black Sea. (Dr. von Martens, Zool. Record for 1872.)

1872. WHITEAVES, J. F.

Notes on a Deep-Sea Dredging Expedition round the Island of Anticosti, in the Gulf of St. Lawrence. The Annals and Magazine of Natural History. Number LIX. Vol. X. Fourth Series. London, 1872. p. 341.

Under Crustacea he says, "Several curious Amphipods were taken, among the more conspicuous of which were fine specimens of an *Epimeria*, which Mr. Smith refers doubtfully to *E. coniger* of Boeck." *Epimeria cornigera* is obviously intended.

1873. HARTMANN, R.

Sitzungsberichte der Gesellschaft naturforschender Freunde zu Berlin, 1873. p. 94.

"The strange shovel-shaped appendages in the male of *Gammarus pulex* are mentioned." (Dr von Martens, Zool. Record for 1873.)

1873. HESSE, E.

Mémoire sur les Crustacés rares ou nouveaux des côtes de France. (Vingt et unième article.) Description de Crustacés nouveaux appartenant à la légion des *Edriophtalmes*, de l'ordre des *Amphipodes*, de la famille des *Piscicoles*, de la tribu des *Enoplopodes*, Nobis, du genre des *Ichthyomyzoques*, Nobis. Annales des Sciences Naturelles. Cinquième série. Tome XVII. Paris, 1873. pp. 1-16. Pl. IV.

The new genus *Ichthyomyzocetus* is thus defined :—

"Corps ovalaire, légèrement déprimé, bombé en dessus, plat et même un peu creux en dessous.

"Tête petite, aplatie, triangulaire ; front lamelleux s'avancant horizontalement en pointe arrondie et recouvrant la base des antennes ; celles-ci grosses, courtes, à peu près d'égale longueur et composées de cinq à sept articles.

"Yeux grands, réniformes, très-écartés, placés obliquement, en dessus de la tête et formés de cornéoles bien distinctes.

"Abdomen moins large que le thorax, formé seulement de cinq ou de deux anneaux, également sans bordure épimérienne, les derniers portant de chaque côté des tiges arrondies terminées par de petites lames ovales et pointues.

"Bouche proéminente, formée d'un labre supérieur, de pattes-mâchoires latérales armées de griffes, et d'autres plates, sous lesquelles ou aperçoit de petites mandibules qui environnent l'orifice buccal.

"Pattes thoraciques au nombre de sept paires, dont les trois premières sont ancreuses et dirigées du côté de la bouche ; les quatre autres paires plus grêles et plus longues, terminées par un ongle légèrement recourbé, quelquefois l'article femoral étant large et plat. Les fausses pattes branchiales composées d'une double tige cylindrique, fusiforme, divisées en nombreux anneaux garnis de longs poils rigides et pennés. L'abdomen, dans l'état de repos, se repliant sous le thorax, et celui-ci garni, chez la femelle, de larges plaques membraneuses qui, en s'imbriquant les unes dans les autres, forment une poche incubatoire.

"Ces Crustacés vivent en parasites sur les Poissons."

The species are described and figured under the following headings :—“ A.—Abdomen formé de cinq artieles et termiué par trois tiges.” Ichthyomyzoque orné.—*Ichthyomyzoculus ornatus* n. s., figs. 1, 2, on *Morrhua vulgaris*. “ C'est probablement un mâle.”

“ B.—Abdomen formé de cinq artieles et terminé par trois paires de tiges.” Ichthyomyzoque du Gade morue.—*Ichthyomyzoculus Morrhus*, n. s., figs. 3–7, on *Morrhua vulgaris*. “ C'est un individu femelle.” Ichthyomyzoque de la Baudroie commune—*Ichthyomyzoculus Lophii*, n. s., figs. 8–18, ou *Lophius piscatorius*. “ Notre dessin représente une femelle adulte, mais sans œufs.”

“ C.—Abdomen formé de deux articles et terminé par deux paires de tiges.” Ichthyomyzoque de la Squatine ange—*Ichthyomyzoculus Squatinæ*, n. s., figs. 19–27, on *Squatina angelus*.

In *Ichthyomyzoculus lophii*, a singular appendage is described on the thoracal feet of the first three pairs, “ placé à leux extrémité et à la base des griffes qui les termiment. Cet appendice ressemble, pour la forme, à un pistil dont on aurait conservé seulement l'ovaire et le style. Nous ignorons si les autres espèces ont aussi des appendices de ce genre, ou s'ils sont propres à celle-ci seulement.” He compares it to the *gaffe* which sailors use.

By the front of the body, M. Hesse considers that these animals come very near to the Isopods, but by the lower extremity of the body they resemble the Amphipods. The upper part of the head is broader than the lower, at the extremity of which the buccal opening is placed. “ Du haut du front et de la base du prolongement frontal part une ligne verticale en relief, nasiforme, qui descend perpendiculairement en diminuant de longueur jusqu'à l'orifice de la bouche, dont elle forme le labre supérieur. De chaque côté et au dessus de cet orifice, on aperçoit une paire de pattes-mâchoires composées de deux artieles, dont le second est terminé par une longue griffe échancrée et acuminée, dont la pointe est dirigée vers le bas. Au-dessous de celle-ci sont également placées deux paires de pattes-mâchoires plates et ovales, dont la première, qui est la plus grande, est large, plate et accompagnée de son fouet ; l'autre, plus petite, se trouve des deux côtés de la bouche. Enfin, entre celui-ci on aperçoit les mandibules, qui sont petites et échancrées, en ne laissant voir que les denticules dont elles sont bordées. La région thoracique est, comme cela a lieu pour les femelles de *Cymothoadiens ravisseurs*, entièrement recouverte de larges lames ovalaires membraneuses et très-minces, qui partent de l'insertion de chaque patte et se portent horizontalement en dedans, de manière, en s'incurvant les unes dans les autres, à former une poche incubatoire. Les fausses pattes abdominales ou les organes de la respiration ne se composent pas, comme dans les *Cymothoadiens*, de grandes lames plates, ovalaires, membraneuses, recouvrant en se superposant ; elles se rapprochent, par leur conformation, de celles des *Amphipodes*. Elles ont un péduncule aplati, presque aussi large que long, sur lequel sont fixées, de chaque côté, deux tiges assez longues, presque cylindriques, multiarticulées, larges au milieu et étroites à leur extrémité, chaque anneau étant bordé d'une série de poils longs et rigides, et pennés. Les pattes thoraciques sont au nombre de sept paires. Les trois premières, et la première surtout, sont ancreuses.” “ Les quatre autres paires de pattes sont ambulatoires.” “ Elles sont formées de cinq ou six articles, dont le premier et le dernier sont les plus longs. On remarque aussi que, dans les pattes ambulatoires, l'article fémoral est très-large et très-plat, et que, sous ce rapport, ils ressemblent aux *Amphipodes*.” In the abdomen, which is much narrower than the thorax, the last segment “ se termine par un prolongement gros et arrondi, vers le bas duquel on aperçoit facilement l'orifice anal qui est relativement très-grand. Les trois derniers anneaux donnent attache, de chaque côté, à deux ou trois paires de tiges arrondies, dont les extrémités ne se dépassent pas, bien que cependant elles soient, à raison de leur point de départ, d'une longueur inégale. Elles sont terminées chacune par deux petites lames ovales et pointues à leurs deux extrémités ; et sous ce rapport, ils ressemblent aux *Amphipodes* de la division des *Crevettines marcheuses*, tel que les *Corophies* ou les *Hypérines*, ainsi que les *Vibiliés* et les *Phronimes*.”

The expressions "les fausses pattes branchiales" and "les fausses pattes abdominales ou les organes de la respiration" would appear to be incorrect; if accurate, they would be inconsistent with the arrangement of this genus in the order Amphipoda. That one species of the genus should have a pleon of only two segments, while its congeners have the five segments which are the normal number for the pleon among the Hyperina, is a very strange peculiarity. But as to this and other points, see additional Note on Hesse, in Appendix.

1873. LÜTKEN, CHR. FR.

Bidrag til Kundskab om Arterne af Slægten *Cyamus* Latr. eller Hvallusene. Med 4 Tavler og et fransk Résumé. Vidensk. Selsk. Skr. 5 Raekke, naturvidenskabelig og mathematisk Afd. 10 B. III. Kjbenhavn, 1873. (Mémoires de l'Aeadémie Royale de Copenhague. 5^{me} série. Classe des Scienees Vol. X. No. 3.)

After repeating the observations on *Cyamus* which he had made in 1860, Lütken gives an exceedingly valuable report upon the historical development of our acquaintance with the group of Crustacea, which are called whale-lice. From Frederik Martens in 1675 to the date of his own work, Lütken's vigorous research can scarcely have let any statement of importance on the subject escape him, or any serious error pass the ordeal of his criticism without correction.

The definition he gives of *Cyamus*, Latr., is as follows:—

"Corpus crassum, hanc laminare. Pedes primi paris minuti, sub pedibus secundi paris fere vel omnino absconiti; annulus corporis primus a capite indistincte sejunctus vel cum hoc plane confluens. Pedes maxillares quinque-articulati. (Mares feminis vulgo majores.)"

The species described are, 1. *Cyamus mysticeti*, Ltk., from *Balaena mysticetus*, the common, or Greenland Whale; 2. *Cyamus monodontis*, Ltk., from *Monodon monoceros*, the Narwhal; 3. " *Cyamus Kessleri*," Brandt, " coming from the northern part of the great eastern ocean, probably from a true whale of the group of *Balaena australis* and *Balaena biscayensis*"; 4. *Cyamus erraticus*, Roussel de Vauzème, from *Balaena australis*, the Cape Whale; 5. *Cyamus boopis*, Ltk., the *Oniscus ceti* of O. Fabricius, 1780, from the Northern Hump-back, the Krepokak of the Esquimaux, *Megaptera boops*, and possibly parasitic on other species of *Megaptera*; 6. ? *Cyamus pacificus*, Ltk., from a whale (of unknown genus and species) in the Pacific in the neighbourhood of Panama, a species nearest in form to *Cyamus boopis*, but also near to *Cyamus erraticus*; 7. *Cyamus ovalis*, Rouss. de Vauz., from protuberances on the head of *Balaena australis* and from the North Pacific "Sletbag" (*Balaena japonica* ?); 8. " *Cyamus Rhytinx*," J. F. Brandt, Steller's species, for which Brandt proposed a new genus *Sirenocystamus*, and which Lütken agrees with Brandt in thinking possibly akin rather to *Proto* than to *Cyamus*; 9. *Cyamus nodosus*, Ltk., the *Oniscus ceti* of the *Zoologia Danica*, III. p. 69, pl. 119, f. 13-17, 1789, from the Narwhal, *Monodon monoceros*; the name " *Cyamus Beluge* " sometimes given to this species being rejected by Lütken as grounded on the mistaken supposition that the creature is also a parasite of *Delphinapterus beluga*; 10. *Cyamus globicippitis*, Ltk., a species already noticed as possibly new, but not named, by Steenstrup in 1843 [? 1850], parasitic on the Caaing, or Pilot Whale, *Globicephalus melas*; 11. *Cyamus gracilis*, Rouss. de Vauz., from the protuberances of the head of *Balaena australis* and *Balaena japonica* ?; 12. *Platycyamus thompsoni*, Gosse, parasitic on the Bottlehead, or Beaked Whales, *Hyperoodon rostratus* and *Hyperoodon latifrons*.

The new genus, *Platycyamus*, instituted to receive Gosse's *Cyamus thompsoni*, is defined as follows:—

"Corpus valle depresso, laminare fere; pedes primi paris pedes secundi paris magnitudine

fere æquantes hisceque antepositi, annulo primo corporis a capite bene sejuncto; pedes maxillares hanc articulati. (Mares foeminiis minores.)

The opinion that *Cyamus pacificus* may perhaps better be classed as a variety of *Cyamus boopis*, "seems confirmed," Lütken says, "by the fact that young *Cyami*, taken upon unknown Cetacea, in the Pacific, near the Isles of Tonga and Rarotonga, come extremely near to the species parasitic on the *Megaptera* of the northern seas, and are probably identical with it."

In addition to the ten well-defined species of the above list, Lütken calls attention to various others less well-known. These are:—

1. The species which, according to Bennett, are parasitic on the *Cachalot* and several *Delphini* and *Globiocephali* (plusieurs Dauphins et Globiocéphales) of the southern seas. The parasite of the *Cachalot*, he notes, may possibly be *Cyamus pacificus*, though Roussel de Vauzème did not find any *Cyamus* upon the *Cachalot*.
2. "*Cyamus Delphini*," Guérin (from some species of *Delphinus* in the West Indies), "very near to *Cyamus globicipitis*, if not identical with it."
3. A *Cyamus*, also from some unknown *Delphinus*, regarded by Lütken as certainly a distinct species, though as the specimen is not full grown, and its habitat uncertain, he leaves it unnamed.
4. A whale-louse, which according to a plate published by Dr. Monedero, is, or used to be, parasitic on the Sarde or Basque whale (*Nordkaperens* eller *Sardens Hvallus*), instead of which on the plate in question a *Pycnogonum* is figured.

The species are pretty equally divided between the Mysticete, or Whalebone whales, and the Denticete, or Toothed whales, but hitherto not a single species has been found on a genuine Fin-whale (*Balaenoptera*). One species of Cetacean may entertain more than one species of these parasites, and the same species of *Cyamus*, just as the same species of Cirripede, may occur on very nearly related species of Cetacea, especially on species of the same subgenus.

A postscript mentions Dall's new species "*Cyamus Scammoni*," which lives on the Californian Grey whale, *Rhachianectes glaucus*, Cope, and which Lütken thinks will stand between *Cyamus ovalis* and "*Cyamus Kessleri*." Another species, *Cyamus suffusus*, Dall, from the Humpback, *Megaptera versabilis*, he considers to come near, perhaps to be identical with, *Cyamus pacificus*.

1873. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1871; being Volume Eighth of the Record of Zoological Literature. London, M.DCCC.LXXIII. pp. 179–196.

A synopsis is given of Bocck's Amphipoda, 1870. The name *Tryphosa* is noted as preoccupied in *Lepidoptera*, but I am informed by Mr. Edward Saunders, the entomologist, that the name as used by Stephens for a genus of *Lepidoptera* has a different spelling, *Triphosa*, not *Tryphosa*, and that without variation so far as he could trace it.

1873. MÖBIUS, KARL, and METZGER, A.

Jahresbericht der Commission zur wissenschaftlichen Untersuchung der deutschen Meere in Kiel für das Jahr 1871. 1. Jahrgang. Berlin, 1873. (With second Title page); Die Expedition zur physikalisch-chemischen und biologischen Unter-

suchung der Ostsee im Sommer 1871 auf S. M. Avisodampfer Pommerania nebst physikalischen Beobachtungen an den Stationen der preussischen Ostseeküste. Berlin, 1873.

On behalf both of those who have to make catalogues of books, and of those who have to consult them, it is much to be wished that short titles should be used to name rather than to describe a work, and that above all things double title pages should be avoided.

"IV. Die faunistischen Untersuchungen. A. Die wirbellosen Thiere der Ostsee," pp. 97-144.
K. Möbius.

The Amphipoda are catalogued on pages 117-119, with particulars as to the place of capture, depth, nature of ground, and distribution. Fifteen species are named, beginning with "*Caprella linearis L.*" and "*Leptomera pedata* Abildg." and ending with "*Talitrus locusta L.*" To *Pontoporeia femorata*, Kröyer, *Pontoporeia affinis* is made a synonym, with the remark, "Herr Lindström schickte mir Exemplare, die er bei Gotland gefangen hatte, mit dem Namen *P. femorata* zu; er hat also seinen Speciesnamen *affinis* selbst zurückgenommen." To "*Orchestia littorea* Mont." the remark is appended, "Der Vorsprung am unteren Rande des 5. Gliedes des 2. Fusspaars ist bei Exemplaren von Stubbenkammer und Kiel kleiner als bei Exemplaren von Greifswald; bei Exemplaren von Sylt fehlt er ganz. Im Uebrigen stimmen alle überein." To this species "*Orchestia Euchore*," Fr. Müller, is assigned as a synonym. Müller's "*Orchestia Gryphus*" is made synonymous with "*Orchestia Deshayesii* Savig." In the general observations, *Gammarus locusta* and *Pontoporeia femorata* are mentioned among those species which occur in the greatest numbers. *Gammarus locusta* was occasionally found along with the *Temora longicornis* which made up the chief part of the contents of the stomachs of herrings. In various other fishes, less suited for consuming the *Temora*, *Gammarus locusta* was found as one of the constituents of the food.

In the preface, Möbius remarks that "Die Fauna der Ostsee ist ein verkümmerter Zweig der reichen Fauna des nordatlantischen Oceans und des nördlichen Eismeeres." One of the conclusions drawn is that "Die Ostsee enthält überhaupt nur eine Auswahl solcher atlantischen und Eismeerthiere, welche grosse Temperaturdifferenzen zu ertragen im Stande sind." Such animals are distinguished as *eurytherm*, in opposition to *stenothenrm* animals, which can live only in warm or only in cold water. All Baltic marine animals can live in water of varying saltiness, and are therefore said to be *euryhaline*. In Section "C. Die auf der Fahrt nach Arendal gefangenen Thiere," on page 153, he mentions, "*Caprella linearis L.*"; "*Protella phasma* Mont.;" "*Ampelisca Gaimardii* Kröy.;" "*Gammarus longimanus* Leach." *Anhang I. Physikalische und faunistische Untersuchungen in der Nordsee während des Sommers 1871*, von A. Metzger in Hannover, pp. 165-176.

In this Appendix the Amphipoda are described on pages 173-174. They are fourteen in number. Among them is mentioned "*Kröyera arenaria* Sp. Bate." This is no doubt Spence Bate's *Kröyera arenaria*, which Boeck calls *Kröyeria arenaria*, and identifies with his *Pontocrates norvegicus*. "*Atylus* (Dexamine) *Vedlomensis* Bate and Westwood" was dredged "zwischen Helgoland und Spiekeroog." *Atylus falcatus* and *Siphonocetes cuspilatus* are described as new species, but the descriptions had already appeared in 1871. See Note on Metzger under that date. It is here noted that "*Lestrigonus Kinahani* Bate," given as a separate species in the earlier list, must be referred as the male to "*Hyperia Medusarum* Müll. (= *Hyp. Galba Montagu*). At page 176 a preliminary list is given of seven species of Amphipoda obtained by the "Pommerania" in the summer of 1872.

A translation of the paper above-mentioned by Karl Möbius, "On the invertebrate Animals of the Baltic," is given by Dallas in The Annuals and Magazine of Natural History. No. 68. August 1873. Vol. XII. Fourth Series. London, 1873. pp. 81-89.

1873. PARFITT, EDWARD.

The Fauna of Devon. Part. IX. Sessile-eyed Crustacea (Read at Sidmouth, July, 1873.) Report and Transactions of the Devonshire Association for the advancement of Science, Literature and Art. Vol. VI. Part I. 1873. pp. 236–251.

The opening remarks include observations on the heart and circulation in *Niphargus aquilonius*, Schiödte, in which, he says, "the pulsations of the heart are at the rate of 100 in fifty seconds." In the catalogue there are some remarks on the habits of *Corophium longicorne*, Latr. Eighty-two species of Amphipoda are named; some of the names, however, can only rank as synonyms.

1873. THOMSON, CHARLES WYVILLE, born March 5, 1830, died March 10, 1882 (John Murray).

The Depths of the Sea. An account of the general results of the Dredging cruises of H.M.S.S. "Porcupine" and "Lightning" during the summers of 1868, 1869, and 1870, under the scientific direction of Dr. Carpenter, F.R.S., J. Gwyn Jeffreys, F.R.S., and Dr. Wyville Thomson, F.R.S. 1873.

On page 125, *Eusirus cuspidatus*, Krüyer, is figured, and the remark made that it "had previously been known only in the Greenland seas," whereas this specimen was dredged on the third cruise of the "Porcupine" in 1869, among the fauna of the "Cold Area" in the channel between Færöe and Shetland. Fig. 19 is said to be "a large and hitherto unknown species of the genus *Caprella*." It is named *Caprella spinosissima*, Norman. But Mayer, Caprelliden, p. 35, quotes a letter from Norman saying that this was a mistake on Thomson's part. "It should have been *Caprella spinosissima*, Stimpson. It is = *Aegina echinata* of Boeck." Judging from a Spitzbergen specimen, which Norman sent as a female of the same species, Mayer inclined to regard the species as new, under the name *Aegina spinosissima*, Norman. This name, however, is preoccupied. The original specimen, which I have had an opportunity of seeing, confirms the view taken by G. O. Sars, 1885, that it is the same species as his *Caprella horrida*, and since the name *Caprella spinosissima* is preoccupied, *Caprella horrida* will be the name of the species. The remarkable resemblances between this species and *Aegina spinifera*, Bell, will easily account for any confusion that has arisen between them, in spite of their belonging to different genera.

1873. WIEDERSHEIM, R.

Beiträge zur Kenntniss der württembergischen Höhlenfauna. Verhandlungen der physikalisch-medicinischen Gesellschaft in Würzburg. Neue Folge IV. Bd. pp. 207–222. [pp. 4, 5 of separate copy].

He records, according to Fries, the finding of an eyeless *Gammarus* on a stone of the brook at the entrance of the Falkenstein cavern, strikingly distinguished by its milk-white colouring from its brownish companions with well-developed eyes.

1873. WILLEMOES SUHM, RUDOLPH von, born September 11, 1847, died September 13, 1875 (John Murray).

"On a new genus of Amphipod Crustaceans." (March 6, 1873.) Proceedings of the Royal Society of London. Vol. XXI. London, MDCCCLXXIII. pp. 206–208.

The new genus *Thaumops* is thus defined:—

"Caput oblongum, inflatum, oculis maximis superiorem capitis partem tegentibus. Segmenta thoracica 6, abdominalia 5. Antennarum in feminis par unum, maxillarum par unum, pedum paria duo minima maxillarum locum tenentia. Mandibulæ nullæ. Pedes thoracici 5, abdominales 3 in quoque latere. Appendices caudales 4. Ganglionum pectoralium paria 5, abdominalium 3."

The type is given as "*Thaumops pellucida*, n. sp. Corpus longitudine 14 [84] mm., latitudine 21 mm., pellucidum."

The full description, with plates, was afterwards published in the Transactions, with various corrections, but both genus and species were, shortly after their institution, identified by their author with Guérin's "*Cystisoma Neptunus*." The "new family, Thaumopidæ, belonging to the tribe of *Hyperina*," which he here proposes to establish, was dropped, and a new family, Cystisomidæ, proposed. See Notes on Willemoes Suhm, 1874, 1875, 1879.

1874. Bos, JAN RITZEMA.

Bijdrage tot de kennis van de Crustacea Hedriophthalmata van Nederland en zijne kusten. Groningen. 1874.

The introduction contains a short historical review of carcinology, and, among other points, suggests that the Hedriophthalmata, in spite of their comparatively small size, are the highest representatives of their class, on account of their dispensing with the nauplius- and zoëa-stages, on account of their including many terrestrial forms, and on account of their late appearance in the strata of the earth, the Podophthalmata having been met with as early as the carboniferous, the Hedriophthalmata not till the Jurassic period.

Descriptions are given of several well-known species, with interesting remarks upon them; the "calceolus" on the antennæ of *Gammarus pulex* is figured and discussed.

1874. BUCHHOLZ, RUDOLF, died April 17, 1876 (Taschenberg).

Die zweite Deutsche Nordpolarfahrt in den Jahren 1869 und 1870 unter Führung des Kapitän Karl Koldewey. Zweiter Band. Wissenschaftliche Ergebnisse. Zoologie. Leipzig, 1874. pp. 262–270, 294–388—Pls. I.–XV.

This report opens with some occasional remarks on the appendages of the antennæ, the eyes, comparative measurements, and classification of Amphipoda.

Valuable remarks are made on the Lysianassidæ, with the species *Anonyx lagena*, Kr., properly *Anonyx nugax*, Phipps; *Anonyx littoralis*, Kr.; *Anonyx plautus*, Kr., for this and the preceding species the genus *Anonyx* being adopted in preference to *Onesimus*, Boeck; the Syrrhoïnæ, species *Syrrhoë crenulata*, Goës; the Pardaliscinæ, species *Pardaliscus cuspidata*, Kr., which, as well as most of the following, is fully described and strikingly figured; the Leucothoinæ, species *Eusirus cuspidatus*, Kr., *Amphithonotus aculeatus*, Lepechin, identified with *Tritropis helleri*, Boeck, as well as his *Tritropis aculeata*; *Tritropis* (now *Rhachotropis*)

fragilis, Goës; the Oedicerinæ, species *Oediceros borealis*, Boeck, retransferred from *Monoculodes* to *Oediceros*; *Oediceros lynceus*, Sars; the Pleustinæ, a new family, species *Pleustes panoplus*, Kr.; *Parapleustes gracilis*, n. g. et s., perhaps the same as *Paramphithoë exigua*, Goës, and *Paramphithoë glabra*, Boeck: the Iphimedinae, species *Vertumnus serratus*, Fabricius (of which the name *Vertumnus*, White, being preoccupied, has since been changed by Boeck to *Acanthonotozoma*); the Gammarinæ, species *Gammarus locusta*, L. (not figured), *Amathilla sabini*, Leach, *Amathilla pinguis*, Kr.; the Atylinæ, species *Atylus carinatus*, Fabricius, *Atylus smitti*, Goës (not figured), *Acanthozone hystrix*, Owen, probably, as Miers has pointed out, a new species, distinct from Owen's; *Paramphithoë inermis*, Kr.; *Paramphithoë fulvocincta*, Sars; *Paramphithoë megalops*, n. s.; the Ampeliscinæ, species *Ampelisca eschrichtii*, Kr., with the suggestion that *Ampelisca macrocephala*, Lilljeborg, may be only a local variety; the Podocerinæ, species *Podocerus anguipes*, Kr.; the Corophinæ, species *Glauconome leucopis*, Kr. (not figured); the Hyperidae, species *Themisto libellula*, Mandt; the Caprellidæ, species *Ægina spinifera*, Bell, with which he identifies *Æginella echinata*, Boeck (the name *Æginella* being probably an accidental slip of the pen for *Ægina*).

The Syrrhoïnæ are said to come near the Oedicerinæ in general form and in the structure of the mouth-organs, although having this distinction that only the left mandible is provided with a *processus accessorius*. (But this distinction is not universal in the group.)

In the Pardaliscinæ, Dr. Buchholz corrects the supposition of Boeck that a *processus accessorius* is wanting to the right mandible. He also considers that Bruzelius and Boeck have both of them confused the joints in the gnathopods of *Pardalisca cuspidata*, that which they have taken for the wrist being really the hand, and the finger being, contrary to the general rule in Amphipods, two-jointed. This would be extremely remarkable, and would contravene the rule well laid down by Spence Bate that in the Amphipoda the third (free) joint always underrides the fourth in the gnathopods and overrides it in the pereopods, but my own observation of members of the genus *Pardalisca* compels me to believe that the earlier authors are right, and Dr. Buchholz himself in error. It is in any case clear from the figures that Dr. Buchholz and Boeck are not referring to the same species under the title of *Pardalisca cuspidata*, Kr. The species so named by Buchholz agrees with *Pardalisca abyssi*, Boeck, a specimen of which was brought home by the Challenger and is figured in this Report..

From the Lencothoinæ, which he considers too heterogeneous a group, Dr. Buchholz is inclined to transfer the genus *Tritropis* (since called *Rhachotropis* by S. I. Smith) to the group containing *Paramphithoë*.

For the Pleustinæ, a new family, he mentions as characteristics, the antennæ rather short, the lower shorter than the upper (sexual differences not ascertained); the head small, with distinct, well-developed rostrum, the eyes small and lateral; the body frequently carinate, the first four side-plates well developed; the mandibles with broad dentate process but no molar tubercle; the gnathopods large, subchelate, the three last pairs of pereopods not much elongated, and the seventh not especially so; the uropods slender, pretty strongly elongated.

It is a little difficult to reconcile the expression "das gänzliche Fehlen des Kauhöckers der Mandibeln" in the above account of the family, with the description "des sehr verkümmerten Kanthöckers" of *Pleustes panoplus*. This degenerate molar tubercle is figured by Buchholz himself, as well as by Krøyer and Boeck.

The new genus *Parapleustes* is thus defined:—"Corpus epimeris quatuor anterioribus mediocribus, dorso rotundato epidermide tenui. Rostrum exiguum. Antennæ breves, inferiores [qnam] superiores breviores. Mandibulæ processu dentali brevi, lato cum processu accessorio coalito, tuberculo molari nullo. Labium superius breve et latum, profunde emarginatum. Ceterum generi *Pleustes* valde affinis."

The differences in the mouth organs, the absence of a dorsal carina, and the very weakly developed rostrum are thought to justify the establishment of this new genus.

Among the Gammarinæ, a species taken by von Heuglin at Spitzbergen, is described in a supplementary note, p. 345, as being probably new and coming near to *Amathilla pinguis*. It is named "*Amathilla Heuglini* (Buchh.)." The diagnosis is as follows:—"Corpus sat altum, magnum, epidermide crassa, quasi loricatum, dorso rotundato lato, medio tumidum. Oculi nigri, mediocres, reniformes. Antennæ superiores inferioribns paullo breviores tertiam fere corporis longitudinem æquautes; flagello accessorio mediocri quatuor articulos præbente. Epimera anteriora medioeria, quartum mnlto latius, postice in spinam validissimam acutam horizontalem productum. Epimera segmentorum abdominalium; secundum et tertium angulo posteriore in dente acutum producta, primnm rotundatum, tertium preterea in margine posteriore in dentem acutum sursum spectanteum productum. Appendix caudalis elongata iudivisa, apice incisura media perparva emarginatnm. Pedes saltatoriis tertii paris, ramis æqualibus compressis, anterioribus non longiores. Color pallide flavus. Long. total. 36 mm."

A full account, illustrated by numerous figures, is given of the differences between the young and adult forms of *Amathilla sabini* (*homari*, Fabr.). These, as Buchholz observes, had been already noted by Bruzelius, Skand. Amph. Gamm., p. 51. See also what is here said of *Grayia inbriicata*, Spence Bate, p. 332.

Among the Atylinæ, the genus *Paramphithoë*, Bruzelins, is thus limited, to comprise—small, delicate Atylinæ, thin-coated, with slender bodies, very elongate filiform antennæ, slender, elongate feet, gnathopods with linear, weakly-developed, subchelate hands; back rounded, body compressed, rostrum very small; uropods very slender, elongate, the last pair with lanceolate compressed rami; the males uniformly possessing numerous specific appendages to the antennæ. The genus, besides including species assigned by Boeck to *Pontogeneia* and *Halirages*, contains the new species *Paramphithoë megalops*, with the following diagnosis:—"Corpus parvum gracile, tencrum, dorso rotundato ubique inermi, oculis permagnis nigris, transversis, ovali-reniformibus, antennis perlóngis, subæqualibus, longitudine totius animalis paullo brevioribus, pedum anteriorum manibus parvis ovatis; epimeris quatuor anterioribns parvis, illis segmentorum trium abdominalium primorum margine postico fortiter serrato dentatis; pedibus saltatoriis elongatis gracilibus. Longit. tot. ad 7mm." The application of the term epimera to the hind margins of the first three pleon-segments cannot, I think, be justified.

In regard to the account given by Buchholz, pp. 375–377, of the Ampeliscinæ, Spence Bate, and the species, "*Ampelisca Eschrichtii*, Kröyer, Taf. XIII. Fig. 1," Metzger, in 1875 (p. 298, note), says of Buchholz's work, "Auf. p. 375 u. ff. ist *Ampelisca Eschrichti* zum Theil ziemlich ausführlich beschrieben und auf Taf. VIII. Fig. 1. durch Abbildungen erlantert. Beschreibung und Zeichnung weichen ebenfalls von Boeck's Diagnose in verschiedenen Punkten ab; leider hat außerdem der Verfasser gewisse specifische Merkmale gäuzlich unberücksichtigt gelassen, so dass ich in meiner Hoffnung, hiernach die Richtigkeit meiner Bestimmung zu prüfen, getänscht wnrde. Znnächst muss ich der Behauptung von BUCHHOLZ entschieden widersprechen, dass die beiden vorderen Fusspaare nur *einfache Krallenfüsse* seien mit nicht gegen das vorhergehende Glied zurückslagbarer Kralle, ein Charakter, den Verfasser auf Grund dreier untersuchter Individuen sogar der ganzen Familie der Ampeliscinen vindicirt. Allerdings ist bei allen bis jetzt bekannten arteu der Palmarrand nicht deutlich ausgeprägt und geht unmerklich in den Hinterrand über, nichts destoweniger kann aber die Kralle gegen diesen eingeschlagen werden; beide Glieder bilden also das, was man allgemein als manus subcheliformis zu bezeichnen pflegt.—In der Figur 1, Tab. XIII, hat das 7. Bein nmr 5 Glieder! Die Contonnen des oberen und hinteren Randes vom zweiten Gliede sind offenbar in der Zeichnung vergessen. Sodann ist auf die Beschaffen-

heit dieses Beines auch in der Beschreibung wenig Gewicht gelegt, obschon doch die Diagnosen von BOECK und die Beschreibungen von BRUZELIUS genugsam beweisen, wie dasselbe fast für alle Ampelisca-Arten gute specifische Merkmale darbietet; dafür ist die Bewaffnung des 6. Beines, Fig. 1b, vorzüglich detaillirt dargestellt, nur Schade, dass darin fast alle übrigen Arten bis auf geringe Dimensionenverhältnisse genau übereinstimmen. Spräche der Fundort nicht für KRÖYER's Ampelisca Eschrichti, so könnte man nach der Abbildung unbedenklich auf die männliche Form von macrocephala schliessen. Die sexuellen Unterschiede der Ampeliscinen, über welche der Verfasser kurzweg als 'nicht bekannt' hinweggeht, sind von LILLJEBORG und BRUZELIUS für macrocephala, lavigata und æquicornis ganz bestimmt angegeben." Buchholz says that his specimens were collected "zwei im Germania-Hafen, ein kleineres von Sabine-Insel 10 Faden."

L'Encyclopédie d'histoire naturelle. Crustacés—Mollusques—Zoophytes. Paris,

1858. Table Alphabétique des noms vulgaires et scientifiques de tous les sujets

décris et figurés dans cette encyclopédie. Crustacés, Mollusques et Zoophytes.

Paris 1874.

In this work, which should rather have been mentioned under the earlier date, the Crustacea probably, and the Alphabetical Table certaiuly, should be ascribed to Desmarest alone. Accepting the "Édriophthalmes, Leach" as deuxième légion of the "Crustacés maxillés, Edwards," he makes the "Amphipodes, Latreille," the premier ordre, p. 46. All the species, he says, are very small, "car on n'en connaît pas qui dépasse une longueur de 0,002." The "Première Famille, Crevettes, Latreille," includes two tribes. The first tribe has twelve genera assigned to it, the fifth being given as *Philius*, Guérin. Of *Gammarus*, the tenth, he says, "Le type est la Crevette des ruisseaux ou Chevrette (*Gammarus fluvialis*, Edw.). Longueur, 0^m,010 à 0^m,015." "Fig. 27.—Crevette des ruisseaux" has a perfectly smooth back; nevertheless the text says, p. 48, "une espèce que l'on confond souvent avec la Crevette des ruisseaux, ayant les mêmes mœurs, se trouvant dans les mêmes lieux, et n'en différant guère que parce que son abdomen est lisse, est la Crevette puce (*Gammarus pulex*, Fabr.)" The second tribe has seven genera, the third being thus given, "Cesapodina, Templeton (C. obdita, trouvée en mer)."

The "Deuxième Famille, Hypérines, Edwards," includes three tribes, the first being "Hypérines grammarioïdes," with one genus; the second, "Hypérines ordinaires" has thirteen genera, among which it may be noted that *Lanceola* is kept distinct from *Hyperia*; to the seventh "Lestrigonus, Edw., *L. Fabricii*" is assigned as the type; *Anchylomera* is the ninth, and its synonym *Hieraconyx* the tenth, while the thirteenth is "Sperchius, Leach," *Sperchius* being, in fact, an obscure genus instituted by Rafinesque. The third tribe, "Hypérines anomales," receives four genera, the second being given as "Orione, Cocco," by a substitution of the Italian for the Latin name *Orio*.

"The "Deuxième ordre, Lœmodipodes, Latreille" is said to correspond with the "genre *Cyame* de De Lamarck," and contains two families, the first Caprelliens, with three genera, *Caprella*, *Leptomera* and *Naupridia*; the second Cyamiens, with the one genus, *Cyamus*.

In the Alphabetical Table *Phlias*, *Cerapodina abdita*, *Hypérines gammaroïdes* and *Lœmodipodes* are given correctly; "*L. Fabricia*" becomes *Lestrigone Fabreii*." The preface (avis), dated "15 octobre 1858," thinks that the table, like the body of the work, will be "d'un très-grand secours pour les recherches des naturalistes et des gens du monde." Yet in 1858 no notice had been taken of Dana's researches, and in 1874 no hint is given that carcinology had made any advance in the preceding sixteen years.

1874. DYBOWSKY (DUIBOVSKY), BENEDICT N.

Beiträge zur näheren Kenntniss der in dem Baikal-See vorkommenden niederen Krebse aus der Gruppe der Gammariden. Herausgegeben von der Russischen Entomologischen Gesellschaft zu St Petersburg. Beiheft zum X Bande der Horae Socientatis Entomologieae Rossicæ. Mit 3 colorirten und 11 schwarzen Tafeln. St Petersburg, 1874.

In the Preface, he mentions *Piscicola torquata*, Grube, as a parasite on the branchial plates of species of *Gammarus*.

In the Introduction, he says that the Crustacean fauna of Lake Baikal consists mainly of Amphipoda, all belonging to the *Gammarina*. Between "*Gammurus Petersii*, with slender body, long extremities and extremely long antennæ, and on the other side *Gammarus inflatus*, with short thick body, short extremities and short antennæ," he finds so many gradations of form and combinations of likeness and difference, that he cannot venture under existing circumstances on separating more than a single species from the genus *Gammarus*. This one species he places in a new genus, *Constantia*, a name unfortunately preoccupied among Mollusca in 1860. The accidental misspelling *Costantia* had therefore better be adopted for this genus.

A full table of terminology is given, in which the homologous joints of the appendages receive a needlessly great variety of names.

General remarks on the genus *Gammarus*, Fabr., are concluded by the following diagnosis of it, as applicable to the species from Lake Baikal :—

"Die Fühler sind als Gefühlsorgane ausgebildet; an den Stielgliedern kommen nämlich einzelne Fiederborsten, an den Geisselgliedern der oberen Fühler Leydig'sche cylinder und an den Geisselgliedern der unteren Fühler oft Lavalet'sche Kolbenorgane vor. Die Stiele der oberen und der unteren Fühler sind immer länger als das Kopfsegment. Die Nebengeissel ist immer vorhanden, sie ist 1-40gliedrig. Die Geissel der oberen Fühler ist immer länger als ihr Stiel. Der Riechconus [Riechconus] endet mit einem cylinderförmigen Röhrchen. Die Seitenplatten der Rumpfsegmente tragen oft an ihren unteren Rändern einfache Borsten, nie Fiederborsten. Die Oberkieferbeine haben 4gliedrige Taster. Die Basalglieder der Hand und Afterhandbeine sind cylindrisch, schmal, nicht erweitert. Die Hände haben eine deutliche Palmarrinne. Die Basalglieder der Gangbeine sind meist erweitert, oft mit langen einfachen Borsten am Hinter-rande besetzt, nie mit Fiederborsten. Der Schwanzanhang ist zweitheilig oder einfach. Die Steuerbeine sind einblättrig oder zweiblättrig. Die Thiere dieser Gattung sind eigentlich Grundthiere, welche sich nie weit von dem Boden entfernen." The two gnathopods are called Handbeine; the first two peræopods Afterhandbeine; the last three Gangbeine; the pleopods Schwimmbeine; the first and second uropods Springbeine; the third uropods Steuerbeine; the telson Schwanzanhang.

The species are grouped into two sections, with numerous divisions and subdivisions, and are thus numbered and named in the preliminary review :—"Erste Abtheilung. Die Nebengeissel viergliedrig: zwei- bis vierzig-gliedrig." 1. *G. Flori*, n. s.; 2. *G. Flori* var. *albula*, n.; 3. *G. calcaratus*, n. s., Taf. vii, Fig. 4; 4. *G. margaritaceus*, n. s.; 5. *G. Wahlii*, n. s.; 111. *G. Wahlii* var. *platycercus*, n.; 112. *G. Klukii*, n. s.; 113. *G. pachytus*, n. s.; 114. *G. pachytus* var. *dilatatus*, n.; 115. *G. perla*, n. s.

Of the new genus *Constantia* (*Costantia*), the following diagnosis is given:—"Die beiden Fühlerpaare sind zu Locomotionsorganen umgewandelt, die oberen Fühler sind mächtiger und länger als die unteren. Die beiden Endglieder der oberen Stiele etwas flach gedrückt, ihr Innenrand mit einem dichten bürstenförmigen Borstenbesatze versehen. Die Geissel-

glieder beider Fühlerpaare tragen aussen und innen gleich lange, steife, einfache Borsten, was ihnen eine Aehnlichkeit mit einer Federfahne verleiht. Die Ncbengeissel fehlt, der Leydig'sche Cylinder, die Lavalett'schen Kolbenorgane und die Stäbchenorgane nicht vorhanden. Der Riecheporus mit einem Endzylinder. Die Augen seitlich gestellt, flach. Die Oberkiefer mit dreigliedrigen, stark entwickelten Tastern, die Unterkiefer mit zweigliedrigen, die Unterlippen mit eingliedrigen, die Unterkieferbeine mit viergliedrigen Tastern verschen. Der Körper schwach seitlich zusammengedrückt. Der Schwanztheil stark entwickelt. Der Schwanzanhang lang, zwei-theilig. Die Seitenplatten klein, niedrig, ohne Borsten. Alle Beine sind zart und lang, besonders aber das zweite Paar der Gangbeine und das vordere Paar der Springbeine. Die Hände haben eine sehr schwach angedeutete Palmarrinne. Die Basalglieder der Gangbeine schmal. Das innere Scheerenglied der hinteren Springbeine und die beiden langen Blätter der Steuerbeine sind mit langen und kräftigen Fiederborsten bewachsen."

The type species is named "*Constantia Branickii*," n. s., Taf. iii, Fig. 7; var. *Alexandri*, Taf. iii, Fig. 6, is only distinguished by the greatly developed dorsal spine-process on the first pleon-segment.

Die Falkensteiner Höhle, ihre Fauna und Flora. Jahreshefte des Vereins für vaterländische Naturkunde in Württemberg. 30 Jahrg. 1874. pp. 86-163.

Gammarus puteanus is recorded on p. 114; lists of species from other caves are also given.

1874. MACDONALD, JOHN DENIS.

"On the Anatomy and Habits of the genus *Phronima* (Latr.)." (Read February 5, 1874.) Proceedings of Royal Society of London. Vol. XXII. London, MDCCCLXXIV. pp. 154-158. Pl. I.

A description and figures are given of "a species of *Phronima* captured in lat. 30° 16' S., long. 176° 27' W."

1874. M'INTOSH, WILLIAM CARMICHAEL.

On the Invertebrate Marine Fauna and Tides of St. Andrews. The Annals and Magazine of Natural History. No. 82. October 1874. Vol. XIV. Fourth Series. London, 1874. pp. 258–274. Also published separately.

The habits and special habitats of some of the sessile-eyed Crustacea are noticed. Acknowledgment is made to Mr. Spence Bate and the Rev. A. M. Norman for assistance in determining doubtful forms. In the list of Amphipoda, *Allorchestes nilssonii* of Bate and Westwood is transferred to "Hyale Nilssonii," H. Rathke; the species *monoculoides*, Mont., *marina*, "Alderii," *pollexiana*, *clypeata*, assigned to *Montagna* by Bate and Westwood, are here referred to *Stenothoë*, Dana; their *Anonyx denticulatus* to *Anonyx holbellii*, Kröyer, their *Ampelisca gaimardi* to *Ampelisca carinata*, Bruzelius, their *Ampelisca belliana* to (= *A. macrocephala*, Lilljeborg ?). "Calliopius bidentatus" (n. sp.), Norman, Nat. Hist. Trans. Northumb. & Durham, vol. i. 1865, p. 24," said by Mr. Norman to be not uncommon all along the east coast, is thus described:—"The body is about two-fifths of an inch long, of a pale straw colour, tinted with brownish at the joints and the bases of the limbs. Superior antennæ twice as long as the inferior, beautifully banded with red. Eyes irregularly rounded, brownish red or pale brick-red. The first and second gnathopods are nearly equal (the second, however, being larger) and similar in structure. Hand almond-shaped, the palm being furnished with a series of very distinct stout spines, and a row of smaller spines reaching the base of the finger; the latter is long, boldly curved, and regularly divided on the concave side. The first and second pleopods [? pleon-segments] have spines, that of the former, however, being sometimes indistinct. A very characteristic convexity occurs at the junction of the third and fourth pleopods [? pleon-segments]; and the dorsal margin of the latter is concave."

Eiscladius longicaudatus of Bate and Westwood is here given as *Heiscladius longicaudatus*, their *Amphithoë littorina* as *Amphithoë podoceroides*, H. Rathke, and distinct from *Amphithoë rubricata*, Mont. "Most of the fine specimens," it is said, "have the hand of the second pair defined by a distinct tooth, as Rathke and Dr. Johnson state." *Podocerus falcatus*, Mont., is given as including *Podocerus pulchellus* and *Podocerus pelagicus* of Bate and Westwood, *Podocerus variegatus*, Leach, as including their *Podocerus capillatus*. "Siphonæctes Whitei," Gosse, is said to be probably the female of "Siphonæctes typicus," Kröyer. The three species, *tuberculosa*, *rimapalmata* and *excavata*, assigned by Bate to *Nænia*, are all recorded as found together in the "débris from the coralline ground." *Hyperia medusarum*, O. F. Müller, is given as including *Hyperia galba* of Bate and Westwood, with the remarks "The *Lestrigonus Kinahani*, Bate, is a sexual variety (male). Some large specimens are found swimming freely on the surface of the water." "*Ægina phasma*, Mont.; B. & W. op. cit. ii. p. 45," appears without notice that the authors quoted do not assign it to *Ægina*. "*Caprella tuberculata*, Guérin; B. & W. op. cit. ii. p. 68," is said to be common on *Ceramium rubrum* in rock-pools, and in the stomachs of cod and haddock. Mr. Norman's opinion is given that the *Caprella hystrix* of Bate and Westwood is not the *Caprella lystrix* of Kröyer, but rather is *Caprella septentrionalis*. The list includes several other Amphipoda, with occasional notes on colouring.

1874. MARION, ANTOINE FORTUNÉ.

Recherches sur les animaux inférieurs du golfe de Marseille. Description des Crustacés Amphipodes parasites des Salpes. Annales des Sciences nat., 6 sér. Zool. et Paléont. Tome I. Article No. 1. Paris. 1874. pp. 1-19. Pls. 1, 2.

The Salpæ are, he says, extremely abundant in some years, and then may not reappear during several springs. They were found in long chains in 1869, with *Sulpa maxima* predominant, which he never took without finding upon it the parasitic Amphipods which he here describes. The first is *Vibilia jeangerardii*, Lucas, 1849, of which he considers *Vibilia speciosa*, Costa, 1853, and *Vibilia mediterranea*, Claus, Grundzüge der Zoologie, 2d Ed., to be in all probability synonyms. In describing the maxillipeds, "la lèvre inférieure, constituée par la réunion des deux *siagonopodes* de la troisième paire, appelés souvent pattes-mâchoires," he remarks, "il est très-important de constater que cette lèvre sternale est totalement dépourvue d'appendices palpiformes, tandis que M. Milne Edwards décrit et figure chez le *Vibilia Peronii* deux petites tiges rudimentaires représentant ces organes développés dans les Gammarines." Secondly, *Lycæa pulex*, n. s., is figured and very fully described. It is compared with *Lycæa ochracea*, Dana. G. O. Sars in 1882 considers that it comes very near the northern species *Lycæa (Tryphana) malmi*, Boeck. Claus in 1879 establishes *Lycæa robusta*, n. s., but gives as a synonym "L. pulex Marion? . . . Junges ♂."

Crustacea. The Zoological Record for 1872 ; being Volume Ninth of the Record of Zoological Literature. London, M.DCCC.LXXIV. pp. 185-204.

1874. SMITH, S. I., and HARGER, OSCAR.

Report on the Dredgings in the region of St. George's Banks, in 1872. From the Transactions of the Connecticut Academy of Arts and Sciences, Vol. III, Part I, 1874.

Lists are given of the Crustacea taken at the various localities in which dredging was carried on. "Notes on some of the Species enumerated ; by S. I. Smith," include remarks on the following Amphipoda, pages 29 to 35 ; "Phoxus Kroyeri, Stimpson," "very closely allied to, and probably identical with, the *P. Holbollii* Kroyer which is found in Greenland, Iceland and northern Scandinavia;" *Harpina fusiformis*, Smith (*Phoxus fusiformis*, Stimpson), "this species is very likely identical with the *H. plumosa* Boeck (*Phoxus plumosus* Kroyer), which has very nearly the same range as *Phoxus Holbollii* ;" *Stenothoë peltata*, Smith, n. s., Pl. IV [III], figs. 5-8 ; *Syrrhoë crenulata*, Goës, "seems to be an exceedingly arctic form, being found in Europe from Spitzbergen to the western coast of Norway ;" *Tiron acanthurus*, Lilljeborg (*Syrrhoë bicuspis*, Goës ; ? *Thessarops* [*Tessarops*] *hastata*, Norman) ; *Ædiliceros lynceus*, Sars (*Ædiliceros propinquus*, Goës ; *Monoculodes nubilius*, Packard, Mem. Boston Soc. Nat. Hist. i. p. 398, 1867) ; *Monorulodes borealis*, Boeck (*Ædiliceros affinis*, Goës) ; *Paramplithoe pulchella*, Bruzelius (*Kroyer* sp.) ; *Paramplithoe cataphracta*, (*Amphithonotus cataphractus*, Stimpson), "this species is apparently a true *Paramplithoe*, as restricted by Boeck, and closely allied to, if not identical with, *P. panopla* Bruzelius (*Amphithoë panopla* Kroyer). Boeck places *Pleustes tuberculatus* Bate as a

synonym of Kroyer's species, and if he is correct in this our species is undoubtedly distinct"; *Vertumnus serratus?*, Goës (Fabricius sp.), (*Acanthonotus serratus*, Stimpson), "Our specimens all differ from the descriptions and figures given by Boeck and Kroyer in the armature of the posterior margin of the third segment of the abdomen. In our specimens the upper process from this margin is armed with four or five teeth above and at the tip, while the lower process is armed with five or six teeth similarly situated, but with no teeth on the lower margin except just at the tip. In Kroyer's figure (Grönlands Amfipoder. plate ii. figure 8) the upper process is represented as terminating in a single tooth and the lower process as toothed along both sides; Boeck's description agrees with this, except that he says there are two teeth at the tip of the upper process"; Boeck afterwards changed the name to *Acanthonotozoma serratum*; *Acanthozone cuspidata*, Boeck; *Byblis gaimardi*, Boeck (Kroyer sp.), "the *Ampelisca Gaimardi* of Bate, and Bate and Westwood, is not this species, but a true *Ampelisca*. All the species of this subfamily are undoubtedly tube dwellers. . . . In this species, the glands which secrete the cementing fluid are situated principally in the meral and basal segments of the third and fourth pairs of thoracic legs;" *Xenoclea megachir*, Smith, n. s., Pl. IV [III], figures 1 to 4. "'Pedes 3tii et 4ti paris articulo 1mo latissimo' of the generic description would scarcely apply to our species, but in all the other generic characters it agrees perfectly, as it does also with the diagnosis of the subfamily Photinæ, except that the mandibles each bear six serrated spines instead of the usual number, four." In this species Professor Smith noticed a peculiar "glandular structure filling a large portion of the third and fourth pairs of thoracic legs." "The terminal segment (dactylus) in these legs is not acute and claw-like, but truncated at the tip and apparently tubular." "A large cylindrical portion of the gland lies along each side of the long basal segment, and these two portions uniting at the distal end pass through the ischial and along the posterior side of the meral and carpal segments, and doubtless connect with the tubular dactylus. There can be no doubt that these are the glands which secrete the cement with which the tubes are built, and that these two pairs of legs are specialized for that purpose." In *Amphithoë maculata* the gland is in the middle of the basal segment. Other arrangements with reference to this gland are mentioned for *Cerapus rubricornis*, *Ptilocheirus pinguis*, *Byblis gaimardi*, and a species of *Ampelisca*.

1874. SMITH, S. I.

Tube-building Amphipoda. The Annals and Magazine of Natural History. No. 81. September 1874. Vol. XIV. Fourth Series. London, 1874. p. 240. Silliman's American Journal, June, 1874.

The cement-glands are described in *Xenoclea* sp., and noted in *Amphithoë maculata*, *Ptilocheirus pinguis*, *Cerapus rubricornis*, *Byblis gaimardi*, *Ampelisca* sp. In the *Cerapus* "the orifice in the dactylus is not at the very tip, but subterminal on the posterior side." In *Ampelisca* and *Byblis* "the remarkable elongation of the two distal segments in the third and fourth pairs of legs is perhaps a special adaptation to enable them to reach back over the deep epimera." See Note on Smith and Harger, 1874.

1874. SMITH, S. I.

The Crustacea of the fresh waters of the United States. pp. 637-661. Sketch of the Invertebrate Fauna of Lake Superior. pp. 690-706. Food of fresh-water fishes. pp. 708-709. Extract from the report of Prof. S. F. Baird, Commissioner of fish and fisheries, Part II, Report for 1872-'73. Washington, 1874.

At page 645, the account of the Amphipoda begins with the family ORCHESTIDÆ, and the new genus *Hyalella*, thus described:—

“First pair of maxillæ with rudimentary, very short, and uniarticulate palpi. Palpus of the maxillipeds composed of five segments; the terminal segment being slender and styliform, and the penultimate broad. Antennulæ, antennæ, and thoracic legs much as in *Hyale*. Telson short, stout, and entire.

“This genus seems to be closely allied to *Hyale*, but differs from it and from the rest of the *Orchestidæ* in the palpus of maxillipeds, which has five instead of four segments, showing in this respect a remarkable approach toward the gammaroid group of *Amphipoda*. From *Hyale* it differs also in the telson.”

For a discussion of the genera *Hyale* and *Hyalella*, see Note on Rathke, 1837. *Hyalella dentata*, n. s., pl. ii, figs. 8-10, is here described. After the description had been sent to the printer, Professor Smith received many additional specimens from Lake Okeechobee, Florida. In some of these, he says, “the dorsal teeth upon the first and second segments of the abdomen are very small; and, in a very few specimens, they are wholly, or almost wholly, wanting.” The *Amphilochus aztecus*, Saussure, “undoubtedly belongs to this genus, and may be called *Hyalella azteca*.” *Allorchestes knickerbockeri* of Bate “belongs probably to this genus”; “the palpus of the first pair of maxillæ, in Bate’s species, is figured (perhaps incorrectly) as composed of two segments.”

In the family LYSIANASSIDÆ, “*Pontoporeia Hoyi*,” pl. ii, fig. 5, is entered as a new species, with the synonymy, “*Pontoporeia affinis* Smith, American Journal of Science, 3d series, vol. ii, p. 452, 1871; and Preliminary Report on Dredging in Lake Superior, p. 1022, 1871. *Gammarus Hoyi* Stimpson, MSS., (full-grown male form.) *Gammarus brevistylis* Stimpson, MSS., (female).” Professor Smith had originally regarded his specimens “as specifically identical with the *Pontoporeia affinis* of the Scandinavian lakes and the Baltic. A subsequent and more minute comparison has, however, revealed some differences, which are apparently constant.” “The most remarkable differences are in the peculiar, elongated, papilliform appendages upon the sternal portion of the thoracic segments.” These, it appears, are more numerous in the American specimens than in the European, as described by G. O. Sars in 1867. A second new species, *Pontoporeia filicornis* (*Gammarus filicornis* Stimpson, MSS.), is founded on a single specimen. “This species differs remarkably from all the heretofore known species of *Pontoporeia* in the excessive elongation of the flagella of the antennulæ and antennæ, a character which might be regarded by some naturalists as of generic value. The very close agreement with *P. affinis* and *Hoyi* in all other parts of the animal, however, seems to indicate a very close affinity with those species, especially the latter; and as this one peculiarity is very likely only a sexual character of the old males of the species, I retain the species in the genus.” The detailed account seems to make it doubtful whether the name *Pontoporeia affinis* would not suffice both for this and the preceding species.

In the family GAMMARIDÆ, is described *Gammarus limnaeus*, Smith, pl. ii, figs. 6, 7, (*Gammarus lacustris*, Smith, 1871), “this species is very closely allied to the *Gammarus neglectus* of G. O. Sars, which inhabits the lakes of Norway,” of which *lacustris* is a synonym, or

perhaps rather the rightful name, and from which Professor Smith says that his species, though differing only in minor details, is undoubtedly entitled to be considered distinct. Very large specimens had been obtained in Colorado, from an elevation of 9000 feet. He next describes *Gammarus fasciatus*, Say. Of *Gammarus minus*, Say, he remarks that he has "not yet been able to rediscover this species, which is very likely not a true *Gammarus*." The *Gammarus minus* of De Kay, he says, "is made up principally of Say's original description," with a "rude attempt at a figure" apparently from some other species, probably *Gammarus fasciatus*. He describes both sexes of *Crangonyx gracilis*, Smith, 1871, and mentions *Crangonyx vitreus*, Packard, 1873, giving under protest as a synonym, "?? *Stygbromus vitreus* Cope, American Naturalist, vol. vi, p. 422, 1872; Third and Fourth Annual Reports of the Geological Survey of Indiana, p. 181, 1872." He describes *Crangonyx tenuis*, n. s., "a slender, elongated species, with very low epimera, resembling more in form the species of *Niphargus* than the typical species of *Crangonyx*."

In the "Sketch of the Invertebrate Fauna of Lake Superior," four Amphipoda are mentioned, *Hyalella dentata*, "*Pontoporeia Hoyi*," *Gammarus limnaeus*, *Crangonyx gracilis*, with references to the descriptions already given.

In the Section on the "Food of Fresh-water Fishes," "*Pontoporeia Hoyi*," is mentioned as found in the stomach of the White-fish (*Coregonus albus*), at various stations.

1874. STEBBING, THOMAS ROSCOE REDE, born February 6, 1835.

Amphipodous Crustacea. A new species, and some items of description and nomenclature. The Annals and Magazine of Natural History, July 1874. Ser. 4. Vol. 14. London, 1874. pp. 10-15. Pls. I. II.

"*Liljeborgia Normanni*" is described and figured as a new species, near to *Liljeborgia shetlandica*, Bate and Westwood, both species being synonyms of *Cheirocratus sundevalli*, Rathke. A variety of *Iphimedia eblanæ* is described and figured, as intermediate between that species and *Iphimedia obesa*, with the suggestion that distinction implied by the two specific names may, in fact, be one of sex. The male of *Microdeutopus versiculatus*, Sp. Bate, is figured and discussed. This species, in Boeck's opinion, may be the same as *Autonoe longipes*, Lilljeborg, but the first gnathopods do not suit that view. The alteration of *Microdeutopus* to *Microdeuteropus*, accepted in this paper, I no longer think necessary. *Microprotopus maculatus*, Norman, is figured, and some notes are given on that species. *Gammarella brevicaudata*, ♀, Milne-Edwards, is figured and discussed to show that "*Gammarella Normanni*," Bate and Westwood, is in fact the female of Milne-Edwards' species. This had been already suggested by Mr. Spence Bate in the Brit. Mus. Catal., p. 379.

1874. STEBBING, T. R. R.

On some species of *Amphithoë* and *Sunamphithoë*. The Annals and Magazine of Natural History, for August 1874. Ser. 4. Vol. 14. Pls. XI. XII. pp. 111-118.

Amphithoë cuniculus, n. sp., is described and figured. *Amphithoë rubricata*, Montagu, is compared with *Amphithoë littorina*, Sp. Bate, and the inference drawn that they are varieties only of the same species. *Amphithoë littorina* is by Boeck identified with *Amphithoë podoceroides*, Rathke, but Montagu's name being still older will take

precedence. Figures and descriptions are given of both sexes of *Sunamphithoë gammaroides*. This I believe to be identical with the partially described *Amphithoë gammaroides* of Spence Bate. Both sexes are described of *Sunamphithoë conformata*, Sp. Bate, with the suggestion that *Sunamphithoë hamulus*, Sp. Bate, is in fact not a separate species, but the female of *Sunamphithoë conformata*. The name of the species, however, should be *hamulus*, although the synonymy, as given both in the Brit. Mus. Catal. and in the Sessile-eyed Crustacea, leads to the (erroneous) inference that *conformata* was the earlier established. As a matter of fact *hamulus* stands first at the original contemporary institution of the two names.

1874. STEBBING, T. R. R.

The sessile-eyed Crustacea of Devon. (Read at Teignmouth, July, 1874.) The Transactions of the Devonshire Association for the Advancement of Science, Literature and Art. Vol. VI. Part II. Plymouth, 1874. pp. 764-773, with plate.

No new species are described in this paper, which was intended as a supplement to Mr. Parfitt's Catalogue, 1873. *Grayia imbricata*, Sp. Bate, is figured, and notice taken that, contrary to one of the characters assigned to the genus *Grayia*, it has an accessory flagellum on the upper antennæ. This species has since been recognised as the young of *Amathilla sabini* (*homari*, Fabr.). The suggestion is made that *Sulcator arenarius*, Sp. Bate, is probably the same as the *Lepidactylis* of Say. This surmise has since been confirmed by S. I. Smith. *Phaedra kinahani*, Spence Bate, was included in the list by mistake.

1874. VERRILL, A. E., and SMITH, S. I.

Report upon the invertebrate animals of Vineyard Sound and adjacent waters, with an account of the physical features of the region. Extracted from the Report of Professor S. F. Baird, Commissioner of Fish and Fisheries, on the condition of the sea-fisheries of the South Coast of New England in 1871 and 1872. Washington, 1874.

The Amphipoda in this report were identified by Mr. S. I. Smith. At page 19 (313) Mr. Verrill says, "these small crustacea . . . together with the shrimps, constitute a very large part of the food of most of our more valuable edible fishes, both of the fresh and salt waters." The *Orchestia agilis* of Smith, "occurs in countless numbers beneath the masses of decaying sea-weeds." "A much larger species, and one of the largest of all the amphipods, is the *Gammarus ornatus*." "The males are much larger than the females, and sometimes become nearly an inch and a half long." "The only good English name that I have ever heard for these creatures is that of 'seuds,' given by a small boy, in reference to their rapid and peculiar motions." Other species are mentioned, which will be noticed further on. In a "list of species inhabiting the rocky shores of the sounds and bays," p. 37 (331) eleven Amphipods are named.

Of *Talorchestia longicornis* and *Talorchestia megalophthalma*, of the sandy shores, he says, "when driven from their burrows by unusually high tides or storms they are capable of swimming actively in the water," p. 42 (336). Of the sandy shore species he mentions also *Orchestia agilis*, *Lepidactylis dytiscus*, *Unciola irrorata*. To the muddy shores six species of Amphipoda are assigned, p. 83 (377). Among the species commonly found on

submerged woodwork six Amphipoda are mentioned, p. 98 (392), among which it is curious to note that *Chelura terebrans* is not included. Of Amphipods ordinarily found on the bottoms of the bays and sounds, he enumerates for those that are rocky, p. 115 (409), nine species; for those that are gravelly and shelly, p. 128 (422), seven species; for those that are sandy, p. 134 (428), two species, *Lepidactylis dytiscus* being included in this and the two preceding lists; lastly, for those that are muddy, p. 140 (434), "several species" of Lysianassinae, and eight of genera in other families.

In the section on "free-swimming and surface animals," he says, "several species of Amphipods are also common at the surface. The most abundant were *Calliopius lærusculus*, of which Mr. V. N. Edwards also took numerous large specimens in February and March; *Gammarus natator*, which was usually common, and occurred in immense numbers August 10 and on several other occasions; and a *Hyperia*, which infests several species of large jelly-fishes, and also swims free at will. The *Phronima* is a related genus, but is very remarkable for its extreme transparency, which renders it almost invisible in water." The list, p. 158 (452), mentions "several species" of Lysianassinae, and eleven species of genera in other families.

At p. 163 (457), he says, "among the Crustacea there are a few species of Amphipods that are parasitic. One of these, *Laphystius sturionis*, lives upon the gills of fishes and upon the surface of the body. It was found on the gills of the "goose-fish" (*Lophius*), in Vineyard Sound, and on the back of skates at Eastport." In the list of external parasites, he mentions, besides *Laphystius sturionis*, "Hyperia, species, on jelly-fishes."

On the sandy shores and bottoms of estuaries, three Amphipods are recorded, p. 170 (464); on the muddy shores and bottoms of brackish waters, eight species, p. 177 (471); on oyster beds in brackish waters, four species, p. 182 (476); among eel-grass in brackish waters, eight species, p. 186 (480); on piles, etc., in brackish waters, four species, p. 188 (482); on outer rocky shores, nine species, p. 193 (487); on sandy shores of the open coast, four species, p. 196 (490); on the stony and rocky bottoms on the open coast, nine species, or more, since he says, "species of *Caprella* occur in considerable numbers," p. 200–204 (494–498); on sandy and gravelly bottoms off the open coast, eight species, p. 210 (504); on soft mud and sandy mud off the outer coast, seven species, p. 217 (511).

In the "lists of species found in the stomachs of fishes," pp. 220–227 (514–521), he mentions "SCUP; PORGE; (*Stenotomus argyrops*.) Forty young specimens, one year old, taken at Wood's Hole in August, contained large numbers of Amphipod Crustacea, among which were *Unciola irrorata*, *Ampelisca*, sp., etc." "HADDOCK; (*Melanogrammus aeglefinus*). . . . A specimen taken at Wood's Hole, November 6, 1872, contained a large quantity of *Gammarus natator*." "TOM-COD; FROST-FISH; (*Microgadus tom-codus*.) Several specimens from New Haven Harbor, January 30, contained numerous Amphipods, among which were *Mura levis*; *Gammarus*, sp.; *Ampelisca*, sp.;" others at Wood's Hole, in March, contained "large quantities of Amphipods, especially of *Gammarus annulatus*, *G. natator*, *Calliopius læruscula*, and *Microdeutopus minax*; and smaller numbers of *Gammarus ornatus* and *G. mucronatus*. Another lot of twelve, taken in April at the same place, contained most of the above, and in addition several other Amphipods, viz., *Mura levis*, *Pontogeneia inermis*, *Ptilochirus pinguis*, and *Caprella*." "OCELLATED FLOUNDER; SUMMER FLOUNDER; (*Chænopsetta ocellaris*). . . contained . . . Amphipod Crustacea belonging to the genus *Ampelisca*." "SPOTTED FLOUNDER; (*Lophopsetta maculata*). . . contained . . . numerous Amphipods, *Gammarus mucronatus*." SEA-HERRING; (*Clupea elongata*). . . contained . . . large numbers of an Amphipod, *Gammarus natator*."

The Systematic Catalogue of the Amphipoda inhabiting the coast between Cape Cod and New York, drawn up by Mr. S. I. Smith, occupies pages 261–273 (555–567). It includes

Orchestia agilis, n. s., pl. iv. fig. 14; *Orechestia palustris*, n. s.; *Talorchestia longicornis*, Smith (*Talitrus longicornis*, Say, *Orchestia longicornis*, M.-Edw., and De Kay); *Talorchestia megalophthalma*, Smith (*Orchestia megalophthalma*, Bate, *Talitrus quadrijidus*, De Kay, "may be based on the female of one of the preceding species, but it is so badly described and figured as to be indeterminable"); *Hyale littoralis*, Smith (*Allorchestes littoralis*, Stimpson); *Lysianassa*, species; *Lepidactylis dytiscus*, Say; *Phoxus kroyeri*, Stimpson; *Urothoë*, species; *Monoculodes*, species; *Laphystius sturionis*, Kroyer (*Darwinia compressa*, Bate); *Calliopius lærusculus*, Boeck (Kroyer); *Pontogeneia inermis*, Boeck (*Amphithoë inermis* and *crenulata*, Kroyer, *Iphimedea vulgaris*, Stimpson); *Atylus inermis*, *crenulatus*, and *rufus*, Bate; *Atylus vulgaris*, Packard, not *Atylus (Paramphithoë) inermis*, Packard, Mem. Boston. Soc. Nat. Hist., vol. i. p. 298, 1867); *Gammarus ornatus*, M.-Edw., pl. iv. fig. 15 (*Gammarus locusta*, Gould; *Gammarus pulex*, Stimpson); *Gammarus annulatus*, n. s.; *Gammarus natator*, n. s.; *Gammarus marinus*, Leach; *Gammarus mucronatus*, Say (*Gammaracanthus mucronatus*, Bate, on which Smith remarks, "our species cannot be referred to Bate's genus *Gammaracanthus*, for the dorsal margin is not distinctly earinated, and the third, fourth, and fifth segments of the abdomen are furnished with fascicles of spines."); *Mora levis*, n. s.; *Melita nitida*, n. s.; *Ampelisca*, sp., pl. iv. fig. 17, undescribed; *Byblis serrata*, n. s.; *Ptilochirus pinguis*, Stimpson, which falls to Zaddach's genus *Leptocheirus*; *Microdeutopus minax*, n. s.; *Autonoe*, sp.; *Amphithoë maculata*, Stimpson, pl. iv. fig. 16; *Amphithoë valula*, n. s.; *Amphithoë longimana*, n. s.; *Amphithoë compta*, n. s.; *Podocerus fucicola*, Smith (*Cerapus furcicola*, Stimpson); *Podocerus*, sp.; *Cerapus rubricornis*, Stimpson, pl. iv. fig. 18, which Smith later identifies with *Erichthonius difformis*, M.-Edw.; *Cerapus minax*, n. s., presumably *Erichthonius minax*, since in 1880, Smith attributes to the genus *Cerapus, tubularis*, Say, as the only species); ? *Cerapus tubularis*, Say, subsequently identified without doubt; *Corophium cylindricum*, Smith (*Podocerus cylindricus*, Say, not of Bate); *Siphonoecetes cuspidatus*, n. s.; *Unciola irrorata*, Say, pl. iv. fig. 19; *Hyperia*, species, "upon the large red jelly-fish (*Cyanea*)"; "another species of *Hyperia* was taken at the surface in company with *Salpa*"; *Phronima*, species, "closely allied to the *P. atlantica* of Guérin. According to Professor Verrill's notes it is, in life, translucent, scarcely tinged with yellowish-white, and nearly invisible in the water; the eyes red. Another form allied to the last was taken with it, and is possibly the male of the same species, but differs from it, and from the characters usually assigned to the genus, in possessing well-developed antennulae. In life, according to Professor Verrill, it was translucent whitish, the body spotted with dark brown, and the eyes blackish."; *Thyropus*, species; *Caprella geometrica*, Say, pl. v. fig. 20, which Mayer identifies with *Caprella acutifrons*, Latreille; *Caprella*, species.

In the addenda, p. 451 (745), is given, *Themisto*, species undetermined. "It occurred swimming at the surface in vast numbers, and was thrown up by the waves in windrows, extending several miles along the shores of Martha's Vineyard."

1874. WILLEMOES SUHM, RUDOLPH VON,

On a new Genus of Amphipod Crustaceans. Received February 27,—Read March 6, 1873. Philosophical Transactions of the Royal Society of London. For the year MDCCCLXXIII. Vol. 163. London, MDCCCLXXIV. pp. 629–636. Pls. XLIX., L.

Thaumops pellucida, already mentioned in the Proc. R. S., 1873, but here figured and more fully described, was afterwards recognised as *Cystisoma neptunus* or *neptuni*, Guérin, 1842,

for which see Note under that date, and compare the account of *Oniscus spinosus*, Fabr., 1775. Some mistakes made in this paper were corrected in an appendix. See the following Note. The specimen was included in a haul made by the Challenger on January 28, 1873, when "the trawl was sent down, in lat. $35^{\circ} 47'$, long. $8^{\circ} 23'$, to a depth of 1090 fathoms." Among other points of interest Dr. Willemoes Suhm here mentions that the muscles of the thoracic legs are only very weakly developed, from which he infers "that the movements of the animal are not very rapid when it is obliged to walk over the sea-bottom." "The transparency of the body makes it possible likewise [to distinguish clearly the cephalic ganglion and the ventral chain, consisting of five thoracic and three abdominal ganglia (Plate XLIX. fig. 1). The cephalic ganglion is situated in the anterior part of the head, more on the dorsal than on the ventral side; it is 3·50 millims. in width, and is horse-shoe-shaped with pointed ends. From the middle of its anterior margin two large nerves run straight to the end of the antennae, while from the opposite side two commissural cords run backwards, traversing the head and, after having encircled the mouth, uniting with the first thoracic ganglion. The nerves passing from the sides of the cephalic ganglion are all employed as ocular nerves to supply the huge compound eyes. These of the anterior end are better seen, as they go to the anterior part of the eyes, while those of the posterior end seem to go to the posterior parts.

"The first thoracic ganglion is seated just underneath the ovary in the second segment, and sends out the nerves for the mouth and the genital organs. The two cords then separate till they are united again in the third segment in the second ganglion; thence they run backwards in a single chain and form a ganglion in each of the subsequent segments, sending nerves to the legs. Altogether we find five thoracic ganglia for six segments, and in the abdomen three ganglia for five segments. The last ganglion of the abdomen is more slender than the preceding ones, and seems to send out nerves in different directions, especially to the anus and caudal appendages. In *Phronima* there are ten pairs of ganglia, five of which, as in the present case, are thoracic and five abdominal." Claus, 1879, it will be found, assigns only four ganglia to the abdomen in the Phronimidae.

The caecal appendage of the stomach, described by Claus for *Phronima*, "has, in the present species, assumed so large dimensions as to have replaced the stomach, which does not exist morphologically, but is physiologically represented by the cæcum."

"The heart is an elongated tube extending from the second to the fifth segment (Plate XLIX. fig. 3, c). Probably there are three openings in it as in *Phronima*, one in each segment; but of these nothing could be made out.

"The respiratory organs consist of three pairs of small transparent sac-like gills at the bases of the second, third, and fourth pairs of feet (Plate XLIX. fig. 1, br). They are in form and number nearly the same as in *Phronima*."

"Genital Organs.—The single specimen taken is a female. There is a large ovary, distinguished by its rose-colour, occupying the middle portion of the first body-segment (Plate XLIX. fig. 3, ov). I suspect that it consists of two ovaries lying close together, and having two excretory ducts leading to the genital papilla." "The genital papilla is an elevation in the centre of the ventral surface of the first thoracic segment between the two limbs [the first pair of ambulatory legs], which, as I have already mentioned, are destined to bear the eggs at their base, as in the females of *Nymphon*. The colour of the papilla is rose, with scattered scarlet points produced by small spines on the surface of the carapace. In the centre of the genital papilla there is a large spine (Plate L. fig. 6, d) with a groove leading into a depression (c), in which I believe are seated the apertures of the ovarian ducts. This pit is protected by two soft appendages (Plate L. fig. 6, l), answering to the valves which are to be found in most female Amphipods, and in which they keep their eggs. In the present species, however, they are only rudimentary, and they do not seem to be

used for that purpose, as I found the eggs attached to the bases of the first pair of ambulatory legs."

The definition of the genus is given as in the "Proceedings," 1873. Willemoes Suhm thinks it nearly related to *Phronima*, but as "the genital papilla in *Thaumops* is in the centre of the first thoracic segment, while in *Phronima* it is in the seventh body-segment," and for other reasons, he thinks it cannot form a member of the family Phronimidae. In mentioning the seventh body-segment of *Phronima*, instead of the fifth, he was probably thinking not of the female but of the male.

Bovallius, 1886, says, "for my part, I am convinced that the specimen first described as *Thaumops pellucida*, must be ranged as a distinct species, which still may keep its [specific] name. The males described 1875 (l. c.) [Trans. Linn. Soc.] are perhaps identical with Guérin's species and may be placed there, awaiting a closer examination." This point, and others connected with the specific distinctions necessary to be established in this genus, will be more conveniently discussed later on in this Report.

1874. WILLEMOES SUHM, RUDOLPH VON.

Appendix. *On the Male and the Structure of Thaumops pellucida.* Received October 24,—Read December 11, 1873. Philosophical Transactions of the Royal Society of London. For the year MDCCCLXXIII. Vol. 163. London, MDCCCLXXIV. pp. 637ff.

Since the preceding paper was read three males had been caught, the largest "103 millims. in length, exceeding in length the large female by 19 millims." "These males differ from the females by the absence of the genital openings at the base of the first segment and of the breeding lamellæ. The two elongate testes begin just behind the cæcum of the stomach, and their vasa deferentia run down to the last segment of the pereion, where they terminate by two simple openings between the last pair of pereiopods." "There is not a trace of a second pair of antennæ, either in the male or in the female. In the former, however, the first pair of antennæ, the five pairs of ambulatory pereiopods, and the caudal appendages are distinguished by the want of the glandular apparatus. In the females these glands cause an enlargement at the top of each of the appendages in question, and this enlargement is of course also wanting in the male." "The mandibles, which at first I thought were entirely wanting, have now been found. They are very much like those of *Phronima*, only shorter and not so elongate as in that animal; the palps, which is present in the mandibles of the male *Typhidae*, could not be detected in *Thaumops*. The first maxillæ are also very small, and differ by their shortness from those of *Phronima*, but otherwise show the same characters. The second maxillæ could not be found with certainty; they are either wanting or represented by an organ which I thought was the labium (Plate L. fig. 6, *lab*). This organ arises from the second joint of a very peculiar appendage, which I have interpreted in my first paper as maxillæ (Plate L. fig. 6, *ma*). I am now satisfied, however, that these are the maxillipeds, consisting of three joints. Two of these joints are united together, the first being attached to the oral apparatus, and the second giving rise to a peculiar organ which consists of two chitinous claws united by a thin layer of the same substance, so as to form a sort of plate. I have already mentioned that I am not quite sure whether this is a labium or, as it seems more probable, the result of the displacement and union of the second maxillæ. This organ is situated at the inner side of the maxillipeds, the third joint of which consists of two strongly denticulated and separate claws. The two appendages (Plate XLIX. fig. 1, *mx*) which I first thought act as maxillæ are the gnathopoda of SPENCE

BATE, followed by five pairs of pereiopods. The pleopods or swimmerets consist in the male, as well as in the female, of only three pairs."

He still thinks it represents a new family of Hyperidæ, to be placed next to the Phronimæ. It approaches the Typhidae, he says, by "the elongate shape of the head, with the mouth underneath and the claws terminating the gnathopods. On the other hand, however, the want of the second antennæ in the male, the elongate slender shape of its first antennæ, which show nothing of the enlargement and the olfactory hairs peculiar to the male *Typhidae*, and the want of the palpus in the male mandible, show that it differs widely from the *Typhidae*."

He now defines it thus:—

"Caput oblongum, oculis maximis superiorem capitidis partem tegentibus. Segmenta thoracica septem, abdominalia quinque. Antennarum in utroque sexu par unum. Mandibulæ et maxillæ minimæ. Maxillipedum par unum conjuuctum. Pedum thoracicorum paria septem, anteriora duo parva et chelis armata. Pedum abdominalium paria tria." There is no doubt, he says, that *Thaumops pellucida* is a pelagic Crustacean, retreating sometimes to considerable depths, and coming up only in the night.

1874. WILLEMOES SUHM, R. VON.

The largest Amphipod. Nature. January 8, 1874. Volume IX. London and New York, 1874. p. 182.

This is a letter remarking that *Thaumops pellucida* "has been already described by Guérin-Méucville under the name of *Cystosoma neptuni*," and that the female caught in the Atlantic "had a length of 84 mm., not of 14 mm.," as had been erroneously reported.

1874. WRZEŚNIOWSKI, AUGUSTUS.

On Callisoma Branickii, a new Species from Nice. The Annals and Magazine of Natural History. No. 79. Vol. XIV. Fourth Series. London, 1874. pp. 15–16.

The new species is compared with "*Callisoma Hopei* and *C. crenata*," which it is said to resemble in the first and second gnathopoda, and in the coxae of the five anterior pairs of appendages, "but those of the fourth pair of pereiopoda considerably deeper than the ones appertaining to the fifth pair." "The basis in the fourth pair" of pereiopoda "considerably broader and higher than in the fifth pair." There are notches on the dorsal surface of the fourth and fifth pleon-segments. "Telson deeply cut, but single."

1875. CATTA, J. D.

Amphipodes du Golfe de Marseille. Comptes rendus hebdomadaires des séances de l'Académie des Sciences. Tome Quatre-vingtième. Paris, 1875. p. 831.

In this extract, Catta says, "en résumé, des Amphipodes normaux sont déjà représentés, dans le Golfe de Marseille, par une trentaine de genres, dont un au moins nouveau, et par soixante-dix à soixante-quinze espèces différentes. Six espèces nouvelles et deux variétés, de formes surtout adriatiques, donnent pour ainsi dire la physionomie de la faune locale."

1875. CATTÀ, J. D.

Note pour servir à l'histoire des Amphipodes du Golfe de Marseille. Revue des Sciences Naturelles. Tome IV.—No 1. 15 Juin 1875. Montpellier. pp. 161—169.

The first species mentioned is "*Iridium Rissoanum*," for which the synonymy is thus established. *Iridium fuscum*, Grube, 1863, *Phlias rissoanus*, Sp. Bate, 1862. *Pereionotus testudo*, Sp. Bate and Westwood, "ne saurait se distinguer d'*I. Rissoanum* que par la petitesse de ses yeux et par les dents qui garnissent le bord interne de son antenne supérieure. Ce sont là *tout au plus* des différences spécifiques; les deux Amphipodes appartiennent donc au même genre, et, comme la publication de Grube est de quelques mois antérieure à celle des auteurs anglais, *Pereionotus testudo* doit deveuir aussi *Iridium testudo*." Professor Catta had previously said, "si on ne met pas en doute la description de Guérin de Mennevile, le genre *Phlias* doit rester pour ne renfermer uniquement que le *P. serratus*, dont le Pléon serait tout-a-fait normal." The question of the telson seems here to be left still in obscurity, unless we may presume that it is present, from the identification of the names given above, since, although Grube's *Iridium* is described as having "telson nullum," both *Phlias* and *Pereionotus* are described with a telson. In my opinion *Phlias* should be accepted as the generic name in preference to *Iridium* and *Pereionotus*. But of the two latter, *Pereionotus*, having been instituted in 1862, has the precedence.

"*Peltocora Marionii*" (n. g.) is thus described:—

"Ce nouveau Crustacé a été trouvé dans les fonds coralligères de la calanque de Podesta. Sa longueur, du bout des antennes à l'extrémité du pléon, n'atteint pas 1 millim. Deux de ses coxas sont énormément développés et forment par leur réunion un véritable bouclier rond, large et bombé. Comme cette disposition se répète des deux côtés du corps, l'animal peut se rouler complètement entre ses deux armures et ne plus offrir dans cette position que l'aspect d'une lentille microscopique. L'antenne supérieure, courte et trapue, est terminée par un singulier flagellum dont les articles décroissent très-brusquement et très-inégalement de diamètre. Je ne connais rien, chez les Amphipodes, d'analogue à cette antenne; aussi est-ce avec quelques réserves que je rapproche ce nouveau genre de la famille des Stégocephalidés. Je dédie cette espèce typique à M. Marion." In 1880 Mr. Haswell instituted the genus *Cyproidilia*, with the species *ornata* and *lineata*, to which in 1885 I added an English species, *damnoniensis*. In 1882 Sars instituted the genus *Stegoplax*, family Amphilochidae. It is possible, or even probable, that *Cyproidilia* and *Stegoplax* are synonyms of *Peltocora*, but with so brief a description as the above, it is difficult to decide either as to genus or species.

Phoxus erythrophthalmus, n. s., is said to come near "*P. Holbölli* de Kröyer," from which it differs, "surtout par la présence d'un œil très parfait de chaque côté de la tête." This eye, he says, does not disappear even when the creature has been long kept in spirit.

"*Anonyx Brocchii*," n. s., is said to be near "*A. Edwardsii* (Kröyer), dont il se distingue par la forme plus ramassée de l'antenne supérieure, par quelques particularités caractéristiques du cinquième siagonopode et par le telson, dont chaque moitié se termine par un poinçon très aigu."

"*Nicea Pontica* (Rathke sp.)," is mentioned as belonging to *Nicea*, rather than to *Hyale*, because of Rathke's error in describing the last uropod as bifurcate. But this seems an insufficient reason for cancelling a generic name. It is noted that Czerniavski, though knowing Rathke's species, nevertheless institutes a variety of "*Nicea Pereiri*," under the name of "*Pontica*."

"*Nicea Prevostii* (H. Milne-Edw.)" is given, with "*Amplithoë Prevostii*," M.-Edw., and "*Nicea Macronyx*," Heller, for its synonyms.

Of *Liljeborgia pallida*, Sp. Bate, he confirms Sp. Bate's suspicion, that the telson is not only cleft, but double.

Of *Microdeutopus anomalus* (Rathke), he thinks it probable that it is the female of *Microdeutopus gryllotalpa*. He mentions *Eurystheus erythrophthalmus*; *Iphimedia obesa*, Rathke; *Ampelisca belliana*, Sp. Bate; *Leucothoe denticulata*, Costa; *Leucothoe articulosa*, Montagu; *Moera truncatipes*, Spinola, with which he thinks Heller's *Mera scissimana* identical; *Moera integrifrons*, Heller; *Lysianassa audouiniana*, Sp. Bate; *Lysianassa spinicornis*, Costa; and alludes to unnamed species in various other genera of Amphipods, which may be found in the gulf.

1875. GRIMM, OSCAR.

Briefliche Mittheilungen an C. Th. v. Siebold über eine zoologische Untersuchungs-Expedition nach dem Kaspischen Meere. Zeitschrift für wiss. Zool. 25 Band. Leipzig. 1875. pp. 323-326.

He collected 350 specimens of Gammarids, belonging to four or five species, some of them colossal forms.

1875. HELLER, CAMIL.

Die Crustaceen, Pyenogoniden und Tunicaten der K. K. Österr-Ungar. Nordpol-Expedition. Mit fünf Tafeln. Vorgelegt in der Sitzung am 19. Juli 1875. The plates are inscribed "Denkschriften d. k. Akad. d. W. math. naturw. Cl. II. Abth. XXXVI. Bd. 1875." The back of the title page says "Besonders abgedruckt aus dem XXXV. Bande der Denkschriften," etc.

A full description and figures are given of the new species *Cleippides quadricuspis* and *Amathillopsis spinigera*. Some of the differences pointed out between *Cleippides quadricuspis* and *Acanthonotus (Cleippides) tricuspidatus*, Kröyer, may be due to age or accident; it is highly improbable, for example, that the mandible in the one should possess an accessory cutting-plate and a spine-row, and the other be without them. These would rather be generic differences, of which there does not seem to be any question.

The new genus *Amathillopsis* has its definition included in the Latin description of the species:—

"Corpus compressum, dorso carinato, carina segmentorum in spinas retroversas exenti; epimeris parvis, rigidis, extorsum flexis. Antennæ superiores inferioribus longiores, pedunculo elongato, flagello appendiculari brevi. Mandibulæ robustæ, in apice dentatae, processu accessorio etiam dentato, palpo triarticulato, articulo tertio breviore quam secundo. Maxillæ primi paris lamina interiore lata, longa, in margine anteriore setis sex plumosis instructa. Pedes maxillares lamina exteriore brevi, vix ad dimidium articulum palpi secundum elongatum porrecta. Pedes 1st et 2nd paris ferme eadem forma, subcheliformes, non pervalidi; articulo quarto et quinto longitudine ferræ æqualibus, carpo in angulo inferiore posteriore in processum parvum producto, manu ovali in margine interiore setis et spinis tenuibus instructa. Pedes trium parium ultimorum articulo primo sat angusto, pedes septimi paris iisdem parium duorum praecedentium breviores. Caput rostro frontali

brevi instructum, oculi rotundati. Dorsum carinatum, omnia segmenta thoracis et quatuor segmenta postabdominis anteriora carina in margine posteriore in dentes aeutos desinenti. Angulus inferior posticus lateralis segmenti postabdominis 1st, 2nd et 3rd in dentem aeustum productus. Pedes saltatorii ultimi paris praelongati, ramis laminiformibus, in margine spinulosis. Appendix caudalis obovata, usque ad dimidiam partem styli pedum saltatoriorum ultimi paris porrecta, in margine posteriore sinuata." It is further remarked that this new genus stands between *Amathilla* and *Gammaracanthus*, that it has in common with *Amathilla* the compressed carinate body, the small similarly shaped subcheliform first and second gnathopods, and the simple emarginate telson, while it is distinguished from it by the elongated upper antennæ, the presence of an accessory flagellum, the slender form of the first (femoral) joints of the three last pereopods, the elongate third propods and the shortened third joint of the mandibular palp. With *Gammaracanthus* it agrees in the form of the antennæ, in the shape of the first joints of the three last pereopods, as well as in the elongated last uropods. It is easily distinguished from it by the short rostrum, the feeble gnathopods, the form of the telson, the structure of the mandibles and mandibular palp, the strongly outward curved lateral edges of the pereon-segments, and the small inferiorly toothed side-plates.

It is rather doubtful whether this genus belongs to the Gammarinæ, among which Heller in the above remarks seems inclined to place it. It seems to approach the subfamily Epimerinæ, Boeck, notwithstanding the minute secondary appendage to the upper antennæ, in the presence of which it in fact resembles *Amathilla* as well as *Gammaracanthus*. An additional species, *Amathillopsis affinis*, from Franz-Josef Land, has been contributed to the genus by Mr. E. J. Miers.

Figures and descriptions are given of " *Anonyx lagena* Kroyer," " *Aristias tumidus* Kroyer," "*Onisimus littoralis* Kroyer," with some notes on " *Acanthostephia Malmgreni* Goës," and some other known species. To Kroyer's *Anonyx lagena*, " *Cancer ampulla* Phipps" is given as a synonym, obviously only by a slip for *Cancer mugax*.

1875. LENZ, HEINRICH.

Die wirbellosen Thiere der Travemünder Bucht. Berlin, 1875. pp. 14-17.
Also in Schrift. d. Naturwiss. Ver. Schleswig-Holstein. I. Bd. pp. 291, 292,
1875.

Seven species of Amphipoda occur in the inlet of Travemünde, Baltie. (Dr. von Martens, Zool. Record for 1875.)

1875. LOCKINGTON, W. N.

Observations on the genus Caprella, and description of a new species. Proceedings of the California Academy of Sciences. Vol. V. 1873-4. (San Francisco, June 1875) pp. 404-406.

Of this paper P. Mayer, Caprelliden, p. 70, gives the following account, " *Caprella spinosa*. Lockington, from Hakodadi Bay, is distinguished by the considerable length of the male (body exceeding 1 inch, anterior antennæ 1 inch long). From the description, however, nothing further can be derived, than that the author does not know the genera with more than five pairs of legs, and also that he takes no account of the mandibular-palp, etc. The species must therefore be considered indeterminate."

1875? MAITLAND, R. T.

Naamlijst van Nederlandsche schaaldieren. Tijdschrift der Nederlandsche Dierkundige Vereeniging. Eerste Deel. 'S Gravenhage, Rotterdam, 1875 ? pp. 228-269.

The Amphipoda, pages 241-246, include the names and localities for species of Gammarina numbered 45-60, one of the Hyperina, 61, and Caprellina numbered 62-68. For *Gammarus fluviatilis*, Roesel, Maitland gives the locality as "Onder steenen in een helder stroomende beek buiten de tolsteeg-barrière nabij Utrecht en int Gein bij Abcoude." Of *Gammarus pulex*, Fabr., he says, "In groote menigte in bijna alle slooten en staande wateren onder steenen en balken, tusschen waterplanten enz. zeer gemeen." *Lysianassa*, Edw., he naturalizes into *Lysianassa*. "*Amphitoë Jurini*, Edw." he gives doubtfully. He retains the name *Leptomera* in place of the earlier *Proto*. "*Caprella acutifrons*, Edw. III, pag. 108, No. 5. Bate & Westw. II, p. 60," he also gives doubtfully, and likewise "*Caprella obesa*, v. Bened." Of "*Naupridia tristis*, v. Bened.," he is doubtful. He closes the list with "*Cyamus*, Lam. 68. eeti. Lin. Edw. III, pag. 113, No. 1. Bate & Westw. II, p. 85. Walvischluis. Op een vinnisch, Balkenoptera rostrata, den 10 Dec. 1862 in 't IJ, nabij Zaandam, gestrand." It would have been interesting to have had some description of this *Cyamus*, since Lütken in 1873 says that "hitherto not a single species has been found on a genuine Fin-whale (*Balaenoptera*), although some Fin-whales, for instance *B. Sibbali*, have been the object of fishery, and the opportunity has been used for looking after parasites. See S. Hallas, Vidensk. Medd. fra den naturhist. Forening for 1867, p. 162."

Among the Isopoda, after *Anceus* is given on page 248, "*Pterygocera* Latr. 76. arenaria. Latr. Zandpissebed. *Slabber*. bl. 92, Pl. XI, Fig. 3, 4. Aan de kust van Walcheren (Slabber.) N. B. Waarschijnlijk de larve toestand eener Idotea-soort." It is curious that in Slabber's own country he should not have accredited to him the specific name which he gave to this now well-known Amphipod, *Haustorius arenarius*.

1875. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1873 ; being Volume tenth of the Record of Zoological Literature. London, M.DCCC.LXXV. pp. 183-196.

Thaumatops is suggested in place of *Thaumops* as the name of the Hyperid (*Cystosoma*) [*Cystisoma*] described as a new genus by Willemoes Suhm. Hesse's *Ichthyomyzocus*, 1873, is criticised.

1875. METZGER, A.

Jahresbericht der Commission zur wissenschaftlichen Untersuchung der deutschen Meere in Kiel für die Jahre 1872, 1873. II. and III. Jahrgang. Berlin, 1875. (With second Title page); Die Expedition zur physikalisch-chemischen und biologischen Untersuchung der Nordsee im Sommer 1872. Die Resultate der Beobachtungen an den Stationen der deutschen Ostsee- und Nordsee-Küsten in den Jahren 1872, 1873. Berlin 1875.

V. Zoologische Ergebnisse der Nordseefahrt.. X. Crustaceen aus den Ordnungen Edriophthalmata und Podophthalmata. Bearbeitet von Prof. Dr. A. Metzger in Münden. Hiezu Abbildungen auf Kupfertafel VI. pp. 277-310.

A list of Amphipoda is given, pages 278 to 284, numbering eighty-three species, with particulars as to place of capture, depth, nature of ground and geographical distribution. Species previously taken by Leuckart or by Metzger himself, even if not observed on the present expedition, are included. On *Amphithoe gibba*, R. Leuckart, the note is given, "Von späteren Forschern nicht wieder aufgefunden, oder doch nicht erkannt. Die L. c. [Frey und Leuckart, Beiträge p. 162] gegebene Beschreibung ist zu unvollständig. Nach der Uebereinstimmung mit A. Rathkei zu urtheilen, gehört die Art wahrscheinlich der Gattung *Calliopius* an." See Note on Frey and Leuckart, 1847. Of *Gammarus elongatus*, Leuckart, he says, "Später, wie es scheint, noch nicht wieder aufgefunden." He notices Boeck's opinion that it may be *Mæra longimana*, Thompson. He here gives *Kroyera arenaria*, Bate, with Boeck's *Pontocrates norvegicus* as a synonym.

Fuller notes and descriptions of new species are given on pages 296-300. *Dulichia monacantha*, n. s., Tab. vi. fig. 8, is thus described:—

"Caput antice paulum productum et rotundatum. Epimerum primum in spinam longam productum, epimerum secundum margine posteriore rotundato, margine interiore recto et parum modo producto. Pedes secundi paris manu longiore quam latio, dentibus duobus instrueta, dente postico longiore et acuminato. Pedes quinti et sexti paris articulo tertio longitudinem quarti et quinti junctorum vix superanti. Pedes septimi paris articulo quarto longiore quam quinto, articulo tertio prælongato, longiore quam primo. Pedes saltatorii ultimi paris pedunculo vix dimidiat longitudinalem rami interioris æquanti. Longitudo animalis c. 5 mm." It comes, he says, very near to *Dulichia porrecta*. Of another *Dulichia*, spec. dubia, he had only a single defective specimen, a female with eggs. This he describes, as also the female of *Hela montrosa*, Boeck, in which his two specimens showed the first gnathopods larger than the second, having the hand curved, not with three, but only two teeth. He describes the tubes of *Siphonarcetes cuspidatus*, Metzger, as apparently very fragile.

Byblis crassicornis, n. s., Tab. vi. fig. 9 is thus described:—

"Femina. Corporis forma angustior, antennæ vero robustiores quam in B. Gaiuardi; segmentum postabdominis quartum in anteriore parte paulum transverso impressum, postice obtuso carinatum; segmentum postabdominis tertium in angulo inferiore posteriore rotundatum. Caput inter antennas superiores parum productum. Antennæ superiores inferioribus haud multum breviiores, articulo pedunculo secundo prælongato, ter longiore quam primo. Antennæ inferiores articulo quarto parum longiore quam quinto. Pedes priui paris manu paulum breviore quam carpo; pedes secundi paris manu multo breviore quam carpo angusto. Pedes tertii et quarti paris ungue tenui longo quam articulo quinto. Pedes quinti paris articulo primo altiore quam lato, ovali, in margine posteriore lobo lato semiorbiculare instructo. Pedes sexti paris articulo primo marginibus fere rectis. Pedes septimi paris articulo primo ad marginem inferiorem articuli tertii deorsum et postice productum, articulo quinto linearis, vix breviore quam quarto, unguis styliforme paulo breviore quam articulo quinto. Appendix caudalis parum longior quam ad basin lata, postice angustior et rotundata in summo dimidio fissa, lacinia utraque in superficie spinis singulis armata. Longitudo corporis 8mm.—Habitat extra oras Norvegiae Jæderenses in profunditate 106 orgyarum."

On "Ampelisca Eschrichti," Kröyer, he notes some differences from Boeck's account. For his criticism of the description and figures assigned by Buchholz to this species, see Note on Buchholz, 1874. He gives some account of *Tritropis helleri*, Boeck, and observes that,

according to Buchholz, it is probably the young of *Tritropis aculeata*, Lepechin. He comments on *Stenothoë marina*, Bate, *Stenothoë monoculoides*, Montagu, *Metopa pollexiana*, Bate. He retains the last name, though agreeing with Bate and Westwood (vol. ii. p. 499), in the view that Kroyer's *Leucothoe clypeata* is probably the female of *Metopa pollexiana*.

Lepilepecreum, Bate and Westwood, distinguished, he says, from *Orchomene*, Boeck, only by the want of an accessory flagellum, should find its place in Boeck's arrangement of the Lysianassina just after *Orchomene*. To supply defects in the original description of the genus, he gives the following :—

“Alle Mundtheile von dem seitlichen Kopflappen und der erste Epimere bedeckt. Mandibeln viel länger als breit, an der löffelförmigen oder flach-helmförmigen Spitze ungezähnt; Palpus sehr lang und schlank, 2gliedrig, Sförmig geschwungen und weit hinter dem elliptischen, nicht sehr hervortretenden Kauhöcker eingeleucht. Innere Lade (lobus interior) des ersten Maxillenpaars kurz und schmal, am Ende mit zwei Borsten; äussere Lade kräftig, an der Spitze mit ungleichen und unregelmässig zweireihig gestellten Zähnen; Palpus zweigliedrig mit feinzähnigem Endrand und hinter denselben schwach gerieft. Maxillen des zweiten Paares mit schmalen und nicht sehr langen Laden, die äussere unbedeutend länger als die innere, beide nach den Enden zu mit Borsten bewaffnet. Die hintere oder äussere Lade der Maxillarfüsse, welche eben über das dritte Glied des Palpus reicht, hat einen crenulirten Innenrand und ist hinter der Crenulirung bogenförmig gerieft; innere oder vordere Lade viel kürzer und schmäler, nur bis zum Ende des ersten, verhältnissmässig starken, Palpungsgliedes reichend, an dem schief abgestutzten Eude mit einigen kleinen zahnartigen Vorsprüngen und am Innenrande mit spärlichen Borsten bewaffnet.” This is followed by a description of the species *Lepilepecreum carinatum*, Bate and Westwood.

Callisoma krüyeri, Bruzclins, was found in great numbers within dead specimens of *Echinocardium cordatum*.

Section III. is “Ueber die Crustaceenfauna der Nordsee diesscits und jenseits der Doggerbank,” pp. 306–309. From the Deutsche Bucht, 97 Crust. Podophthalmata et Edriophthalmata were known, of which 46 species were Amphipoda, from Northumberland a total of 167, of which 89 were Amphipoda, and of this 89, 41 were common to both districts. The five Amphipods not known to occur from the Northumberland side were *Amphithoë gibba* and *Atylus falcatus*, from Heligoland; *Orchomene pinguis* from the west coast of Norway; and the southern species *Melita palmata* and *Orchestia deshayesii*. Various speculations are entered into, to account for the facts of distribution so far as ascertained. The districts compared were “von Texel (Holland) bis Blaavandshuk (Jütland)” and the Nordseegebiet “zwischen dem westlichen Abhang der Doggerbank und den Küsten von Yorkshire bis zum Firth of Forth.” Among the important relations of temperature it is said that “alle Wasserschichten der Nordsee diesscits der Doggerbank, oder, um die Lage genauer zu fixiren, diesscits einer Linie etwa von Scarborough bis zum südlichen Eingang in den Skagerrack oberhalb Houstholmen und Hirshals, im Monat August von der Oberfläche bis zu 20 bis 30 Faden nahezu eine gleichhohe Temperatur besitzen, während jenseits dieser Linie die tieferen Wasserschichten erheblich kühler bleiben als diejeniger der Oberfläche.”

Among the species, six in number, named as likely still to be found in the Deutsche Bucht, “*Noenia caudalidata*” is given, perhaps by mistake, for *Nænia tuberculosa*, Sp. Bate, as it is accompanied by “*Noenia undata*,” and Spence Bate's two other species of *Nænia* are recorded as actually found.

1875. The Micrographic Dictionary. London, MDCCCLXXV.

An article on *Gammarus* mentions the species *pulex* and *fluvialis*, adding that “there are twenty-three species of *Gammarus*, many of them marine.” It also names *Talitrus*

saltator as belonging to the Gammarina. The bibliography refers to Desmarest, Milne-Edwards, Gervais, Westwood, Bate and Westwood in the Annals and Magazine of Natural History.

1875. MIERS, EDWARD JOHN, born 1851 (E. J. M.)

Descriptions of new species of Crustacea collected at Kerguelen's Island by the Rev. A. E. Eaton. Annals and Magazine of Natural History, for July and August 1875. Ser. 4. Vol. XVI. pp. 73-76, 115-118.

"*Lysianassa Kergueleni*," n. s., is described. This species was subsequently transferred by Mr. Miers to the genus *Anonyx*. It was again found by the Challenger Expedition.

A new genus *Paramæra* is thus defined:—"Superior antennæ exappendiculate, but little longer than the inferior. Gnathopoda subequal, well-developed; dactylos closing along the inferior margin of the palm. Posterior pair of pleopoda with the rami very unequal, the inner ramus short or rudimentary. Telson cleft nearly to the base."

"This genus will apparently include *Melita Fresnelii*, Audouin, and *Melita tenuicornis*, Dana, which latter species is placed by Mr. Spence Bate provisionally in the genus *Mura*." The type species is *Paramæra australis*.

In the August number of the Annals, p. 117, Mr. Miers changes the name of *Paramæra australis* to *Atylus australis*, and in the Phil. Trans. Royal Soc. for 1879, he says, "it is probable that a separate genus will eventually have to be formed for the reception of the two species just mentioned [*Atylus australis*, Miers, and *Atylus (Iphimedea) fissicauda*, Dana], and *A. austrinus*, Speuce Bate. They differ from the normal species of the genus *Atylus*, as restricted by Boeck, in being destitute of dorsal carination, and in some other particulars. For *A. australis* I originally founded a new genus *Paramæra*, allied to *Melita* in having the inner rami of the posterior pair of pleopoda short or rudimentary, but differing from it in the absence of an accessory appendage to the upper antennæ. A subsequent examination of a series of younger examples showed, however, that my original types had sustained injury, the rami in question having been broken off and lost, and that in reality the inner rami are as well developed as the outer in *A. australis*. Yet though the genus *Paramæra* is unavailable for *A. australis*, it will hold good for the reception of *Melita tenuicornis*, Dana ♀, and *Gammarus Fresnelii*, Andouin, mentioned at the time of its publication as apparently included in it; unless, as is probable, there be some error in the figures and descriptions published of these species." In a letter dated October 19, 1885, Mr. Miers says, "I suppose the genus *Paramæra* will hardly stand." The species *Atylus australis* is, I think, without doubt the same as that described by S. I. Smith, under the title *Atylus (?) australis*, Miers (?), of which Mr. Smith has very obligingly sent me specimens, which will be further noticed later on in this Report.

Podocerus ornatus, n. s., is briefly described, the length given being $\frac{1}{6}$ inch, which is probably a misprint, as the length mentioned in the subsequent fuller report is 13 mm.

1875. NORMAN, A. M.

Submarine-cable Fauna. By J. Gwyn Jeffreys, LL.D., F.R.S., and the Rev. A. M. Norman, M.A. The Annals and Magazine of Natural History for March 1875.

Among the animals found attached to the Falmouth-and-Lisbon telegraph-cable laid in June 1870 and taken up for repairs in the autumn of 1874, Mr. Norman mentions four Amphipoda; *Amplithopsis latipes* (Sars), giving reasons for using this name in preference

to *Calliope ossiani* or *Calliope fingalli*, Bate and Westwood; " *Gammaropsis erythrophthalmus*, Lilljeborg = *Eurystheus erythrophthalmus*, B. & W.;" " *Probolium* (= *Montagna*, Bate); fragment"; and " *Aegina plasma* (Montagu) = *Protella plasma*, Bate."

1875. PACKARD, A. S.

Life-histories of the Crustacea and Insects. The American Naturalist. Volume IX. Salem, Mass., 1875. pp. 583-622.

At page 599, speaking of the embryo in *Oniscus* and *Asellus*, he says, "The abdomen is curved up and backwards, while in the Amphipods it is bent beneath the body, as in Fig. 254, and this is really, as Fritz Müller observes, the only important difference between the embryos, at an early stage, of the two groups. The embryo Isopod at the time of hatching closely resembles the adult, there being no metamorphosis.

"The development of the Amphipods or beach fleas, is nearly identical with that of the Isopods. The eggs of certain species undergo total segmentation, while those of other species of the same genus (*Gammarsus*) partially segment, as in the spiders, and in a less degree the insects, showing the slight importance to be attached to this matter, and that Haeckel's term *Morula* when used for the total segmentation of Crustacea is of little significance, how [ever] much it may be in the lower animals."

"Summary of changes:—

"1. Segmentation of the yolk partial, or total (Morula).

"2. Nauplius state in the egg.

"3. Larva hatching in the form of the adult with the full number of feet; no metamorphosis."

He refers to the works of E. van Beneden, Dohrn, Rathke, and Bobretzky, all concerned with the embryology of Isopods.

1875. POWELL, LL.

Description of a new Crustacean, *Phronima novæ-zealandiæ*. Transactions and Proceedings of the New Zealand Institute, 1874. Vol. VII. pp. 294, 295, pl. xxi. figs. 1-2, 1875.

This species will be considered later on in this Report. It bears a strong general resemblance to *Phronima sedentaria*, Forskål, the distinction between the two being based on characters which are not very striking at first sight.

1875. ROUGEMONT, PHILIPP DE, born 1850, died 1881.

Quæstio inauguralis: Die Fauna der dunkeln Orte. München, 1875. 13 pp.

The author bases an argument on the relationship between *Gammarus pulex* and *Gammarus puteanus*. He makes the pungent observation that the errors which zoologists have made in the establishment of species during the last fifty years it will take a hundred years to correct.

1875. ROUGEMONT, PH. DF.

Natur-Geschichte von *Gammarus puteanus* Koch. Inaugural-Dissertation. München. 1875. 40 pp.

The general structure of the Gammaridæ is described and the sensory appendages discussed. The cylindrical appendages to the flagellum of the upper antennæ are recognised, in

agreement with Leydig and contrary to the view of Spence Bate, as organs of smell. The fact that they are longer in the blind *Gammarus puleanus* and *Asellus* from the wells than in *Gammarus pulex* and *Asellus aquaticus* is regarded as a natural compensation made to the former for their want of sight. To the plumose hairs at the base of the upper antennæ, which Sars and others accept as auditory organs, like those described by Hensen for the Decapods, Rougemont disallows this function, on the ground that to the well- and eaves-shrimps hearing would be of no particular service, and that in Amphipods neither auditory vesicle nor otolith has been discovered. He regards the hairs in question as ministering to the sense of touch, and were there any word to express something intermediate between the senses of touch and hearing, he would be willing to adopt it for the function of these organs. He agrees with some earlier writers in ascribing to the cone of the antennary gland a sense of smell, and supposes, while the cylinders of the flagellum smell more distant objects, the cone takes cognizance of food approaching the mouth, an ingenious but not highly probable suggestion. He mentions that Felix Plateau, who like Spence Bate recognised eyes in *Gammarus puleanus*, briefly described these organs as "dreieckig mit sphärischen Winkeln, klein und pigmentlos." But de Rougemont himself had never been able to find any Krystallkörperchen, and is convinced that these animals cannot see and distinguish objects, though the light, penetrating their transparent skin to the rudiment of the optic nerve, may produce a disagreeable impression, which leads them to prefer a safe obscurity.

To the single species, *Gammarus puleanus*, Koch, are referred all the following forms:—I. Form. *Gammarus minutus*, Gervais. *Cranonyx subterraneus*, Sp. Bate. II. Form. *Niphargus kochianus*, Sp. Bate. III. Form. *Gammarus puleanus*, Caspari. *Gammarus puleanus*. Hosius. *Niphargus fontanus*, Sp. Bate. IV. Form. *Gammarus puleanus*, Koch. V. Form. *Niphargus stygius*, Schiödte. *Gammarus puleanus*, Koch, de Lavalette St. George, and Felix Plateau. VI. Form. A colossal specimen, 33 mm. long, from Neuchatel. These identifications were sharply criticised by Alois Humbert, in 1876.

1875. SCHIÖDTE, J. C.

Krebsdyrenes Sugemund. Med fem Kobbertavler. Naturhistorisk Tidsskrift
3. R. 10. B. Kjobenhavn. 1875. pp. 211–252.

Schiödte considers that the structure of the mouth in the Amphipoda offers three principal types, best distinguished by the connections which determine the movements of the mandibles. The first type belongs to the *Gammarus-Caprella*-forms. Here the mandibles are short, three-sided, with broad triangular base, the outer angle of which is socketed by a short process in the pleural border of the head. On this process and the outer side of the shaft they have an oscillating movement, but being free from the special arrangements for regulating their movements which are found in the other two types, he calls this group *Eleutherognatha*, defined by the formula, "*Mandibulæ trigonæ, condylo articulatio antico carentes. Labrum planiusculum, transversum, simplex.*" The lower lip he describes as having four comparatively soft cushion-like lobes and two more strongly chitinized and calcified horns directed backwards, stiffer than the cushions, yet yielding towards their free ends, so as to constitute a sprung stiff enough to hold the mandibles up for their oscillation, yet elastic enough to yield to pressure, and which he therefore designates as "*processus mandibularii labii inferioris.*"

The second type includes most of the *Lysianassina*, Dana. Here, in addition to the arrangements above mentioned, "from the front end of the shaft, on the upper side, in front of the palp, there issues a club-shaped, articular process, rounded at the end, which fits into a corresponding cup on either side of a saddle-shaped process on the palate, close behind

the upper lip, descending into the mouth-cavity." It is this arrangement in connection with the development of the upper and lower lips, that determines the scissor-like movement of the mandibles in this group, which he therefore calls *Trochalognatha*, thus defined, "*Mandibulae productæ, condylo articulatio instructæ antico, acetabulo epiharyngis accommodato. Labrum crassum, conicum, simplex.*" Of this group he considers that there are, as suggested by Krøyer, only two principal types, *Anonyx* and *Opis*, and as the first group correspond with the *Onisci*, as defined by Schiödte, so this with the *Cirulanæ* under the same limitation.

The third type includes the *Hyperina*, and because the outer lobes of the mandibles are pressed into a transverse furrow of the upper lip he calls this group *Piezognatha*, thus defined, "*Mandibulae productæ, condylo articulatio antico carentes, mala exteriore fossæ transversæ labri accommodata. Labrum planiusculum, transversum, duplex.*"

As abnormal among the Elentherognatha, the mouth-organs are described of *Stegocephalus*, *Cyamus* and *Laphystius*. The illustrations are taken from "Caprella septentrionalis Kr. ♀"; "Laphystins Sturionis Kr. ♀"; "Cyamus ovalis Ronss. de Vauz. ♀"; "Anonyx Lagena Kr. ♀"; "Stegocephalns Ampulla Kr. ♀"; "Themisto libellula Mandt. ♀" "Anchylomera sp. ♀."

The English reader will be glad to know that there is a translation of this highly important paper, "partly condensed with the sanction of the author," in the Annals and Magazine of Natural History, for September, 1876. The beautiful and elaborate plates of the original do not, however, accompany the translation.

1875. SIMON, EUGÈNE.

Journal de Zoologie. IV. pp. 114-116.

He enumerates and shortly describes several species of Crustacea living in caves, among them, "*Niphargus subterraneus* (Leach) = *puteanus* (C. Koch) *aquilex* and *stygius* (Schiödte), Carniola, also in wells." (Dr. von Martens, Zool. Record for 1875.)

1875. SMITH, SIDNEY I.

Report on the Amphipod Crustaceans. Reports on the Zoological collections of Lieut. W. L. Carpenter made in Colorado during the summer of 1873. (Extracted from the Annual Report of the United States Geological and Geographical Survey of the Territories for 1873.—F. V. Hayden, Geologist in charge.) Washington, 1875. pp. 608-611. Pls. I. II.

"*HYALELLA, genus nov.*" is here defined as in 1874, except that the penultimate segment in the maxilliped-palps is here said to be "longer than broad." *Hyalella dentata*, pl. i. figs. 3-6, is again described as "sp. nov." *Hyalella inermis*, n. s., pl. i. figs. 1-2, is described, "closely allied to the last species, but wholly without teeth upon the dorsal margin of any of the abdominal segments." On this, Faxon in 1876 says, "after an examination of a large number of *Hyalella dentata* and *H. inermis* from Utah, I am satisfied that they are but varieties of one species." The policy of coining, or retaining, names for varieties is open to question. Where the variation is not sufficiently important to be regarded as specific, it might well, in my opinion, be left without a special name. In the present instance it seems highly inconvenient to have a species named from a particular character, and a variety named from the absence of that very character. If it is impossible to retain both

names as specific, this would seem to be one of the rare cases in which original names might justifiably be changed on account of their inappropriateness. The difficulty, however, will not arise, if, as already suggested, the names may be considered synonyms of *Hyaletella andina*, Philippi, 1860. *Gammarus limnaeus*, Smith, pl. ii. figs. 13-14, from "Lake near Long's Peak; elevation, 9000 feet," is described, and *Gammarus robustus*, n. s., pl. ii. figs. 7-12, from Wahsatch Mountains, Utah.

1875. SMITH, SIDNEY I.

The Crustaceans of the Caves of Kentucky and Indiana. From the American Journal of Science and Arts, Vol. IX., June, 1875.

Stygobromus vitreus, Cope, from Mammoth Cave, is said to be really a *Crangonyx*, which should stand as *Crangonyx vitreus* (Cope). *Crangonyx vitreus*, Packard, from Indiana, is very different from Cope's species, but closely allied to *Crangonyx gracilis*, from Michigan, Lake Superior, etc., differing principally in the structure of the eyes. Since Packard's species in any case must yield its specific name, one is led by Professor Smith's account to regard it as a synonym of *Crangonyx gracilis*.

1875. STEBBING, T. R. R.

On the genus *Bathyporeia*. The Annals and Magazine of Natural History for January 1875. Ser. 4. Vol. 15. Pl. III. pp. 74-78.

Bathyporeia pilosa, Lindström, is figured and described, with an argument to show that *Bathyporeia pelagica*, Sp. Bate, is the adult male, and "*Bathyporeia Robertsoni*," Sp. Bate, a younger form of the male, of the same species of which *Bathyporeia pilosa* is the female. G. O. Sars, has expressed the opinion that *Bathyporeia robertsoni* is a distinct species. H. Blanc accepts my view.

1875. STEBBING, T. R. R.

On some new exotic Sessile-eyed Crustaceans. The Annals and Magazine of Natural History for March 1875. Ser. 4. Vol. 15. Pl. XV. A. pp. 1-4.

In this paper a new species is described under the name *Dexamine antarctica*. This in November 1878 I transferred to *Atylus* on the ground of its likeness to *Atylus gibbosus*, Sp. Bate, and of its residing, like that species, in a sponge. *Atylus gibbosus*, however, having no palp to the mandibles, belongs not to the Atylinæ, but to the Dexaminæ, and is made by Boeck the type of a new genus *Tritæta*, which name he derives from the Greek Τριτæτα, without explaining why he introduces an additional letter into the Latinized form of it. My species will become *Tritæta antarctica*, and will probably include as synonyms, *Polycheria tenuipes*, Haswell, from Port Jackson, and *Polycheria obtusa*, Thomson, from New Zealand.

Another new species, described and figured as "*Seba Saundersii*," is said to come from Algoa Bay, South Africa. In 1883, a new genus and species from New Zealand was described by Mr. Chilton under the name *Teraticum typicum*. This is probably the same as my *Seba saundersii*. A specimen brought home by the Challenger was taken in the Strait of Magellan, so that the range of this little species in the south would seem to be very extensive.

1875. WILLEMOES SUHM, R. VON.

Briefe von R. v. Willemoes-Suhm an C. Th. E. v. Siebold. III. Zeitschrift für wissenschaftliche Zoologie. Fünfundzwanziger Band. Leipzig. 1875. pp. xxxvi–xxxvii.

In this letter, dated "H.M.S. Challenger, Cap York, in September 1874," under the heading "die Thiere der Oberfläche," he says, "Die Crustaceen traten namentlich auf der Fahrt von den neuen Hebriden nach Cap York massenhaft auf, doch fangen die *Euphausiden*, die bei den Fidschi-Inseln noch gemein waren, an, seltener zu werden.—Namentlich schön war die Ausbeute an Stomatopoden Decapodenlarven und an Hyperiden. Von letzteren waren diesmal nicht nur *Hyperia*, *Phronima*, *Cylopus*, *Cystisoma*, und *Oxycephalus* sondern auch *Rhabdosoma* vorhanden, die abenteuerliche langgestreckte *Typhida*, die wohl zu den seltensten Bewohnern der Oberfläche gehört, da es uns bisher noch nie gelang eines Exemplars derselben habhaft zu werden."

1875. WILLEMOES SUHM, R. VON.

On some Atlantic Crustacea from the 'Challenger' Expedition. (Read May 7th, 1874). The Transactions of the Linnean Society of London. Second Series.—Zoology. Volume I. Part the First. London, M.DCCC.LXXV. Plates VI.–XIII. pp. 23–59.

The part of the paper referring to the Amphipoda is on pp. 24–26, under the heading "On *Cystisoma Neptunus* (*Thaumops pellucida*). (Pl. XI. figs. 4–8)." Willemoes Suhm here objects to supposing that the antennæ in *Cystisoma* represent the second pair, an opinion which he wrongly attributes to Guérin-Méneville. "Against a union of *Cystisoma* with the Hyperids may be advanced," he says, "besides the form of the head (which is more Typhid-like) and the absence of the second antennæ in both sexes, the absence of a palpus on its mandible (Pl. XI. fig. 6). The palpus is always present, according to Claus, in Hyperids, but is wanting in Phronimids." (But on this last point see Note on Claus, 1879.) "The male," he says, "differs by the absence of glands at the top of nearly all the appendages, especially in the last pair of pereiopoda, which, according to this, have not the same clumsy appearance as in the female. The two testes begin just behind the stomach (fig. 5, t), and send vasa deferentia to the last segment of the pericard, where two simple genital openings are to be seen between the last pair of legs (fig. 5, a g)." He further says somewhat mysteriously, "probably (as in *Phronima*) the full-grown male is somewhat smaller than the female; it seems that *Cystisoma Neptunus* can attain a very considerable size; for the last and largest male which we got in the trawl has a length of 103 millims." This male is the largest specimen of *Cystisoma* as yet on record, so that the probability that the female grows still larger seems to be but slight. The figure 4, apparently of this specimen, is drawn rather less than life-size, although the "Explanation of Plates" gives it as "Nat. size."

1876. BATE, C. SPENCE.

Report on the present state of our knowledge of the Crustacea. Part I. On the homologies of the dermal skeleton. [From the Report of the British Association for the Advancement of Science for 1875.] Plates I. & II. pp. 41–53.

Referring to his earlier report, in 1855, Mr. Spence Bate says that in the present report he is desirous "to show:—that the epimera, as sectional pieces in a theoretical construction of a

somite, cannot exist; that the so-called epimera are portions only of the integumentary structure of the appendages of the animal, and that the apodema are formed out of this structure, more or less thinned out by lateral pressure and internal arrangement; and that the head of the lower types and carapace of the higher are homologically the same, the carapace being a monstrous development intended for the covering and protection of the more complicated branchial appendages of the higher types" (p. 47). On page 41 it is stated that "the third pair of maxillipeds in the Brachyurous Crustacea are identical with the first pair of walking-legs in the Stomopoda, Amphipoda, and most of the Isopoda." But, at least as regards the Amphipoda, second gnathopods must have been intended instead of the first pair of walking legs.

1876. BOECK, AXEL.

De skandinaviske og arktiske Amphipoder, beskrevne af Axel Boeck. Andet Hefte. (Med 25 kobberstukne Tavler.). Efter Forfatterens Død udgivet ved Hakon Boeck. Christiania, 1876. pp. 161-713.

A preface in French by Hakon Boeck explains that, when Axel Boeck died in May 1873, he left his Manuscript almost complete, but the figures not in all cases named. This deficiency Hakon Boeck had to supply to the best of his ability. In regard to the synonymy he was obliged to depend in part, he says, upon the data supplied by Bate and Westwood. His editorial task must have been one of no slight difficulty, and he deserves the gratitude of the student for his labours.

At page 190 is given *Opisa*, new genus, thus defined:—

"Mandibulæ palpo profundius quam tuberculo molari affixo. Maxillæ 1mi paris lauina interiore angusta, non longa, in apice setas duas plumosas gerenti. Maxillæ 2di paris laminis angustis, non vero longis. Pedes maxillares lamina exteriore elongata, angusta, in margine interiore denticulis instructa, fere ad finem articuli palpi brevis 3tii porrecta; articulo palpi 4to ungviformi. Pedes 1mi paris manu permagira, inflata, in angulo inferiore antice producta et acuta. Appendix caudalis prælongata, profunde fissa." Kröyer's name for this genus, *Opis*, was preoccupied.

For *Opis leptochela*, Bate and Westwood, 1868, Boeck here proposes a new genus, to be called *Leptochela*, of which he says, "I Munddelenes Bygning afviger deu ikke saa meget fra slægten *Anonyx*, men dog især derved, at Kjæbefæddernes ydre Plader ere temmelig smale og væbnede med smaa Tænder istedetfor Knuder paa den indre Rand. Springfædderne ere forlæugede, og Halevedhæuget er særdeles langt, dybt kløvet." By the structure of the first gnathopods it approaches, he says, the Oedicerinæ. Besides that *Leptochela* contravenes the rule against adopting a specific name as generic, it falls as a synonym to the earlier *Euonyx*, Norman, 1867.

The Iphimedinae are accidentally introduced at page 235, as Subfamilia V. of the Gammaridae, instead of coming later as Subfamilia VII. of the Leucothoidæ. Among these the first genus is *Acanthonotozoma*, A. Boeck. This name supersedes the earlier *Acanthonotus* of Owen and *Vertumnus* of White, both of which are preoccupied. *Acanthonotozoma* itself might have been presumed to be an accidental misspelling or misprint for *Acanthonotosoma*, but that it occurs several times without variation. It is thus defined:—

"Labium superius prælongatum. Maxillæ 1mi paris palpo 2articulato; articulo 1mo longo; lamina interiore permagna, triangulare, multis setis plumosis instructa. Pedes maxillares palpo robusto; articulo palpi ultimo parvo. Pedes 1mi et 2di paris gracieles, manu subcheliformi destituti; articulo 5to 1mi paris prælongato, gracili; ungve in margini postico perserrato. Corpus compressum; epimeris magnis, rigidis."

In the Subfamily Dexaminæ, for his genus *Lampra*, 1870, a preoccupied name, Boeck now gives " *Tritaeta*. n. g." It is thus defined :—

" Pedes maxillares laminis exerioribus angustioribus, valde curvatis et modo in summo dimidio spinis paucis sed validis armatis ; laminis interioribus latioribus et longioribus quam apud genus Dexamine, spinis multis curvatis et gracilibus armatis. Epimera minima ; epimera quatuor anteriora 5to non altiora, in margine inferiore armata. Pes quinque parium ultimorum articulo 4to et 5to perbrevibus ; ungve parvo." The type is *Atylus gibbosus*, Sp. Bate.

In his notice of the genus *Haploops*, Liljeborg, Boeck says, " Hos denne Slægt fandt jeg først og noitig undersøgte den eiendommelige Halsring, eller rettere Øsophagusring, som ligger indenfor Læberne og er saaledes den indeste og en constant Del af Tyggeapparatet."

1876. CATTA, J. D.

Note sur quelques crustacés erratiques. Annales des Sciences naturelles. 6^e Série. Zoologie. Tome 3, Janvier 1876. Paris. pp. 1-32. Pl. 1. 2.

From some Algae attached to a vessel, which had come from India round the Cape of Good Hope into the harbour of Marseilles, were taken a group of Crustacea. Among others there were specimens of *Probolium polypriion*, A. Costa, and *Amphithoë penicillata*, A. Costa. Professor Catta gives a full description and figures of *Probolium polypriion*, showing that *Probolium megacheles*, Heller, cannot properly be distinguished from it. He applies the rather inconvenient nomenclature of 1st, 2d, 3d, 4th, and 5th *siagonopodes* respectively to the first and second maxillæ, the maxillipedes, and the first and second gnathopods. Both in the description and figures, however, it is clear that the *premier siagonopode* represents the second maxilla, and the *deuxième siagonopode* the first maxilla. The " saillie très-volumineuse, arrondie et surmontée d'un long poil cylindrique " given as part of the " premier siagonopode " is probably the base and inner plate of the first maxilla. The palp or " pièce externe " of the " deuxième siagonopode " (first maxilla) should no doubt have been represented as two-, instead of one-jointed. The species should moreover have been assigned to *Stenothoë*, Dana, as the mandibles are without palp.

Under the heading, *Amphithoe penicillata*, Professor Catta investigates the relationship between " *Amphithoe Desmarestii*," Sp. Bate, and *Amphithoe penicillata*, as described first by Costa and then by Heller. He points out that the figures given by the Italian and Austrian authors do not correspond with their descriptions. Carefully figuring and describing the second gnathopod of his own specimen, he decides that the species " *Desmarestii* " of Bate must be united with *penicillata* of Costa. In my opinion the name must be carried back a step further to " *Amphithoe Vaillanti*," Lucas, 1849, in which the hand of the second gnathopods " est profondément échancré à son bord inférieur, et qui, à la naissance de cette échancrure, est armé d'une épine forte et très-saillante." Costa describes this hand " col dorso prolungato un poco al di là della insersione dell' unghia ; il margine unguicolare assai obliquo ed a curva rientrante ; il margine dorsale ornato di lunghi peli, che all'estremità formano un folto pennello." Sp. Bate gives it in his species, " ovate, the upper margin furnished with four or five fasciculi of hairs ; palm oblique, deeply concave, defined by one or two short spines." When it is remembered that in the species of *Amphithoë*, the second gnathopod varies with age and sex, but little confidence will be felt in the multitudinous species at present established on subtle distinctions, referring to the shape of the gnathopods, the length of the antennæ, the colouring of the animal, or perhaps even the locality in which it was captured.

1876. CLAUS, C.

Untersuchungen zur Erforschung der genealogischen Grundlage des Crustaceen-Systems. Ein Beitrag zur Descendenz-lehre. Wien, 1876.

1876. FAXON, WALTER.

Exploration of Lake Titicaca by ALEXANDER AGASSIZ and S. W. GARMAN. IV. Crustacea. By WALTER FAXON. Bulletin of the Museum of Comparative Zoölogy, at Harvard College, Cambridge, 1876. Vol. iii. pp. 361-375.

Of the Crustacean fauna of the lake, Mr. Faxon says, "excepting a species of *Cypris*, all the specimens collected belong to one amphipodous genus, *Allorcheses*, which had hitherto afforded but one or two authentic fresh-water species, ranging from Maine to Oregon and the Straits of Magellan. Seven new species are described in this paper from Lake Titicaca. Several of them are remarkable among the *Orchestilæ* for their abnormally developed epimeral and tergal spines. Some are also noteworthy as comparatively deep-water forms of a family commonly regarded as pre-eminently littoral."

The genus *Allorcheses* is thus defined :—"First maxillæ with small uniarticulate palpi. Palpus of the maxillipeds composed of four segments, the distal segment usually bearing a movable spine at its apex. First antennæ shorter than the second antennæ, longer than the peduncle of the second antennæ. First and second thoracic legs subcheliform. Propodite of second pair larger than propodite of first pair, and much larger in the male than in the female. Telson short and entire." *Hyalella*, Smith, 1874, is given as a synonym. My reasons for preferring *Hyalella* to *Allorcheses* are given in Note on Rathke, 1837. Mr. Faxon describes *Allorcheses armatus*, n. s., figs. 1-18; *Allorcheses echinus*, n. s., figs. 19-21; *Allorcheses longipes*, n. s., figs. 22-25; *Allorcheses lucifugax*, n. s., fig. 26; *Allorcheses latimanus*, n. s., figs. 27-28; *Allorcheses longipalmus*, n. s., figs. 29-31; *Allorcheses cupreus*, n. s., figs. 32-34. He also figures *Allorcheses denlatus*, var. *inermis*, fig. 35, for *Hyalella inermis*, Smith. Of his specimens he says, "they differ from specimens from the United States in having a firmer and less transparent shell, and a little differently shaped propodite to the second pair of thoracic legs in the male; hardly enough to warrant the establishment of a new species when one considers the variability of the species within the limits of the United States."

In a note Mr. Faxon says, "Among the Crustacea collected by the Thayer Expedition in Brazil are two species of *Allorcheses*. One is represented by a unique female specimen taken from a canal at Campos by C. F. Hartt. It differs from *A. dentalis*, var. *inermis*, only in the second pair of antennæ, which are half as long as the body and twice as long as the first pair; flagellum composed of thirteen segments. Length of body, 4^{mm}. In the absence of more specimens, I would consider this a variety (*gracilicornis*) of *Allorcheses dentalis*," fig. 36. "The second species is represented by several specimens. It may be called *Allorcheses longistilus*, sp. nov." Fig. 37. "Differs from *A. dentalis*, var. *inermis*, in its slenderer body, longer antennæ, and especially in the length of the third pair of caudal styles."

1876? FORBES, S. A., born May 29, 1844 (S. I. Smith).

Bulletin of the Illinois Museum. 1. [1876], p. 6, Illinois.

Deserption du *Niphargus puteanus*, var. *Forelii*, in Forel's Matériaux pour servir à l'étude de la Faune profonde du lac Léman. Bulletin de la soeiété Vaudoise des scienees naturelles. 2. 3. Vol. XIV. N^r. 76. 1876.

1876. GIARD, ALFRED MATHIEU.

On an Amphipod (Urothoë marina), a Commensal of Echinocardium cordatum. The Annals and Magazine of Natural History. Number XCIX. Vol. XVII. Fourth series. London, 1876. pp. 261–263. (Comptes Rendus, Jan. 3. 1876, p. 76.)

“ *Urothoë marinus* presents a strongly marked sexual dimorphism. The most striking character of the male sex is the length of the inferior antennæ, which greatly exceeds the superior ones. It is well known that it is a character of the same kind that distinguishes the male *Hyperiae* (*Lestrigonus*) from their females.” Judging from the antennæ, as figured by Spence Bate, he argues that “ *Urothoë Bairdi* and *Urothoë elegans* must be regarded as representing male individuals; while *Urothoë brevicornis* and *Urothoë marinus* are, on the contrary, figured from the female sex.”

1876. HUMBERT, ALOIS.

Description of Niphargus puteanus, var. Forelii. By Alois Humbert. (Translated by W. S. Dallas, F.L.S., from an abstract by the author in the “ Bibliothéque Universelle : Archives des Scienees,” 15th January, 1877, pp. 58–75. The original paper appeared in the “ Bulletin de la Société Vaudoise des Scienees Naturelles,” tome xiv. 1876. pp. 278–298, pls. 6 and 7.) The Annals and Magazine of Natural History. Number CXI. Vol. XIX. Fourth Series. London, 1877. pp. 243–254.

Humbert assigns the first discovery of well-Amphipods to the year 1835, in point of time, and for the persons, to Gervais and Koch, but Leach's *Gammarus subterraneus*, which he after-

wards mentions, is earlier. Schiödte followed with his *Niphargus* from the caverns, and then new species of *Niphargus* and even new genera allied to it were discovered in wells, caverns, and in the sea. "Finally, in 1869 M. F. A. Forel indicated for the first time the existence of blind Gammaridae (*Niphargus*) in the depths of the Lake of Geneva, and in 1873 he found the same animals in the Lake of Neuchâtel."

After mentioning the different species belonging to *Niphargus* and its synonym *Eriopis*, and the *Crangonyx subterraneus* of Sp. Bate, he reviews the work of de Rougemont, with whose conclusions he is unable to agree. He has himself found forms agreeing with none of the six described by de Rougemont. One of these, from the Lake of Geneva, he calls "*Niphargus puteanus*, Koch, var. *Forelii*"; the other from a well at Onex, in the environs of Geneva, he calls *Niphargus puteanus*, var. *onensiensis*. In the species of *Niphargus* he has examined, he has "been unable to perceive the least trace of eyes or even of a deposit of pigment."

He minutely describes, and gives the name of *sensitive capsules* to, the very small organs on the dorsal parts of the segments already noticed by de la Valette. These he finds also along the anterior margin of the head and on the first two joints of the peduncle of the superior antennae. On the antennae he enumerates *sensitive setæ*, *olfactory cylinders*, *sensitive rapsules*, *olfactory setæ*, and *hyaline bacilli*. The last he describes; he says that they "perfectly resemble those figured by Sars upon the joints of the outer branch of the superior antennae of *Mysis oculata*. He thinks that Jarschinski may refer to them in his paper (in Russian) On the Leydigian organs of the antennæ of the Crustacea Amphipoda, 1868.

As to the idea of practically making *Gammarus pulex* one and the same species with those assigned to *Crangonyx* and *Niphargus*, he points out that, "in the *Gammari* proper the last pair of saltatory feet are biramous; *Gammarus pulex* even has the two branches nearly equal. The *Niphargi* have these branches very unequal, but both of them still exist. In *Crangonyx*, on the contrary, there is only a single branch." Also the telson "is double in *Gammarus*, of a single piece but deeply cleft in *Niphargus*, and completely entire in *Crangonyx*." He believes that *Niphargus* is an ancient genus descended from a form now extinct.

1876. MAITLAND, R. T.

Determinatie der dieren beschreven en afgebeeld in de werken van JOB BASTER en MARTINUS SLABBER. Tijdschrift der Nederlandsche Dierkundige Vereeniging. Tweede Deel. 'S Gravenhage & Rotterdam, 1876. pp. 7-15.

For Baster's work he gives in I^e Deel, "Tab. IV. Fig. II. Caprella linearis, Latr," in II^e Deel, "Tab. III, Fig. VII. VIII. Orchestes littoreus. Leach." For Martinus Slabber, he gives "Tab. X, Fig. 1. 2. Leptomera pedata. Mull," and "Tab. XI, Fig. 3. 4. Pterygocera arenaria. Latr. (door v. d. Hoeven de soort ongedetermineerd geleten)." See Notes on Baster, 1759, 1762, and Slabber, 1769.

1876. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1874; being volume eleventh of the Record of Zoological Literature. London, M.DCCC.LXXVI. pp. 199-220.

1876. MIERS, E. J.

Catalogue of the Stalk- and Sessile-eyed Crustacea of New Zealand. London.
1876.

Dana's classification, with some slight alterations and additions, is adopted in the catalogue. The Amphipoda occupy pages 117–130. The genus *Paramoera* is provisionally retained for Dana's *Melita tenuicornis*. No new species are described, but, as was reasonable to expect, and as Mr. G. M. Thomson recognises, the publication of the Catalogue gave an impulse to the study of local zoology in New Zealand which has produced many excellent results.

1876. MIERS, E. J.

Description of a new species of *Talitrus* from Rodriguez. Annals and Magazine of Natural History for May 1876. Ser. 4. Vol. XVII. p. 406.

The species in question is named "*Talitrus Gulliveri*," after Mr. Gulliver who found it.

1876. NORMAN, A. M.

The "Valorous" Expedition. Reports by Dr. Gwyn Jeffreys, F.R.S., and Dr. Carpenter, C.B., F.R.S. [From the Proceedings of the Royal Society, Vol. XXV. No. 173, 1876]. London: 1876. (Crustacea, etc., by the Rev. A. M. Norman, M.A.)

No new Amphipoda are recorded, but Tables are given showing that the "Valorous" brought home from Greenland and Davis Strait 39 species of Amphipoda, of which 12 were previously known as North-American, 32 were known as European, 9 were known as British, while the total number of species brought home by other British Arctic Expeditions had been 18. 6 species were brought by the "Valorous" from the North Atlantic, its total of Amphipod species being 42.

1876. ROUGEMONT, PH. DE.

Études de la Faune des Eaux privées de Lumière. Histoire Naturelle du *Gammarus puteanus*, Koch. Paris, 1876.

See Notes on Rougemont, 1875.

1876. SARS, G. O.

Prodromus descriptionis crustaceorum et pycnogonidarum, quæ in expeditione Norvegica anno 1876, observavit G. O. Sars. Separatastryk af Archiv for Mathematik og Naturvidenskab. Kristiania. 1876. pp. 337–371.

The new Amphipods here described are:—103. *Lilljeborgia equicornis*; 110. *Pleustes euacanthus*, with the observation "Pl. pulchello Kr. affinis sed diversus dorso toto carinato et spinoso, spinis multo majoribus," subsequently called *Paramphithoë euacantha*; 116. *Halirages quadridentatus*, with the remark "H. tridentato affinis, sed major et diversus spinis dorsalibus 4, oculis multo majoribus, antennis et pedibus magis elongatis, segmento 3^{to}

postabdominius in margine postico non serrato;" 117. *Amphithopsis pulchella*, "A. latipedi M. Sars affinis sed diversa segmentis postabdominis non carinatis nee spinosis, antennis superioribus longioribus, podibus angustioribus;" 119. *Mæra tenella*, a name preoccupied by Spence Bate for the still smaller *Gammarus tenellus* of Dana, and since changed to *Mæra tenera*; 134. *Dulichia hirticornis*. 131. *Glauconome planipes*, Norm.? is given, with the following notice, "'Unciola planipes, Normau, Report of deep-sca dredging off the coast of Northumberland and Durham,' pg. 3, Pl. VIII. fig. 9-15.—Specimina observata a forma typica differunt manu pedum 2^{di} paris elongato-quadrangulari carpi longitudinem æquante adqve apicem fero ad lineam rectam truneata, antennis inferioribus maris structura valde singulari, articulo pedueuli penultimo et antepenultimo insolito modo dilatatis et complanatis articulationem mobilissimam inter se formantibus." This, in 1879, is given as a distinct species, *Glauconome petalocera*, and in 1885 is renamed *Unciola petalocera*. 137. "*Caprella horrida*, n. sp. (= *Caprella spiosissima* Norman, non Stimpson)" has been already mentioned in the Notes on Stimpson, 1854, and Wyville Thomson, 1873. It is clearly not an *Ægina*, since Sars expressly describes it as having "Mandibulæ palpo earentes." In 1885 he names it *Caprella spinosissima*, Norman. For his reasons see Note on his work of that date.

1876. SMITH, SIDNEY I.

Contributions to the Natural History of Kerguelen Island, made in connection with the United States Transit-of-Venus Expedition, 1874-75. By J. H. Kidder, M.D. Washington, 1876. Crustaceans. Described by S. I. Smith. pp. 57-64.

The Amphipoda include *Hyale villosa*, n. s.; *Lysianassa kidderi*, n. s., in which "the antennulae, mandibles, second maxillæ, maxillipeds, and posterior uropods are more like some of the species of *Orchomene* than they are like the species of *Lysianassa*, as described and figured by Boeck, and the characters assigned to *Lysianassa* by this author would require considerable modification to admit our species." *Lysianassa kerqueleni*, Miers, "is quite a different species, and not a *Lysianassa*," having the first gnathopods subchelate. Lastly, Professor Smith describes "*Atylus* (?) *australis*, Miers (?)," with references to ? *Paramera australis*, Miers, and ? *Atylus australis*, Miers. Dr. Kidder's specimens have "minute secondary flagella upon the antennulae." "This species cannot be referred to the genus *Atylus* as restricted by Boeck." It will be discussed among those brought home by the Challenger.

1876. STEBBING, T. R. R.

Description of a new species of Sessile-eyed Crustacean, and other notices. The Annals and Magazine of Natural History for January 1876. Ser. 4. Vol. XVII. Pl. IV., V. pp. 73-80.

The species here figured and described as new, under the name *Microdeuteropus bidentatus*, is probably at most not more than a variety of *Autonoe longipes*, Lilljeborg. Notes are made upon *Acidostoma obesum*, Lillj.; *Kroyera arenaria*, Sp. Bate; *Lilljeborgia normanni*, which is a synonym of *Cheirocratus sundevalli*, Rathke; *Melita gladiosa*, Sp. Bate; *Proto goodsiri*, Sp. Bate. It is remarked that the last species possesses two pairs of styliform appendages of the pleon, not a single pair as Spence Bate had stated. It is further suggested that *Proto goodsiri* is a form of *Proto pedata*, Leach. This suggestion is confirmed by Mayer, who unites them as synonyms of *Proto ventricosa*, O. F. M.

1876. STEBBING, T. R. R.

Amphipodous Crustaceans. On the genera *Hyale* and *Anonyx* and a new species of *Probolium*. The Annals and Magazine of Natural History. May, 1876. Ser. 4. Vol. XVII. London, 1876. pp. 337-346. Pls. 18. 19.

The species named in the Brit. Sess. Crust., "Allorchestes Nilsonii," Rathke, and "Nicea Lubbockiana," Sp. Bate, are here called respectively "Hyale Nilsonii," and "Hyale Lubbockiana," Boeck's view being accepted that *Allorchestes* and *Nicea* are both synonyms of the earlier *Hyale* of Rathke. Boeck's opinion that the two species in question are also identical is rejected. I am at present inclined to believe that *Hyale lubbockiana* is a synonym of *Hyale pontica*, Rathke. Under the heading "Anonyx serratus, Boeck," the suggestion is made that *Orchomene pinguis*, Boeck, *Orchomene serratus*, Boeck, and *Orchomene minutus*, Kröyer, are but one species, which might be retained in the genus *Anonyx*. It is proposed that "Anonyx Edwardsi" and *Anonyx minutus* of the Brit. Sess. Crust., i. pp. 94, 108, should fall to the same name. G. O. Sars decides, in 1882, that *Lysianassa longicornis*, Sp. Bate, and "Anonyx Edwardsi," Sp. Bate (non Kröyer), are respectively the male and female of one species, which he names "Orchomene Batei;" but the first gnathopods of the species which Spence Bate accepts as *Lysianassa longicornis*, Lucas, will not admit of this identification. The male specimen which I have described in this paper is no doubt "Orchomene Batei," Sars.

"*Probolium Spence-Batei*," n. sp., is described and figured, but as nothing is said about the mandibles, and the specimen itself has perished, the true position of this species must remain indefinite. It may possibly belong to *Amphilochus*, rather than either to *Steuothoë* or *Metopa*, to one or other of which species of *Probolium* are generally synonymous.

Some notes on *Urothoë* are given.

1876. STEBBING, T. R. R.

On some new and little-known Amphipodous Crustacea. The Annals and Magazine of Natural History. December 1876. Ser. 4. Vol. XVIII. Pl. XIX., XX. pp. 443-449.

Amphilochus concinna is described as a new species, but as subsequently explained in the Annals for November 1878, it is probably identical with *Amphilochus manudens*, Sp. Bate, though differing to some extent from that author's account of his species. Meinerz records it from Storebelt. *Danaia dubia*, Sp. Bate, is figured and described. *Callimerus acudigitata* is described and figured as a new genus and species, but this is subsequently cancelled in the Annals for November 1878, as being a synonym for *Amphilochus manudens*. *Exunguia stilipes*, Norman, 1868, and *Cratippus tenuipes*, Sp. Bate, 1862, are compared, the conclusion drawn being that the genera are the same. No doubt the species are also identical. *Colomastix pusilla*, a new genus and species described by Grube in 1861, bears a strong resemblance, and in regard to the generic name, *Colomastix* supersedes both *Cratippus* and *Exunguia*.

1876. WILLEMOES SUHM, RUDOLF VON.

Preliminary Report to Professor Wyville Thomson, F.R.S., Director of the Civilian Scientific Staff, on Observations made during the earlier part of the Voyage

of H.M.S. Challenger; and on Crustacea observed during the cruise of H.M.S. Challenger in the Southern Seas. (Read March 16, 1876.) Proceedings of the Royal Society of London. Vol. XXIV. London, MDCCCLXXVI. pp. 569–592.

On page 570 he refers to the capture of "a large female of *Cystisoma Neptunus*," on the way from Gibraltar to Madeira. In the "List of the land animals collected in the Tristan d'Acunha group," for Crustacea, he gives, p. 585—

"1. *Oniscus*, everywhere under stones; 2. *Gammarus*, everywhere under stones."

After describing, page 587, a gigantic Ostracod brought up by the deep-sea dredging between Prince Edward Island and the Crozets, he says, "this is not the only example, however, of gigantic forms in the deep sea, for the same trawlings brought up two specimens (from 1375 and 1600 fathoms) of a Gammarid Amphipod, the larger of which has a length of 60 millius. and a height of 35 millius. Though we now know that certain Hyperids (*Cystisoma Neptunus*, both sexes of which we found in the Atlantic, and described in the Phil. Trans. 1873; see also Trans. Linn. Soc. 1875, 2nd ed. Zool. i. p. 24) attain the considerable length of more than 4 inches, these transparent and elongated animals do not make such an impression as the Gammarids, which are besides in no way peculiar, being perfectly normal, and approaching perhaps most the genus *Typhimeda*. I shall therefore give later a more accurate description of them, and here only direct attention to the fact that in the deep sea, as well as in the sedimentary strata, animals are found which, compared with their relations living now-a-days, and in shallow water, are of a very considerable size; and I may perhaps best in this place add that in this dredging of 1375 fathoms a Nymphoid (Pyenogonid) was got measuring nearly two feet across the legs." The Gammarids referred to I have described under the name *Andania gigantea*. The genus *Typhimeda* is probably an error for *Iphimedia*.

On page 589 he says, "In Kerguelen Island, where we stayed nearly a month, much shallow-water dredging took place in the different harbours, most of which was done by Professor Wyville Thomson himself, while I was on shore collecting the land animals of the place. There is no *Gammarus* with terrestrial habits nor any *Oniscus* to be found in these barren islands, animals which still exist on the Tristan d'Acunha Islands." Nevertheless, for An amphipods found on the rocky beaches of Kerguelen, see Note on S. I. Smith, 1874.

On page 590, he says, still referring to Kerguelen, "the Crustacea inhabiting the shallower water are several species of *Serolis*, *Sphaeroma*, *Areturus*, some Gammarids, several species of *Caprella*, one of which has a very slender and long manus, and some Pycnogonida. There is scarcely anything interesting to be found in that zone [going from a few fathoms down to forty]. In the second zone [40–120 fathoms] of deeper water (though not deep-sea fauna, which we scarcely ever have found in less than 500 fathoms) we had a richer harvest; *Tanais* and *Praniza*, very curious Amphipods, Mysids, and *Nebalia* are the inhabitants, about which I shall now say a few words."

The long-handed *Caprella* is no doubt the species since named *Dodecas elongata*.

In this second zone, with a larger species of *Serolis*, "an Amphipod occurred, a Gammarid, distinguished by a bright red frontal prolongation of the head and having no eyes. These I first thought might be discovered in some form or other in the red proboscis; but my expectations were not justified by the results of the dissection. The organ is divided by a line along its top into a right and left portion. The chitinous layer has got no facettes, and the whole organ is filled by a finely granulated red pigment. What its function may be I cannot say, having never met with anything like it." This is no doubt the species named *Oediceropsis rostrata*, in the Annals and Magazine of Natural History for March 1883, but transferred to a new genus, *Oediceroides*, in this Report.

On page 591 he says, "between Kerguelen and Heard Islands we dredged in 150 fathoms, but

got only a *Scalpellum*, an *Arcturus*, and a spiny Amphipod, which is the corresponding form to the *Gammarus loricatus* of the North. Near Heard Island, in 75 fathoms, we found the same animal and a Sphaeroma, but no other Crustacea at all." The spiny Amphipod is named in this Report *Acanthechinus tricarinatus*. I have seen no second specimen of this striking species, but as *Iphimedia pulchridentata* was dredged in 75 fathoms near Heard Island, it is probable that on a cursory inspection this species was mistaken for the other.

1877. BATE, C. SPENCE.

Report on the present state of our knowledge of the Crustacea. Part I. On the homologies of the dermal skeleton (*continued*). [From the Report of the British Association for the Advancement of Science for 1876.] London, 1877. Plates II. & III. pp. 75-94.

At page 81 Mr. Spence Bate says, "the fact that the supposed side-plates, or epimera, were merely the first joint of the normal legs or appendages has been satisfactorily demonstrated in the Edriophthalmia, as far as relates to the somites of the pereion; but hitherto the relation of the side-plates of the pleon to the normal condition of the mobile appendages had not been demonstrated until the structure of the dermal anatomy of the genus *Apseudes* had been made out. [Hist. Brit. Sessile-eyed Crust., vol. ii. p. 146 (*Apseudes*)]; that 'one interesting and, as far as we know, unique feature in these Crustacea yet remains to be noticed. The segments of the pleon have the lateral walls (long known as the epimera of Milne-Edwards, called also the pleura by many authors) existing as articulated appendages, demonstrating two important features in the homologies of these parts: 1st, that they are all really portions of the appendages, being the first joint or coxae of the pleopod . . . and 2nd, that, since the peduncle consists of three joints, the second branch in the appendages of the pleon, as in other parts, is shown to take place invariably at the extremity of the third joint.'" It seems to me, however, that the force of this argument is weakened or destroyed, by the fact that numerous species of *Apseudes* have now been examined and described by various authors, and in regard to no one of the species has any author followed Mr. Spence Bate in speaking of the epimera of the pleon as articulated.

As a curious fact in comparative carcinology, Mr. Spence Bate observes, that "contrary to a possible condition of all other appendages, the coxal joint of the first pair of antennæ is never absorbed into or fused with the sternal portion or ventral arc of the somite to which it belongs" (p. 85). Numerous allusions to the Amphipoda occur, as might be expected, in different parts of this memoir.

1877. CHATIN, JOANNES.

Recherches pour servir à l'histoire du bâtonnet optique chez les erustacés et les vers. Annales des Sciences Naturelles. Sixième série. Zoologie, Tome V. Paris, 1877.

A list is given of earlier works bearing on the subject. In regard to the *cône*, "cette pièce généralement brillante et réfringente qui surmonte le bâtonnet optique dans les Arthropodes," he says, "La forme du cône est, de tous ses caractères, celle qui présente les variations les plus nombreuses et les plus considérables. Il est en général prismatique chez les *Typton*, *Epimeria*, *Lichomolgus*; ovoïde dans les *Eupagurus*, *Paguristes*, *Caprella*, *Notopterophorus*;

pyramidal chez les *Cypridina* et *Lysianassa*; elaviforme chez les *Isæa*; cylindro-eonique dans certains *Squilla*, etc."

1877. HOEK, P. P. C.

Carcinologische Aanteekeningen. Bijdrage tot de Kennis der Noordzee-Fauna (2de Jaarslag, 1877).

No new Amphipoda are reported.

1877. HUXLEY, THOMAS HENRY.

A Manual of the Anatomy of Invertebrated Animals. London, 1877.

The Edriophthalmia are described on pages 359 to 367. "These resemble the *Podophthalmia* in never possessing a greater than the typical number (20) of somites, though, in some members of the group, the body is composed of fewer somites, in consequence of the abortive or rudimentary condition of the abdomen." The genus *Amphithoë* is chosen for special description, but it is not easy to see why this name should have been chosen for the animal figured, which has a large rostrum, the back earinate and almost every segment dentate, the fifth side-plate shorter than the fourth, and the upper antenna showing a secondary flagellum, suggesting, therefore, *Gammaracanthus loricatus* rather than any *Amphithoë*. The head proper, in Professor Huxley's view, has only five pairs of appendages, the sessile eyes not being counted. These are the antennules, antennæ, mandibles, and two pairs of maxillæ. The first pair of thoracic appendages "are applied against the mouth, and form a large lower lip." "The 'head' of *Amphithoë*, therefore, is formed by the coalescence of the seven anterior somites of the body; but I believe that the tergum of the seventh (or first thoracic) somite is obsolete, as in a Stomatopod, and hence that the tergal surface of the head of the Edriophthalmia corresponds exactly with the cephalostegite (or that part of the carapace which lies in front of the cervical groove) in *Podophthalmia*. Mr. Spence Bate has shown in his valuable 'Report on the *Edriophthalmia*,' that, in the *Crustacea* at present under discussion, a strong apodeme arises on each side from the posterior part of the sternal region of the head, and passing inwards and forwards meets with its fellow, to form an endophragmal arch, which supports the oesophagus and stomach and protects the nervous commissure between the first and second sub-oesophageal ganglia, which runs under it. The discoverer of this structure conceives that it represents the terga of the three somites immediately succeeding the mouth; but I cannot see that it is other than the representative of the precisely similar mesophragm formed by the anterior apodemes in *Astacus*. In fact, the correspondence in structure between the head of an *Amphithoë* and the cephalic portion of the cephalo-thorax of *Astacus* is not a little striking. There is the same sternal flexure, the same relative position of the stomach, and of the insertions of the mandibular muscles. The great difference lies in the abortive condition of the ophthalmic appendages." In treating of the embryology the remark is made that "in certain Amphipods (*Gammarus locusta* and *Desmophilus*) the vitellus undergoes complete division; while, in closely allied forms (*Gammarus fluvialis* and *pulex*), and still more completely in those *Isopoda* which have been studied, the part of the vitellus which divides into blastomeres, becomes more or less completely separated from the rest immediately after fecundation, and the so-called partial yolk division, take place." A note gives a reference to "E. van Beneden, Recherches sur la Composition et la Signification de l'Oeuf, 1870." By consulting this work Mr. W. E. Hoyle has found for me the clue to the mysterious

word *Desmophilus*. In the first place it is a misprint for *Dermophilus*, which should have been noticed under the date 1870. In that year Beneden and Bessels, in their Mém. sur la Formation du Blastoderme chez les Amphipodes, etc., p. 26, footnote, say, "Nous avons eu l'occasion de constater le portionnement total du vitellus et un mode de formation du blastoderme tout à fait identique à celui que nous avons reconnu chez le *Gammarus locusta*, dans un groupe d'Amphipodes tout nouveau, dont nous proposons de donner prochainement la description.

"Ces crustacés remarquables vivent en parasites sur le *Lophius piscatorius*, et les modifications qu'ont subies les caractères du groupe auquel ils appartiennent, par l'influence de leur vie parasitaire, sont d'un haut intérêt à divers points de vue. Nous proposons pour cet animal le nom de *Dermophilus lophii*.

"On connaîtra bientôt des parasites dans tous les groupes de crustacés. On connaît des cyrrhipèdes parasites en grand nombre ; certaines espèces de baleines en sont littéralement couvertes ; les Lernéens sont véritablement des Copépodes parasites ; on connaît depuis longtemps des Isopodes parasites ; enfin nous venons de découvrir un parasite qui, anatomiquement comme embryogéniquement, est un véritable Amphipode."

E. van Beneden, in the paper to which Professor Huxley refers, says at p. 132, "l'épithélon envoie souvent à l'intérieur des tubes ovariens des prolongements, en forme de cloisons transversales . . . ; quelquefois comme dans le genre *Dermophilus* (Ed. van Ben. et Em. Bess.), ces prolongements sont de véritables lames cellulaires qui séparent complètement dans le vitellogène deux œufs voisins." At page 136, a footnote gives a reference, in regard to this genus, to Édouard van Beneden et Émile Bessels. Mém. cour et des sav. étr. de l'Aead. roy. de Belg., t. xxiv., by error for t. xxxiv. It is obvious that van Beneden applies the term *parasitic* to any creature which lodges upon another, whether it feeds upon the carcase of its host or not. It is probable that the *Dermophilus lophii* here mentioned is the same as the *Ichthyomyzocetus lophii* of Eugène Hesse, 1873, while Hesse's *Ichthyomyzocetus* appears to be partly, if not entirely, identical with Kroyer's *Lajystius*, 1842. See additional Note on Hesse, 1873, in Appendix.

For the comparative anatomy of the Crustacea, the English student will do well to read what Professor Huxley has to say in this volume on all the groups, or to study his work entitled, *The Crayfish, an introduction to the Study of Zoology*.

1877. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1875 ; being Volume twelfth of the Record of Zoological Literature. London, M.DCCC.LXXVII. pp. 213–234.

The following account is given of M. Hesse's curious new genus :—

"Piscicolæ. A new family proposed for the reception of *Ichthyomyzocetus*, g. n.; 3 anterior pairs of feet directed forwards with hooked claws; the 4 posterior longer, with nearly straight claws; abdomen composed of 2 or 5 segments; respiratory organs in the form of a double cylindrical multiannulated hairy rod on the under side of the abdomen; end of the abdomen two-branched, each branch terminated by several leaflets. This family connects the *Amphipoda* with the *Isopoda*. *I. ornatus*, *morrhae*, *lophii*, and *squatinae*, spp. nn., living as parasites on the cod, toad-fish, and angel-fish on the Atlantic coast of France. Hesse, Ann. Sci. Nat. (5) xvii, pp. 1–16, pl. iv. [The description is not quite satisfactory; according to the position of the respiratory organ, this genus should be placed rather with the Isopods than with the Amphipods.]" There seems here to be some misconception in the account of the abdomen. The pleopods also, to which Hesse attributes respiratory functions, are, according to his description, of the character usual among the Amphipoda, not like those of Isopoda. Compare the Note on Hesse, 1873.

1877. MEINERT, FREDERIK VILHELM AUGUST, born March 3, 1833 (J. J. S. Steenstrup).

Crustacea Isopoda, Amphipoda et Decapoda Daniae: Fortegnelse over Danmarks Isopode, Amphipode og Decapode Krebsdyr. Naturhistorisk Tidsskrift. III. Raekkes, 11. Bind. 1877–1878. pp. 57–248.

A list of Crustacean literature is given, pages 58 to 68. The discussion of the Amphipoda begins at page 91. Meinert prefers to reinstate Montagu's specific name for *Hyperia galba*, on the ground that O. F. Müller's account of *Cancer medusarum* is too indefinite, and not like Montagu's, supported by figures. But Montagu's figure is of so little service for specific distinction as to constitute but a weak reason for displacing the older and well-established name *medusarum*. Meinert includes in the synonymy *Hyperia obliterata*, Krøyer, and *Lestrigonus kinahani*, Sp. Bate, in regard to which compare Note on Thomas Edward, 1868. Meinert also prefers the name *Orchestia littorea*, Montagu, to *Orchestia gammarellus*, Pallas, on the ground that the figures and descriptions in Pallas are "insufficient to distinguish his *Oniscus Gammarellus* from his O. Loeusta." But the Notes on Pallas, 1766, 1772, will, I think, show that this opinion is erroneous.

Pontoporeia furcigera, Bruzelius, is kept distinct from *Pontoporeia femorata*, Krøyer, on the ground that Krøyer could not possibly have overlooked the striking furcate process on the back of the fourth pleon-segment. But it seems that Krøyer did not do so, although in his specimen it may have been weakly developed. It is figured in the "Voy. Seand. Crust. t. xxiii., f. 2, a–y;" to which Meinert himself refers under *Pontoporeia femorata*, Kr.

To *Bathyporeia pilosa*, Lindström, are assigned as synonyms "?Bathyporeia Robertsonii Sp. Bate," and "Bathyporeia pelagica Sp. Bate," both as male forms. *Bathyporeia tenuipes*, n. s., is thus defined:—"Antennæ superiores subnudæ, flagello appendiculari biarticulato. Antennæ inferiores articulo tertio et quarto longis atque tenuibus. Angulus capitidis acutus, productus. Pedes omnes tenues, modice hirsuti; pedes saltatorii ultimi parvis setis simplieibus instruti."

Under "*Phoxus Holboelli* Krøyer," is given "Forma altera maris: Antennæ superiores paulo longiores. Antennæ inferiores tenuissimæ, fere corporis longitudinis. Pedes saltatorii parvis ultiui multo longiores, setis longis plumosis obsiti."

Urothoë marina, Sp. Bate (♂), and *Urothoë brevicornis*, Sp. Bate (♀), are accepted, in accord with Bate and Westwood's suggestion, as the two sexes of one species.

Paramphithoë glabra, Boeck, and *Paramphithoë bicuspis*, Krøyer, are the names given to two species which Boeck in his latest work assigned to *Pleustes*.

Of *Calliopus norvegicus*, Rathke, Meinert remarks that it is by no means easy to distinguish it from *Calliopus laeviusculus*, in which I quite agree with him. He thinks it may be no more than a variety of *laeviusculus*. Of *Gammarus locusta*, Linn., he says that the young differ from the adults in having the eyes small, round or oval, and the rami of the last uropods often of different lengths. He agrees therefore with the general view in making *Gammarus pacificus*, Rathke, a synonym of *locusta*; but he also thinks that *Gammarus marinus* is only a shallow water variety.

In the synonymy of *Gammarus pulex*, Pennant, he places *Gammarus pulex*, of Hosius and others, "Gammerus Roeselii Gervais," *Gammarus fluvialis*, Milne-Edwards, ? *Gammarus lacustris*, G. O. Sars, ? *Gammarus neglectus*, G. O. Sars. Between *Gammarus pulex* and *Gammarus neglectus* he has met with the intermediate gradations. If Sars' species is maintained, he thinks that the earlier name for it should not have been altered, in which also I agree with him.

Pallasea, Sp. Bate, he spells *Pallasia*, but this improvement must be avoided, as with it the name is preoccupied.

"*Amathilla sabini* Leach," is considered to include as a variety, *Gammarus angulosus*, Rathke, and *Amathilla carino-spinosa*, Sp. Bate. Zaddach's *Leptocheirus* is (not rightfully) made a synonym of the later *Ptilocheirus*, Stimpson. To the species *Leptocheirus pilosus*, "*? Protomediea hirsutimanus* Sp. Bate," is given as a synonym. *Eiscladus longicaudatus*, Sp. Bate and Westwood, is retained as a separate species under the name *Photis longicaudata*. To *Protemedeia fasciata*, Kröyer, are assigned as synonyms *Autonoë macronyx*, Lilljeborg, and "*Microdeutopus Websteri*," Sp. Bate.

Under *Gammaropsis erythrophthalmus*, Lilljeborg, he mentions that a specimen from Nyborg was labelled "Autonoë Karmoensis Boeck." "Without doubt," he says, "hereby a new species is designated, which, however, I have not found described by Boeck. I found no difficulty in determining it as above."

Of "*Podoceropsis Sophia*," Boeck, he mentions finding a specimen labelled, "Harpulia typica Bk." In this genus he gives *Podoceropsis excavata*, Sp. Bate, and *Podoceropsis rimapalmata*, Sp. Bate, both transferred from Sp. Bate's genus *Nænia*.

With "*Siphonæcetus Colletti*, Boeck," he found one of Boeck's labels bearing the name "*Corophium Steenstrupii*," and with "*Glauconome Steenstrupii*," Boeck, he found a label, "*Harmophia Krøyeri*, B."

The localities and synonyms of various other species are given in this work, but without descriptions, as indeed is the case with most of those above-mentioned.

1877. MIERS, E. J.

List of the species of Crustacea collected by the Rev. A. E. Eaton at Spitzbergen in the summer of 1873, with their localities and notes. Annals and Magazine of Natural History for February 1877. pp. 131–140. Vol. XIX. Fourth Series. London, 1877.

No new species are here recorded, but for *Lysianassa (Anonyx) lagena*, Kröyer, is substituted the name *Anonyx nugax*, Phipps, with the remark, "Phipps's figure of this common Arctic species is quite recognizable; and his name must therefore be adopted for it." *Lysianassa bidenticulata*, Sp. Bate, 1858, which its author had in 1862 transferred to *Cancer (Lysianassa) nugax*, Phipps, and which Boeck identified with *Gammarus nugax*, Owen, under the name *Socernes vahli*, Kröyer, is here re-established as *Anonyx bidenticulatus*, Spence Bate, being "distinguished by the form of the third segment of the pleon, which has a second tooth on its posterior margin above that of the postero-lateral angle," instead of being "valde rotundatus" as in *Socernes vahli*. Sars, in 1885, calls it *Socernes bidenticulatus*, Sp. Bate. *Acanthozone (Acanthosoma) hystrix*, Owen, is re-established, with the observation, "This species has been referred by Boeck to the *Oniscus cuspidatus* of Lepechin (Acta Acad. Sci. Petrop. p. 249, pl. viii. fig. 3, 1780); but the species figured by that author differs in having vertically projecting spines upon only the first four segments of the pereion. The species figured by Buchholz (Zweite deutsche Nordpolarf. Zool. Crust. p. 362, pl. xi.) as *Acanthozone hystrix* differs from that figured by Owen in the more numerous and closely placed spines upon the posterior margins of the basa of the pereiopoda, and in the form of the rostrum, and is, I think, distinct."

1877. MIERS, E. J.

Report on the Crustacea collected by the Naturalists of the Arctic Expedition in 1875-76. The Annals and Magazine of Natural History. Number CXV. pp. 52-66. Number CXVI. pp. 96-110. Vol. XX. Fourth Series. London, 1877.

The account of the Crustacea "is confined to the species collected between lat. 78° and 84° N."

"The most northerly species collected is *Anonyx nugax*, one of the commonest and most abundantly distributed of the Arctic Amphipoda, and first made known to science a hundred years ago by Phipps." At page 56 a table is given of "the Geographical distribution of the Crustacea collected by the Arctic Expedition north of lat. 78° N." This includes 12 species of Amphipoda, common to Greenland and Spitzbergen, 9 of them being also Scandinavian, 5 or 6 of them belonging to Arctic America, 3 to Iceland, 4 to Britain, 2 to north-east Asia. A species of Amphipod, "perhaps belonging to the genus *Pherusa*," is mentioned as having been collected by A. C. Horner, Esq., while on board the yacht "Pandora."

On *Anonyx nugax*, Phipps (*Anonyx lagena* of Sp. Bate, Boeck and Buchholz), Miers says, "my observations scarcely agree with those of Hr. Buchholz and other authors as regards the rare occurrence of the males of this very common and well-known Amphipod." The far longer flagella of the inferior antennæ distinguish the males. The largest male taken measured 1½ inch, the largest female 1 inch 9 lines.

For "*Anonyx gulosus* ? Pl. III. fig. 2," the synonymy gives *Anonyx gulosus*, Kröyer, Sp. Bate, and Boeck; *Anonyx norvegicus*, Lilljeborg, and ? *Anonyx holbølli*, Sp. Bate, Brit. Mus. Catal., p. 75. The description is followed by these remarks, "I have referred the specimens collected by Mr. Hart with some doubt to the *Anonyx gulosus* of Kröyer, as the antero-lateral margin of the head is less broadly rounded, and the accessory flagellum is longer than that of *A. gulosus* according to Boeck's diagnosis. In the form of the first and second pairs of legs and of the terminal segment they agree well with the descriptions of *A. gulosus*, and particularly in the presence of a tooth on the inner margin of the dactyl, which is mentioned by Lilljeborg as characteristic of that species. From *A. pumilus* they differ in the shorter antennæ, and in the absence of a tooth on the posterior margin of the fifth postabdominal segments."

"*Onesimus Edwardsii*. Pl. III. fig. 3," has for synonymy, "*Anonyx Edwardsii*, Kröyer," "*Lysianassa Edwardsii*, Goës," and "*Onesimus Edwardsii*, Boeck." After the description, Miers says, "the specimens collected differ from Boeck's diagnosis in one particular, the third segment of the postabdomen is slightly produced upwards at the postero-lateral angle. Nothing is said of the form of this segment by Kröyer in his description of the species or in the Latin diagnosis that follows. In Kröyer's figure of the species in the Atlas of the 'Voyage en Scandinavie,' the postero-lateral angle of this segment is represented as not produced upward, but acute. There is, however, a manifest inconsistency between the diagnosis of Boeck and the figures in the Atlas referred to; e.g., in *Onesimus plautus* the third postabdominal segment is described by Boeck as 'sursum preductus acutus,' but figured by Kröyer as broadly obtuse and rounded at the postero-lateral angle. *Onesimus edwardsii* has been recorded from Greenland, Spitzbergen, and Britain."

Notes are given upon *Atylus carinatus*, Fabr. To *Acanthozone hystrix* is attached the synonymy, *Acanthosoma hystrix*, Owen and Ross, Bell; *Amphithoe hystrix*, Kröyer, M.-Edw.; *Paramphithoe hystrix*, Bruzelius, Sp. Bate; *Acanthozone cuspidata*, Boeck, nec Lepechin; *Acanthozone hystrix*, Miers, Ann. and Mag. Nat. Hist. (ser. 4) xix. p. 137 (1877); with the remark, "in the elaborate plate that illustrates this species in the 'Zweite deutscho Nordpolarf.' [1874], the rostral spine is represented as conical, straight, and acute, and the basos joint of the sixth and seventh pairs of legs as armed with four strong spines upon its

posterior margin. In all the specimens of both sexes that I have examined the rostral spine is laterally compressed and bent near its base, projecting horizontally forwards, and there are but two spines upon the posterior margins of the basos joint of the sixth and seventh pair of legs. It is probable, therefore, that a distinct species is figured by Buchholz in the plate referred to." *Halirages fulvocinctus*, Sars, is next mentioned, followed by *Gammarus locusta*, Linn.; *Gammaracanthus loricatus*, Sabine; *Amathilla pinguis*, Kröyer. *Eusirus cuspidatus*, Kröyer, is thus remarked upon, "The single example in the collection is fully adult and bears ova. Length 1 inch $7\frac{1}{2}$ lines (41 millims.).

"The basos joint of the sixth and seventh pairs of legs is considerably narrowed to its distal extremity. The second and third segments of the abdomen have the posterior margins rounded and very finely serrated. This species has been described at great length and figured by Buchholz, *l. c.*; but either the figure is carelessly executed as regards many details, or it represents a very distinct species. The rostrum is represented as much longer than in the specimens I have seen; the coxa of the fourth pair of legs with its inferior margin straight (not rounded as in the examples I have examined), the second and third segments of the abdomen with the posterior margins strongly angulated, &c."

Notes are given on "*Tritropis aculeata*," chiefly referring to the development of the ovigerous lamellæ in the females.

Ægina spinosissima is given with references to *Ægina spinosissima*, Stimpson, *Caprella spinifera*, Bell, ?*Ægina echinata*, Boeck, *Caprella spinosissima*, Spence Bate. "The largest specimen, length nearly 2 inches 2 lines (54 millims.) is very robust, of a green colour, and with but very few small spines and many indistinct very small tubercles; the second pair of legs has the hand armed upon its inferior margin with two very strong teeth, and a third small tooth close to the distal extremity; the finger is strong and very much curved; the first joint of the first pair of postabdominal appendages is short and much broader than the second joint.

"The smaller specimen, length a little over 11 lines (24 millims.), is of a whitish colour, purplish brown at the bases of the spines, which are numerous, especially on the back. The hand of the second pair of legs is nearly of the same form as in the preceding, but the finger is less arcuate; the basal joint of the second pair of legs not broader than the second joint.

"In the specimens I have before me the teeth on the inferior margin of the palm of the second pair are not only much larger than in *Æ. echinata*, but the palm itself is not tuberculated as in that species, as figured by Boeck (*l. c.*) [pl. 38, fig. 6. 1876]. It is possible that the two forms are distinct; but the variation in the spines of the body and its limbs are known to be very great in some species of the genus.

"Probably the specimens referred by Ross in Parry's 3rd and 4th Voyages to *Caprella scolopendroides*, and which he describes as having 'a great number of small spines along the back,' should be referred to *Æ. spinosissima*. They were collected at Port Bowen and Low Island.

"This species has been recorded from the coasts of Greenland, Spitzbergen, and Norway; and if, as I believe, the species of Stimpson is identical, from the Grand Manan at the entrance of the Bay of Fundy."

1877. STALIO, LUIGI.

Catalogo metodico e descrittivo dei crostacei podottalmi ed edriottalmi dell' Adriatico. Estr. dal Vol. III., Serie V degli Atti del R. Istituto Veneto di scienze, lettere ed arti. Venezia, MDCCCLXXVII.

The preface briefly reviews the literature of Adriatic carcinology. The Edriophthalmia are divided into three orders, Amphipoda, Leptodipoda, Isopoda. Among the characters of the

Amphipoda, p. 162, are included "a pair of mandibles with two palps," although on the same page, in the first family, the Orchestidae, the mandibles are rightly said to be without palps. In the second family, the Gammaridae, the mandibles are said to be provided with palps; but that is not the case with two of the genera here mentioned, *Probolium* and *Dexamine*. The only other family assigned to the Amphipoda is the Corophidae. No new species are described or mentioned. *Probolium polypriion*, A. Costa, is given without explanation as a synonym of the later *Probolium megacheles*, Heller. *Elasmopus rapax*, A. Costa, is given as a synonym of *Podocerus largimanus*, Heller, although Heller himself points out that the last uropods and telson of *Elasmopus rapax* do not admit of its inclusion in the genus *Podocerus*, where nevertheless J. V. Carus has since placed it under the name *Podocerus rapax*.

In the Læmodipoda, according to the definition here given, "the mouth is furnished with a circular labrum, with two maxillæ strongly dentate and without palps, and with a pair of maxillipeds provided with palpiform branches." It is possible that by the "due mascelle fortemente dentate e prive di palpi," not maxillæ, but mandibles are intended, but "mandibole" is elsewhere used for mandibles, which in many of the Caprellidae are furnished with palps, though not in the genus *Caprella*, which alone claims Stalio's notice. In the Caprellidæ he says "l'apparato orale ha la medesima conformazione dei Gammaridi saltatori," probably by this phraseology intending to intimate that in *Caprella* as in *Orchestia* the mandibles are palpless.

1877. STREETS, THOMAS H.

Contributions to the Natural History of the Hawaiian and Fanning Islands and Lower California, made in connection with the United States North Pacific Surveying Expedition, 1873-75. Bulletin of the United States National Museum. No. 7. Washington, 1877. Amphipoda, pp. 124-138.

The lower antennæ and "posterior stylets" which were missing in Dana's specimen of *Clydonia longipes* are here described. *Lestrigonus rubescens*, Dana, is reported. *Hyperia tricuspidata*, n. s., is described, in which the first gnathopods have "the meros produced antero-inferiorly," "carpus broad, produced inferiorly, but not anteriorly," while "the second pair has none of the joints produced." "When the animal is at rest, the inferior antennæ are evidently folded up . . . in the concavity in the front of the head." At the end of the description the opinion is urged that the genus *Lestrigonus* should be retained, instead of being regarded merely as the male sex of *Hyperia*, but the argument seems to rest entirely on the account given of the inferior antennæ in the male of the so-called *Hyperia tricuspidata*, which, however, with its folded antennæ, cannot be a *Hyperia*, but must belong to the Platyscelidae. *Phronima pacifica*, n. s., is described from the "North Pacific Ocean. Latitudes 4° and 21° north; longitudes 127° and 151° west." "This species is distinguished from *P. sedentaria* by the broadly-quadrata form of the carpus of the third pair of thoracic feet, and by having the carpus of the gnathopoda less produced anteriorly. In other respects they are similar. The shape of the hand more nearly resembles the hands of *P. custos* and *P. borneensis*; but it is distinguished from both of the latter, by the character of the anterior surface of the carpus and of the propodus. In the latter both the carpus and propodus are furnished with a crenulated tubercle; in *custos* the tubercle is single and tooth-like. There is a striking resemblance between the propodus, and the anterior surface of the carpus of the third pair of thoracic feet, of the smaller specimens of *pacifica*, and the corresponding parts of *P. atlantica*, which is said to be the female of *sedentaria*; the broad hand, however, separates them. It is a remarkable fact, that in all the species of *Phronima*

that have been described, even from widely-separated localities, the variation is very slight indeed." See also Note on Streets, 1882.

Anchylonyx, new genus, is thus described:—"Head moderately large, broad and rounded at the top, tapering inferiorly to the oral apparatus, and excavated in front. Eyes on the lateral and dorsal surfaces of the head. Both pairs of antennæ present, long; base of the superior pair long and stout, three-jointed; inferior pair slender, four-jointed. Flagellum very attenuated and elongated. Thorax broad, somewhat compressed; segments six. Abdomen narrow. The gnathopoda not subchelate, nor much reduced in size, when compared with the following feet; the first and second pairs of thoracic feet long, slender; carpus and meros linear. The third pair enlarged; carpus and meros dilated, with the anterior margin armed with teeth; propodus flexes on the carpus, impinging against the teeth on its anterior margin; dactylus fused with the propodus. The fourth and fifth pairs of feet subequal, shorter than the preceding. The three posterior pairs of abdominal appendages biramous, laevoelate; rami pointed." In the additional observations it is noted that "the mandibles are without appendages," and that, as in *Phronima*, "a pair of wing-like plates exist at the base of the dactylus of both pairs of gnathopoda."

The type species is *Anchylonyx hamatus*, but in 1882 Dr. Streets makes it a synonym of *Phronima elongata*, Claus, 1862, and *Phronimella elongata*, Claus, 1872.

Anchylomera thyropoda, Dana, is reported, with the additional observation that "the inferior distal angle of the propodos of the third and fourth pairs of thoracic feet is produced, and when the joint is flexed this projection impinges against the antero-inferior angle of the carpus."

Platyscelus batei, n. s., is described, with the remark that "this species is closely related to *P. rissoinæ*; the differences are chiefly in the structure of the gnathopoda, and of the third and fourth pairs of thoracic feet. The gnathopoda bear a striking resemblance to those of the young of *P. serratus*, but as the rest of the structure of the animal shows no evidence of immature development, this is undoubtedly their normal adult condition." Yet, as the length is given as ".12 of an inch," and the inferior antennæ are said to be short, the specimen could scarcely be full-grown, and the independence of the species is therefore very doubtful. *Platyscelus serratus*, Bate, is regarded by Claus as a synonym of *Typhis ovooides*, Risso, and *Platyscelus rissoinæ* as perhaps a synonym of his own *Eutyphis armatus*. Dr. Streets' work does not seem to have come under the notice of Claus. *Amphipronoë serrulata*, n. s., is described, and *Oxycephalus tuberculatus*, Sp. Bate, a species which Claus identifies with *Oxycephalus piscator*, Milne-Edwards.

The new genus *Leptocotis* is thus described:—"Animal long and slender. Head large and produced anteriorly into a rostrum; narrowed behind the eyes; the constricted portion short, and not narrower than the thorax; under surface excavated anteriorly on each side for the reception of the superior antennæ. Superior antennæ short, sickle-shape. Inferior antennæ five-jointed, folded upon themselves four times, and concealed beneath the head; first and second joints distally enlarged. An elongate mandibular appendage. Gnathopoda short, and complexly chelate. Third and fourth pairs of thoracic feet having the coxae dilated; the fifth pair small. Fourth and fifth abdominal segments fused into one; sixth small. Caudal appendages long, biramous. Telson cylindrical, long." The type species, *Leptocotis spinifera*, is described in detail.

This genus, Dr. Streets says, exhibits a remarkable blending of the characters of *Oxycephalus* and *Rhabdosoma*. Much the same is said by Claus of his species *Oxycephalus tenuirostris*, 1871, to which, in 1887, he makes *Leptocotis spinifera*, Streets, a synonym, without explaining why he rejects the genus *Leptocotis*. Streets here speaks of "a long, acute spine, pointing upward, on each side of the fifth" segment of the abdomen. In 1878, he says nothing of this, but describes "the first three segments of the abdomen subequal,

inferior margins finely serrated, the third segment with the postero-inferior angle produced into a long, spinous process, the angle of the first and second segments square behind, not produced." Claus, on the other hand, for his species gives "die Seitenflügel der Abdominal-semente unbewaffnet," yet he figures the postero-inferior angle of the third pleon-segment produced into a sharp point, the same angle on the two preceding segments being well rounded.

1877. THÉEL, HJALMAR.

Relation de l'expédition Suédoise de 1876 au Yenissei. Upsala, 1877. p. 33.

"*Gammarus pulex* found in lakes of the Tundra, near Dondino, Siberia, at 69° N. lat." (Dr. von Martens, Zool. Record for 1877.)

1877. THOMSON, C. WYVILLE.

The Voyage of the 'Challenger.' The Atlantic. A preliminary account of the general results of the exploring voyage of H.M.S. 'Challenger' during the year 1873 and the early part of the year 1876. Vol. I. London, 1877.

There is but one passage specially referring to the Amphipoda (pages 129–132). On January 28, 1873, the trawl was employed successfully "at a depth of 1090 fathoms, about 90 miles to the south-east of Cape St. Vincent." "The trawl on this occasion contained a single example of the female of a very large amphipod crustacean, briefly described under the name of *Cystosoma neptuni* by Guérin-Méneville from a single specimen obtained in the Indian Ocean. We have since taken several specimens at different stations in the Atlantic; and as a small male was in one case captured in the towing-net, there can be little doubt that, like *Phronima*, to which genus it is allied, *Cystosoma* is a pelagic animal, probably retiring during the day to a considerable depth, but occasionally coming to the very surface of the water. The male example figured (Fig. 27), which is 103 mm. in length, was taken in Lat. 1° 22' N., Long. 26° 36' W., a little to the east of St Paul's Rocks, where the depth was 1500 fathoms.

"The animal presents a very remarkable appearance. It is absolutely colourless and transparent, so that by transmitted light the internal organs can be perfectly seen through the test—the cephalic ganglion with the nerve-fibres running to the antennæ and the eyes; the ganglia of the double ventral cord with the filaments passing to the appendages; the heart, an elongated tube with three openings; the stomach, a large sac with a small intestine leading from its base to the excretory opening in the telson; in the female two large rose-coloured ovaries, the oviducts passing to an opening covered by two small lamellæ, at the base of the first segment of the pereion; in the male two elongated testes, their ducts opening between the appendages of the seventh segment.

"The head is large and greatly inflated, and its upper surface is entirely occupied by two enormous faceted eyes, rivalling one of the eyes of *Aegina* among trilobites. There are two rows of spines along the lateral borders of the head, and some spines are placed round the mouth, which is in the usual position at the base of the cephalic segment on the lower surface of the body. The first pair of antennæ only are developed in either sex. The antenna consists of two joints, and is attached to the anterior margin of the head.

"The parts of the mouth and the maxillipeds are very small; the two gnathopods are terminated by claws as in the Typhids, and act functionally as second and third maxillipeds.

"The pereion consists of seven segments; and the pleon of five, to the two last of which the

caudal appendages are attached. The five pairs of ambulatory legs are long and slender, and the three pairs of 'swimmerets' are normal. The eggs are large and few in number; some of those observed contained embryos in which nearly all the appendages were developed, showing that the young undergo no metamorphosis.

"Dr. von Willemes-Suhm, who has carefully described this singular form, has proposed to establish for the genus a family CYSTOSOMIDÆ, holding a place intermediate between the TYRPHIDÆ and the PHRONOMIDÆ."

A casual allusion to Amphipods occurs on p. 388.

1877. WOODWARD, HENRY.

A Catalogue of British Fossil Crustacea, with their synonyms and the range in time of each genus and order. London, 1877.

The notices of Amphipoda in this work are as follows:—Introd., p. vi. "The order Amphipoda has one representative in the Upper Silurian (the *Necrojanmarus Salweyi*, H. Woodw.); it is represented by *Gampsouyx* in the coal of Rhenish Prussia, and by the genus *Prosoponiscus* in the Permian of Durham. Other (Secondary) species occur in Bavaria, etc. The living genera of Amphipoda are abundant, both marine and freshwater; and some species are even terrestrial in their habits."

The table of genera and species, etc., on p. viii., assigns but one genus and one species to the British fossil Amphipoda.

Page 62 gives "Order V. Amphipoda.

"*Trilobites problematicus*, Schloth. 1820, Petrefact. p. 41.

"*Prosoponiscus problematicus*, Kirkby, 1857. Quart. Journ. Geol. Soc. vol. xiii. p. 214, pl. vii. figs. 1-7; Spence Bate, 1859, Quart. Journ. Geol. Soc. vol. xv. p. 137, pl. vi. figs. 1-7."

In regard to the above, see Notes on Schlotheim, 1820, 1822; Schauroth, 1854; Kirkby, 1857; Woodward, 1871.

1877. WRZEŚNIOWSKI, AUGUST.

Ueber die Anatomie der Amphipoden. Protocolle der Sitzungen des Section für Zoologie u. vergleichende Anatomie des V. Versammlung russischer Naturforscher u. Aerzte in Warschau in September 1876, mitgetheilt von Prof. Hoyer. Zeitschrift für wissenschaftliche Zoologie. Achtundzwanzigster Band. Leipzig, 1877. pp. 403-404.

Synurella polonica, a new genus and species, is here introduced, but not described, since the account of its circulation can scarcely stand either for generic or specific description. The name *Synurella* was afterwards, with perhaps unnecessary purism, changed to *Goplana*. The change indeed would have scarcely been legitimate, had *Synurella* at its first introduction been attended by sufficient description to give it a status in scientific nomenclature. The interesting details in regard to the heart, etc., were subsequently repeated with improvements. Reference is made to "*Callisoma Branickii*," earlier described, and to "*Hyale Jelskii*" described subsequently.

1878. BATE, C. SPENCE.

Two new Crustacea from the coast of Aberdeen. Annals and Magazine of Natural History for May, 1878. p. 411. Fig. 2.

The new species *Lestrigonus spinidorsalis*, closely resembling *Lestrigonus exulans*, differs from any species of the genus known to Mr. Spence Bate in having the last two somites of the pereion and the first three of the pleon produced in the median line of the dorsal surface posteriorly to a sharp-pointed tooth or spine. [Surely this is *Parathemis compressa* (Göes) 1865.]

1878. BATE, C. SPENCE.

On the Willemoesia Group of Crustacea. Annals and Magazine of Natural History for December, 1878. pp. 484-489.

The name *Lestrigonus spinidorsalis* is here altered to *Hyperia (Lestrigonus) spinidorsalis*, since *Hyperia* is the older name, and *Lestrigonus* is probably founded not on specific but sexual differences, containing the male forms, as suggested in the British Museum Catalogue, 1862.

1878. BATE, C. SPENCE.

The Crustacea in Coue's Cornish Fauna revised and added to by C. Spence Bate, F.R.S. 1878. *Reprinted from Part II, No. XIX. Journal Royal Institution of Cornwall.*

The Amphipoda, pages 43 to 62, are not a revision of Conch's work but an addition, taken from Mr. Spence Bate's own writings. On page 47 the genus *Grayia* is given as *Graya*. There is reason to believe that this only represents the young of *Amathilla homari*. *Acanthonotus owenii* is here said to have been taken from *Maia squinado*, but the remark properly applies to *Isaea montagui*, Milne-Edwards, as may be seen in the Brit. Sess. Crust., i. p. 216. *Siljeborgia* is printed by mistake for *Liljeborgia*.

1878. BATE, C. SPENCE.

Report on the present state of our knowledge of the Crustacea. Part III. On the homologies of the dermal skeleton (*continued*). [From the Report of the British Association for the Advancement of Science for 1877.] London, 1878. pp. 36-55.

In discussing the first pair of antennæ, Mr. Spence Bate remarks that "in Amphipoda there is never more than one secondary appendage, and that is always of a rudimentary character, and frequently only determinable in the very young stage of the animal and obsolete in the adult." Dybowsky, however, among the *Gammari* of the Baikalsee found the secondary appendage sometimes consisting of forty articulations, and therefore scarcely to be called rudimentary. "As we descend," Spence Bate observes, "in the scale of Crustacean forms the antennæ naturally become simplified; but as they lose their internal structural character they increase their external functional arrangement. Thus in Amphipoda the auditory chamber and otolithes are wanting, but in all the aquatic normal forms the

(ZOOL. CHALL. EXP.—PART LXVII.—1887.)

Xxx 60

filaments are long, and richly studded with those membranous organisms that I have named *auditory cilia*." The discovery by Claus of otoliths in the Oxycephalidae is not noticed.

In speaking of the second pair of antennæ, Spence Bate says, "in the Amphipoda this antenna is simple and normally well defined, the five joints of the peduncle and the flagellum being separate and distinct." But according to my experience the two first joints of the peduncle are as a rule more or less fused together.

"Among the Hyperidae," he further says, "the [second] antenna is considerably impoverished, and in many genera it is rudimentary, while in *Phrosina* it appears to be absent." In regard to *Phrosina*, however, I may state that I have just received (June 27, 1887) from Dr. Bruce specimens taken at Malta, of *Phrosina semilunata*, Risso, ♂, in which both pairs of antennæ are well developed with long flagella.

The three sections of this paper are headed respectively "Correlation of Appendages," "On Exuviation," and "On Renewal of Appendages."

1878. BOVALLIUS, CARL, born 1849 (Hj. Théel).

Notes on *Pterygocera arenaria*, Slabber. (Bihang till Svenska Vetenskaps-Akad. Handlingar, IV, No. 8), pp. 1-27, pls. 1-4. 1878.

It has been shown by S. I. Smith that the names *Sulcator*, Sp. Bate, 1854, and *Pterygocera*, Latreille, 1825, must yield to the earlier name, *Lepidactylis*, Say, 1818, but in my opinion the name *Haustorius*, proposed by P. L. S. Müller in 1775, has the preference over all its competitors. The elaborately and beautifully illustrated notes by Bovallius (in English) open with an account of the adventures of Slabber's species, not however taking into account *Lepidactylis dytiscus* of Say. A chronological list of the literature is given, with a corresponding omission. A new subfamily is created, *Pterygocerinæ*, thus defined :—

"Cephalon rostrum fereus minimum, articulum primum antennarum non tegens.
"Labium superius breves, apice rotundatum.
"Mandibulæ magnæ, palpo elongato, articulo palpi secundo tertio longiore.
"Maxillæ primi paris parvæ, palpo biarticulato.

"Pedes maxillares palpo laminari.

"Antennæ superiores flagello appendiculari instructæ.

"Gnathopoda primi paris dactylo unguiculato, secundi paris dactylo minimo dupli.

"Pereiopoda primi et secundi paris articulis ultimis ligulas formantibus.

"Pereiopoda sequentia dactylis carentia.

"Telson simplex.

"Corpus non valde compressum.

"The family *Pterygocerinæ* is distinguished from the *Pontoporeiæ* and *Phoxinæ* by its general form as well as by the abnormal structure of the dactyli of the gnathopoda. Another remarkable character is presented by the peculiar form of the carpus and propus of the first and second pairs of the pereiopoda, which I have thought proper to denote as spoon-shaped 'liguliformis.' *Pterygocera* differs, moreover, from the *Phoxinæ* by the second joint of the mandibular palpus being larger and longer than the third, and also by the telson not being bifid, but simple and only incised."

In the very full and detailed account of the species it is mentioned that "with the age of the animal the size of the eyes diminishes also, and in the oldest they are discovered only with difficulty. The pigment is red, the eye-lens short, thick, bluntly conical, the surface of the eye irregularly faceted."

1878. CATTA, J. D.

Sur un Amphipode nouveau, le Gammarus Rhipidiophorus. Aetes de la Société Helvétique des Sciences naturelles réunie à Bex les 20, 21 et 22 août 1877. 60^e session. Compte-rendu 1876/1877. Lausanne, 1878. pp. 257–263.

The Amphipod in question has been only found in a well at La Ciotat (Bouches-du-Rhône, France), a hundred yards or so from the Mediterranean. The water of the well becomes brackish in summer. Professor Catta observes that in the carpus and propodus of the first pereopod his new species has, with exaggerated development, a character common also to *Gammarus pulex* and *Gammarus locusta*, in that these joints are "garnis d'immenses poils plumeux disposés par rangées transversales et entremêlés de piquants." From the sweeping movement of these setæ he formulates the name "*Rhipidiophorus* (*ῥιπιδίος*, *balai de plumes*)."
The first pereopod in this species, he says, is much longer than the second; the first uropods are much shorter than the second; the third are enormous, whether compared with those that precede or with the size of the animal, and have one branch rudimentary; the other branch "garnie de nombreuses rangées de grandes soies et de piquants, est composée de deux articles dont le dernier est assez réduit."

An argument follows to show that the genus *Niphargus* ought to be again merged in *Gammarus*. It is urged that in *Gammarus pulex*, and in *Gammarus neglectus*, Sars, one ramus of the third uropod is biarticulate, as in *Niphargus*; that Humbert's "*Niphargus puteanus*, var. *Forelii*" has "des poils et des poinçons sur le bord postérieur des derniers Somites," as in *Gammarus*; that the presence or absence of eyes is not of great importance; and that the telson is practically alike in the species assigned to both genera. As to the dorsal hairs and prickles, he says, "*G. Rhipidiophorus* qui est *Niphargus* par les antennes, le cinquième Siagonopode et le Pléon, porte aussi ces poils et ces piquants." It may, on the other hand, be argued that in *Niphargus aquilex* the biarticulate ramus of the third uropods is strikingly distinguished from that in any species of *Gammarus* by the length which the second articulation attains, as well as by its cylindrical shape. The discovery of transition-forms between two genera will always cause some difficulty, but as such forms have probably existed in innumerable cases where they have not been discovered, it is a question how far the discovery of them should be allowed to interfere with well-established distinctions either of genera or species. When *Niphargus aquilex* and *Gammarus pulex* are side by side, it is rather the difference of the *facies* than the likeness which attracts attention.

1878. CHATIN, JOANNES.

Recherches pour servir à l'histoire du batonnet optique chez les crustacés et les vers. (Suite 1). Annales des Sciences naturelles. Sixième série. Zoologie. Tome VII. Paris, 1878.

Accounts are given of the eye in *Lysianassa spinicornis*, Costa, fig. 24; *Isæa nicea*, Thor., fig. 25, 26; *Caprella acanthifera*, Leach, figs. 28, 29; *Epimeria*, nov. sp., Catta, figs. 30–34. This new species lives parasitic upon *Suberites domuncula*, Nardo. The pigment-sheath is rouge vif, while other species of *Epimeria* have it brown, and others again almost black. The genus, he thinks, requires a complete revision.

1878. CLAUS, C.

Ueber Herz und Gefäss-system der Hyperiden. Zoologischer Anzeiger. I. Jahrgang. No. 12. Leipzig, 1878. pp. 269-271.

He here notices the two lateral pairs of arteries belonging to the heart of *Phronima*, which he had at one time supposed to be merely strings of connective tissue. The same pairs of vessels, he says, are found also in *Phronimella*, and in two new Mediterranean Phronimidæ from Messina, for which he institutes the new genera *Phronimopsis* and *Paraphronima*. In the latter genns there is a third pair of arteries in the fifth pereon-segment. This he finds also in *Phrosina*, *Hyperia*, *Oxycephalus*, *Thamyris*, *Platyscelus* (*Typhis*) and *Vibiliæ*. He is inclined to consider three pairs (in the third, fourth, and fifth segments) the normal number for the Platyscelidæ and Oxycephalidæ, especially as three is the prevailing number for the pairs of venous ostia (in the second, third, and fourth segments) in the Phronimidæ and Gammaridæ. Sometimes the first pair of ostia is wanting, and sometimes the third pair of arteries. "Two pairs," he says, "of lateral slits, which then uniformly belong to the third and fourth pereon-segments, I find in almost all Platyscelidæ, e.g., *Typhis*, *Lycœopsis*, n. gen., and in *Oxycephalus*, *Vibiliæ*, and *Hyperia*."

He assigns three pairs of lateral ostia (in the second, third, and fourth pereon-segments) alike to the Gammaridæ and Caprellidæ. In the genus *Tanais* the elongate heart is, he says, quite Amphipod-like in its relations, but has only two lateral openings in the third and fourth very elongate pereon-segments.

The heart as a rule runs from the beginning of the first to about the middle of the sixth pereon-segment, but in *Oxycephalus* the cephalic aorta begins at the beginning, and in *Typhis* and *Lycœopsis* at the end of the second segment. The two pairs of valves are described which are found at the origin both of the cephalic and abdominal aorta, and some other details are entered into.

1878. DEZSÖ, BÉLA.

Ueber den Zusammenhang der Kreislaufs- und respiratorischen Organe bei den Arthropoden. Zoologischer Anzeiger. I. Jahrgang. Leipzig, 1878. p. 274.

The general results only of Dr. Dezsö's investigations are given in the following terms:—

"Bei Crustaceen, die ihre Kieme als Körperanhänge an der Bauchseite des Abdomens und Postabdomens haben, kommen ebenfalls so viele Paare von Spalten am Dorsalgefäß vor, wie viele Paare von Kiemen existiren."

"Bei Crustaceen, die ihre Kiemen unter der Thoraxschale beherbergen, kommen am Herzen so viele Paare von Spalten vor, wie viele Paare von Kiemen sich unter der Thoraxschale vorfinden."

These results do not seem to tally with those arrived at by Fritz Müller, Claus and Delage, with regard to the heart in the Amphipoda, among which five pairs of branchiae are commonly combined with three pairs of lateral slits in the heart.

1878. FOREL, F. A.

Faunistische Studien in den Süsswassersseen der Schweiz. Zeitschrift für wissenschaftliche Zoologie. Dreissigster Band. Supplément. Leipzig, 1878. pp. 383-391.

In respect to the general conditions of life in a fresh-water lake he distinguishes three regions, "die littorale, die pelagische und die tiefe Region." The deep fauna is tolerably rich in

species and in number of individuals; most types of fresh-water animals have their representatives there (mit Ansnahme der Najaden und der Spongien). In this region in the Lake of Geneva he found, among others, "Niphargus puteanus, var. *Forelii*, Al. Humbert." References are given to Professor Forel's earlier writings on lake-fauna.

1878. GAMROTH, ALOIS.

Beitrag zur Kenntniss der Naturgeschichte der Caprellen. Mit Tafel VIII-X. Zeitschrift für wissenschaftliche Zoologie. Einunddreissigster Band. Leipzig, 1878. pp. 101-126.

The investigations were made on "Caprella equilibra Sp. B. (?)". Its food Gamroth considers to be the larvae of Bryozoa and perhaps the adult Bryozoa likewise. The work is one of importance, discussing the whole organisation of the creature in question, but it has been to some extent superseded by the later labours of Paul Mayer and Delage. Mayer points out that Gamroth erroneously attributes only one joint, instead of two, to the flagellum of the lower antennæ in *Caprella equilibra*; that he figures on the first maxilla an inner basal plate (Kaulade) with setæ, as found in the normal Amphipoda, but not present in any of the Caprellidae with which Mayer is acquainted; and that he leaves unnoticed the want of symmetry in the mandibles, and makes no mention of the Paragnath (lower lip). He calls the hairs on the lower antennæ "Strudelorgane," a term which Mayer considers appropriate, as well as Haller's "Ruderhaare," and "Fangorgane" which would suit Gosse's description. The "Frontal organ" or "Naekenorgan," which Gamroth discovered, one on either side the median line of the body, in front of the brain, and above the origin of the upper antennæ, is considered by Mayer to be a gland rather than, as Gamroth suggested, an organ of sense. His mistake in supposing that the colouring matter was in the epidermis instead of under it, is explained by Mayer by the fact that the Chromatophores do push excrements in between the cells of the epidermis, giving an appearance as if the epidermis were itself pigmented.

1878. GEGENBAUR, CARL.

Grundriss der vergleichenden Anatomic. 2te Aufl. 1878.

Elements of Comparative Anatomy. By Carl Gegenbaur, Professor of Anatomy and Director of the Anatomical Institute at Heidelberg. Translated by F. Jeffrey Bell, B.A., Magdalen College, Oxford. The translation revised and a preface written by E. Ray Lankester, M.A., F.R.S., etc. London, 1878.

The Arthropoda occupy the fifth section, pages 228-305. The Crustacea are divided into
a) Entomostraca, b) Malacostraca. The latter are divided into 1. Thoraeostraea (Podophthalma), and 2. Arthrostraea (Hedriophthalma). The latter are exhibited as follows:—

"Amphipoda. *Gammarus, Orchestia, Hyperia, Phronyma*.

"Læmodipoda. *Caprella, Cyamus*.

"Isopoda. *Bopyrus, Cymothoë, Sphaeroma, Oniscus, Asellus, Idothea*."

In the preface, pages xiii-xv, there are some important remarks on "Nomenclature of the Parts of the Digestive Tract." Mr. Lankester proposes "to distinguish the primitive digestive space which develops from the endoderm (in fact the gastrula stomach) as the 'enteron.' The anterior passage leading into this from the mouth, and formed by an ingrowth of

ectoderm," he says, "I have termed the 'stomodaeum,' and the corresponding passage leading from the anus I similarly propose to call the 'proctodæum.' These three primary factors of the alimentary tract are most equally developed in the Arthropoda and some Mollusea."

In Professor Lankester's Classification the Arthropoda are the "Branch. Gnathopoda" of the "Appendiculata," which "include animals with lateral locomotive appendages, and usually a segmented body," a group, "excepting that it has the addition of the Rotifera, nearly coextensive with the Annulosa" of Huxley's Classification in 1869.

1878. GODET, PAUL.

Note sur le *Gammarus puteanus*. Bullet. de la soc. des Scienc. nat. de Neufchâtel. XI. 2. pp. 284-5. 1878.

Gives measurements. See also Note on Godet, 1873, in Appendix.

1879. HALLER, GOTTFRIED OTTO, born May 30, 1853, died May 1, 1886 (Mlle. A. Haller).

Vorläufige Notizen über die Systematik der in Mittelmeer vorkommenden Caprelliden. Zoologischer Anzeiger. II. Jahrgang. Leipzig, 1879. pp. 230-233.

Short descriptions are given of the following species, *Protella major*, n. s., subsequently recognised by Haller as the male of *Protella phasma*, Montagu; *Caprella liparotensis*, n. s.; "*Caprella Helleri*," n. s.; "*Caprella Dohrnii*," n. s.; *Caprella elongata*, n. s., for which, and for the two preceding, see the next Note; *Caprella antennata*, n. s., identified with *Caprella acanthifera* by Mayer, who notices that Haller himself does not again mention this species; and lastly, "*Podalirius Kröyeri*," n. s.

1879. HALLER, G. O.

Beiträge zur Kenntniss der Læmodipodes filiformes. Mit Tafel XXI.-XXIII. Zeitschrift für wissenschaftliche Zoologie. XXXIII. Band. Leipzig, 1879. pp. 350-422.

Of the genera *Podalirius*, *Proto*, *Protella*, and *Caprella*, Dr. Haller found *Protella* most, *Podalirius* least, suited for his anatomical investigations. His discussion of the nerve-system should be read under the light thrown by Mayer's later investigations. In the section headed "Sinnesorgane," Haller denies the existence of the "trichterförmige Frontalorgan" which Gamroth discovered lying immediately behind the origin of the upper antennæ. But the existence of this frontal- or nuchal-gland is reaffirmed by Mayer. After the discussion of various hairs destined for sensation, Haller gives in his third section, "Einige mikroskopische Beobachtungen über Haargebilde, welche theils zum Ergreifen und Festhalten, theils zum Schwimmen dienen." While, he says, the upper pair of antennæ is "stets und überall Sinnesorgan," and therefore beset with all sorts of hairs for purposes of sensation, the hinder pair does not always agree with it in this purpose. It often loses almost entirely the importance of an organ of sense, and by way of compensation becomes destined to support the organs of locomotion. Hence arise swimming-antennæ, as among the Copepoda. In the genus *Caprella* it is possible to form two subgenera, one with the lower antennæ acting as organs of sense, the other in which they have become swimming organs. In this

latter case they have the whole under side closely set with long stiff hairs, arranged in two simple rows. These swimming-bristles are movably socketed, and on each joint increase in size from behind forwards. Their peculiar structure is described. The structure, positions and uses of various spines are investigated.

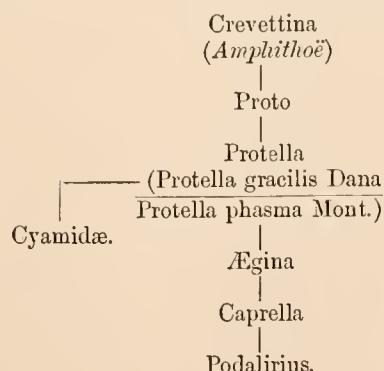

Sections of the work are devoted to the heart and circulation, the organs of reproduction, the apparatus of nutrition and glands of the intestine, a gland in the hand of the second gnathopod of some Caprellidae (e.g., *Caprella dohrnii* and *Protella phasma*), remarks on large connective-tissue cells in the bodies of the Caprellidae, sexual differences, adaptability, mode of life, epizoic plants and animals, classification.

Proto pedata, Fleming, and "Proto Goodsiri," Spence Bate and Westwood, (Figs. 23-25), are given as distinct species, but the better opinion unites them under *Proto ventricosa*, O. F. Müller. *Proto brunneovittata*, n. s., is described and figured. Remarks are made on the genus *Protella*, Dana, and the species *Protella phasma* (Fig. 26). *Caprella*, Lamarck, is defined, and in "Subgenus I. Caprellen, deren unteres Fühlerpaar Ruderborsten trägt," he places 1. *Caprella aequilibra*; 2. *Caprella acutifrons*; 3. *Caprella liparotensis*, n. s. (Figs. 41, 42), which is described in detail; 4. " *Caprella Helleri*," n. s. (Fig. 43), which Mayer considers to be the young form of some *Caprella* which cannot be determined.

In "Subgenus II. Die unteren Antennen sind Sinnesorgane." Here are placed, 5. *Caprella linearis*; 6. " *Caprella Dohrnii*," n. s. (Fig. 44), which is given by Mayer as a synonym of his subsequently published *Caprella grandimana*; 7. *Caprella acanthifera*, Leach; 8. *Caprella elongata*, n. s. (Fig. 45), which Mayer considers to be a smooth variety of *Caprella acanthifera*.

Of *Podalirius*, Kröyer, two species are given, *Podalirius typicus*, Kröyer, and *Podalirius kröyeri*, n. s. (Figs. 46-49), both species being described in detail.

In the conclusion, Haller draws out the following genealogical tree of the Caprellidae, which he regards as probably Crevettina metamorphosed by a parasitic mode of life.

1878-HAYEK, GUSTAV VON.
1879.

Handbuch der Zoologie. Siebente, (des II. Bandes erste) Lieferung. Wien,
1878. Achte (des II. Bandes zweite) Lieferung. Wien, 1879.

Von Hayek divides the "Unterreich, Arthropoda, Gliederfüssler," into four classes, Crustacea, Arachnoidea, Myriopoda, Insecta. In the higher forms, he says, the body is clearly divided into three principal sections, constituting the head, thorax, and abdomen, but "bei den Krebstieren, als den niederst organisierten Gliederfüßlern, ist eine derartig ausgesprochene Sonderung niemals zu bemerken, sondern eine mehr oder weniger weitgehende Verschmel-

zung des Kopfes mit den folgenden Segmenten, und wäre es auch nur das vorderste des Bruststückes, der sogenannten Prothorax, zur Regel geworden." He divides the Crustacea into seven orders, the Amphipoda standing sixth, between the Isopoda and Decapoda. At page 89 he defines the Amphipoda (Flohkrebse), as "Getrennt-schechtliche Krebstiere mit entwickeltem Bruststücke, von den Seiten her zusammengedrücktem Leibe, und kiemlosen Postabdominal-Gliedmassen." The illustrations are taken from "*Amphilochus Jurivii*," M.-Edw.; *Gammarus neglectus*, Lillj.; *Gammarus locusta*, Montagu; *Caprella linearis*, L.; and *Phronima sedentaria*, Forsk. Fig. 10-14, "*Gammarus neglectus*, Lillj. Partie eines sehr vergrösserten Embryos," exhibits the heart with six "seitliche Spaltöffnungen." Of the eyes it is said, "Die zusammen gesetzten, sitzenden Augen werden von der zu einer Hornhaut umgewandelten, ganz glatten, niemals facettirten Körperdecke überzogen."

1878—KIRK, T. W., born 1856 (Chilton).
1879.

Additions to the Crustacean Fauna of New Zealand. The Annals and Magazine of Natural History. Vol. II. Fifth Series. London, 1878. pp. 465-466.

On Additions to the Carcinological Fauna of New Zealand. [Read before the Wellington Philosophical Society, 31st August. 1878.] Transactions of the New Zealand Institute. Vol. XI. pp. 392-397. 1879.

"*Caprella novae-zealandiae*, sp. nov." is described. It is said to approach "*C. geometrica*, Say, from which it differs, however, in the form of the spine on the cephalon, in the length of the antennæ, and in the articulation and arming of the second pair of gnathopoda." Mayer considers that this, together with *Caprella caudata*, G. M. Thomson, is probably a local variety of *Caprella equilibra*, Say. A second species is described as "*Caprella lobata*, Guérin."

In *Notes on Some New Zealand Crustaceans*, [Read before the Wellington Philosophical Society, 11th January, 1879]. Trans. N. Z. Inst. Vol. xi. pp. 401-402, Mr. Kirk mentions the capture of *Podocerus cylindricus*, Say, and *Pleustes panoplus*, Kröyer, at Worsley Bay. He says, "these are both Arctic species, and their occurrence on our coast is somewhat remarkable." It has since been suggested that the *Pleustes* is a variety.

1878. LEYDIG, FRANZ.

Ueber Amphipoden und Isopoden. Anatomische und zoologische Bemerkungen. Zeitschrift für wissenschaftliche Zoologie. XXX. Bd. Suppl. pp. 225-274. Mit Tafel IX-XII. Leipzig, 1878.

On the antennæ of the Amphipoda, Leydig distinguishes:—

1. Gewöhnliche Borsten. These ordinary bristles, for most of their length dark-rimmed, but with bluntnish ends of finer, clearer structure, and often a fine hair given off some way short of the termination, are found on other parts of the body as well as the antennæ.
2. Fiederborsten. These plumose bristles, spoken of by Humbert as "capsules sensitives," may, Leydig says, be sensitive, but they are not capsules, they are modified pores (Hautcanäle). For the explanation of the like in other Crustacea and in insects, he refers to his own work Ueber Geruchs- und Gehörorgane der Krebse und Insecten., Archiv f. Anat. u. Physiol., 1860. Between this and the preceding class he places a sort of Halbfiederborsten, such as are found on the rim of the head and the back of *Gammarus puteanus*.
3. Cylinder oder Keulen. In these cylinders or clubs, the end swelling into a sort of knob

shows a pale, fine structure, but no opening. They may be seen on the flagellum of the lower antennæ of *Gammarus puleanus*.

4. Riechzapfen. These olfactory tubes are on the flagellum of the upper antennæ. They have a narrower dark-rimmed stem and a paler, broader body, in which there is a slight indentation at about midway. A cloud of fine granular substance may sometimes be seen issuing from the terminal aperture.
5. Schuhartige Anhängsel. Calceoli. These shoe- or slipper-like stalked appendages are supposed to belong only to the lower antennæ of the male, but it is now known that they occur on both pairs of antennæ and in both sexes.

In the ordinary bristles, called by de Rougemont tactile bristles, Leydig could not find a nerve, though inclined to regard both the bristle and still more the fine offshoot near the tip as the sheathing of a nerve-end. That Claus should have seen the nerve in other Crustacea [the Argulidae] he thinks open to doubt. This doubt Claus criticizes in "der Org. d. Phron. p. 10–11, n." The plumose bristles Leydig had always regarded as tactile bristles, having in other subjects shown how they were placed upon indubitable ganglia. If the view of recent observers, that these are auditory hairs, be justified, the sense of sound, Leydig infers, must be distributed over a considerable portion of the surface of the body, a conclusion not of necessity to be rejected.

He defends his attribution of an olfactory function to the "Riechzapfen" against the objections of Graber in 1877. In the lower animals he considers that the different senses are not necessarily very sharply distinguished, so that one and the same nerve-end-apparatus may serve for the sense of touch, taste and smell, may even not be quite inaccessible to light and sound. He illustrates his meaning by the popular use of the German word "Wittern" (compare English "savour") employed sometimes of taste and sometimes of smell.

In *Gammarus fluviatilis* and *Gammarus pulex* he thinks the eyes are pretty much alike in shape. In both the cornea is smooth and without facets. The crystal cone, he says, consists of four pieces, which can scarcely be correct; see Note on Grenacher, 1879. In view of the very varying statements of authors on the eye of *Gammarus puleanus*, he made investigations from which he determines that the optic ganglion is present, but not the eye, though pigment-spots mimicking the eye have led some observers to believe that an eye existed in fact.

Under the heading, "Ueber die Schalendrüse," Leydig reminds us that in his *Naturgesch. d. Daphnidien*, 1860, pp. 28, 29, he had described his discovery in *Gammarus* of the homologue of the "green gland" in *Astacus*, but when he says that O. Sars seven years later only knew of the presence on the lower antennæ of "un procès couique dirigé en bas et appelé l'épine olfactoire," he is very much in error as to the state of Sars' knowledge. See Note on Sars, 1867. Claus, in 1879, objects that the name "Schalendrüse" has no sense when applied as by Leydig to the gland in the base of the antennæ, "sondern passt lediglich für das *in die Schale gerückte Drüsenvorpaar der Phyllopoden*, welches der Kieferregion gehört." The pair of glands corresponding to the shell-gland is entirely wanting, he adds, in all developed Malacostraca, and has hitherto been made out only during the larval life in *Sergestes* and *Euphausia*, while on the other hand in the *Phyllopoda* and many other Entomostraca the antennary gland corresponding to the green gland of *Astacus* only exists in the larval stage, but afterwards becomes completely degraded (Der Org. d. Phron., p. 13).

On the digestive system, Leydig recalls the investigations he had described in 1855 in regard to the stomach, histological structure of the intestine, liver and adipose body. He here remarks that the fat-drops are always colourless, and that in the fatty body of the body cavity, round the intestine, there are besides the fat-drops also layers of those concretions

which he had formerly pointed out as existing in *Asellus aquaticus*, and in some insects and Myriapods. On the term Kaumagen here employed for the stomach, Claus says that in the general use by authors of this terminology obviously borrowed from the Decapoda, we must not lose sight of the fact that for the Amphipoda "die Kaufunction des Vormagens bislang keineswegs bewissen worden ist." In fact, he continues, the importance of the supposed Kauplatten (triturating organs) at least in the Phronimidae appears to be limited to a closing apparatus (as in a lobster-pot), whereby the food that has passed into the Vormagen (cardiac portion of the stomach) is restrained on the one hand from returning into the oesophagus, and on the other from passing over too rapidly into the Magendarm (pyloric portion of the stomach) (Der Org. d. Phron., p. 25).

On the circulation, Leydig calls attention to the presence (observed apparently in *Gammarus puleanus*) of a sharply defined aorta proceeding from the anterior end of the heart, with a furcate division in the head. Also, he says, in the antennæ and pleopoda the arterial course is so definitely distinguished from its surroundings that the expression vessel (Gefäss) is more appropriate for it than lacuna. I do not therefore understand the criticism of Delage (p. 89) upon this paper by Leydig that "cet auteur, au lieu de faire avancer la question, reproduit, au contraire, une erreur ancienne en niant absolument que les courants sanguins des membres possèdent des parois."

Remarks are made by Leydig on the distribution of, and distinctions between, *Gammarus pulex*, de Geer, *Gammarus fluviatilis*, Rösel, and *Gammarus (Niphargus) puleanus*, Koch. Adopting the view of de Rougemont that *Gammarus pulex minutus*, Gervais, is identical with Koch's *puleanus*, he says that this last was made known by Koch and Gervais at the same time. "Wenn man freilich, wie es hin und wieder geschieht, zu Koch citirt: 'Faunæ insectorum Germaniæ initia, 1798,' so käme die Beobachtung von Koch weit vor jener GERVAIS'; allein das erste Heft des Koch' schen Werkes, welches als Fortsetzung der von PANZER begonnenen und bis zum 109. Heft fortgeführten Fauna insectorum Germaniæ auftritt, erschien 1835, nachdem zuvor HERRICH-SCHÄFFER die Hefte bis zum 132. herausgegeben hatte. Dieselbe Jahrezahl, 1835, trägt auch der Band der Annales des sciences, welcher die Beobachtungen von Gervais bringt."

Leydig in this work gives a summary of his earlier investigations on the structure of *Gammarus*, which may be quoted in his own words, "So habe ich die histologische Beschaffenheit der Haut schon im Jahre 1855 erörtert und später im Jahre 1860, da ich früher die Cuticula als 'nicht verkalkt' bezeichnet hatte, aufmerksam gemacht, dass doch auch bei *Gammarus* nach Essigsäurezusatz die Haut Luftbläschen entwickle. Ferner wurde, was unten noch einmal zur Sprache kommen soll, die Schälendrüse nachgewiesen, auf die Anwesenheit eines Kaumagens hingedeutet, und die histologische Beschaffenheit des Darmes, der Leber und des Fettkörpers dargethan. Endlich habe ich bereits im Jahre 1848, also um 20 Jahre vor E. van Beneden's Arbeit über die Furchung der Amphipoden, den Furchungsprocess von *Gammarus* beschrieben und abgebildet."

1878. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1876; being Volume thirteenth of the Record of Zoological Literature. London, M.DCCC.LXXVIII. pp. 1-18.

An analysis is given of Claus' "Untersuchungen zur Erforschung der genealogischen Grundlage des Crustaceen-Systems. Wien, 1876." "*Nebalia* and *Branchipus* among the living forms may give an approximate idea of those primordial forms, from which the Decapods, Stomapods, Amphipods and Isopods are to be derived."

1878. MAYER, PAUL, born July 20, 1848 (P.M.).

Carcinologische Mittheilungen. Mit einer Tafel und 4 Holzschn. Mittheilungen aus der Zoolog. Station zu Neapel. 1. Bd. 1. Heft. pp. 40. Taf. 1.

The first chapter is "über die Drüsen in den Beinen der Phronimiden," the second discusses "die Gehäuse der Phronimiden" (Gerstaecker).

This paper, according to Haller, explains in great detail the gland in the grasping-hand of *Phronima selenaria*, pointing out its position, form, number of outlets, microscopic constitution, and suggesting that it is either a poison-gland, or more probably emits a secretion necessary for dissolving the interior of the creature used by the *Phronima* as a nest or nursery.

1878. MIERS, E. J.

Narrative of a Voyage to the North Polar Sea, by Captain Nares. 8vo. 2 vols. 1878. Appendix (No. VII.). pp. 240–248. Crustacea.

The account of the Crustacea appeared in the Annals and Magazine of Natural History in 1877.
See Note on Miers, 1877.

1878. SCHMIDT, OSCAR.

Die Form der Krystallkegel im Arthropodenauge. Zeitschft. f. wiss. Zool. Vol. XXX. Suppl. pp. 1–12. Plate 1. Leipzig. 1878.

This paper raises certain objections to the views of Exner and Grenacher on "mosaic vision," which are met by Grenacher in an appendix (pp. 168–170) to his great work on the subject, Untersuch. über das Sehorgan, 1879.

1878. STEBBING, T. R. R.

Notes on Sessile-eyed Crustaceans, with Description of a new species. The Annals and Magazine of Natural History. January 1878. Ser. 5. Vol. 1. London, 1878. pp. 31–37. Pl. 5.

Caprella fretensis, n. sp., is described and figured, from two specimens found at Salcombe in South Devon, at which place the estuary yields *Proto ventricosa*, O. F. M., and many other Amphipods. Meyer accepts *Caprella fretensis* as a distinct species, but considers it extremely close to *Caprella septentrionalis*, Krøyer. It is abundant at Ilfracombe, and very variable, some specimens coming far nearer than others to the published accounts of Krøyer's species just mentioned.

The correlation between the spines on the palms of the hind legs, *die Einschlagdorne*, in the Caprellidae, and the generic divisions of that family, is noticed. Mayer, die Caprelliden, p. 13, remarks that it would be difficult to carry through the employment of this character for generic division, since *Caprella acanthifera*, for example, would then have to be transferred to another genus. This indeed is on other grounds suggested by Boeck, who thinks that *Caprella acanthifera* may belong to his genus *Æginella*. Of *Stimpsonia*

chelifera, Sp. Bate, the male is figured and both sexes are described. The female is said to bear a close resemblance to that of *Aora gracilis* and that of *Microdeutopus anomalus*. Of the genus *Callimerus*, Stebbing, the following characters are given:— “Antennæ subequal; superior antennæ without secondary appendage; first pair of gnathopods simple; second pair having the carpus infero-anteriorly produced, the coxae of the second pair covering those of the first. Penultimate pleopoda shorter than either of the other pairs. Telson simple.” This genus is a synonym of *Amphilochus*, Sp. Bate, the maxillipeds having given rise to the description of the first gnathopods as simple.

1878. STEBBING, T. R. R.

On two new species of Amphipodous Crustaceans. The Annals and Magazine of Natural History. November 1878. Ser. 5. Vol. 2. London, 1878. pp. 364–370. Pl. 15.

“*Amphilochus Sabrinæ*,” n. sp., is figured and described. It is very like *Amphilochus bispinosus*, Boeck, but the second side-plate is not serrate as in Boeck’s species, having only a single indentation. The two first segments of the pleon have not a dorsal tooth, and in the last uropods the rami are very much shorter than the peduncle, instead of being only slightly so. There are other minute differences, but not such as I should venture to rely on without an examination of fresh specimens. I am aware also that in creatures whose full size is one-twelfth of an inch, the presence of the dorsal teeth on the pleon may sometimes be overlooked.

This paper contains the remarks on *Amphilochus concinna* and *Callimerus acudigitata*, which have been already referred to.

Under the name *Podoceropsis intermedia*, a species is described as new, which is no doubt a synonym of “*Podoceropsis Sophiae*,” Boeck, 1860.

An additional note mentions various “Amphipoda in Sponges.”

1878. STREETS, THOMAS H.

Pelagic Amphipoda. Proceedings of the Academy of Natural Sciences of Philadelphia. 1878. pp. 276–290. Pl. 11.

The collection described was made by Surgeon William H. Jones, U. S. Navy, according to whose experience might be “about the only time when surface dredging can be carried on with any prospect of success.” Dr. Streets gives a definition of the Oxycephalidae, and in a note observes, “Claus classifies the *Oxycephalidae* along with the *Phronimidae* in his family *Phronimides*, and states that the mandibular palpus is absent, which is an error. Though absent in both sexes of the *Phronimidae*, it is present in the male of the *Oxycephalidae*.” (On these points see Notes on Claus, 1879.) Descriptions and (small, inadequate) figures are given of *Oxycephalus tuberculatus*, Sp. Bate, which Claus identifies with *Oxycephalus piscator*, M.-Edw.; of *Oxycephalus bulbosus*, n. s., taken between Lat. 28°00 and 35°45 N., Long. 140°00 and 144°25 W., and given doubtfully by Claus in 1877 as a synonym of his own *Oxycephalus typhoides*, 1879, from Zanzibar and Messina; of *Oxycephalus scleroticus*, n. s., which shares with Claus’ *Oxycephalus typhoides* the peculiarity of having “on the fifth epimeral a prominent spine, directed backwards”; and of *Leptocotis spinifera*, Streets, 1877. The new genus *Calamorhynchus* is thus defined:—“Body elongated, slender, almost rod-like. Head large, depressed, produced anteriorly to the eyes in a broadly-

expanded, triangular rostrum; constricted behind the eyes into a short, narrow neck. Superior antennæ with the peduncle three-jointed; in the female straight. First and second pairs of thoracic legs small, chelate, the fourth joint broad and long, the fifth short and narrow. The last three pairs of legs with the basal joint narrowly dilated; the seventh pair diminutive. The sixth segment of the abdomen long and narrow. Caudal appendages long and linear. Telson short, triangular." The type species, *Calamorhynchus pellucidus*, n. s., is described from a female specimen, the head and second thoracic foot being figured. *Rhabdosoma whitei*, Sp. Bate, and "Rhabdosoma armatum (Edw.), Adams and White," are figured and described, two species which Claus unites as identical. *Rhabdosoma armatum*, Sp. Bate, is curiously treated by Dr. Streets as a separate species, to which he gives "provisionally the name *Rhabdosoma longirostris* (Bate)," although he recognises that Spence Bate took his description and figure from the same specimen that furnished White's figure.

1878. ZADDACH, G.

Die Meeres-Fauna an der preussischen Küste beschrieben von Professor G. Zaddach. Erste Abtheilung. Königsberg, 1878. 31 pages.

Zaddach here expresses the opinion that the epimera or side-plates of the Amphiopoda are parts of the segments, an inheritance from the unarticulated pleura of the Trilobites, and a higher development of these. For the first joint of the leg after the epimera he adopts the term Hüfte, for the second and third Drehgelenk and Schenkel, for the fourth and fifth Schienenglieder, and for the sixth Tarsus. He gives a table to show the differences between the eight species which he has to describe, namely, *Talitrus locusta*, *Gammurus locusta*, *Melita palmata*, *Calliope lœviuscula*, *Protomediea pilosa*, *Pontoporeia femorata*, *Bathyporeia pilosa*, *Corophium longicorne*. In 1843, he says, specimens of *Corophium longicorne* and *Protomediea pilosa* were taken by Rathke in lake Geserich. Zaddach himself had not been able since to find them in that, or hear of them in any other, inland water of Prussia. In describing the family Orchestidæ, he calls attention to the "endophragmal arch," which is wanting in other Amphiopoda, with a reference to Bate and Westwood, i. p. xvii, fig. 3; he says that the maxillipeds bear not two, as in the Gammaridæ, but three laminar processes on the three lowest joints, and that they are only five-jointed, because the claw-shaped terminal joint is wanting; the telson, he says, is wanting. But the telson, though small in *Talitrus*, is not wanting in this or any other known genus of the Orchestidæ, and the fourth joint of the maxilliped-palp, though rudimentary or obsolete in *Talitrus* and *Orchestia*, is developed in *Hyale* and *Hyalella*; while, lastly, it is not correct to give as a family

characteristic that the three lowest joints of the maxillipeds are expanded, since alike in *Talitrus*, *Orchestia* and *Talorchestia* it is not the first but the second joint of the palp that has an expansion, nor is that one of such a laminar form as to be properly comparable with the plates attached to the two joints below the palp. The remark that the palp is wanting to the first maxillæ also requires qualification, since in *Talitrus locusta*, for example, one is present though rudimentary in size.

In describing *Talitrus locusta* (Taf. 1) Zaddach affirms that there is no trace of a mandibular palp; he says that the function of the mandibular spine-row is obviously to pass on the morsels bitten off by the cutting-edge to the molar tubercle. What is commonly called the under lip should, he thinks, be called the tongue, both from its function and from its answering morphologically to the tongue of many insects. He considers that Linnæus in the description of his *Cancer locusta* in the Fauna suecica could not have intended any other species of Amphipod than this.

In describing the family Gammaridæ, Zaddach maintains that the peduncle of the lower antennæ has but four joints, not admitting the composite character of what he calls the first joint. In the description of *Gammarus locusta* (Taf. 2) he points out that young specimens (Taf. 3) differ from the adults in the size and shape of the eyes, in the number of the joints of the antennary flagella, in the rami of the third uropods, and in the telson. He argues that Linnæus in the Fauna suecica, No. 2041 and No. 2042, by *Cancer pulex*, which gnaws the fishing-nets, meant only *Gammarus locusta*, and by *Cancer locusta* meant only *Talitrus locusta*, since that alone by its leaping, its powerful head and long antennæ, was fit for comparison with a grasshopper or locust. At the same time he considers the name *Gammarus locusta* too firmly established for alteration. He here recognises that the Amphipod in anuber, *Palæogammarus sambiensis*, which he described in 1864, may belong to the genus *Gammarus*, or come very near it.

In describing *Melita palmata* (Mont.) Leach, (Taf. 4), Zaddach mentions that the side-plate of the sixth pereon-segment in the female, and not as Boeck states in the male, is prolonged downwards at the front angle and bent upwards into a blunt hook, destined, he thinks, to provide the large claw of the male with a holdfast. (Bruzelius had already, in 1859, rightly ascribed the peculiarity in these side-plates to the female.) *Amphitoe norvegica*, Rathke, he does not consider distinct from *Calliope læviuscula* (Krøyer) Bate, which he figures (Taf. 5) and describes.

It may be noticed that in this paper Zaddach accepts the name *Protomedæia pilosa* for the species which he himself in 1844 named *Leptocheirus pilosus*, but Boeck maintains that *Leptocheirus*, Zaddach, is a genus quite distinct from *Protomedæia*, Krøyer.

1879. BRANDT, A.

Von den armenischen Alpenseen. Zoologischer Anzeiger. II. Jahrgang. 1879.
p. 525.

In a letter to the editor, dated from Dorf Elenowka am Goktschai, den 26. Juli 1879, Dr. Alexander Brandt reports that in the Goktschai there were swarms of Gammarids, especially on the shore. Those discovered were very uniform, corresponding in size and habit to *Gammarus pulex*. Individuals brought up from a depth of 34 fathoms showed a brighter colouring than those from the upper waters. He remarks that their eyes are not dark or continuously pigmented, but offer only lighter pigment-flakes of a roundish stellate form, so that at first sight he could fancy them destitute of eyes. Have we, he asks, by any chance here to do with a blind variety in *statu nascenti*?

1879. CLAUS, C.

Der Organismus der Phronimiden. Mit. 8 Tafeln. Wien, 1879.

Following Milne-Edwards, Claus here sets the Typhidæ or Platyscelidae (Hyperines anomales), distinguished by a marked sexual dimorphism as well as by the zig-zag antennæ of the male, over against the Hyperina with normal antennæ. In the latter group he arranges, in three families, the Phronimidæ, Hyperidæ and Vibiliidæ. The Vibiliidæ are easily distinguished by the general form resembling the Gammaridæ, the small size of the head and eyes, as well by the short dilated anterior antennæ. The border line is less easily marked out between the other two families. He characterises them as follows:—

“Hyperidæ. Head of considerable size, more or less globular, with large pair of eyes, extending over almost the whole surface of the head. The antennæ in both sexes with multiarticulate peduncle, in the female without or with rudimentary, in the male with long multiarticulate, flagellum. Gnathopods frequently armed with weak clasper (Greifhand); the rest of the thoracal-limbs end with simple claw and are formed like one another (*Hyperia*), those of the fifth (*Themisto*), and sixth pair (*Cylopus*, *Cystosoma*) are sometimes considerably elongated, those of the seventh or last pair only as an exception (*Cylopus*) rudimentary.

“Phronimidæ. Head of considerable size, generally with strongly prominent snout, and divided pair of eyes extending over almost the whole surface of the head. The anterior antennæ with multiarticulate peduncle, in the female short and without flagellum, in the male long with multiarticulate flagellum. The antennæ of the second pair in the male like those of the Hyperidæ, in the female reduced to the coxal-joint coalescent with the cephalic integument and accompanied by the antennary gland. The thoracal legs partially (principally the fifth pair) armed with powerful chelæ (Greifzange), often of different form and size. Elongate backward directed liver-tubes absent from the stomach (am Magendarm fehlen).”

The Phorcinæ, Claus here says, are to be referred to the Typhidæ. The Phronimidæ he subdivides into two subfamilies thus:—

“1. *Phrosininx*. Form of body broad and compact. The three pairs of uropods broad-leaved with fin-like rami. Besides the powerfully developed fifth pair of legs of the peræon (*Primno* Guér.), generally also the third and fourth pairs (*Anchyliomera* Edw. = *Hieraconyx* Guér.), as well as the sixth (*Phrosina* Risso = *Dactylocera* Latr.) armed with powerful claspers (Greifhand).

“2. *Phroniminæ*. Body slender and extended, with the last segment of the peræon elongate. The three pairs of uropods elongate stiliform, with narrow lanceolate rami. Thoracal legs extremely varied, those of the fifth pair [third peræopods] often armed with broad or more elongate (compound) chelæ.”

The genus *Phronima*, Latr., is thus defined:—

“Körper gestreckt mit stark verjüngtem und langgezogenem Endsegment der Brust, mit drei Paar wohlentwickelter stiltörmiger Uropoden. Kopf kurz, aber hoch mit sehr verlängerter Scheitelnundachse. Vorderantennen des Weibchens zweigliedrig. Basalglied des hintern Antenneupaares im weiblichen Geschlecht kuglig gewölbt und mit kurzer Borste besetzt. Die Mandibeltaster fehlen auch dem Männchen. Unterlippe (Maxillarfusspaar) stark comprimirt, mit lanzenförmig zugespitzten Laden und conischer Zunge. Die beiden Gnathopodenpaare schmächtig, mit schwacher zusammengesetzter Greifhand, fünftes Beinpaar mit mächtiger (zusammengesetzter) Scheerenhand bewaffnet. Drei Paare von Kiemenschläuchen am 4., 5. u. 6. Thoracal segment.”

Phronimella, Cls., is thus defined:—

“Körper sehr gestreckt, überaus pellucid, mit nur 2 Paar stiltörmiger Uropoden. Kopf kurz,

mit hohem, gewölbtem Scheitel, Scheitelmundachse sehr verlängert. Die zwei vordern Brustsegmente ohne Grenzen verschmolzen. Mandibeltaster fehleu auch dem Männcheu. Zunge der Unterlippe (Maxillarfusspaar) auf euen warzenförmigeu Höcker reducirt. Die beiden Gnathopodenpaare schmächtig mit schwacher (zusammengesetzter) Greifhand. Das dritte Beinpaar etwas weniger, das vierte stark verlängert. Das fünfte Beinpaar endet mit sehr langgestreckter (zusammengesetzter) Greifhand. Drei paare von Kiemenschläuehu am 4., 5. und 6. Brustringe." *Phronimella elongata* is the type species, with which Dr. Streets has idcntified his own *Anchylonyx hamatus*. In fact, as Streets has already observed, there are in the male three pairs of uropods, and I find that a rudiment of the middle pair is, at auy rate sometimes, persistent in the adult female. The first peræopod (das dritte Beinpaar) is longer than the second, not vice versa. The error in the generic definition was made by Claus in his original account of "*Phronima elongata*," but corrected by Claus himself in the same year, 1862.

Phronimopsis, n. g. (figs. 1-3), is thus defined :—

"Körper zoëa ähnlich, mit gedrungenem, fast kuglichem Vorderleib, schmalem, lauggestrecktem Abdomen und 3 Paar langer stilförmiger Uropoden. Kopf kurz und hoch. Die beideu vordern Brustsegmente ohue Grenzen verschmolzen. Vorderantenne des Weibchens zweigliedrig, relativ lang, hintere Antennen mit Stachel. Das Mäunchen mit dreigliedrigem Mandibeltaster. Zweites Gnathopodepaar dick und stark, mit vollkommenem Scheere bewaffnet. Die fünf nachfolgeuden Beinpaare des Thorax dünn und langgestreckt, sämmtlich mit schwacher langgezogener Greifhand endigend. Die Uropodenäste schmal und griffelförmig, fast so lang als das stilförmig gestreckte Basalglied."

Phronimopsis spinifer, u. s., is the type species, for which the numerous red-brown stellate pigment-spots on the sides of the peræon, the spine-processes on the antennæ and upper lip, and the angular curvature of the femoral-joint of both gnathopods, are given as distinguishing characters.

Paraphronima, n. g. (figs. 4-10), is thus defined :—

"Körper ziemlich stark comprimirt, mässig gestreckt, mit nur schwach verjüngtem, wenig verlängertem Endsegmeut der Brust, mit 3 Paar stilförmiger Uropoden. Kopf sehr umfaugreich, in Seitensicht fast quadratisch, mit gewölbtem Scheitel. Vorderanteunen des Weibchens viergliedrig, mit kurzen Zwischengliedern. Hinterantenne des Weibchens rudimentär, griffelförmig. Maudibeltaster fehleu auch dem Mäuuchen. Laden der Unterlippe (Maxillarfusspaar) breit, lamellös. Das vordere Guathopodepaar endet mit schwach ausgeprägter (doppelt zusammengesetzter) Greifhand und bleibt ebenso wie das zweite Gnathopodenpaar kurz. Die nachfolgeuden Beine gestreckt und wie bei Hyperia unter einander gleich gebildet. Vier Paare von Kiemenschläuehu am 3. bis 6. Brustringe." *Paraphronima gracilis*, ♀, n. s. (fig. 4), and *Paraphronima crassipes*, n. s. (fig. 4. and fig. 10), are the two species assigned to this genus.

From page 8 to page 78 the investigation is conduced which is indicated in the title of the paper. The principal results are thus summarised by the author himself :—

1. The two new genera *Phronimopsis* and *Phronimella* prove that the armature of the fifth pair of legs [third peræopods] with a chelate hand (Scheereuhand) is a character only of generic value.
2. The females of the Phrouimidæ possess a rudiment of the second pair of antennæ, which is generally reduced to the spherically protuberant coxal-joint containing the coiled antennary gland.
3. In front of the mouth lies a rudiment of the upper lip, an atrium bounded by the side-plates of the mandibles and the lower lip (Paragnathen), into which cavity flows the secretion of powerful glands when food is being taken.
4. These glands are complexes of four gland-cells with long emission-duets, and lie partly in

the periphery of the œsophagus, partly in the maxillæ, in which in point of form and structure they repeat the leg-glands.

5. The function of these glands is the preparation of the ferment (Enzyme), which is mixed with the food at its entrance into the œsophagus, to facilitate the digestion of starch and albuminoid substances.
6. The alimentary canal (Darmcanal) is devoid of every form of gland-cells. To the mnsenlar œsophagus of complicated structure, lined with chitinons *Intima*, succeeds the œophageal stomach (Schlundmagen, Vormagen), with two cæca (Nebentaschen), stretching into the crop (Magendarm). In this digestion is carried ont. The crop which surrounds it, situate in the head and the two first pereon-segments is, like its two forward-directed pairs of so-called liver tubes, lined with a deep cylindrical epithelium, which repeats the strncture of the epithelium of the mid-gut (Dünndarm-epithel), and serves for resorption. The narrow intestinal tube (Darmrohr), is lined with a polygonal pavement epithelium, and in the sixth pleon-segment passes over into the short rectnm (Afterdarm), which is fastened to the integument by means of dilators. [At page 23, in the *Mundharm* of *Phronima* three sections are distinguished as *Mundhöhle*, *Schlundkopf* and *Schlundrohr* or œsophagus.]
7. The annular muscles of the intestinal tube correspond to single muscle-cells, the nuclei of which follow one another in a median row on the dorsal side of the intestine.
8. The heart stretches from the boundary of the head to the middle of the sixth pereon-segment, and possesses, besides the three pairs of ostia provided with valves and the two aortas, two pairs of lateral arteries.
9. Each artery arises over an oblong slit bounded by two side-flaps (Seitenklappen) while at the base of each aorta lie two obliquely set ostia with a pair of flaps (valve-opening) to each.
10. The obliquely transverse muscle-rings of the heart are developed from two lateral rows of cells, between which a dorsal and ventral median-suture remains.
11. Under the heart, adjoining the ventral wall of the heart, there stretches across through the body-cavity a septum composed of large cell-plates. Besides this there is a second septnm which occupies a similar position in regard to the intestine, so that the space of the body is divided into three blood-channels bounded by connective-tissue, and communicating with one another by definite openings. Besides these main channels, which are continued on into the head, there exist a number of more peripheral accessory channels, likewise bonnded by connective-tissue, which represent the blood-courses of the regular circulation.
12. The ventral ganglionic chain contains, excluding the subœsophageal ganglion-mass, nine ganglia, of which five belong to the pereon, four to the pleon. The last pereon- (thoracal) ganglion, just as the last pleon- (abdominal) ganglion, follows the next preceding ganglion immediately. The last pleon-ganglion has arisen out of the concretion of three ganglia for the fourth, fifth and sixth pleon-segments, these ganglia in the embryo being separate.
13. The subœsophageal ganglion-mass corresponds to six ganglionic nuclei, or to seven if we take into account the ganglionic centre belonging to the commissures which provides for the nerves of the second antennæ. Besides the nervcs of the second antennæ also all the maxillary nerves are derived from the œsophageal commissure, to which their place of origin has shifted itself.
14. The peripheral nerves are rooted, not in the so called "Pnnktsnbstanz" [Dietl's *Mark-substanz*, p. 57, *myeloid substance*, Packard], but derive their fibres from ganglion-cells partly of the corresponding ganglion—as well crossed as uncrossed fibres—partly of the preceding ganglion, partly from the brain.
15. The fibre-tracts of the so-called œsophageal commissnre which enter the brain pass partly to the ganglion-layers of the same half of the brain, partly in crossed conrse to those of the

opposite side. In the brain there exists a powerful commissural system, from which portions reach laterally into the powerful optic-ganglia.

16. The ganglion-cell-layers are thickenings of the superficial layer. Inner ganglionie nuclei do not exist. The small-celled ganglion formation of the cap-shaped hinder lobe answers to the fungus-like structure on the brain of the higher Crustacea and insects.
17. The optic-fibres of the lateral eye and of the frontal eye run in planes that cross at nearly a right angle.
18. Each eye is surrounded by a firm sheath, the continuation of the outer nerve-sheath of the brain, which also wraps itself over the front surface, and before each complex of two crystal cone-cells between the rounded vesicles of their nuclei contains two flat oval nuclei.
19. The euticular cornea is not derived from the crystal cone-cells, but from a special hypodermis-layer separated from those cells by the eye-sheath, and is renewed at the time of exuviation.
20. The eye continuously increases in extent with the growth of the body, by the formation of new peripheral elements.
21. The objection to the possibility of mosaic vision based on the form of the crystal cone is thoroughly untenable. [At p. 72, Claus expresses his agreement with Grenacher's opinion, that the Hyperidae are not dim-sighted.]
22. At the ovary there is a special germinal layer. The geniculate terminal seetion of the oviduct ends with a sack-like expansion in a seminal pocket.

Of parasites, Claus found in the crop of *Phronima* and *Phronimella* almost constantly a little oval Gregarine, free or encysted; more rarely, in the body-cavity of *Phronima*, embryos of *Echinorhynchi*, and sometimes in the brain a young Nematode, spirally rolled.

To judge by the short list of literature on page 81, Claus was unacquainted with the papers on the pelagic Amphipoda by Dr. T. H. Streets, which are dated 1877 and 1878.

1879. CLAUS, C.

Die Gattungen und Arten der Platysceliden in systematischer Übersicht. Wien, 1879. (Separat-Abdruck aus den Arbeiten des Zoolog. Instituts zu Wien, Tom. II., Heft 2.)

This work, which has been since its publication the leading authority on the group with which it deals, is practically embodied, though with a few modifications, in the larger and finely illustrated work by the same author published this year (1887).

It is noticed that in external form the Platyscelidae show an astonishing number of gradations from the egg-like Typhidae to the rod-like Oxycephalidae. The common features are to be found in the structure of the antennae in the male and of the fifth and sixth thoracal legs (third and fourth pereiopods) in both sexes. Five families are established, in two divisions, division A. containing the Typhidae and Scelidae, division B. the Pronoidae, Lycaeidae and Oxycephalidae. In 1887 the Lycaeidae form a separate division.

The Typhidae contain five genera:—1. *Eutyphis*, taking the place of *Typhis*, Risso, preoccupied, and having in the synonymy "(*Thyropus*, Dana, Sp. Bate ♂ = *Dithyrus* Dana ♀, *Platyscelus* Sp. Bate ♀)," of which names *Dithyrus*, Dana, must take precedence of *Eutyphis*. In this genus both pairs of gnathopods have compound chelae, the two end-joints of the hinder antennae in the male are very much shorter than the two preceding joints, and the lobes of the maxillipeds (Unterlippe) are slightly concave on the inner edge. The species assigned to it are—1. *ovoides*, Risso (including *Platyscelus serratus*, Sp. Bate (♀), and *Thyropus ovoides*, Sp. Bate (♂)); 2. *armatus*, n. s.; 3. *serratus*, n. s.; 4. *globosus*, n. s. In 1887 Claus adds "*E. inermis* Cls. (*Dithyrus* Faba Dana ?)."

2. *Hemityphis*, n. g., thus defined:—

“Körpergestalt und ebenso die Bewaffnung der Gnathopoden wie bei *Eutypphis*. Die beiden Endglieder der hinteren Antennen des Männchens sehr lang, nur wenig kürzer als die beiden vorausgehenden Glieder. Die Seitenlappen der Unterlippe durch eine tiefe Ausbuchtung getrennt. Subterminaler Zahn der linken Mandibel sehr gross und gezähnelt. Drüse im Schenkel der Gnathopoden und in der Tibia des dritten und vierten Beinpaars. Femoralplatte des sechsten Beinpaars mit kleiner, kurzer Grube oberhalb der Firste des Unterrandes.” (“Die Oberlippe bildet eine helmförmig gewölbte Klappe mit zwei seitlich vorragenden Flügeln,” 1887.) *Hemityphis tenuimanus*, u. s., and *Hemityphis crustulum* (*crustulatus*, 1887), u. s., are described.

3. *Paratyphis*, n. g., thus defined:—

“Körpergestalt ganz ähnlich wie bei *Hemityphis*. Die beiden Endglieder der hinteren Antenne des Männchens lang. Die vordern Gnathopoden ohne, die des zweiten Paars mit kurzem und schwachem Scheerenfortsatz des Carpus. Drüse im Schenkel der Paragnathen [lower lip, for which in 1887 Gnathopoden is substituted] und im proximalen Abschnitt von Tibia und Carpus des dritten und vierten Beinpaars. Femoralplatte des fünften Beinpaars schlank und gestreckt. Femoralplatte des sechsten Beinpaars mit grosser taschenförmiger Grube oberhalb der (linearen, 1887) Firste des Unterrandes.” (“Abdomen relativ umfangreich. Das Basalgleid der hinteren männlichen Antenne etwa halb so lang als die nachfolgenden Glieder. Femalglied des siebenten Beinpaars mässig breit, blattförmig, gekrümmmt, mit rudimentärem ungegliederten Auhang. Die Epimeren sämmtlicher Segmente stark vorspringend, die des fünften Beinpaars mit Zahnfortsatz. Uropodenäste lanzenförmig. Aussenast des letzten Paars sehr klein. Telson gross,” 1887.) The type is *Puratyphis maculatus*, n. s. *Paratyphis parvus*, n. s., is added in 1887.

4. *Tetrathyphus*, n. g., thus defined:—

“Kopf breit und kurz mit dreieckiger Stirn. Körpergestalt wie bei *Eutypphis*. Die beiden Endglieder der hintern männlichen Antenne mit den vorausgehenden nahezu gleich lang. Oberlippe helmförmig erhoben und seitlich umgebogen. Seitenblätter der kahnförmig gekrümmten Unterlippe über die Zunge und Oberlippe hinausragend. Mandibel relativ kurz und geradgestreckt. Die beiden Gnathopodenpaare enden mit kleiner einfacher Zange. Drüse im proximalen Theil der Tibia des dritten und vierten Beinpaars. Femoralplatte des sechsten Beinpaars mässig lang und hoch, ohne spaltförmige Grube der Aussenfläche. Siebentes Bein auf die langgestreckte Femoralplatte reducirt.” Type *Tetrathyphus forcipatus*, n. s.

5. *Amphithyphus*, n. g., thus defined:—

“Körpergestalt ähnlich wie bei *Eutypphis*. Mundwerkzeuge kegelförmig vorgestreckt. Mandibeln kurz und gedrungen. Die beiden Endglieder der hinteren männlichen Antennen mit den vorausgehenden nahezu gleich lang. Beide Gnathopodenpaare enden mit zusammengesetzter Zange. Drüsen im proximalen Abschnitt von Femur und Tibia des dritten und vierten Beinpaars. Femoralplatte des fünften Beinpaars gestreckt eiförmig, die des sechsten Beinpaars relativ kurz und hoch, mit hoher taschenförmiger Grube an der Aussenfläche. Stiel des ersten und zweiten Uropodenpaars gestreckt.” (“Unterlippe zu einer kurzen Saugröhre umgestaltet,” 1887.) The species described are *Amphithyphus bispinosus*, n. s.; *Amphithyphus sculpturatus*, n. s.; *Amphithyphus similis*, n. s.

The remaining genera must be described in the less detailed form, which is given in advance of the fuller definitions.

The second family, Scelidae, contains:—

1. *Euscelus*, n. g., in which “Beide Gnathopodenpaare enden mit zusammengesetzter Scheere.

Femoralplatte des sechsten Beinpaars ohne Spalte.” Type, *Euscelus robustus*, n. s.

2. *Schizoscelus*, n. g., in which “Das vordere Gnathopodenpaar endet klauenförmig, das

hintere mit zusammengesetzter Scheere. Femoralplatte des sechsten Beinpaars mit langer sichelförmig gebogener Längsspalte." Type, *Schizoscelus ornatus*, n. s.

3. *Tanyscelus*, n. g., in which "Beide Gnathopodenpaare enden klauenförmig. Femoralplatte des sechsten Beinpaars sehr lang gezogen und vorn verschmälert mit taschenförmiger Grube der Aussenfläche. Endglied der hinteren männlichen Antenne kurz. Uropodenäste flossenförmig verbreitert." Type, "*Tanyscelus sphæroma*, n. sp. (*Thyropus diaphanus* Dana ?)."
4. *Parascelus*, n. g., in which "Beide Gnathopodenpaare enden klauenförmig. Femoralplatte des sechsten Beinpaars relativ kürzer und ohne Grube an der Aussenfläche. Endglied der hintern männlichen Antenne von mittlerer Länge. Uropodenäste relativ schmäler, fast lanzenförmig." Species, "*Parascelus Edwardsii*," n. s.; *Parascelus typhoides*, n. s.; *Parascelus parvus*, n. s.

The third family, Pronoidæ, contains:—

1. *Pronoë*, Guérin, in which "Beide Gnathopodenpaare enden klauenförmig, vordere Antennen des Männchens mit zweigliedrigem Geisselanhang. Hintere Antennen kurz, nur ein- oder zweimal gefaltet." Type species, *Pronoë capito*, Guérin.
2. *Eupronoë* (*Pronoë*, Dana, ex parte), in which "Das hintere Gnathopodenpaar mit zusammengesetzter Scheere, vordere Antennen des Männchens mit dreigliedrigem Geisselanhang. Hintere Antennen lang, zickzackförmig gefaltet, mit sehr kurzem Endglied. Doppelsegment des Abdomens (5 und 6) relativ kurz. Aeste des letzten Uropodenpaars sehr lang, flossenförmig," with the species *Eupronoë maculata*, n. s.; *Eupronoë armata*, n. s. (*Pronoë brunnea*, Dana, ?); *Eupronoë minuta*, n. s. For the opinion that this genus is a synonym of *Orio*, Cocco, see Note on de Natale, 1850; to the small female specimen from Lagos there mentioned, Claus in 1887 gives the name *Eupronoë serrata*, n. s.
3. *Parapronoë* (*Amphipronoë*, Spence Bate, ?), which resembles the preceding genus, except that it has "Doppelsegment des Abdomens ungewöhnlich verlängert. Aeste des letzten Uropodenpaars kurz." This has the species *Parapronoë crustulum*, n. s.; *Parapronoë parva*, n. s. Spence Bate assigns to *Amphipronoë*, "first pair of gnathopoda complexly subchelate; second pair not subchelate." On the supposition that the words "first" and "second" in this account ought possibly to be transposed, Claus gives *Amphipronoë* as a doubtful synonym of *Parapronoë*. *Amphipronoë serrulata*, Streets, 1877, has the gnathopods described in accordance with Spence Bate's generic account.

The fourth family, Lyceidæ, contains:—

1. *Thamyris*, Spence Bate (with *Brachyscelus*, Spence Bate, ♀, and *Schnehagenia*, Claus, for synonyms). In this genus "Beide Gnathopodenpaare enden mit zusammengesetzter gezackter Scheere. Stiel des ersten Uropodenpaars kaum länger als die Aeste. Fünftes Beinpaar mit dem sechsten ziemlich gleich lang." It receives the species *Thamyris rapax*, Claus (*Schnehagenia rapax*, Claus, 1871), and *Thamyris globiceps*, n. s. Claus has also examined a female specimen of a much smaller and perhaps distinct form. Independently of this, and another larger specimen of some species of *Thamyris* of unknown locality, Claus describes in 1887 two fresh species, *Thamyris lycaeoides*, n. s., and *Thamyris mediterranea*, n. s. Whether Spence Bate's *Thamyris antipodes* and *Thamyris (Brachyscelus) crusculum* are separate species he cannot determine with certainty; in 1887 he thinks it probable that they are.
2. *Lycea*, Dana, in which "Beide Gnathopodenpaare enden mit scharfrandiger zusammengesetzter Scheere. Das erste Uropodenpaar stielförmig verlängert, mit kurzen Aesten. Fünftes Beinpaar stark verlängert." Species, *Lycea nasuta*, n. s.; *Lycea similis*, n. s.; *Lycea serrata*, n. s.; *Lycea robusta*, n. s. (*Lycea pulex*, Marion (?). Junges ♂). To the description of *Lycea robusta* in 1887 Claus adds, "Hier schliesst sich die von Marion beschriebene *Lycea pulex* an, von welcher lediglich Individuen in der

Athemhöhle von Salpen gefunden wurden," without explaining why he does not in that ease adopt Marion's earlier specific name.

3. *Simorhynchus*, Claus, in which "Das vordere Gnathopodenpaar endet einfach klauenförmig, das hintere mit halber Scheerenhand. Stiel des ersten Uropodenpaars so lang als die Aeste. Fünftes Beinpaar nur wenig verlängert," with the species *Simorhynchus antennarius*, Claus. In 1887 *Simorhynchus rapax*, Claus, is given as a synonym, with a reference to the Untersuchungen, 1871, but this is probably an accidental confusion with *Schnehagenia rapax*, the synonym of *Thamyris rapax*.
4. *Pseudohycæa*, n. g., in which "Beide Gnathopodenpaare enden einfach klauenförmig. Fünftes Beinpaar ungefähr so lang als das sechste. Stiel des ersten Uropodenpaars lang, zwei- bis dreimal so lang als die Aeste. Siebentes Beinpaar mit breiter Femoralplatte, ungewöhnlich gross und vollzählig gegliedert," with type species *Pseudohycæa pachypoda*, n. s.
5. *Paralycaea*, n. g., in which also "Beide Gnathopodenpaare enden einfach klauenförmig," while it has "Fünftes Beinpaar stark verlängert. Stiel des ersten Uropodenpaars so lang als die Aeste. Siebentes Beinpaar mit dünnen, gebogenen Femoralplatten und rudimentärem Anhang." Type species, *Paralycaea gracilis*, n. s.
6. *Lycæopsis*, n. g. "Beide Gnathopodenpaare enden einfach klauenförmig. Sechstes Beinpaar stark verlängert, siebentes Beinpaar dünn und gestreckt, vollzählig gegliedert." Type species, *Lycæopsis themistoides*, n. s.

In 1877 Claus remarks that *Phoreus*, M.-Edw., belongs to the Lycæidæ, while he no longer definitely includes *Lycæopsis* in that family. Among other exceptional characters of that genus, he notes that there are only two pairs of branchial vesicles. These are on the third and fourth peræopods.

The fifth family, Oxycephalidae, contains:—

1. *Oxycephalus*, Milne-Edwards, in which "Beide Gnathopodenpaare enden mit zusammen gesetzter Scheere. Körper mässig gestreckt, Stirnschnabel nicht merklich länger als der Kopf, die Femoralstücke des fünften und sechsten Beinpaars sind ziemlich hohe Platten." The species assigned are *Oxycephalus piscator*, M.-Edw., with *Oxycephalus oceanicus*, Guérin, and *Orycephalus tuberculatus*, Sp. Bate, as synonyms (to which in 1887 *Oxycephalus tuberculatus*, Streets, 1878, is added); *Oxycephalus similis*, n. s.; *Oxycephalus latirostris*, n. s.; *Oxycephalus tenuirostris*, Claus, 1871 (to which in 1887 *Leptocotis spinifera*, Streets, 1878, is given as a synonym); *Oxycephalus porcellus*, n. s.; *Oxycephalus longiceps*, n. s.; *Orycephalus typhoides*, n. s. (to which in 1887 *Oxycephalus bulbosus*, Streets? 1878, is assigned as a possible synonym). For the suggestion that *Orycephalus typhoides* might be the *Ornithoramphus coccoi* of de Natale, see Note on de Natale, 1850. De Natale's species is clearly an *Oxycephalus*, but further than this its identification perhaps cannot be carried.
2. *Rhabdosoma*, White (properly Adams and White), in which "Beide Gnathopodenpaare enden mit zusammengesetzter Scheere. Körper stabförmig verlängert, Stirnschnabel zu einem langen Stachel ausgezogen; ebenso die Uropodenpaare. Die Femoralglieder des fünften und sechsten Beinpaars dünn und gestreckt, denen der vorausgehenden Beine ähnlich." ("Siebentes Bein auf die Femoralplatte reducirt," 1887.) The single species is *Rhabdosoma armatum*, M.-Edw., of which "*Rhabdosoma Whitei*," Spence Bate, is the male.

1879. EDWARD, THOMAS.

Selections from the Fauna of Banffshire, by Thomas Edward, A.L.S., in Life of a Scotch Naturalist, by Samuel Smiles. Sixth Edition. London, 1879. pp. 391-438.

The list of Amphipoda extends from page 432 to page 435. Some notes are given on the colouring of various species, and on the times of the year at which specimens were taken with eggs. The colouring of the eggs of sundry species is also noticed. To *Nænia tuberculosa* the note is appended, "With eggs in December. The female has the palms of the two first pairs much narrower than the male." After the names *Lestrigonus exulans* and "Kinahani," *Hyperia galba* and *Hyperia obliqua*, the observation is made, "These are the only species of this family which I have ever found on the Medusæ. I consider Lestrigonus Exulans to be the male of Hyperia Galba, and L. Kinahani the male of H. obliqua." After the names "Hyperia tauriformis, n. s.," "prehensilis, n. s.," "cyanea, n. s.," he writes, "All these three new species were first taken at Banff by T. E.; the males and females of all three being procured. The males differ but little from the females, except that they are somewhat larger." No notice is taken of the name *Hyperia minuta*, which he spoke of in 1868. Of *Dulichia porrecta* and *Dulichia falcata* he says, "I look upon these as being male and female of the same species."

The list, like the rest of Mr. Smiles' entertaining book, is disfigured by numerous misprints. *Phocus* is given for *Phoxus*, *Zetlandica* for *Shetlandica*, *Bedlomensis* for *Vellomensis*, *Phersua* for *Pherusa*, *grandaculus* for *grandoculus*, *Hora* for *Aora*, *Megamdera* for *Megamoera*, *Siphondecetes* for *Siphonecetes*, *Protomedia* for *Proto*, the last being perhaps due to a slip of the pen on the author's part.

1879. FRIES, S.

Mittheilungen aus dem Gebiete der Dunkelfauna. *Gammarus (Niphargus) puteanus*, Koch. Zoologischer Anzeiger. II. 1879. pp. 33-38, 56-60, 129-134, 309.

The occurrence of well-shrimps in the slightly brackish wells of Heligoland and in England is discussed, and the view advocated that they must have existed in these localities before the islands were separated from the mainland. Fries has examined specimens from the above mentioned wells of Heligoland, from the Falkenstein caverns, from the springs running out of the caverns, from the Hilgerhäuser caverns, and from the depths of the Lake of Geneva. In all he finds no greater differences than would justify the naming of varieties. He therefore adheres to the view of Rougemont in uniting the various so-called species of the well-shrimp, and considers that the name *Gammarus puteanus*, as the earliest and best known, should be retained, though appearing unduly to restrict the distribution of the species to wells. Humbert's definition of the genus *Niphargus*, he considers, may be applied to the specific definition of *Gammarus puteanus*. The addition, however, to "Oculi nulli" of "vel rudimentarii" must be struck out. In the second maxillæ, which according to Humbert have the setæ of the inner lobe only at the apex, specimens from the Falkenstein spring show three bristles somewhat further down the inner rim than is the case in Humbert's drawing, Pl. VI. Fig. 8a. A constant character in all specimens of *Gammarus puteanus* examined by Fries is, that the secondary flagellum of the upper antennæ has only two joints, not four or three as in *Gammarus pulex* ♂ and ♀ respectively.

At pages 129-134 he discusses the Isopod "Asellus cavaticus, Schiödte (in litt.) (= Asellus Sieboldii,

Rougemont)." He has uniformly found this in company with *Gammarus puleanus*, which, according to Rougemont, is its mortal foe. He agrees with Rougemont in considering that *Asellus cavaticus* is related to *Asellus aquaticus* very much as *Gammarus puleanus* is to *Gammarus pulex*.

At p. 309 other localities are mentioned for the occurrence of *Gammarus puleanus* and *Asellus cavaticus*.

1879. GRENACHER, H.

Untersuchungen über das Sehorgan der Arthropoden, insbesondere der Spinnen, Insekten und Crustaceen. Göttingen. 1879.

Preliminary notices of these investigations were given in the Göttinger Nachrichten, 1874, Nr. 26, and in the Klinischen Monatsblätter für Augenheilkunde, supplementary number for May, 15th year, 1877.

The elaborate and exquisite illustrations to this work seem to show all that is at present known as to the organs with which the book is concerned. Grenacher maintains "the theory of Mosaic Vision," propounded by Johannes Müller in 1826, and gives references to numerous works more or less opposed to or agreeing with his own views. In pages 109-114, and on Plates IX. and X., he treats of the eyes of the Amphipoda, referring especially to *Gammarus locusta*, *Talitrus saltator*, *Gammarus neglectus*, *Hyperia galba*, *Phronima sedentaria*. Fig. 99 gives a "Sehnitt, parallel der Längsaxe des Thieres und senkrecht auf die Längsaxe der Gesamtaugen, von Gammarus locusta." Fig. 100 shows a single ocellus from the same animal with the "nuclei of Semper" on the surface over the crystalline cone, composed as usual of two longitudinal segments. Fig. 102, A. and B., shows two ocelli of *Talitrus locusta*, one from the middle, the other from the rim of the eye. Fig. 103 shows the "Zellkerne der Retinula" on either side of the inner end of the crystalline cone of one of these ocelli. Fig. 104 shows the "Krystalkegel mit Retinula aus dem Auge von Hyperia galba (H. Latreille). Der Krystalkegel aus dem peripherischen Theilen des Auges ist von einer weiten Hülle umgeben, deren Kerne vorn gelegen sind. Besondere Zellen, um das Hinterende des Krystalkegels. Das fein querstreifte Rhabdom hat in seinem Innern einen deutlichen Canal." Fig. 105, a.b., is a "Querschnitte durch den Krystalkegel desselben Thieres in verschiedene Höhen, um das Verhalten desselben zu seiner Hülle zu zeigen." Fig. 106, a.b.c., shows "Querschnitte durch die Retinula desselben Thieres in drei verschiedenen Gegenden. An allen ist die Zusammensetzung der Retinula aus fünf Zellen, an den beiden ersten auch die des Rhabdoms aus ebensoviel Stäbchen, sowie der centrale Canal desselben zu erkenneu."

1879. HOEK, P. P. C.

Carcinologisches, grösstentheils gearbeitet in der zoologischen Station der niederländischen zoologischen Gesellschaft. Tijdschrift der Nederland. Dierkund. Vereeniging. Deel IV. 1879. pp. 97-161. Mit Taf. V.-X.

The work contains five chapters:—

I. On the anatomy and classification of the Caprellidae.

II. Contributions to the knowledge of the Corophidae. Dr. Hoek here goes into detail to confirm the opinion of A. M. Normau that "*Corophium Bonelli*," Bate and Westwood, is the female of *Corophium crassicornis*, Bruzelius. He unites, in agreement with Axel Boeck,

Podocerus pulchellus, Leach, and *Podocerus pelagicus* with the earlier *Podocerus falcatus*, Montagu. He describes a new species, "Orthopalame Terschellingi," thus defining the new genus *Orthopalame*, "Epimera anterora quinque magna, quinto in margine posteriore non inciso. Antennæ superiores flagello elongato, flagello accessorio parvo 2-articulato. Antennæ inferiores non subpediformes, superioribus parum breviores, flagello multiarticulato. Mandibulae robustæ, palpo elongato, 3-articulato, articulo tertio palpi non perditatato. Pedes 2di paris iisdem primi multo validiores. Pedes saltatorii ultimi paris uniramosi. Appendix caudalis recurvata, hamulo parvo armata," and further remarking that it has affinities in some respects with *Cerapus*, in others with *Amphithoe*. He suggests that the gland in the first joint of the first and second pereiopods will be found common to all the Corophidæ, and connected with their mode of life in building nests or lining their excavated passages, a matter on which S. I. Smith in the following year published some interesting observations (Trans. Connect. Acad., vol. iv., July 1880).

- III. On an *Orchestia* from terra firma. The *Orchestia* in question was found in a walled garden in the town of Zalt-Bommel in the province of Gelderland, many miles from the sea, and is identified by Dr. Hoek with *Orchestia cavimana*, Heller, taken on Olympus in Cyprus at a height of 4000 feet.
- IV. On some insufficiently known Gammarids. These are—1. *Atylus swammerdammii*, Milne-Edwards; 2. *Calliopus larvulus*, Kröyer, on which Dr. Hoek observes that the genus *Calliopus* is intermediate between the Atylinæ, to which Boeck assigns it, and the Gammarinæ; 3. *Melita obtusata*, Montagu, as to which he adopts Norman's statement that *Melita proxima*, Bate and Westwood, is the most frequent form of the male of *Melita obtusata*, and *Megamœra alderi*, of those authors, its female; 4. *Cheirotrochus brevicornis*, n. s., which, however, is the same as *Cheirotrochus sundevalli*, Rathke, and has also been described under the names *Liljeborgia shetlandica*, Sp. Bate, and *Liljeborgia normanni*, Stebbing, though some of its characteristic points were first clearly brought out by Dr. Hoek; 5. *Ampelisca æquicornis*, Bruzelius, is distinguished from *Ampelisca levigata*, Lilljeborg; *Tetromatus typicus*, Sp. Bate, later incorrectly identified by Sp. Bate with *Ampelisca gaimardi*, Kröyer, and by Norman and Boeck and Hoek considered synonymous with *Ampelisca carinata*, Bruzelius, and by Sars with *Ampelisca tenuicornis*, Lilljeborg, is here attached, in accordance with Norman's suggestion, to *Ampelisca æquicornis*, Bruzelius, as the male form. But Bate's species is distinct, and is entitled to the name *Ampelisca typica*, if a species which is not the type can lawfully be called *typica*; see discussion in Note on Sars, 1882.
- V. Short anatomical notes on Gammarids, referring to the structure of the antennæ with their "caleoli," etc., and to the branchiæ of *Atylus swammerdammii*.

1879. JOSEPH, GUSTAV.

Zur geographischen Verbreitung von *Niphargus puteanus*, Koch. Zoologischer Anzeiger. II. Jahrg. 1879. pp. 380–381.

In regard to the *Niphargus puteanus* from Venice, it is shown that their introduction into the carefully covered wells (Pozzi) of Venice is best explained by the transport of water from the mainland to replenish these wells in the dry season.

1879. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1877; being Volume fourteenth of the Record of Zoological Literature. London, M.DCCC.LXXIX. pp. 1–36.

1879. MIERS, E. J.

Japanese Crustacea. Proc. Zool. Soc., 1879.

Only an incidental allusion to the Amphipoda is here made.

1879. MIERS, E. J.

An account of the petrological, botanical and zoological collections made in Kerguelen's Land and Rodriguez during the transit of Venus expeditions. Philosoph. Transact. of the Royal Society of London. Vol. 168. Crustacea. pp. 200–214, 485–496. Pl. XI. 1879.

The description of *Talitrus gulliveri* from Rodriguez is here repeated. In the account of the Kerguelen Amphipoda, notice is taken of *Hyale villosa*, Smith, *Lysianassa kidderi*, Smith; *Lysianassa kergueleni*, Miers, is transferred to *Anonyx*, and will be discussed further on in this Report. This species, together with *Atylus australis* and *Podocerus ornatus*, is figured and more fully described than when first published.

1879. PAGENSTECHER, H. ALEX.

Ueber die Thiere der Tiefsee. Sammlung gemeinverständlicher wissenschaftlicher Vorträge, herausgegeben von Rud. Virchow und Fr. von Holtzendorff. XIV. Serie. Heft 315 und 316. Berlin, 1879. 64 pages.

On pages 25 and 26 Pagenstecher describes the course of the Challenger's voyage. On page 39 he gives the following account of Amphipoda found "in grösseren Tiefen." "Sitzäugige [Crustacea] treten mit sonderbaren Formen reichlich auf. Unter den *Amphipoden* zeichnet sich durch Grösse mit über 10 cm *Cystosoma Neptuni Guérin Méneville* aus in 1096 F. bei Cap S. Vincent, 1500 bei S. Paul's Felsen, auch an den Aru. Der Kopf dieses ganz durchsichtigen meist in 50 bis 100 F. schwimmenden, wenig Eier führenden Krebses ist fast so gross als die sieben Rumpfsegmente zusammen und wird oben gänzlich von den Augen eingenommen. Dabei haben, was Krebsen äusserst selten und bei Phronima dem Weibe allein zukommt, beide Geschlechter nur ein Fühlerpaar. Den *Gammarus loricatus* des hohen Nordens vertritt bei Heardinsel eine ähnliche stachliche Art. Ein Amphipode, dessen Kopf in einen Augenlosen Rüssel ausgezogen ist, lebt bei Kerguelen in 40–120 F., ein gigantischer nahe Iphimedia in 1600 F. zwischen diesen und den Crozet's, eine Hyperide von 7 cm nur mit rothen Pigmentflecken statt der Augen in grossen Tiefen der Arusee. Amphipoden in grosser Zahl fand Nordenskjöld mit dem Pröven 1875 im nordischen Eismeer. Den arktischen Strom begleiten nordische Arten wie *Eusirus cuspidatus* Kroyer, welche man auf Grönland beschränkt hielt, in englische Meere. Ein bei den Meangisinseln auf Comatula in 500 F. schmarotzender, in den Magensack eingegrabener Amphipode hatte gleich seinen Nebenparasiten die schwarz- und weißgescheckte Farbe des Wohlmüthers angenommen."

Compare the Note on Willemoes Suhm, 1876.

1879. SARS, G. O.

Crustacea et pycnogonida nova in itinere 2do et 3tio expeditionis Norvegiae anno 1877 & 78 collecta. (Prodromus descriptionis.) Separataftryk af Archiv for Mathematik og Naturvidenskab. 4de Bind. 1879. Kristiania, 1880.

The new species of Amphipoda described are:—12. *Anonyx typhlops*; 13. *Anonyx (Onisimus) turgidus*, since called *Onesimus turgidus*; 14. *Anonyx (Onisimus) leucopis*, since called *Onesimus leucopis*; 15. *Anonyx (Tryphosa) pusillus*, since called *Tryphosa pusilla*; 16. *Anonyx (Hippomedon ?) calcaratus*, since called *Anonyx calcaratus*; 17. *Acidostoma laticornis*, since called *Acidostoma laticorne*; 18. *Phoxus oculatus*; 19. *Harpinia abyssi*, “Syn: *Harpina* [*Harpinia*] *crenulata*, G. O. Sars, Prodromus descriptionis etc.: non Boeck.”; 20. *Harpinia carinata*; 21. *Harpinia serrata*; 22. *Harpinia mucronata*; 23. *Urothoë abbreviata*; 24. *Bruzelia serrata*; 25. *Oedicerus macrocheir*, since called *Oediceros macrocheir*; 26. *Epimeria loricata*; 27. *Tritropis ? appendiculata*, of which Sars remarks, “specimen singulum speciei hujus anomala, verosimile ad novum genus referendae . . . in prof. 1280 orgyar. captum”; which will probably be the type of the new genus *Cleonardo* established in this Report; 28. *Metopa spectabilis*, “Syn: *Metopa* Alderi, G. O. Sars. Prodromus descriptionis etc, ex parte; non Sp. Bate”; 29. *Metopa equicornis*; 30. *Cressa abyssicola*, since called *Danaia abyssicola*; 31. *Ampelisca odontoplax*; 32. *Ampelisca minuticornis*; 33. *Byblis abyssi*; 34. *Melita pallida*; 35. *Autonoë megacheir*; 36. *Podocerus assimilis*; 37. *Podocerus brevicornis*, “Syn: *Podocerus latipes*, G. O. Sars, Prod. Crust. et Pyenogonid., non Kröyer”; 38. *Podocerus longicornis*, a preoccupied name since changed to *Podocerus lenicornis*; 39. *Cerapus megalops*, since called *Erichthionius megalops*; 40. *Glaueome petalocera*, “Syn: *Glaueome planipes*, G. O. Sars, Prodromus descriptionis etc.; non Norman,” since called *Unciola petalocera*; 41. *Dulichia septentrionalis*, since identified with *Dulichia tuberculata*, Boeck; 42. *Dulichia macra*; 43. *Caprella microluberculata*. For further observations on some of these species see Note on G. O. Sars, 1885.

1879. SMITH, SIDNEY I.

Occurrence of *Chelura terebrans*, a crustacean destructive to the timber of submarine structures, on the coast of the United States. Proceedings of United States National Museum. pp. 232–235. Fig. 1.

The synonymy is given, as well as a description, and other notes. Compare Note on Verrill and Smith, 1874, p. 436.

1879. STEBBING, T. R. R.

Sessile-eyed Crustacea of Devonshire. Supplementary List. (Read at Ilfracombe, July 1879.) The Transactions of the Devonshire Association for the Advancement of Science, Literature, and Art. 1879. 9 pages.

A suggestion made by the Rev. A. M. Norman is here mentioned that *Grayia imbricata*, Sp. Bate, is the young of *Amalhilla sabini*, Leach. It is proposed to unite the species *Nænia excarata*, Sp. Bate, with that author's *Nænia rimapalmata*.

1879. STEBBING, T. R. R.

On Hyale Lubbockiana (=Allorchestes imbricatus, Sp. Bate, and Nieea Lubbockiana, Sp. Bate). The Annals and Magazine of Natural History. Vol. IV. Fifth Series. November. London, 1879. p. 396.

These names I now regard as synonyms of *Hyale pontica*, Rathke.

1879. STUDER, TH.

Verzeichniss der bis jetzt auf Kerguelensland beobachteten Thierspecies nebst kurzen Notizen über ihr Vorkommen und ihre zoogeographischen Beziehungen. Archiv für Naturgeschichte. Fünf und vierzigster Jahrgang. Erster Band. Berlin, 1879. pp. 104–141.

Lists are here given both of the literature of the subject and of the species of animals. The Amphipoda are enumerated at page 126. They are named as follows:—*Atylus australis*, Miers; *Atylus*, n. s.; “*Anonyx Kergueleni*,” Miers; “*Lysianassa Kidderi*,” Smith; *Hyale villosa*, Smith; *Leucothoe* sp. ?; *Podocerus ornatus*, Miers.

In the “Vertheilung der Meeresthiere,” I notice also, at p. 136, among Crustacea, “Eusirus? 150 Faden Sandschlamm.” *Atylus australis*, Miers, is noted as approaching *Atylus fissicauda*, Dana, from Valparaiso.

1879. THOMSON, GEORGE M., born 1848 (Chilton).

New Zealand Crustacea. Transactions of the New Zealand Institute. 1878. Vol. XI. 1879. pp. 235–248. Pl. X. b. c. d.

Of “*Talitrus ? novæ-zealandiæ*, Dana (*Orchestoidea ? novi-zealandiæ*)”, Mr. Thomson remarks, “This species is certainly the female of *Talorchestia quoyana*,” M.-Edw. “The males of the *Talitrus*, and the females of the *Talorchestia*, have never yet been described as such.” The new species described are *Nieea novæ-zealandiæ*; *Nieea fimbriata*; *Nieea rubra*; *Dexamine pacifica*; *Atylus danai*; *Pherusa novæ-zealandiæ*; *Calliope didactyla*; *Calliope fluvialis*; *Gammarus barbimanus*; *Platyscelus intermedius*, with the remark appended, “I have named this species as above, from the fact that it is almost intermediate between the only two species hitherto described—*P. rissoina*, Bate, and *P. serratus*, Bate”; *Caprella caudata*, recorded by Mayer as a near relation, if not a local variety, of *Caprella aquilibra*, Say; *Caprellina novæ-zealandiæ*, according to Mayer identical with *Caprella longicollis*, Nicolet, the genus only, not the species, being new.

Caprellina, new genus, is thus defined:—“Body cylindrical. Cephalon confluent with first segment of pereion. Pleon rudimentary. Gnathopoda subchelate; branchiæ attached to second pair. First two pairs of pereiopoda represented by the branchiæ attached to their respective segments; third pair feebly developed; two posterior pairs well developed, subequal. First and second pairs of pleopoda rudimentary in the male, rest obsolete.”

“This genus appears to be intermediate between *Cereops* and *Caprella*. From the former, it differs in not having the pleopoda developed, but agrees with it in having branchiæ attached to the second gnathopoda. In respect to this latter character it differs from its nearer ally *Caprella*, and also in having the third pair of pereiopoda feebly developed.” Mayer, instead of placing the genus between *Cereops* and *Caprella*, sets it next to *Proto*, in common

with which it has a mandibular palp, the flagellum of the lower antennæ consisting of more than two articulations, branchiæ on the second, third and fourth peræon-segments, and a pleon with two pairs of appendages in both sexes.

The three species of *Nicea* may be assigned to the genus *Hyale*, as in each the telson is deeply divided; for the species of *Calliope*, the altered generic name *Calliopius* has since been adopted; *Gammarus barbimanus* has been recognised as identical with *Corophium lenzenfeldi*, Chilton, 1883, and by Thomson and Chilton, 1886, called *Corophium barbimanum*, with *Haplocheira typica*, Haswell, in the synonymy; but the right name will, I think, be *Haplocheira barbimanus*; *Platyscelus intermedius*, if really distinct from *serratus*, which Claus identifies with *ovoides*, will become *Dithyrus intermedius*. For the species described as *Lysianassa kröyeri*, Spence Bate (*Ephippiphora kröyeri*, White), see Note on Miers, 1884, and Note on Thomson and Chilton, 1886; *Paramœra tenuicornis*, Miers, Mr. Thomson says "must be replaced in the genus proposed by its original describer, Dana, viz., *Melita*." The sexes and young of *Themisto antarctica*, Dana, are described, but specimens which Mr. Thomson has had the kindness to send me, with this name attached, belong, I believe, to the genus *Parathemisto*. The minute illustrations to this paper by no means fairly represent Mr. Thomson's own drawings, for "instead of lithographing the plates, the draughtsman traced them on to a large sheet, from whence they were photo-lithographed."

1879. THOMSON, GEORGE M.

Additions to the Amphipodous Crustacea of New Zealand. The Annals and Magazine of Natural History. Vol. IV. Fifth Series. No. 23. November. London, 1879. pp. 329–333. Plate XVI.

A short description is given of Mr. Thomson's earlier paper in the New Zeal. Inst. Trans., and four more species are added to the local fauna:—"1. *Amphithonotus larvis*, sp. nov. (Pl. XVI. figs. 1–4.)" "Though agreeing closely in generic characters, this species is very distinct in appearance from *A. Edwardsii*, as figured in the British Museum catalogue, and also apparently from *A. spiniventris*, Costa," in regard to which it must be observed that, of the two species compared, the former belongs to the genus *Rhachotropis*, the latter to *Decamine*; "2. *Aora typica*, Kröyer," in which "the superior antennæ were about as long as the animal; the propodos of the first gnathopoda, as well as the last four joints of the second gnathopoda, were very hairy; telson quite smooth"; "3. *Microdeutopus maculatus*, sp. nov. (Pl. XVI. figs. 5–8)," accepted by Thomson and Chilton, 1886, as the female of *Aora typica*, Kröyer; "4. *Cyrtophium cristatum*, sp. nov. (Pl. XVI. figs. 9–15)." "This species differs from the generic characters of *Cyrtophium* in possessing an appendage on the superior antennæ; but as it agrees in every other respect, I do not feel justified in placing it in a new genus. It comes nearest to *C. brasiliense*, obtained by Dana in the harbour of Rio Janeiro." Dana's species here referred to is *Platophium brasiliense*.

1879. WRZEŚNIOWSKI, AUGUST.

Vorläufige Mittheilungen über einige Amphipoden. Zoologischer Anzeiger. II. Jahrgang. 1879. pp. 175–178, 199–202.

This paper, the first of an important series, is on new Peruvian species of the genus *Hyale*, Rathke, which genus, in the wider sense accepted by Boeck and Stebbing, he thinks may be conveniently divided into two subgenera, the one *Allorchestes*, Dana, with telson simple

rim entire, the other *Hyale* sensu strictiore (*Nicea*, Nicolet), with the telson more or less divided. Professor Wrześniowski does not appear to have seen Faxon's paper, dated June 1876, on the Fauna of Lake Titicaca, which discusses the genera *Allorchestes* and *Hyale*, and also shows that the species of *Hyale* here described from the fresh-water springs of the Peruvian Cordilleras are not the first of their genus or subgenus known from fresh water, as the Professor supposes.

To the subgenus *Allorchestes*, "Telson einfach, ganzrandig," are assigned three new species, "*Hyale Jelskii*," "Fundort. Süßwasserquelle am Ostabhang der Cordilleren. Pnmamarea, 8000' über der Meeressoberfläche"; "*Hyale Lubomirskii*," "Fundort Süßwasserquelle am westlichen Abhange der Cordilleren. Paeanayo, 8000' über der Meeressoberfläche"; "*Hyale Dybowskii*," "Fundort. Süßwasserquelle am Westabhang der Cordilleren. Paual. Montana de Nancho, 7000' über der Meeressoberfläche."

In the remarks common to all the species it is stated that, in the side-plates of the last six or five pairs of feet, above the branchiae, are inserted cylindrical structures, closed at the point, which are considered to be accessory branchiae (Nebenkiemen). To "*Hyale Jelskii*" he assigns, "Nebenkiemen am 2-5. Fusspaare einfach, von vorn nach hinten immer an Länge zunehmend, am sechsten Fusspaare am längsten und doppelt, am siebten Paare feblend." "*Hyale Lubomirskii*" has "Nebenkiemen einfach, am 2-7. Fusspaare eingefügt. Am zweiten Fusspaare erscheinen sie ganz rudimentär, an den zwei folgenden etwas grösser, doch immer sehr klein, an den drei folgenden Fusspaaren länger als die eigentlichen Kiemen." "*Hyale Dybowskii*" has "Nebenkiemen am 3-7. Fusspaare, einfach."

With these species Wrześniowski would group *Hyale (Allorchestes) piedmontensis*, Sp. Bate, *Hyale (Allorchestes) microphthalma*, Sp. Bate, *Hyale (Allorchestes) hirtipalma*, Dana, *Hyale (Allorchestes) media*, Dana, and *Hyale (Allorchestes) rubricornis*, Stimpson.

To the subgenus *Hyale*, "Telson mehr oder weniger gespalten," are assigned the new species, "*Hyale Stoltzmani*," "keine Nebenkiemen," found under stones on the sea-coast, and as its nearest relations, *Hyale (Nicea) plumicornis*, Heller; *Hyale (Nicea) fasciculata*, Heller; *Hyale (Nicea) nudicornis*, Heller; *Hyale (Nicea) macronyx*, Heller; *Hyale (Nicea) camptonyx*, Heller; *Hyale (Nicea) schumarti*, Heller; *Hyale (Nicea) rufa*, Heller; *Hyale (Orchesia, Allorchestes) perieri*, Lucas, Grube; *Hyale (Allorchestes) imbricata*, Bate, Stebbing.

1879. WRZEŚNIOWSKI, AUGUST.

Vorläufige Mittheilungen über einige Amphipoden. Ueber *Goplana polonica* n. g. et sp. Zoologischer Anzeiger. II. Jahrgang. 1879. pp. 299-302.

The name *Goplana* is said to designate in Polish a water nymph. The genus is thus defined:—
Upper antennæ longer and stronger than the lower and provided with a short accessory flagellum. First and second gnathopods subcheliform, subequal. Last uropods one-branched. Telson simple, emarginate. *The three last pleon-segments coalesced.*

The last character is said to be its chief distinction from *Crangonyx*, Sp. Bate. A description of the species and its habits follows, containing some sufficiently remarkable particulars.

On the second gnathopod and first pereopod of both sexes on the front rim of the fleshy part of the side-plate are seated a pair of cylindrical accessory branchiae; to the fourth and fifth pereopods and to the front rim of the first abdominal segment similar but simple accessory branchiae are attached. They are entirely wanting on the second and third pereopods. [In the original some errors have crept into the printing, which I have ventured to correct according to what I suppose to have been the author's intention.] In the male from the

second gnathopod to the fifth pereopod lamellate appendages are present, homologous according to their position and structure to the lamellæ of the female brood-pouch.

In copulation the considerably smaller male attaches itself with its subcheliform gnathopods to the back of the fifth or sixth pereon-segment of the female so that its body forms almost a right angle with that of the female. Then it bends its body in an arc towards the abdominal surface of the female, the point of its tail remaining at a good distance off from her. Spasmodic movements are made by the male from time to time. As a rule two suitors attach themselves at the same time to the female. The brood-pouch of the female at this period appears always to be filled with eggs.

Goplana polonica generally progresses with an upright walk, and even climbs the smooth walls of a glass aquarium. It swims on its back, but not with facility; at the bottom of the water it hops about in an agile manner.

Gammarus ambulans, Friedrich Müller, is a near relative of this fresh-water species, and is therefore renamed *Goplana ambulans*. It may well, I think, be questioned whether *Goplana polonica* is more than the adult of Müller's species.

1879. WRZEŚNIOWSKI, AUGUST.

Vorläufige Mittheilungen über einige Amphipoden. Zoologischer Anzeiger. II. Jahrg. 1879. pp. 322-325, 348-351.

“*Lada Chałubińska*” is described, a new genus and species from shore-pools in the Gulf of Chin-bote, Peru. It is distinguished from the hitherto described species of *Melita* by the absence in the male of a finger on the first gnathopods, and by the peculiar structure of the hand, in which the front and upper edge forms a short, thick, hook-formed, downward-curved process. The finger in the second gnathopods closes against the inner surface of the hand, as is the case with *Melita palmata*, Leach, and the Brazilian species, *Melita messalina*, F. Müller, and *Melita insatiabilis*, F. Müller. The author is rather doubtful whether to insist on a new genus for his species, or to regard it as a subgenus of *Melita*, in close relationship with the species just mentioned.

Laala in the Slav mythology represents the goddess of love.

The females are distinguished from the males by shorter antennæ, differently formed hands of the gnathopods, the first not being fingerless, and by a hooked process on the antero-inferior edge of the coxa of the fourth pereopod. It is remarked that a similar process in *Melita palmata* is wrongly attributed by Boeck to the male instead of the female.

“*Mæra Miersi*,” a new species collected by Herr J. Stolzman together with *Hyale stolzmani* and *Laala chałubińska*, belongs to the division of the genus *Mæra* which is made by Sp. Bate to form a separate genus *Megamoera*. The differences between the two appear so slight that Wrześniowski follows Heller and Boeck in re-uniting them.

Callisoma Branickii, a new species briefly described by Professor Wrześniowski in 1874, is here compared with *Callisoma krøyeri*, Bruzelius. The latter species is stated to have, in common with *Callisoma branickii*, *Callisoma crenata* and *Callisoma hopei*, on the back of the fourth pleon-segment a saddle-shaped depression, the existence of which is not noticed by Bruzelius, and expressly denied by Boeck. The distinctions given between *Callisoma branickii* and *Callisoma krøyeri* refer to measurements of the eyes, antennæ and hand of first gnathopods, to the number of joints in the flagella of the upper antennæ, and to the armature of the inner rim of the finger of the first gnathopod. To my mind they together barely amount to the value of specific difference. In regard to the saddle-shaped depression on the fourth pleon-segment, it may be noted that this is extremely common among the Amphipoda, but that, even in species which have the character well developed, it is often

concealed beneath the preceding segment. The telescoping of these two segments is facilitated by the depression, and is of obvious importance for the bending and unbending of the pleon.

1879. WRZEŚNIOWSKI, AUGUST.

Vorläufige Mittheilungen über einige Amphipoden. Beiträge zur Anatomie der Amphipoden. Zoologischer Anzeiger. II. Jahrgang. 1879. pp. 447–450, 465–469, 487–491, 511–515, 536–540, 564–569.

Also in a Separat-Abdruck, 24 pp.

These valuable contributions to the anatomy of the Amphipoda are based chiefly on *Goplana polonica*, *Pallasea cancellus*, *Callisoma branickii*, and two varieties of *Gammarus pulex*. The matrix or hypodermis is shown to be completely distinct from the adipose tissue, the former, as examined in *Pallasea cancellus*, presenting a typical stratified cylindrical epithelium, having its small granular cells provided each with a nucleus and nucleolus, the latter consisting of relatively large, rounded and somewhat angular, very pale cells connected together without intercellular substance. This latter forms a sheath for the alimentary canal, and fills the space between it and the heart, for which it forms the serous covering, intercellular substance here making its appearance. By flat or string-like offshoots it connects the various internal organs with one another and with the external covering of the body. On various parts of the inner surface of the matrix it forms a layer of connective tissue to which the offshoots above-mentioned are fastened. The fat-drops, which are met with most constantly between the alimentary canal and the heart, are rare or almost entirely wanting in fasting Amphipods, but abundant in well-fed specimens.

The muscular system in *Goplana polonica* is thus described. The flexors of the back present two separate systems. The one consists of oblique muscles running from above and behind obliquely forwards and downwards. Each muscle begins halfway up the segment and inserts its lower end on the ventral surface of the preceding segment. These are wanting in the four first segments of the body, but present from the fifth to the tenth, the three following segments, which in *Goplana polonica* are coalesced, possessing a common very strong oblique flexor. The other set of flexors is thus constituted. On either side in the lower part of the segments run, from one segment to the next, and interlaced, pairs of muscles parallel to the ventral surface of the body. These muscles are united at the places of insertion, so that they form elongated links. These Wrześniowski calls longitudinal flexors of the back. The regular arrangement of these prevails from the fourth to the ninth segment of the body. Only the upper muscle enters the tenth segment. The three coalesced segments have a single very long longitudinal flexor. In the front part of the body these muscles run without interruption from the hinder rim of the head to unite at a common place of attachment in the fourth segment of the body.

The extensors, which are considerably stronger than the flexors, form strong tracts on either side, extended between the front rims of neighbouring segments. The front divisions of the extensors and flexors raise and lower the head.

The abdominal feet are moved by a complicated system of muscles. The first basal joint of each foot possesses an extensor and a flexor, which draw the whole foot forwards and backwards. The two terminal branches of the foot have each a very thin and broad extensor and flexor, running from the upper rim of the basal joint to the commencement of the corresponding branch. Each branch has its own abductors and adductors, the outer

possessing two abductors and a very strong, thick and long adductor, the inner branch having simple and very weak muscles.

Notes are given (pp. 465-6) on the nerve-system as displayed in *Goplana polonica* and the varieties of *Gammarus pulex*. The "auditory hairs" on the upper antennæ of *Callisoma branickii* are minutely described, and from their likeness in structure and nerve-apparatus to the auditory hairs and auditory nerves of the Decapods, as described by Hensen, it is argued that a like function may be reasonably attributed to these organs in the Amphipods, notwithstanding Leydig's doubts on the subject. The plumose hairs of the last uropods are not considered to have anything in common with the function of hearing. A detailed account is given of the antennary nerves in *Callisoma branickii*.

In describing the so-called "calceoli," the author refers to the work of Dybowsky as showing in agreement with his own observations that these organs are to be found sometimes on the upper as well as the lower antennæ, and in the female as well as the male sex. He thinks it clear that the "trumpet-mouthed auditory cilia" on the upper antennæ of *Gossea microdeutopa*, Sp. Bate, and the oval "auditory cilia" on the upper antennæ of *Bathyporeia robertsoni* of the same author, are really "calceoli."

In *Callisoma branickii* the calcoculus presents a thin-walled, flattened, pedunculate vesicle, nearly of the same form as figured for *Gammarus pulex* and *Gammarus neglectus* by de la Valette, G. O. Sars and Leydig. A large circular ganglion-cell lies close to the base of the calceolus, but the entrance of the nerve into it could not be made out. In the peculiar lanceolate calceoli of *Goplana polonica*, nerve-fibrillæ were traced right to the sharpened rims of these organs, with a fan-like distribution. The calceoli are here regarded as apparatus for smelling in agreement with the view of G. O. Sars. [This view had earlier been advocated by de la Valette and by Bate and Westwood, Brit. Sess. Crust., vol. i. p. 87, 1863; H. Blanc would refer them to the sense of hearing.]

In *Huale jelskii*, the author found on the front rim, both of the outer and of the inner lobe, of the second maxillæ three rows of bristles, each row consisting of differently formed bristles. In the uppermost row no connection was found with the nerves, but in the lowest and middle rows this connection was made out, and the suggestion is offered that the lowest row are perhaps organs of touch and the middle row organs of taste.

Numerous observations are given (p. 511 f.) on the intestinal canal and its appendages. The whole length of this organ appears to be sheathed in a layer of the adipose tissue (Leydig's *serosa*). The muscular covering of the mid-gut consists chiefly of transverse threads, that of the hind-gut of an outer layer of transverse, and of inner, thick, separate, longitudinal muscles. The *membrana propria* of the mid-gut is very thin, that of the hind-gut thick, consisting of a transparent, homogeneous matrix, including groups of spindle-shaped cells which run out into thin, long processes at both ends. In the central part of the mid-gut he believes that no *cuticula* or *intima* exists. [In the Caprellidae Mayer (p. 147) finds, apparently throughout, a fine, not chitinous, intima.] Between the mid- and hind-gut is an outer projection and an inner, ring-shaped flap or valve, with its free edge directed backwards, so that what is passing through the body can easily go from the mid- into the hind-gut, but not easily on the reverse route. In *Pallasaea cancellus* the hind-gut has six rows of dilators (not to be confounded with sphincters).

The appendages of the intestine are next discussed. The caecal diverticulum behind the stomach is designated neck-gland (Nackendrüse.) To this expression Mayer takes exception as not very appropriate. Mayer also remarks that in the Caprellidae there are at this part of the intestine not one diverticulum only, but a pair. The muscles, cells and vesicles of the liver-tubes are minutely described. The cylindrical glands, opening, according to the author, at the beginning of the hind-gut, close behind the above-mentioned valve, are called rectal-glands (rectaldrüsen.) The view of G. O. Sars that these cylindrical glands are homologous

with the Malpighian vessels of insects is accepted. Mayer maintains that these structures which lie on the borders of the mid- and hind-gut belong morphologically to the former, the mid-gut and the caecal appendages being sharply distinguished from the hind-gut by an interruption of the epithelium, and by the absence from the former of the chitinous intima. He agrees with Neheski that, whatever their function, they cannot be morphologically compared with the Malpighian vessels of insects. In addition to the other appendages, in *Goplana polonica* Wrześniowski finds a previously undescribed gland, which lies in the telson, and has a round opening in the terminal part of the hind-gut just before the anus. This he calls the anal gland (Afterdrüse).

A description is given (p. 537) of the windings of the antennary gland in *Goplana polonica*, and of the structure of its tissues. A very accurate account follows of the circulation of the blood, mostly already published in 1877. For a summary of the results see Note on Delage, 1881. Wrześniowski justly gives de la Valette the credit of having observed the three pairs of venous ostia of the heart in the second, third and fourth segments of the pereon respectively, with their oblique direction, on the right side from above and in front downwards and backwards, and on the left side from behind and above forwards and downwards, so that in each pair the slits cross one another at an acute angle. The heart extends from within the hinder limit of the head to the middle of the sixth pereon-segment in *Goplana polonica*, to nearly the end of the fifth in *Pallasea cancellus*. In each segment of the pereon it is fastened to the back by a pair of upper, and to the sides of the body by a pair of lower, wing-shaped muscles; the front end in the head has only the upper pair.

The arterial ostia, one in the hindermost part of the head, the other in the fifth or sixth pereon-segment, are provided with a complicated valve-apparatus. In each a membrane-like diaphragm is extended, with a simple slit in the centre. The edges of the slit are provided with a sphincter-like muscle, and in the whole surface of the diaphragm the author thought he could perceive annular, very delicate muscle-threads. From the edges of the diaphragm on either side ascends a muscular membrane, finding attachment to the dorsal wall of the heart. During the systole the lateral muscular membranes contract energetically, opening the slit in the diaphragm; in the diastole they relax, while the muscle-threads of the diaphragm contract, and act as sphincters to close the slit, so that the cavity of the heart is now completely shut off from that of each aorta. To prevent the valves bulging in into the cavity of the heart, a pair of trabeculae are fastened, on one side to the rims of the diaphragm-slit, on the other to the ventral wall of the heart. The lateral, venous ostia have each an inwardly projecting valve, with its outer and inner lips provided with sphincter-like muscles. The sphincter of the outer lip is formed by muscles of the wall of the heart, which at the lower angle of the slit separate, to re-unite at the upper angle. The inner lips are provided with a separate sphincter. At the systole first the inner and then the outer slit of the ostium closes.

Lateral arteries are not found in the Gammaridæ, so far as observed by Wrześniowski, Claus, [and Delage], although in the Hyperina two or three pairs have been found by Claus. The anterior aorta clings to the upper wall of the stomach, bends sharply down over its front upper edge, descends the front wall of the oesophagus and ends abruptly close to the floor of the head. During this course, in *Goplana polonica*, three branches are given off on either side. The uppermost branch originates just in front of the geniculate bend of the aorta, and provides for the upper antennæ. The middle branch goes down from the bend of the aorta and runs to the eye, where it appears to end. The lowest branch separates from the main stem close to its termination, and provides for the lower antennæ. [In *Talitrus locusta*, Delage describes three arteries proceeding from the anterior extremity of the heart, centrally the upper aorta with a valve, on either side facial arteries, in which he could not discover valves, though for all that they might exist. The facial arteries run at first upwards and

outwards towards the eye, then, making a somewhat abrupt elbow, advance into the lateral parts of the face, ending on a level with the base of the mandibles. Their ramifications supply the massive muscles of the mouth-organs. The upper aorta at first ascends towards the antennæ, then bends forwards and terminates in the upper lip. In its course the aorta forms two vascular rings situated in a vertical median plane, the one round the brain, the next round the cohering bases of the antennary or "renal" glands. From the lower branch of the pericerebral ring springs a minute single artery which supplies the oesophageal nerve-ring. From the upper branch of the pericerebral ring two pairs of lateral branches are given off to the antennæ. Two other pairs originate, one between the pericerebral and perirenal rings, the other beyond the perirenal ring. Finally, a fifth pair of branches forms a periœsophageal vascular collar, with various ramifications to supply the mouth-organs.]

The hinder aorta rises above the intestinal canal to the telson. In *Goplana polonica* it is furcate at the end, each terminal branch being very short and opening abruptly into the body-cavity. Almost in the middle of the compound segment, the aorta gives off a pair of very short lateral branches, embracing the rectal gland and ending abruptly. The aorta, however, terminates differently in other species.

The anterior blood-current flowing from the terminal opening of the corresponding aorta moves in the head from before backwards, rises obliquely upwards, enters the thorax just below the stomach, and pursues its course on either side of the intestine and over the liver-tubes. On the way it gives off lateral currents to the mouth-organs and the four first feet with their branchia, but does not reach beyond the fourth pereon-segment. From the hinder aorta arise on either side two currents, an anterior from the lateral branch (in *Goplana polonica*) or the anterior opening (in *Gammarus pulex*), a posterior from the terminal fork (in *Gammarus polonica*) or the terminal opening (in *Gammarus pulex*). Both currents on either side of the body descend to begin with towards the ventral surface, unite between the articulations of the second and third uropods, and form a common stream which runs forwards on the ventral surface, but at the articulation of the first uropods with most of its mass ascends, and then flows forwards, divided into two parallel streams. The one stream approaches the intestine just under the hinder aorta, the other, somewhat deeper, approaches the liver-tubes. The ventral stream appears to be of subordinate importance. From the hinder streams lateral currents go to the pleon-appendages and to the four hinder pereopods. Thus the fourth pereon-segment is a boundary which is overstepped neither by the anterior nor the posterior blood-currents, and in it they all unite, and flow on into the second pereopod.

In the pleopods the arterial current descends the front margin, in the uropods the hind margin, while the venous current ascends the opposite side in each set. [Between the four first and the three last feet of the pereon, there is a similar diversity in the direction of the currents. See Delage, 1881, and Claparède, 1863; Wrześniowski gives a reference also to Claparède, *Études sur la circulation chez les aranées du genre Lycosa*, 1875.] Into each foot of the pereon two arterial currents enter, but only a single venous current returns. All these streams pass special openings in the articulation between the side-plate (coxa) and the segment, as well as in that between the side-plate and the first joint of the limb (coxa and basis). Each foot possesses a common venous sinus, lying in the under part of the segment above the side-plate, and bounded by the flexors and extensors of the foot. Into this sinus gathers all the blood running back from the foot and its appendages towards the heart. In each branchia the arterial current traverses the hinder rim and passes over by means of numerous transverse currents into the venous current which pursues its course on the front rim. The venous current of each branchia opens into the common venous sinns of the foot, so that the blood oxidised in the branchia flows direct to the heart, without contributing to the nourishment of the foot.

In each foot of the pereon the arterial blood courses as well by the anterior as the posterior rim of the side-plate. In the four first pairs the anterior stream supplies the side-plates and the accessory branchiae (where such exist). The cavity of the side-plate is formed into three longitudinal canals, which on the lower rim unite, and besides communicate with one another by numerous cross canals. The arterial current flows down in the front and middle canals, while the venous current ascends in the hinder. The hinder arterial current of the foot passes partially into the branchiae, partially into the foot itself, and partially into the lamella of the brood-pouch in the female or its homologue in the male. In the three last pairs of pereopods the front arterial current provides for the foot and its accessory branchiae, the hinder sends its secondary currents into the branchia, the side-plate and the marsupial lamella. In the side-plate the current runs round beside the rim. [With this account should be compared Dr. Delage's account of the circulation in corresponding parts of *Talitrus locusta*.]

From each appendage of the pereon and pleon a single venous current proceeds. All these take their way to the dorsal side of the body-cavity and debouch in a spacious venous sinus, bounded below by the intestine and its adipose tissue, on the sides by the muscles of the back, and above by the back of the animal. [This Delage calls the pericardiae sinus, and assigns it a bounding membrane of its own, open only to the thirteen pairs of pericardiae vessels.] In this sinus, which lies over the hinder aorta and over the heart, a hinder and an anterior current are to be distinguished. The former flows from the hinder end of the body forwards to the third pereon-segment, the other has a backward direction and reaches the same segment. In the hinder current debouch the venous currents of the five last pereon-segments and of the whole pleon, to the anterior belong the venous currents of the antennae, the head and the two first pereon-segments.

At the diastole the blood collected in the (pericardiac) sinus passes through the gaping ostia into the heart. This movement is helped by the upper wing-like muscles, as by their contraction the sinus in its horizontal and perpendicular diameter is contracted, and its two streams in this way are pressed towards the third pereon-segment, and rush with greater energy through the slits, the heart acting like a suction pump. The front slit takes only the blood of the front current, the hindmost of the hinder, the middle the leavings of both.

It thus appears that the arterial currents from the two aortas and their branches wash various organs of the body, as the intestinal canal and the nerve-centres, and then in full tide press into the articulated appendages, finally to quit them as venous currents and pass into the dorsal sinus. Wrześniowski found no direct bending round of the hinder arterial current into the dorsal sinus, such as Claus has described in *Phronima sedentaria*. The whole blood-content of the venous dorsal sinus passes, he says, direct into the heart, without previously traversing the branchiae as Spence Bate states, Sessile-eyed Crustacea, i. p. xxxii. On the contrary the branchiae receive their blood from the same arterial streams which supply the feet, and the contents of the venous dorsal sinus present a mixture of the blood returning from all parts of the body, which has been subjected not only in the branchiae, but, at least partially, also in the antennae, side-plates and legs, to oxygenation. A separation of the arterial and venous blood is therefore not arranged for.

The blood-plasma in young specimens of *Goplana polonica* appears of a yellowish-red colour, in adults of more or less greenish, sometimes even emerald-green hue. The body becomes paler, when the blood is drained away. The blood-corpuscles in this species are of considerable size, consisting of a soft, granular protoplasm, in which clear, pseudopodial-like processes sometimes make their appearance. More or less numerous fat-drops in the plasma of the blood circulate with it throughout the body.

1880. ASPER.

Beiträge zur Kenntnis der Tiefseeflora der Schweizerseen. Zoologischer Anzeiger. III. Jahrg. 1880. pp. 130–134, 200–207.

In some of the lakes a Gammarid was met with, which strikingly reminded Dr. Asper of the common *Gammarus pulex*. The lake-form, however, was smaller and of a glassy transparency. Specimens from depths of 140 and of 60 mètres possessed beautiful organs of vision, with clearly observed crystal-cones. At Wädensweil, at a depth of 40 mètres, along with seeing forms were found blind specimens agreeing in the smallest detail with "*Niphargus Foreli*" from the lake of Geneva. Specimens from Oberrieden Dr. Asper regards as intermediate forms between *Gammarus pulex* and the "Foreli" variety of *Niphargus puteanus*.

1880. CLAUS, C.

Grundzüge der Zoologie. Vierter durchaus umgearbeitete und verbesserte Auflage. Erster Band. Marburg, 1880.

The Arthrostraca (Amphipoda and Isopoda) occupy pages 576–600. The Amphipoda are defined as "Ringelkrebs mit seitlich comprimirtem Leib und sieben (seltener sechs) freien Thoracalsegmenten, mit Kiemen an den Brustfüßen und langgestrecktem (ansnahmsweise rudimentärem) Abdomen, dessen drei vordere Segmente ebensoviel Schwimmfusspaare tragen, während die drei hintern mit ebensoviel Paaren nach hinten gerichteter sog. Springfüsse besetzt sind." The first suborder Læmodipoda has two families, 1. Caprellidae; 2. Cyamidae. The second suborder, Crevettina, has five families, 1. Dulichiidae; 2. Cheluridae; 3. Corophiidae, with two subfamilies, Corophiinae and Podocerinae; 4. Orchestiidae; 5. Gammaridae, with seven subfamilies, Atylinae, Oedicerinae, Leucothoinae, Phoxinæ, Gammarinæ, Lysianassinae, Pontoporeinae. The third suborder, Hyperina, has four families, 1. Vibiliidae; 2. Hyperidae; 3. Phronimidae, with two subfamilies, Phrosininæ, and Phroniminæ; 4. Platyscelidae, with five subfamilies, Typhinæ, Scelinæ, Phronoinæ, Lycæinæ, Oxycephalinæ.

Vibilia mediterranea, Claus, is retained. At page 605 it is said that "die ältesten bis jetzt bekannt gewordenen fossilen Podophthalmen sind langschwänzige Decapoden und Schizopoden aus der Steinkohlen-formation (*Palæocrangon*, *Palæocarabus*, *Pygocephalus*)."
Palæocrangon, however, is an Amphipod, but with a misleading name. See Note on von Schauroth, 1854.

1880. D'URBAN, W. S. M.

The Zoology of Barents Sea. The Annals and Magazine of Natural History. No. 34. October 1880. Vol. VI. Fifth Series. London, 1880. pp. 253–277.

The Crustacea brought home from the "Willem Barents" expedition by Mr. W. J. A. Grant, were sent by Mr. D'Urban to the Rev. A. M. Norman and Professor J. O. Westwood, and the Amphipoda are named as follows "Anonyx nngax (*Phipps*), Acanthonotosoma inflatum (*Kröyer*), *Gammaracanthus loricatus* (*Sabine*), *Amphithoë laeviuscula*, Bell ?, *Acanthostephia Malmgreni* (*Goës*), *Tritropis Helleri*, *Boeck*, *Unciola leucopes* (*Kröyer*), *Hyperia cyanæ* (*Sab.*)."
The dates, latitude and longitude, and depths, of the "finds" are given.

1880. GRIMM, OSCAR.

Beitrag zur Kenntniss einiger blinden Amphipoden des Kaspisees. Archiv für Naturgeschichte. Sechs und vierzigster Jahrgang. Erster Band. Berlin, 1880. pp. 117–126.

On some Blind Amphipoda of the Caspian Sea. By Dr. Oscar Grimm. Translated by W. S. Dallas, F.L.S., from the "Archiv für Naturgeschichte," 1880. The Annals and Magazine of Natural History. No. 26. February 1880. London, 1880. pp. 85–92.

Dr. Grimm says, " *Gammaracanthus caspius*, mihi, from a depth of 108 fathoms in the Caspian, *Boeckia spinosa*, *nasuta*, and *hystric*, mihi, from depths of 70–150 fathoms in the Caspian, and various species of *Mysis* from the same sea, and from depths down to 500 fathoms, all have well-developed, large, prominent, and black-pigmented eyes. This sufficiently proves that at the depths indicated the visual organ can be and is made use of, as here absolute darkness does not prevail, but only a dark night."

" In the Caspian Sea, at 0° 12' E. long. (from Baku) and 39° 51' N. lat., I obtained in a single cast of the dredge ten new species of Gammaridae (namely *Gammarus pauxillus*, *G. crassus*, *G. Gregorkowii*, *G. portentosus*, *G. coronifera*, *G. thaumops*, *Pandora curva*, *Iphigeneia abyssorum*, *Gammaracanthus caspius*, and *Amathilinella cristata*), all of which are furnished with eyes, but in very different degrees of development: thus *Gammaracanthus caspius* has very large round eyes, *Gammarus coronifera* and *Amathiliella cristata* long but narrow eyes, *Gammarus thaumops* triangular unpigmented eyes, and *Pandora coeca* small unpigmented eyes, which can hardly be endowed with the faculty of sight. A still better example is furnished by the following new Amphipoda discovered by me in the Caspian Sea:—

Onesimus caspius	from the depth of 75–250 fathoms,		
" pouposus	"	180	"
" platyuros	"	40 and 48	"
Pantoporeia microphthalmia	"	80–90	"
Niphargus caspius	"	35–90	"

of which the last two species, together with *Onesimus caspius*, were also taken in one cast, and, indeed, at a depth of 80–90 fathoms, at 0° 26' E. long. and 41° 6' N. lat. *Pantoporeia microphthalmia* and *Niphargus caspius* possess pigmented but small eyes; of the species of *Onesimus* some possess red, others (*On. caspius*) perfectly unpigmented eyes, which, in the last-mentioned species at least, are deprived of the faculty of sight; and with these more or less blind species there live *Mysidæ*, the large, convex, and black eyes of which certainly absorb a sufficiency of light even in the darkness of the depths."

While taking the quotations from Mr. Dallas's version, I have not followed him in altering his author's *Gammarus coronifera* into *Gammarus coronifer*. It may be observed that the generic name *Boeckia*, is preoccupied, having been used by Malm in 1870, when it forthwith lapsed as a synonym of *Leptocheirus*. *Pantoporeia*, if it be not intended for *Pontoporeia*, is inconveniently near it. *Iphigeneia* makes an even closer approach to *Iphigenia*, a genus of molluscs. *Pandora* is preoccupied over and over again.

Of *Niphargus caspius*, Grimm says, "from this species *N. puteanus* is probably derived. It is possible that it is identical with *N. ponticus*, Czern.; unfortunately I have been unable rightly to determine the latter, as the description which Hr. W. Czernjawskey has given of it appears to be very defective. (See his 'Materialia ad zoographiam ponticam comparata 1868.') It must, however, be remarked that our *N. caspius* differs in many respects from

the other species of *Niphargus*, and, indeed, from *N. puteanus*, as in its shorter antennæ, the differently formed hand of the last pair of limbs, etc.; so that, perhaps, our species may be regarded as the representative of a new genus between *Niphargus* and *Gammarus*." This, however, he does not establish, but remarks that "*Niphargus caspius* is very probably the 'extinct Gammarid' (see Leydig, Ueber Amphipoden und Isopoden, Zeitschr. f. wiss. Zool. xxx. p. 249) which the other species of *Niphargus* have as their ancestor."

Defective eyes, Grimm explains, are compensated for by other sense-organs; for example, in the male of *Niphargus caspius* the five-jointed main flagellum of the upper antennæ has on its first four joints very large olfactory cylinders, with an aperture at the free extremity of each, "from which, perhaps, as Leydig states, thin hairs may actually be exserted; and from within a nervous branchlet penetrates into each cylinder, and forms a cellular inflation (in the cylinder itself) only to disappear immediately afterwards, as I have observed still better in living examples of another species, namely *Gammarus priscus*, mihi, at Krasnovodsk." The species of *Onesimus* being mud-burrowers "have no sense-organs on the antennæ and other external parts of the body, as in *Niphargus*," but, on close examination, "we find very highly developed, although concealed, sense-organs on the outer lamellæ of the maxillipedes, which have already been described or figured by different authors. These are short thick stumps with rounded ends, which stand in corresponding cylindrical depressions of the lamella, from which they usually have only the rounded portion projecting. Some of them, however, appear much longer, inasmuch as they project more and also have the extremities more acute; these are the two cylinders standing at the apex of the lamella, which present a transition towards the ordinary setæ, and thus also prove that we have to do with chitinous setæ metamorphosed for a particular purpose." These he proposes to call "taste cylinders."

1880. GROBBEN, CARL.

Die Antennendrüse der Crustaceen. Separat-Abdruck aus den Arbeiten des zoolog. Instituts zu Wien, Tom. III. Heft 1. 18 pp. m. 1 Taf. 1880.

The antennary gland, originally discovered by Leydig, Naturgeschichte der Daphniden, 1860, is described as consisting of two histologically distinct parts, a terminal pocket, Endstückchen, and a convoluted tube, Harnkanälchen, which, for the Amphipoda, opens in the well-known generally cone-shaped process of the compound basal joint of the lower antennæ. In *Gammarus marinus*, Grobben says, the terminal pocket lies in the dilated basal-joint of the lower antennæ, quite close to the integument, connected with it by trabeculae. Its shape is reniform; at the hinder end, comparable to the hilus of the kidney, rises the renal tube, which at first runs a short space back, then bends forward, at the same time inclining towards the middle, presently turns upward, again turns back downward, and now in a great arc winding close to the terminal pocket, after a short geniculation runs into the antennary cone, in the apex of which the gland has its outlet. The terminal pocket is lined by an epithelium, the cells of which are arched forwards into the interior of the pocket. The protoplasm is coarsely granular. The exterior is sheathed in a delicate supporting membrane. The protoplasm of the cells lining the renal tube shows a finely fibrous structure, as already noticed by Weismann. The nuclei are oval; towards the cavity the cells were covered by a noticeable cuticula. The terminal section of the tube is formed by cells which completely agree with the matrix-cells of the skin, and which also develop a chitinous cuticula, which passes direct into the cuticula of the skin. This terminal section, which in structure does not agree with the renal tube, but shows the

same structure as the skin, he designates Haruleiter. The expressions Harnleiter and Harnkanälehen sufficiently indicate Grobbon's own opinion that the gland in question has a renal function.

1880. HALLER, G.

Miscellanea arthropodologica. Beschreibung zweier neuer Caprellen. Zeitschrift für die Gesammten Naturwissenschaften. Dritte Folge. 1880. Band VI. Berlin, 1880. pp. 742-749.

Haller says that he gave the name *Caprella gigantea* to a new species from the North Sea, which he here describes and figures, on account of its great length, 30 mm., before he was aware that Hoek had observed a specimen of *Caprella linearis* 26 mm. long. He likewise describes and figures the male and female of *Caprella dentata*, n. s., from Isehia.

He refers to "Mittheilungen der schweiz. entomolog. Gesellschaft. No. 10. Jahrgang 1880. pag. 671 nebst Tafel," for a preliminary notice of *Caprella gigantea*.

1880. HASWELL, WILLIAM A.

On Australian Amphipoda. From the Proceedings of the Linnean Society of New South Wales. Vol. IV. pp. 245-279. Pls. VII.-XII. 1880.

The new species described and figured are *Talitrus sylvaticus*; *Talorchestia diemenensis*; "*Orchestia Macleayana*"; *Allorchestes rupicola*; *Allorchestes longicornis*; *Allorchestes crassicornis*; *Stegocephalus latus*; *Amaryllis macropthalmus*; *Amaryllis brevicornis*, evidently the same as *Amaryllis macropthalmus*; *Neobule algicola*; *Lysianassa nitens*; *Lysianassa australis*, not distinguishable from *Lysianassa nitens*; *Glycera tenuicornis*; *Ampelisca australis*; *Phoxus villosus*; "*Phoxus Batei*"; *Pherusa lavis*; *Leucothoë commensalis*; *Leucothoë diemenensis*; *Leucothoë gracilis*, recognised later, together with *Leucothoë diemenensis*, as falling under *Leucothoë commensalis*; *Melita australis*; "*Melita (?) Ramsayi*," afterwards transferred to *Mæra rubromaculata*, Stimpson; "*Megamæra Mastersii*"; *Megamæra diemenensis*; *Mæra spinosa*, afterwards identified with *Mæra rubromaculata*, Stimpson; *Amphithoë cinerea*, to which probably the two described but unfigured species, *Amphithoë grandimanus* and *Amphithoë setosa*, must be united; *Microdeuteropus australis*; *Xenocleira fuscata*; *Haplocheira typica*, probably the same as *Haplocheira barbimanus*, Thomson, sp.; *Cyrtophium parasiticum*; *Icilius australis*; "*Proto Novæ-Hollandiæ*"; *Protella australis*; *Caprella tenuis*, a species since relinquished by its author. Besides these, *Talorchestia quadrimana* and *Mæra rubromaculata* are described and figured as synonyms respectively of *Orchestia quadrimana*, Dana, and *Gammarus rabro-maculatus*, Stimpson.

In this group are included five new genera; in the family Gammaridæ, subfamily Stegocephalides, the genus *Amaryllis*, thus defined:—

"Superior antennæ with a well-developed appendage. Mandibles with a palp. Maxillipedes with well-developed squamiform plates. Anterior gnathopoda sub-pediform. Posterior gnathopoda imperfectly subchelate. Rami of the fourth and fifth pleopoda styliform; those of sixth pair broad-lanceolate. Telson squamiform, eleft." This genus differs from *Stegocephalus* by the possession of a mandibular palp, and cannot, I think, for that and other reasons, stand in the same subfamily with it.

The genus *Neobule* is thus defined:—"Superior antennæ simple. Mandibles without an

appendage. Maxillipedes with a squamiform process on the basos only. Gnathopoda subchelate; second pair the larger; coxae of anterior pair well-developed. Fourth pair of coxae wide, excavated behind to receive the anterior part of the fifth pair. Posterior pleopoda biramous. Telson squamiform." *Neobule* was subsequently transferred by Mr. Haswell to the Orehestidæ, and perhaps is synonymous with *Hyale*, Rathke.

In the subfamily Lysianassides, the genus *Glycera* is defined as follows:—"Superior antennæ slender, rather long, provided with an appendage. Mandibles with a palp, the incisive edge not toothed; no accessory plate; anterior margin with a prominent tubercle. Maxillipedes with large squamiform processes on the basal joints. Four anterior pairs of coxae deeper than their respective segments, the fourth pair slightly produced inferiorly and posteriorly. Gnathopoda filiform, slender; anterior pair smaller than the posterior, imperfectly subchelate; posterior pair subchelate. Posterior pleopoda biramous; the rami broad-lanceolate. Telson double." The name *Glycera*, being preoccupied, was subsequently changed to *Glycerina*.

In the family Corophiidae, subfamily Podocerides, the genus *Xenocheira* is thus defined:—"Body slender. Coxæ small. Superior antennæ very long, longer than the inferior pair, with a secondary appendage. Mandibles with an appendage. Both pairs of gnathopoda non-subchelate, armed with very long hairs; carpus of posterior pair broad, plate-like, applied to the anterior (dorsal) border of the meros. Posterior pleopoda biramous. Telson simple."

The genus *Haplocheira* is thus defined:—"Body not much compressed laterally. Upper and lower antennæ subequal; superior pair without an appendage; inferior subpediform. Both pairs of gnathopoda simple, fringed with long hair. Posterior pleopoda biramous, with unequal rami. Telson single?"

1880. HASWELL, WILLIAM A.

On some additional new genera and species of Amphipodous Crustaceans. From the Proceedings of the Linnean Society of New South Wales. Vol. IV. pp. 319–350. Pls. XVIII.–XXIV. 1880.

The new species described, and in almost all cases figured, are, *Allorchestes niger* (not figured); *Cypridia ornata*; *Cypridia lineata*, not improbably female or young form of *Cypridia ornata*; *Lysianassa australiensis*, to be placed with *Lysianassa nitens*, Haswell, as at most a variety; "*Montagua Miersii*," *Montagua longicornis* (in which, as in the preceding species, the mandibles not being described, the genus remains doubtful between *Stenothoë* and *Metopa*); *Edicerus latrans*; *Edicerus arenicola*, perhaps, according to Haswell, identical with *Edicerus fossor*, Stimpson; *Urothoë pinguis*; *Iphimedea? ambigua*; *Atylus monoculoides*; *Atylus lippus*; *Leucothoë noræ-hollandiae*; *Harmonia crassipes*; *Eusirus* [really *Liljeborgia*] *dubius*; *Mæra* [*Paranænia* Chilton] *dentifera*; *Mæra lamigera*; *Mæra viridis*; *Mæra approximans*, probably to be united with *Mæra* [*Paranænia?*] *dentifera*; *Megamæra subcarinata*; *Megamæra suensis*; "*Megamæra Boeckii*"; *Wyvillea longimanus*; *Anphilhoë quadrimanus*; *Podocerus australis*; "*Microdeuteropus Mortoni*"; *Microdeuteropus tenuipes* (this being in Chilton's opinion the female, and the preceding species the male, of *Aora typica*, Krøyer); *Microdeuteropus chelifer*; "*Colomastix Brazieri*"; *Cyrtophium dentatum* (in 1886 re-named *Dexiocerella dentata*); *Cyrtophium minutum*; *Icilius punctatus*, afterwards identified with *Icilius australis*; *Polycheria* [properly *Tritæta*] *tenuipes*; *Polycheria* [*Tritæta*] *brevicornis*, unfigured and probably a form of the preceding species; *Caprella echinata*, since transferred to *Protella*; *Caprella cornigera*, referred later

on to *Hircella*; *Caprella inernis*, a preoccupied name for a species almost beyond doubt identical with *Caprella danilevskii*, Czerniavski, 1868; *Caprella obesa*, also a preoccupied name, the species itself being reognised by Mayer, and accepted by Haswell, as identical with *Caprella aquilibra*, Say.

The new genus *Cypridilia*, in the family Gammaridæ, is thus defined:—"Body broad. Pereion and pleon of equal length. Coxæ of gnathopoda very small. Coxæ of the first and second pairs of pereiopoda enormously developed; and cemented together to form broad and deep lateral shields, concealing almost entirely the gnathopoda and pereiopoda, and extending forwards to the sides of the cephalon, and backwards as far as the posterior border of the sixth segment of the pereion, excavated posteriorly for the amalgamated shallow coxae of the third and fourth pereiopoda. Coxæ of the last pair of pereiopoda very small. Antennæ subequal, superior without an appendage. Mandibles with a palp. Maxillipedes unguiculate; both basos and ischium armed with small squamiform plates. Gnathopoda subcheliform. Perciopoda slender. Posterior pleopoda biramous. Telson single." Mr. Haswell subsequently discovered that the coxae of the third and fourth percipoda were not amalgamated, but that the coxa "of the fourth pair is entirely rudimentary and covered by that of the third." This character does not apply to the closely related European species *Stegoplax longirostris*, G. O. Sars, or to *Cypridilia damnoniensis*, Stebbing. The genus *Peltocora*, Catta, briefly described in 1875, is perhaps the equivalent both of *Cypridilia* and *Stegoplax*.

The genus *Harmonia* (misprinted *Harmomia* on p. 330, but given correctly on p. 349), is defined as follows, "Coxæ not so deep as their respective segments. Superior antennæ with an appendage. Inferior antennæ longer than the superior pair. Mandibles with a palp. Maxillipedes unguiculate subpediform, provided with a squamiform plate on the basos only. Gnathopoda subchelate, unequal, posterior pair very large. Pereiopoda stout. Posterior pleopoda biramous, the rami short, conical. Telson single, elongate." Mr. Haswell further remarks of this genus that it "has affinities with *Eurystheus* and *Amathia*, but is distinguished from the former by the form of the telson and the stoutness of the pereiopoda, and from the latter mainly by the large size of the posterior gnathopoda." For a different view adopted later, see Note on Haswell, 1885.

The description of the genus *Wyrillea* gives "Coxæ scarcely so deep as their respective segments. Superior antennæ shorter than the inferior pair, appendiculate. Mandibles with an appendage. Maxillipedes exunguiculate, squamiform processes rudimentary. Gnathopoda subchelate, posterior pair very large. Posterior pleopoda uniramous—the ramus large. Telson simple, undivided." The description of the species, *Wyrillea longimanus*, speaks of the "posterior pleopoda with the outer ramus broad," as though there were more than one ramus. The figure which Mr. Haswell gives much resembles *Ischyrocerus (Podocerus) anguipes*, Kröyer. Mr. Chilton supposes that the description given of the pleopoda is the result of an oversight, and that the genus must be cancelled in favour of *Podocerus*. It must, however, be observed that Mr. Haswell's description of the maxillipedes is quite inconsistent with this conclusion.

As a genus *incertæ sedis* is given the genus *Polycheria*, with these characters, "pereion broad; pleon compressed, more or less carinate. Antennæ subequal; superior pair without an appendage. Mandibles exappendiculate. Maxillipedes with well-developed squamiform process. Gnathopoda small, subchelate. Pereiopoda all prehensile, with narrow basa. Posterior pleopoda biramous with equal rami. Telson double." This genus is evidently synonymous with the genus *Tritæta*, Boeck, included in Boeck's subfamily Dexaminæ. It will probably be right to include *Polycheria tenuipes*, Haswell, *Polycheria brevicornis*, Haswell, *Polycheria obtusa*, Thomson, and *Dexamine antarctica*, Stebbing, all under the name of *Tritæta antarctica*.

1880. HASWELL, WILLIAM A.

Preliminary Report on the Australian Amphipoda. The Annals and Magazine of Natural History. No. 25. January 1880. Vol. V. Fifth Series. London, 1880. pp. 30–34.

“Between the amphipodous fauna of Temperate Australia,” Haswell says, “as exemplified in Port Jackson and that of tropical Queensland, a well-marked dividing line may be drawn.” The characteristic Australian Amphipoda are to be found on and near the shores of the temperate latitudes; within the tropics they are comparatively few and not characteristic. “The Orchestidae, however, are quite as abundant on sandy and stony beaches in the tropics as in temperate latitudes.”

Descriptions are given of the new genera *Cyprloidia*, *Amaryllis*, *Glycera*, *Polycheria*, *Xenocheira*, *Haplocheira*, for which see Notes on Haswell, 1880, pp. 511–513. From the present paper the following quotations may be given:—

“Probably nearly allied to *Eusirus* and *Iduna* is a new generic form, which I have named *Macleayia*. It has the superior antennæ appendiculate, shorter than the inferior pair; the mandibles are provided with an appendage; the maxillipedes are exuuguiculate, with the squamiform processes rudimentary; the gnathopoda are subchelate, the posterior pair being very large; the posterior pleopoda have one large ramus; and the telson is small and undivided.” [The same definition (see p. 513) is given for *Wyvillea*, the name *Macleayia* being dropped without explanation.]

“In *Chloris* (mihi) the antennæ are well developed, the superior pair shorter than the inferior and provided with an appendage; the mandibles are palpigerous; the maxillipedes unguiculate, subpediform, provided with a squamiform process on the basal joint only; the gnathopoda are subchelate, unequal, the second pair being very large; the posterior pleopoda are biramous, with short, conical rami; and the telson is single and elongate.” The same definition is given for *Harmonia* (see p. 513), the name *Chloris* being dropped, no doubt for the sufficient reason that it was preoccupied.

1880. HASWELL, WILLIAM A.

On some new Amphipods from Australia and Tasmania. From the Proceedings of the Linnean Society of New South Wales. Vol. V. pp. 97–105. Pls. V. VI. VII. 1880.

This paper includes figures and descriptions of *Talitrus assimilis*, n. s.; *Talorchestia limicola*, n. s.; *Talorchestia terræ-reginæ*, n. s.; *Talorchestia (?) marmorata*, n. s.; *Talorchestia pravidactyla*, n. s.; *Talorchestia quadrimana* (Dana), var.?; *Aspidophoreia diemenensis*, n. s.; *Atylus microdeuteropus*, n. s.; *Atylus megalophthalmus*, n. s.; *Pherusa australis*, n. s.; *Mera crassipes*, n. s.; *Cyrtophium (?) hystrix*, n. s. In the Australian Catalogue, 1882, *Talitrus affinis* is given, apparently by mistake, for *Talitrus assimilis*, and in 1885, Mr Haswell makes *Talitrus affinis* a synonym of *Talitrus sylvaticus*, Haswell. *Cyrtophium (?) hystrix* he subsequently named “*Læmatophilus hystrix*.”

The new genus *Aspidophoreia* is thus defined:—“Coxæ of the posterior gnathopoda and of the first and second pairs of pereiopoda greatly expanded, deeper than the respective segments those of the three last pairs of pereiopoda small, that of the third pair bilobed—the posterior lobe larger than the anterior. Antennæ simple; the superior pair shorter than the inferior. Mandibles without an appendage. Maxillipedes with a pointed dactylos. Gnathopoda subchelate—the posterior pair much larger than the anterior. Posterior pleopoda uniramous

—the ramus uniarticulate. Telson squamiform, eleft to the base." Mr. Haswell adds the remark that in most of its characters this genus "approaches *Allorchestes*—being distinguished from that genus only by the largely developed anterior coxae and the character of the telson." For his subsequent view of the position of this genus, see Note on Haswell, 1885.

1880. JOSEPH, GUSTAV.

Ueber *Niphargus puteanus* aus Venedig. Bericht d. naturw. Sektion d. Schlesiseh. Gesellsehaft für vaterland. Cultur. 1879/80. pp. 35 etc. 1880.

1880. JOURDAIN, S.

Sur les cylindres sensoriels de l'antenne interne des Crustacés. Comptes rendus. Vol. 91. Paris. 1880. pp. 1091–1093.

M. Jourdain concludes that the cylindres à bâtonnets so commonly met with on the upper antenæ (antenne interne) of Crustacea, both podopithalmie and oligognath, are certainly organs of sense; but, relying only on anatomical structure apart from physiological experiment, we have no right to affirm that these cylinders "sont affectés à l'olfaction."

1880. KOSSMANN, ROBBY, born November 22, 1849 (P. Mayer).

Zoologische Ergebnisse einer im Auftrage der königlichen Academie der Wissenschaften zu Berlin ausgeführten Reise in die Küstengebiete des rothen Meeres. Herausgegeben mit Unterstützung der königlichen Academie von Robby Kossmann. Zweite Hälfte, Erste Lieferung. Leipzig, 1880.

In the order Læmodipoda, pages 126–128, Kossmann describes "*Protella Danæ*," n. s., Taf. xii. Fig. 1–7, and *Protella subspinosa*, n. s., Taf. xii. Fig. 8, 9. Both of these are considered by Mayer to be young forms of *Protella phasma*, Montagu.

In the order Amphipoda, pages 129–140, he first of all observes that he cannot acquiesce in that accentuation of small, and generally merely sexual, distinctions in the form of the gnathopods, which has led to the separation of the genera *Talitrus*, *Orchestia*, *Orchestoidea* and *Talorchestia*. He prefers to group in the genus *Orchestia* all forms of the family with short upper antenæ and without unguis on the maxillipeds. He then describes *Orchestia fissispinosa*, n. s., Taf. xiii. Fig. 1–5, from a form probably female, in which the first gnathopod is not in the least cheliform, the second gnathopod has a dactylus which ends in a pointed spine, and also has fine spinules on the whole inner rim, while the rest of the rim is quite bare. The figure shows a hand, terminally rounded, projecting much beyond the dactylus.

It must here be observed that, if the four genera above-named are united, *Talitrus* takes precedence of *Orchestia*, and, in fact, if they are kept separate, *Orchestia* is the only one of the four in which Kossmann's species cannot stand. Provisionally it may be called *Talitrus fissispinosus*, but the possibility remains that a single specimen 5 mm. in length may be the young of some previously known species.

Professor Kossmann uses the term *first pereiopod* as an alternative for *first gnathopod*, thus adding one more to the many confusions in the nomenclature of our subject. It is surely of the first importance in scientific language that as far as possible one word should be restricted to one meaning. Since the inventor of the term *first pereiopod* applied it to the limb behind the *second gnathopod*, it is open to other naturalists to reject the term altogether as inconvenient or erroneous, but not to apply it to the limb in front of the second gnathopod. For other confusions in nomenclature see the Note on Wrzesiowski, 1881.

In the family Gammaridae, to the genus *Edicerus*, Kröyer, Kossmann assigns the synonyms *Westwoodilla*, Spence Bate; *Monoculodes*, Stimpson; *Krøyera*, Spence Bate. To show the close connection of the four he gives the following table:—

“ Zweiter Gnathopode:

“ A. scheerenförmig	Kröyera, Spence Bate.
“ B. smbeheliform, Carpus	
a. bis gegen den Dactylus verlängert	Monoculodes, Spence Bate.
b. nicht bis gegen den Dactylus verlängert	(Edicerus, Kröyer.
“ C. weder subcheliform, noch scheerenförmig	Westwoodilla, Spence Bate.”

The other distinctions, he says, depend only on the proximity or separation of the eyes. For *Edicerus* he offers the following diagnosis:—

“ Kopf in ein spitzes, abwärts gebogenes Rostrum ansgezogen. Vorderantennen ohne Nebenast. Mandibel mit dreigliedrigem Taster. Maxillarfüsse mit starker Endklaue. Letzter Pereiopode ausserordentlich verlängert, mit griffelförmigem Endgliede. Hintere Pleopoden sämmtlich zweitästig, die Aeste ganz oder fast völlig nackt. Telson einfach.”

He describes *Edicerus equimanus*, n. s., Taf. xiii. Fig. 6–8, in which, he says, the eyes appear to be separate; the pigment was no longer visible, but there were two lateral faceted cornea to be seen.

Leucothoë crassimana, n. s., Taf. xiii. Fig. 9–10, is probably, as suggested by Miers in his “Alert” Report, 1884, a synonym of *Leucothoë spinicarpa*, Abildgaard. Kossmann’s largest specimen was a female with eggs, 7 mm. in length. Under *Mæra* (properly *Mara*), he describes *Mæra erythræa*, n. s., Taf. xiv. Fig. 1–8, which he says is very like Dana’s *Gammarus brasiliensis*. That species, he thinks, Sp. Bate ought to have placed in the genus *Mæra*, not in *Gammarella*. It may indeed be noted that the description of the antennæ does not agree with Sp. Bate’s own definition of *Gammarella*. Meantime Kossmann’s species does not well agree with *Mæra*, but suits very fairly with *Elasmopus*, Costa, as defined by Boeck, both in respect of the mandibles, antennæ, uropods and telson. It may well stand at present as *Elasmopus erythræus*.

Mæra massavensis, n. s., Taf. xiv. Fig. 9–11, is described as belonging “to that subdivision of the genus *Mæra* of which *M. tenella*, Dana, is typical. It would perhaps not be impossible to characterise it as a new genus. Apart from the slenderer habit, its characters are the presence of a double claw on the pereiopods (see Dana, Expl. Exp. Crust., Atl., pl. 65, fig. 7d) and the peculiarity, that the second joint of the upper antennæ is much longer and thinner than the preceding.” It is perhaps by some oversight that Kossmann describes “the hinder pleopoda” as quite like those of the preceding species, although with less numerous, finer spines. This is, with little doubt, a species of *Mæra*, and in that genus the last uropods have long rami projecting beyond the first and second pairs.

In the family Podoceridae he mentions *Amphithoë filosa*?, Savigny’s species, and *Amphithoë erythræa*, n. s., Taf. xiv. Fig. 12, 13, with the “general form quite as in *Amphithoë filicornis*, Dana; stellate pigment distributed over the whole body.” I do not think this species can be separated from “*Amphithoë Vaillantii*,” Lueas, 1849.

Under *Amphithoides*, new genus, Kossmann remarks that “Claus says in his Lehrbuch, (3rd Edition, p. 515) of the genus *Amphithoë*: ‘die vordern (Antennen) meist ohne

Nebenast,' while Dana says expressly 'Antennæ primæ non appendiculatæ,' and Spence Bate does not attribute an accessory flagellum to a single one of his 39 species of *Amphithoë*." (Compare Note on Huxley, 1877.) Kossmann having found a form, in other respects near to *Amphithoë*, but with an accessory flagellum, not without show of reason institutes a new genus for it, which he regards as a link between *Gammarus* and *Amphithoë*. The *Podocerus longicornis*, Heller, and *Podocerus largimanus*, Heller, 1867, which Nebeski, 1880, transfers to *Amphithoë*, although they have an accessory flagellum, should perhaps rather be placed in Kossmann's genus *Amphithoides*, unless that itself should yield to *Grubia*, Czerniavski, 1868.

The new genus is thus defined:—"Schaft der obere Antenne kürzer, als der untere, trägt eine Nebengeissel. Gnathopoden ungefähr gleich gross (♀?). Epimeren wie bei *Amphithoë*. Aussenast der letzten Pleopoden mit nur einem ausgebildeten Haken versehen. Telson einfach, flach, ohne Bewaffnung. Breite Brutblätter."

The type-species, *Amphithoides longicornis*, n. s., is not figured. The upper antennæ are as long as the animal. The second joint of the peduncle is more slender and somewhat longer than the first; the third much shorter. The principal flagellum consists of twenty-two (with the terminal rudiment twenty-three) joints distally increasing in length; the accessory flagellum, consisting of one long and one short joint, does not attain the length of the first joint of the principal flagellum. The mouth-organs answer to Dana's figures for *Amphithoë*. Other particulars are given, but it is a great disadvantage that the establishment of a new genus should be unattended by illustrative figures. The specimens did not exceed a length of 4 mm. In the two-jointed accessory flagellum and the last uropods this species agrees with *Podocerus monodon*, Heller, 1866, but the principal flagellum of the upper antennæ is quite distinct.

In the family Corophiidae, he notes that *Colomastix*, Grube, is earlier than either *Exunguia*, Norman, or *Cratippus*, Spence Bate. He describes *Colomastix hamifer*, n. s., Taf. xv. Fig. 1-10, which seems to be separated by very fine distinctions from *Colomastix pusilla*, Grube, as *Cratippus tenuipes*, Sp. Bate, by equally subtle differences from Grube's species. In *Colomastix hamifer* the second gnathopod, however, is described as having the second, third and fourth joints very short; this probably indicates that the specimen was a male form.

In the tribe Hyperina, family Synopiadæ, Kossmann describes *Synopia orientalis*, n. s., Taf. xv. Fig. 11-13. Only the first pereopod, part of the second, and the maxillipeds, are figured. In many respects the species is stated to agree with Dana's *Synopia ultramarina*. The mouth-organs obviously remove this genus, as has been pointed out by Claus, from the Hyperina.

1880. MARKHAM, ALBERT HASTINGS.

The great frozen sea. A personal narrative of the voyage of the "Alert" during the Arctic Expedition of 1875-6. Fourth Edition. London, 1880.

On the 11th of May, 1876, within about 400 miles of the North Pole, in a depth of 71 fathoms, "a bread bag, filled with the scrapings of our pannikins and a little pemmican, was lowered to the bottom, and, having been kept there some hours, was hauled up, and to our great joy was found to be almost alive with numerous small crustaceans and foraminifera; specimens of which were, of course, collected and preserved, being the most northern animal life yet discovered." A footnote to the word "crustaceans" says, "*Anonyx nugax*, a fine adult male example, and several smaller ones. The length of the largest specimen is 1½ inch. This species is one of the commonest and most abundantly distributed of the northern

Amphipoda. It was discovered by Captain Phipps in 1773, and is found along the shores of Arctic America, in the White Sea, on the coasts of Greenland, Iceland, Spitzbergen, Norway, and in the Sea of Okhotsk" (p. 309). On the following day Captain Markham with his party, by a walk of about a mile, reached latitude $83^{\circ} 20' 26''$ N., $399\frac{1}{2}$ miles from the North Pole.

1880. NEBESKI, OTMAR.

Beiträge zur Kenntniss der Amphipoden der Adria. Arb. zool. Inst. Wien, Bd. III. 52 pp. Mit 4 Tafeln. Also separately, Wien, 1880.

The first section is on the unicellular glands in the first and second pereopods of the Corophiidae. Counting seven joints to the leg, the gland-cells are found as a rule in the second, third, fourth and fifth joints. Each single element of the gland presents itself as one cell, with a special cuticular duct, hence the epithet chosen. There are two kinds of cells, the opaque and the clear, the former found only in the second joint, the latter both in this and the three following.

In the unguis there is a little reservoir into which the ducts of the glandular apparatus open to let out the house-building secretion at the point of the finger. The form of the glandular complex varies, but for the same species, or even genus, is constant. Nebeski found the secretory apparatus in all Corophiidae which he was able to examine; "these were species of the genera *Microdeutopus*, *Microprotopus*, *Amphithoë*, *Podocerus*, *Cerapus* and *Corophium*. The genus *Cyrtophium*, which hitherto has been included among the Corophiidae, but which is devoid of the glands and so appears to be an exception, differs in many respects essentially from the Corophiidae, and on the other hand stands so near to the Dulichiidae that it ought to be reckoned in this family, and so the exception is only apparent." In *Orchestia* the arrangement is different; in the Gammaridae, he says, the glands are, so far as he knows, entirely wanting. He considers that the possession of the secretory apparatus in the first and second pereopods may be regarded as the characteristic mark of the Corophiidae. "It has been long known," he says, "that species of the genera *Cerapus*, *Siphonocætes* and *Unciola*, Say (= *Microdeutopus*, Costa) through cementing sand, mud, particles of wood, etc., by means of a secretion hardening in water, form tubes into which they withdraw

when disturbed." He refers to the method, mentioned by Sp. Bate, adopted by species of *Amphithoë* of wrapping themselves about with sea-weed. This he observed in the case of *Amphithoë penicillata*, Costa, and also in Heller's two species of *Podocerus*, which he names *Amphithoë longicornis* and *Amphithoë laryimana*. (See Note on Kossmann, 1880.) The Corophiinæ adopt a third mode of using their secretion, in lining the walls of the chanuels which they burrow in the mud.

The second section treats of the unicellular glands in the genus *Orchestia*. Here the gland-cells are distributed in different places over the whole body, but principally "in the coxal-plates and the analogously formed lamellar expansions which are found on the basos of the three hinder pereopods of both sexes and on that of the second pair of gnathopods of the female." Small groups are found in the other joints of the legs, and in small numbers the cells are found in the antenuæ, mandibles, maxillipeds, last uropods, and elsewhere; in the last pleon-segment they form a large dorsal complex, reaching into the telson. The outlets are not as in the Corophiidæ by numerous tubes of various lengths, often uniting into a bundle before reaching the common exit, but by short courses to independent pores opening in the chitinous walls of various parts of the body. They are found in both sexes of *Orchestia*, of terrestrial habit, but in *Nicea*, more attached to the water, they are wanting, and may hence have the function of preventing too rapid exhalation of moisture.

Comparing his own observations with those of others, Nebeski concludes "that in the *Phronimidæ* and *Caprellidæ* three to five or more gland-cells are united in the formation of a secretory element and from this proceeds a cuticular emission-duct, while in the Crevettina this formation of a complex does not occur, inasmuch as the secretory element coincides with the histological, that is with the cell, and so a special cuticular passage belongs to each cell. The *Hyperidæ* seem to possess both types of glands, so that in this respect they occupy an intermediate position; at least Paul Mayer mentions that in these Amphipoda 'in opposition to the Phronimidæ the complex-formation only occurs in a limited degree or is entirely wanting,' which would consequently betoken a nearer approach to the Crevettina."

The section on the renal glands attached to the intestine of the Crevettina is of considerable interest. Nebeski cannot confirm Spence Bate's view that in *Gammarus* and *Mæra* there is but one gland-tube, at least he himself always found two in *Gammarus marinus* and *Gammarus locusta* as well as in *Mæra brevicaudata*, and with this the statements of Wrześniowski on *Gammarus pulex* agree, although in *Goplana polonica* the right gland suffers degradation in course of development. In *Melita* Nebeski found the gland unpaired. In all the Corophiidæ, he says, we have two small tubular or vesicular structures which rise obliquely from the intestine. Among the Gammaridæ they are small in *Mæra*, but in most they stretch in adult specimens through more than three segments. For these the peculiarity is characteristic, that at their origin they bend forwards, and, lying close to the intestine, run forwards more or less far. In *Cyrtophium* they pass backwards through the long fourth, to the beginning of the fifth, pleon-segment. In *Nicea* to begin with they turn backwards, but again bend forwards and end just over the place of origin. In *Orchestia* they differ both in size and position. While in all other forms, where the rectum quite uniformly occupies the three last pleon-segments, the tubes are placed on the intestine at the boundary between the third and fourth pleon-segments, in *Orchestia* they arise in the seventh pereon-segment at the sides of the intestinal canal, and with gradual elevation run backwards; between the third and fourth pleon-segments they lie dorsally on the intestine and here form the same flexure which *Nicea* exhibits. The difference between *Nicea* and *Orchestia* is shown to depend on the modification which the rectum has undergone in *Orchestia*. That the glands belong to the mid-gut is a point on which Nebeski is in agreement with Mayer, 1882, and Baldwin

Spencer, 1885. In regard to the concretions found in the gland-tubes of *Orchestia* he is also corroborated by Spencer, who found such in *Talitrus locusta*, though apparently of a somewhat different chemical composition.

A section is devoted to the rectum of *Orchestia*, and another to a comparison of its branchiae with those of other Crevettina. A further section discusses the production of ova in the testes of *Orchestia*. The curious fact is affirmed that the males of *Orchestia* produce, not, as the Cymothoidæ, at one time spermatozoa and at another time ova, but both sexual products in parallel development at one and the same time, although the eggs are never laid, and there is no brood-pouch for hatching them if they were.

In the section headed "Beobachtungen über die Crevettinenfauna des Triester Hafens," under *Orchestia cariniana*, Heller, Nebeski remarks that this, which was originally regarded by Heller as a fresh-water form, must really be considered, like *Talitrus*, a land-Amphipod, since it soon dies whether placed in fresh or salt water.

In the Gammaridæ, subfamily Stegocephalinae, Nebeski gives *Probolium tergestinum*, n. s. (fig. 39), "Artcharaktere: 3. Glied der Maxillarfüsse bedeutend verlängert. 6. Glied des ersten Fusspaars länglich viereckig, vorne abgestutzt, 4. und 5. Glied vorne in nach unten vorspringende Lappen ausgezogen." It is said to be very near *Probolium monoculoides*, nor am I inclined to separate it from that species (*Stenotheö monoculoides*, Montagu), even as a variety. The figures given by Nebeski seem to me to agree with those given by Boeck with even more than the usual exactness to be found between authors figuring quite independently of one another.

In the subfamily Gammariinæ, under *Dexamine*, Leach, he notices the large comparative size of the first three pleon-segments as well in this genus as in *Atylus*, *Pherusa* and *Calliope*, giving room for powerful muscles to work the relatively large pleopoda of these capital swimmers. He gives *Dexamine dolichonyx*, n. s. (fig. 40), "Artcharaktere: 1. Glied der oberen Antennen kurz und gedrungen, ohne Zahnfortsatz; das breite Handglied des zweiten Gnathopodenpaars beim Männchen am Oberrande tief ansgebuchtet: Klauen der Thoracalbeine sehr lang; das 2., 3. und 4. Segment des Abdomens am dorsalen Hinterrande in einem spitzen Zahn ausgezogen." The deep narrow cavity in the back of the hand of the second gnathopod was only found in the two male specimens, not in the females. A specimen of this curious species, from the Clyde, sent me by Mr. David Robertson, of Glasgow, shows in the pereopods a short hand and wrist preceded by a very long joint, which is characteristic of Boeck's genus *Tritæta*. The species should, I think, be named *Tritæta dolichonyx*. The branchiae have lateral dilatations.

Nebeski gives "*Pherusa bispinosa* (= *Atylus bispinosus* Sp. B.)," with the remark that "this species, as long as the artificial separation of the genera *Pherusa* and *Atylus* is maintained, must be referred to *Pherusa*, as it possesses a completely lanceolate telson, which is precisely the character that differentiates *Pherusa* from *Atylus*." He seems unaware that Boeck has already named it *Halirages bispinosus*.

"*Gammarus Edwardsi*," Sp. Bate, is considered by Nebeski as undoubtedly not more than a variety of *Gammarus locusta*.

In the Corophiidæ, subfamily Podocerinae, he discusses the connection of the telson and the last propods with the mode of life. He thinks that *Aora* and *Stimpsonia* will probably have to be transferred to the Podocerinae, in which Heller has already placed *Microdeutopus*. (It is, indeed, quite certain that those three genera cannot stand in different subfamilies.) Very near to *Amphithoë penicillata*, Costa, which is among the commonest Amphipods of Trieste Harbour, he places *Amphithoë longicornis* and *Amphithoë largimana*, placed by Heller in the genus *Podocerus* because of the uniarticulate secondary flagellum, although in other respects, Nebeski says, they clearly belong to *Amphithoë*. The four so-called species of *Podocerus*, named *variegatus*, *pelagicus*, *pulchellus* and *falcatus*, he unites into one

species, the females, and especially the younger specimens, agreeing with *Podocerus pelagicus*, Sp. Bate, the adult females having often the *variegatus* form; the males being either of the *pulchellus* or *falcatus* form. Boeck and Hoek, he thinks, were wrong in regarding these two latter as stages of growth, for they attain an equal size, and series of the two forms do not seem adapted for passing one into the other. *Podocerus ocius*, Sp. Bate, he regards as quite distinct.

To *Cerapus abditus*, Templeton, he assigns *Dereothoë punctata*, M.-Edw., as the female, but without giving reasons.

In *Cyrtophium* he points out that the 1-2-articulate accessory flagellum has been overlooked. He considers that the genus should be transferred from the Corophiidæ to the Dulichiidæ. The species *Cyrtophium darwinii*, Spence Bate, to which Nebeski is referring, ought no doubt to be placed in Dana's genus *Platophium*, which Dana himself distinguished from *Cyrtophium* by the presence of an accessory flagellum.

Pages 47-48 contain the list of "Literatur." Fig. 41 refers to *Microdeutopus gryllotalpa*, Costa; Fig. 42 gives the telson of *Podocerus falcatus*, *Amphithoë longicornis*, *Amphithoë largimana*, *Amphithoë penicillata*, *Microdeutopus*, *Amphithoë bicuspis*, *Microprotopus*. Fig. 42 refers to *Podocerus falcatus*; Fig. 43 to *Podocerus ocius*. The earlier figures illustrate the anatomical details given in this important paper.

1880. NICHOLSON, HENRY ALLEYNE.

A Manual of Zoology for the use of students with a general introduction on the principles of zoology. Sixth Edition, revised and enlarged. Edinburgh and London, MDCCCLXXX.

In the Arthropoda, Class I. Crustacea, has in this work, p. 302, Subclass IV. [III., sec p. 283], Malacostraca (*Thoraciopoda*, Woodward), in which Division A. Edriophthalmata, is split up into three orders, Læmodipoda, Amphipoda, Isopoda. In the definition of the Læmodipoda, they have "The first two segments of the thorax amalgamated with the head and carrying legs," which is no doubt a theoretically accurate description, if the maxillipeds are regarded as legs, but in the account which follows the statement is retained from earlier editions that "the first thoracic segment is amalgamated with the head, and the limbs of this segment appear to be inserted beneath the head, or, as it were, beneath the throat; hence the name given to the order." Here the first thoracic segment is the second thoracic segment of the definition. The mandibles are stated to be without palps, which is not the case in all, or even most, genera of this order. A figure is given of "*Caprella phasma*," which belongs to a genus possessing mandibular-palps. The species is known as *Protella phasma*, Montagu, and has rudimentary peræopods, which are not indicated in the figure.

The second order, Amphipoda, is exemplified by *Talitrus locusta*, which is figured, and *Gammarus pullex*. It is remarked that "all the Amphipoda are small," a rather indefinite statement, scarcely indicating the actual range from about a tenth of an inch to something over four inches.

The statement that "the earliest known Isopod is the *Prosoponiscus* of the Permian rocks" is a mistake obviously due to the misleading name *Prosoponiscus*, which is as unsuited as its predecessor *Palaeocrangon* for a genus of fossil Amphipods.

1880? PARONA.

Atti della Società Italiana di Scienze naturali (Modena). XXIII. pp. 42–50.

“*Niphargus puteanus* (Koch). Variety from a cavern in Monte Fcnere Val Sesia, Piedmont; with historical account of that species generally.” (Dr. von Martens, Zool. Record for 1880.)

1880. SMITH, SIDNEY I.

On the Amphipodus genera, Cerapus, Unciola, and Lepidaetlylis, described by Thomas Say. The Transactions of the Connecticut Academy, Vol. IV., July, 1880. pp. 268–284. Pl. IIa.

Professor Smith gives a full description of *Cerapus tubularis*, Say, which he partially figures.

It is, he thinks, “not eongeneric with any described species, and the genus cannot properly be placed in any of the numerous subfamilies defined by Boeck, though it is probably most nearly allied to his Podocerinæ.” He proposes for it a new subfamily, Cerapinæ, thus described:—

“The single known genus differs from the Podocerinæ and allied groups in the following characters. There are only three pairs of branchial lamellæ, which are borne on the third, fourth and fifth segments of the peræon, and only three pairs of ovigerous lamellæ, which are borne on the second, third and fourth segments. The second and third pleopods are much smaller than the first, and their inner lamellæ are rudimentary or very small. The second and third uropods are uniramus and nearly alike, the distal segment in each being short and terminating in a hooked point.

“The only known species inhabits unattached, portable tubes, and, as in many allied genera, has large cement glands in the bases of the first and second peræopods.”

Professor Smith at this date regards *Cerapus tubularis* as the only species, without, however, taking *Cerapus abditus*, Templeton, into account. For other species that had been referred to *Cerapus*, he adopts *Ericthonius*, M.-Edw.

Unciola irrorata, Say, is stated to have precedence over *Glaucome leucopis*, Kröyer. *Lepidactylis*, Say, is preferred to the other names which compete for the designation of Slabber's *Oniscus arenarius*.

1880. STOSSICH, MICHELE.

Prospetto della Fauna del mare Adriatico. Parte 3. Bolletino della Società adriatica di scienze naturali in Trieste. Vol. 6. 1880.

This paper, included in P. Mayer's list, 1882, I have not been able to obtain.

1880. STUXBERG, ANTON.

Evertebratfaunan i Sibiriens Ishaf. Förelöpande Studier grundade på de zoologiska undersökningarna under Prof. A. E. Nordenskiölds Ishafs-expedition

1878-79. Meddeladt den 12 November 1879. Bihang till K. Svenska Vet. Akad. Handlingar. Band 5. N:o 22. Stockholm, 1880. pp. 1-76.

At pages 62-66 Stuxberg enumerates one hundred and fifteen Arctic Amphipoda, which are met with in various localities in the numbers and proportions exhibited by the following table:—

“ 1) Grönland	74 arter = 64,3 %
2) Spetsbergen	73 „ = 63,5 %
3) Skandinavien N. oeh V. kust	69 „ = 60,0 %
4) Sibiriens Ishaf	60 „ = 52,2 %
5) Murmanska och Hvita hafvet, Jugor sehar	31 „ = 26,9 %
6) Matotschkin sehar	30 „ = 26,1 %
7) Arktiska Amerika	25 „ = 21,3 %
8) Britannien	24 „ = 20,9 %
9) Island	23 „ = 20,0 %
10) Danmark	22 „ = 19,1 %
{ deraf a) Skagerrak och Kattegat	15 }
{ b) Öfriga danska sund	20 }
{ c) Danmarks vestkust	11 }
11) Östersjön	4 „ = 3,5 %.”

In the list are named 17. *Anonyx bidentatus*, Stuxberg, n. sp.; 18. *Onesimus zebra*, Stuxberg, n. sp.; 19. *Onesimus vorax*, Stuxberg, n. sp.; 23. *Onesimus abyssicola*, Stuxberg, n. sp.; 30. *Pontoporeia setosa*, Stuxberg, n. sp.; 37. *Vertumnus glacialis*, Stuxberg, n. sp.; 48. *Aceropsis*, u. gen. et n. sp.; 61. *Halirhiages maculatus*, Stuxberg, n. sp.; 67. *Gammarus erythropus*, Stuxberg, n. sp.; 71. *Melita*, n. sp. (dentatae affinis); 72. *Melita diadema*, Stuxberg, n. sp.; 74. *Weyprechtia mirabilis*, Stuxberg, n. sp.; 80. *Stegocephalus kessleri*, Stuxberg, n. sp.; 83. *Metopa gigas*, Stuxberg, n. sp.; 97. *Ampelisca picta*, Stuxberg, n. sp.; 100. *Haploops lineata*, Stuxberg, n. sp.; 111. *Paradulichia* sp. The different stations at which these were severally found are detailed, and as characteristic forms of the Siberian glacial sea, *Atylus carinatus*, Fabr., and “*Acanthostephia Malmgreni*,” Goës, receive much attention. Otherwise descriptions are confined to the following, at pages 27-28:—

“ WEYPRECHTIA. Novum genus Amphipodum, ex familia Gammarinorum BOECK, inter congeneres valde insigne est et ab iis bene diversum, neque cum aliis ejusdem familiæ generibus similitudinem præbet quam eum euere Amathillarum.

“ WEYPRECHTIA MIRABILIS n. sp. Corporis forma robusta, obesa; *cephalocormus* rotundatus, non *carinatus*, eadem ferme latitudine ac altitudine; *cauda* compressa, altitudine duplo majore quam latitudine. *Antennæ superiores* inferioribus tertia parte breviores: *flagello primario* duplo longiore quam pedunculo, 30-32 articulis composito; *flagello accessorio* prope duplo breviore quam pedunculo, 6-7 articulis composito. *Antennæ inferiores* flagello duplo longiore quam pedunculo, 50-59 articulis composito. Caput rostro brevissimo, longitudine paulo minore quam latitudine (= 4:4,5). *Oculi* reniformes, nigri, nitidi. Epimera 1:mum-4:tum duplo altiora quam latiora; 1:mum angulo inferiore aeuminato, 2:dum et 3:tum truneato-rotundato; 5:tum et 6:tum latiora quam altiora, margine inferiore inciso. *Epimeri 4:ti margo posticus supra et infra* valde incisus, in medio cornu magno, valido, acuto, transverso, deorsum currato præditus, angulus infero-posticus subacutus,—ita ut margo posticus bicornis esse videatur. *Caudæ segmenta* 1:mum et 2:dum epimeris angulo postico acutis; 3:tum bidentatum, dentibus subaeutis et sursum productis: 4:tum depressione transversa selliformi hand profunda. *Pedes spurii* biramei, ramis longitudine subæqualibus, lanceolatis, marginibus serratis et setigeris. *Appendix caudalis* tertia parte longior quam

latior; supra finem pedunculi pedum ultimi paris spuriorum porreeta, sursum paullo curvata, non fissa, margine postice 3 sinibus haud profundis, quorum medius latus, laterales arcti, setis singulis prediti. *Integumenta* cephalocormi et eandæ nitida, punetis impressis rotundis confertissime collatis.—*Corporis longitudo* 51^{mm}, *latitude maxima* 17,5^{mm}, *altitudo maxima* 11^{mm}. *Longitudo antennarum superiorum* a) pedunculi 5^{mm}, b) flagelli primarii 10^{mm}, c) flagelli accessorii 3,3^{mm}. *Longitudo antennarum inferiorum* a) pedunculi 7,5^{mm}, b) flagelli accessorii 17^{mm}.

“*Habitat* in Mari Sibiriae Glaciali inter promontorium Vankarema et Fretum Beringianum fundo arenoso, orgyarum 4–6 profunditate.”

No doubt the word “accessorii” is applied to the flagellum of the lower antennæ in the above account by an accidental mistake in writing.

1880. THOMSON, GEORGE M.

New Species of Crustacea from New Zealand. The Annals and Magazine of Natural History. No. 31. July 1880. Vol. VI. Fifth Series. London, 1880. pp. 1–6.

The observations refer to the Crustacean fauna of Dunedin Harbour, the maximum depth of the bay being probably about 6 fathoms. Under “Amphipoda Normalia. Fam. Gammaridæ. Subfam. *Stegocephalides.*,” there is instituted the new genus *Panoplaea*, thus defined:—

“Coxæ of the four anterior segments well developed, those of the second pair of pereiopoda excavated on the upper part of the posterior margin. Antennæ subequal, without a secondary appendage. Mandibles with an appendage. Maxillipeds with a squamiform process on the ischium. Gnathopoda feeble, almost chelate. Three posterior pairs of pleopoda double-branched. Telson simple, squamiform.” Mr. Thomson says, “I have formed this genus to include two species which appear to me to be the southern representatives of the Arctic genus *Pleustes*. It differs from *Pleustes* only in the well-developed squamiform plate on the ischium of the maxillipeds, and in the gnathopoda being slender and more or less chelate. In the general appearance of the species, however, there is a very perceptible difference.” The new species, figured Pl. I. figs. 2, 3, are named *Panoplaea spinosa* and *Panoplaea debilis*. Of these, through the kindness of Mr. Thomson, I have been able to examine specimens, and it appears to me that *Panoplaea spinosa* is certainly an *Iphimedia*, while *Panoplaea debilis* has numerous points of resemblance to *Amphilochus longimanus*, Boeck, but as the species has three dorsal spines, it may be more correct to place it in the closely allied genus *Halirages*, Boeck. It cannot be generically united with *Panoplaea (Iphimedia) spinosa*. In “Subfam. *Phoxides*. Genus *Amphilochus*, C. Spence Bate,” is described “*Amphilochus squamosus*, n. sp. (Pl. I. fig. 4.).” In “Subfam. *Gammarides*. Genus *Eusirus*, Kröyer,” is described “*Eusirus cuspidatus*, Kröyer, var. *antarcticus*, n. var.” Of “*Melita tenuicornis*, Dana (*Möra tenuicornis*, Sp. Bate, *Paramöra tenuicornis*, Miers),” it is said, “the females are remarkable for possessing a hook-like process on the exopal lamellæ of the fourth pair of pereiopoda, almost exactly similar to that figured and described by Fr. Müller (Facts for Darwin, p. 27) as occurring in *M. insatiabilis*.” In “Genus *Megamöra*, Spence Bate,” “*Megamöra fasciculata*, n. sp. (Pl. I. fig. 5), is described. In “Fam. *Corophiidae*. Genus *Corophium*, Latr.” a description is given of *Corophium contractum*, Stimpson.

1880. ULIANIN, B.

Untersuchungen über Blastoderm- und Keimblätterbildung bei *Orchestia Montagui* und *Mediterranea*. Zoologischer Anzeiger. III. pp. 163–165. 1880. (Verhandl. d. zoolog. sect. d. VI. Versamml. russisch. Naturf. u. Aerzte.)

The results of the investigation are here given in summary. There is a notice of this paper by P. Mayer in *Zoolog. Jahresber.* (1880), II. Abt., pp. 53, 54. 1880. An account of the investigation was published in extenso in 1881. See Note on Ulianin under that date.

1880? WEBER, MAX.

Über den Bau und die Thätigkeit der sogenannten Leber der Crustaceen. Archiv für mikroskopische Anatomie. XVII. Bonn, 1880? pp. 385–457. Pls. XXXVI–XXXVIII.

"M. Weber has examined histologically and chemically, and described the so-called liver of terrestrial, freshwater, subterraneous, littoral, and truly marine species of different orders, viz.:—several *Oniscidae*, including the blind *Typhloniscus steini*, *Asellus aquaticus*, and the subterraneous *A. cavaticus*, *Gammarus pulex*, *fluviatilis*, *puleanus*, *marinus*, and *locusta*, *Talitrus* and *Orchestia*, and *Astacus fluviatilis*. He comes to the conclusion that in the *Decapoda*, *Amphipoda*, and *Isopoda*, this gland is tubular and contains at least two sorts of cells, one of which secretes a fluid acting as a ferment (enzyme) on albuminous substances, and the other a pigment allied with a fatty substance and cholesterin, serving for the emulsion for fat. He calls the first ferment-cells, the second liver-cells, and the whole organ 'hepato-paureas,' as it combines the function of the liver and that of the true digestive glands of the Vertebrates. During the embryonal stage the liver is developed and active in the *Crustacea*, as in the *Vertebrata*, which proves that its function is not only digestion, but also excretion. In some Amphipods and Decapods, there is a third sort of cells, probably reserve-cells, which are destined to supply, if necessary, the others." (Dr. von Martens, *Zool. Record* for 1880. He says there is an abstract also in the *Journal of the Royal Microscopical Society*, iii. p. 424.)

1881. BUCKLEY, ARABELLA B.

Life and her Children. Fifth Thousand. London. 1881.

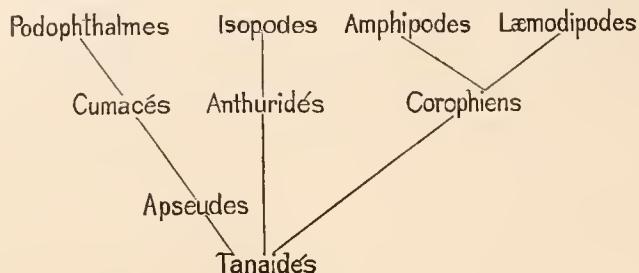

In a popular account of the *Crustacea*, pp. 153–177, the expression "insects of the sea" for these animals is approved and adopted. The figure, 57. C, to which the name *Caprella* is assigned, really represents *Proto ventricosa*, O. F. Müller.

1881. DELAGE, YVES.

Contribution à l'étude de l'appareil circulatoire des Crustacés édriophthalmes marins. Paris, 1881. pp. 173. 12 Plates. From *Arch. de Zool. Exp. et Gen.* Vol. IX. 1881.

This admirably lucid essay discusses the subject successively in regard to the *Isopoda*, *Amphipoda*, *Laeomopoda*, and *Tanaidæ*. An account is given of the ingenious methods of

investigation employed, a historical review is drawn up of the results obtained or errors committed by previous writers on this branch of research, and after a careful record of Dr. Delage's own observations, a graphic representation is submitted of the affinities between different groups of Crustacea to which those observations seem to point:—

Dr. Delage confirms the view of Fritz Müller that the number of lateral slits in the Amphipodan heart consists, with rare exceptions, of three pairs [without, however, noticing that la Valette had already in 1857 plainly stated this fact in regard to *Gammarus puteanus*, and that Spence Bate, Sessile-eyed Crustacea, vol. i. p. xxxii., 1868, describes the course of the blood in the Amphipoda returning to the heart, "which it enters by three lateral pulsating oblique apertures"]; he gives G. O. Sars the credit of having first clearly indicated the existence of a posterior aorta with definite walls; he finds that Wrzesniowski has recognised the existence of the hinder cardio-aortic valve; has described exactly the lower aorta with its termination in the hinder part of the ventral sinus by three openings, two lateral and one terminal; has described the course and branches of the upper aorta, but without seeing the valve that separates it from the heart, or the pericerebral vascular ring; has been the first to recognise that the blood which circulates in the appendages is contained in true vessels, and, lastly, has had a glimpse of the pericardium, since he speaks of a venous cavity above the heart. [In the Zoologischer Anzeiger for 1879 Wrzesniowski very minutely describes the valve apparatus at both extremities of the heart.] Delage believes himself to have proved by injections that, in the principal joints of the legs, instead of occupying half the total breadth, leaving the other half to the venous current, the arterial vessels wind, perfectly rounded and defined, between the muscles, only communicating here and there with the corresponding venous vessels, which are also on their part perfectly individualised. He therefore rejects the view that the cavity of each limb is simply subdivided into two compartments by a single longitudinal membrane. His further discoveries concern the existence of the anterior cardio-pericardiac valve [already known to Wrzesniowski], a pericardium with perfectly definite and continuous walls, a peri-oesophageal vascular collar formed by two branches of the anterior aorta, and a vascular ring formed by the aorta round the brain, a ring characteristic alike of the Amphipoda and the Læmodipoda. His observations were made principally on *Talitrus locusta*, Latr., *Gammarus locusta*, Fabr., in both of which the lateral orifices of the heart are found in the second, third and fourth segments of the pereon; on *Montaguia monoculoides*, Sp. Bate, in which he could not discover an orifice in the second segment; and on *Corophium longicorne*, Latr., in which there is but one pair of lateral orifices, situated in the fourth segment. The Corophinæ are separated from the (other) Amphipoda, not only by this distinction, but also by the absence of two vessels proceeding from the upper extremity of the heart and designated "facial arteries," as well as by the absence of a vascular ring round the so-called "renal organ," and by the circumstances that the lower aorta is not terminally divided, and that the pericardium, instead of occupying the whole length of the body, is limited to the pereon.

In the Caprellina, observations based on *Caprella acanthifera*, Leach, *Caprella acutifrons*, Latr., “*Protella phasma* (Sp. Bate),” “*Proto pedata* (Flemm.) et *P. goodsirii* (Sp. Bate),” show an absence of the peri-oesophageal collar, though the blood-current pertaining to it exists in the usual place. The three pairs of lateral orifices in the heart are present, but the two first pairs are narrow and wanting in activity, especially in *Caprella acutifrons*, thus indicating an affinity between the Caprellina and the Corophinæ, in which the two first pairs of orifices have completely disappeared. They agree with the Corophinæ also in the circumstance that the hind limbs receive their blood from the aorta and return it to the ventral sinus, and do not, as in *Talitrus*, receive it from the ventral sinns and return it to the pericardium.

Of the Tanaidæ Dr. Delage examined more particlarily *Paratanais savignyi* (*Tanais savignyi*, Kröyer), in which the heart has two pairs of lateral orifices, situated in the third and fourth segments, *Tanais vittatus*, Lillj., with a single pair in the fourth segment, and *Apseudes latreillii*, Sp. Bate. He thence tabulates the affinities of the Tanaidæ with the Isopods, Amphipods and Decapods respectively. He connects them with the Amphipods by the form and position of the heart; by the absence of arteries springing from the heart with the exception of the aortas; by the small number of arterial ramifications; by the fact that the ventral sinus is arterial and not venous; by the pericardiac vessels; by the loose peri-oesophageal vascular collar not giving origin to a ventral median vessel, and, above all, by the peri-cerebral vascular ring characteristic of the Amphipoda.

For the Hyperina, which he had no opportunity of examining, he refers to Pagenstecher's account of *Phronima sedentaria*, 1861 (on p. 90 misprinted 1761), and varions treatises by Clans, who has shown that in the Hyperina the heart has three pairs of lateral orifices besides two aortas with valves, the lower aorta communincating with the heart by a double opening, showing perhaps an indication, Dr. Delage suggests, of a tendency to the bifid arrangement actually found in the Isopods and in the two abdominal aortas of the Tanaidæ. For the whole subject, compare Note on Wrześniowski, 1879; for the Tanaidæ, Note ou Blanc, 1884.

1881. GORDON, G.

Phronima sedentaria and its *Beroe*. The Scottish Naturalist. A Magazine of Natural History. Edited by F. Buchanan White. Volume VI. Edinburgh and London, 1881–1882. pp. 56–59.

Mr. William Robertson, residing in Shetland, having procured specimens of *Phronima sedentaria* from Urrafirth, and kept them alive for some time in confinement, informed Dr. Gordon “that the tail of the crustacean was the sole moving power that carried both itself and dwelling round the sides of the vessel; that the *Phronima* often left and returned to its *Beroe*; that hundreds of them were cast ashore about the same time, January 1880, at Ronas Voe.” Of the young, two or three days after their birth, he says, “these young crustaceans kept to the surface of the water, but if it was stirred, they then sank to the bottom, lay on their backs, and kept constantly working with their tails. The adults lay the same way when they were ont of the *Beroes*.” The way in which the *Beroe* is spoken of in parts of this paper might easily produce the impression that it was a still living animal, in which the *Phronima* was ensconced.

1881. HARTWIG, G.

The Sea and its living wonders, a popular account of the marvels of the deep and of the progress of maritime discovery from the earliest ages to the present time. New Edition. London, 1881.

Among the "Edriophthalmia" he mentions, page 247, "the saltatorial sandhoppers (*Talitrus*)," "the ill-famed *Chelurae*," "the parasitical *Cyami* which gnaw deep holes into the skin of the whale." Figures are given of *Chelura terebrans* and a "sandhopper," presumably *Talitrus locusta*. The frequency of the sandhoppers on the shores of the Arctic seas is illustrated by Holböll's account of his experiment with bait in an open basket let down to a depth of seventy-five fathoms. It is scarcely necessary to remark that the Amphipods taken in that instance were not the sandhoppers of the shore.

1881. LESLIE, GEORGE, and HERDMAN, WILLIAM A.

The invertebrate Fauna of the Firth of Forth. Part II. comprising the Protozoa, Polyzoa, Crustacea, and Tunicata. From the Proceedings of the Royal Physical Society of Edinburgh, vol. vi., 1881. Edinburgh, 1881.

The Crustacea extend from page 42 to page 52. "In the arrangement and nomenclature of the Amphipoda and Isopoda," the authors say, "we have followed Bate and Westwood's 'British Sessile-eyed Crustacea,' a work from which we have derived the greatest assistance." They enumerate only sixteen species of Amphipoda, without any descriptions. The "*Caprella linearis* (Linn.)" may probably be the same as the "*C. lobata* (Müll.)," which they identify with "the *C. lavis* of Goodsir." This will reduce the number of species to fifteen, of which five are Caprellidæ. It will be tolerably safe to say that such a list gives no idea whatever of the Amphipod-fauna of the Firth of Forth. Six out of the ten species of normal Amphipoda are given on the authority of Metzger.

1881. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1879; being Volume sixteenth of the Record of Zoological Literature. London, M.DCCC.LXXXI. pp. 1-45.

It is here noted that *Glycera*, Haswell's name for a new genus in the Lysianassinae, is preoccupied in Annelides.

1881. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1880; being Volume seventeenth of the Record of Zoological Literature. London, M.DCCC.LXXXI. pp. 1-61.

It is noted that the name *Chloris*, used by Haswell for a new genus among the Gammaridæ, is twice preoccupied in Aves, and once in Botany.

1881. MAYER, PAUL.

Arthrostraca, in Zoologischer Jahresbericht für 1880. II. Abtheilung. Leipzig, 1881. pp. 51-63.

1881. MEINERT, FR.

Crustacea Isopoda, Amphipoda et Decapoda Daniae: Fortegnelse over Danmarks Isopode, Amphipode og Decapode Krebsdyr. Naturhistorisk Tidsskrift. III. Raekkes 12 Bind. 3. Heft. pp. 456–512.

Lists are given of species and the localities at which they were taken, and an account from Professor Sehiødte of the tubes of *Haploops tubicola*, Lillj., which has small purple-red eyes. No new species of Amphipoda are described in this paper.

1881. MIERS, E. J.

Account of the Zoological Collections made during the Survey of H.M.S. "Alert" in the Straits of Magellan and on the Coast of Patagonia. Proc. Zool. Soc. Lond., January 1881.

There is here only an incidental allusion to the Amphipoda.

1881. MIERS, E. J.

On a small collection of Crustacea and Pycnogonida from Franz-Josef-Land collected by B. Leigh-Smith, Esq., lat. $79^{\circ} 55'$ N., long. about 51° E., in the "Eira." The Annals and Magazine of Natural History. Ser. 5. Vol. VII. pp. 45–49. Pl. VII. London, 1881.

On *Acanthonotozoma inflatum* (Kröyer), Mr. Miers remarks, "A single female was obtained. This specimen agrees very well with Goës's figure of the species; but the anterior margin of the exoa of the 4th thoracic limb is regularly rounded, whereas in Goës's figure it is represented as somewhat angulated. The dorsal carina, which is described by Boeck as very high (altissima), on the first 3 post-abdominal segments, in Goës's figure and in our specimen is distinct, but not much elevated."

Acanthostepheia pulchra, n. s., is figured and described, with a comparison between it and *Acanthostepheia malmgreni*, Goës. *Amathilopsis affinis*, n. s., is figured and in like manner compared with its near ally *Amathilopsis spinigera*, Heller.

1881. MIERS, E. J.

Crustacea, in Markham's Polar Reconnaissance, 1881.

No new Amphipoda reported. Compare Note on Markham, 1880.

1881. MIERS, E. J.

On a collection of Crustacea made by Baron Hermann-Maltzan at Gorce Island, Senegambia. Annals and Magazine of Natural History, September, October, November, 1881.

The only Amphipod included in this account is *Ampelisca tenuicornis*, Liljeborg, of which a detailed description is given.

1881. MOSELEY, HENRY NOTTIDGE.

Report on certain Hydroid, Aleyonarian and Madreporarian Corals proeured during the Voyage of H.M.S. Challenger, in the years 1873-1876. Zool. Chall. Exp., Part vii. London, Edinburgh, Dublin, 1881.

At page 204, Mr. Moseley says that "in nearly all the mesenterial cavities [of *Stephanophyllia formosissima*] were found one or two small crustacea (a Gammarid ?), which must apparently live as commensals within the cavities of the living coral." Three specimens of the coral were obtained at "Station 192, off the Ki Islands. Lat. 5° 42' S., long. 132° 25' E. 129 fathoms;" and several specimens at "Station 209, off Zebu, Philippine Islands. Lat. 18° 10' N., long. 123° 55' E. 95 fathoms."

As I have not found any Gammarids in the Challenger collection from the stations here mentioned, there is little doubt that the Crustacea referred to belonged to the Hyperina.

1881. PACKARD, A. S., JR.

The Fauna of the Nickajaek Cave. By E. D. Cope and A. S. Paekard, jr. The Ameriean Naturalist, November, 1881. Volume XV. Philadelphia, 1881. pp. 877-882.

"Many miles of galleries have been explored, and no end has yet been reached" of this cave on the southern boundary of Tennessee. The Isopod, *Cecidota nickajackensis*, Packard, n. s., is not uncommon in the waters of the cave. "The second crustacean discovered swimming about in the subterranean stream, was a species of Amphipod belonging to the genus *Crangonyx*, and which may be called *Crangonyx antennatum* Packard." The description of pl. vii. fig. 2, gives *Crangonyx antennatus*. "It is a large and purplish species; the first antennæ very long; the flagellum with 20-24 joints; the entire antenna being over one-half, and nearly two-thirds as long as the body; the last joint of the peduncle being slightly more than half as long as the penultimate joint." A comparison of it is made with *Crangonyx gracilis*, Smith. "It is very different from *C. vitreus* Cope, of Mammoth Cave, and from *C. packardi* Smith, differing in its distinct eyes, and larger, more numerously jointed antennæ."

1881. SMITH, SIDNEY I.

Preliminary notice of the Crustacea dredged, in 64 to 325 fathoms, off the south coast of New England, by the United States Fish Commission in 1880. Proceedings of the National Museum; Washington. Vol. III. for 1880, January, 1881. pp. 413-452.

Among the Amphipoda, pages 447-452, is described "*Neohela phasma*, sp. nov.—*Neohela*, nom. nov., vice *Hela* Boeck, praeoc." "This species is apparently very closely allied to *N. monstrosa* Boeck, but has well-developed eyes, and the propodus in the second pair of gnathopods is different in form, besides other slight differences." Altogether seven species of Amphipoda are here recorded.

1881. SMITH, S. I.

Recent Dredging by the United-States Fish Commission off the South Coast of New England, with some Notice of the Crustacea obtained. The Annals and Magazine of Natural History. No. 38. February, 1881. London, 1881. pp. 143-146.

"Few species of Amphipoda were found; but the Arctic species, *Stegocephalus ampulla*, *Haploops setosa*, and *Epimeria loricata*, G. O. Sars, occurred, the last in abundance."

1881. ULIANIN, B.

Zur Entwicklungsgeschichte der Amphipoden. Zeitschr. f. wissenschaftl. Zool., XXXV. pp. 440-460, Taf. XXIV. 1881.

Abstract in Journ. Roy. Microscop. Soc. [2], I. pp. 599, 600. August 1881.

After explaining his methods of investigation, Ulianin refers to eight authors, who have previously treated the same subject. Of H. Rathke's Reisebemerkungen aus Taurien, 1837, he says, "Enthält Beobachtungen über Entwicklung der Amphithoë picta, Gammarus gracilis, Amathia carinata und Hyale pontica.—Die Beobachtungen von RATHKE haben Bedeutung nur in historischer Hinsicht." Of Meissner's paper in 1855, he says, "Enthält die ersten sehr dürftigen und grösstentheils unrichtigen Angaben über das kugelförmige Organ," and at p. 451, "Nach den von Meissner veröffentlichten Abbildungen zu urtheilen, untersuchte er ein zerstörtes Organ, das an Lappen der zerrissenen Cuticularhaut hing. Die Einstülpung der Cuticula in das kugelförmige Organ wurde von ihm als eine Öffnung in der Cuticula, nämlich als eine Micropylöffnung erklärt. Da er die Membran, in der er eine Mikropylöffnung zu finden glaubte, irrtümlich für die Dotterhaut hielt, so zog er den Schluss, das die Befruchtung des Eies der Amphipoden noch im Eierstocke vor der Bildung des Chorions geschehe." In Müller's Für Darwin, 1864, he says, "Das Vorhandensein der Larvenhaut bei Amphipoden-Embryonen wird zum ersten Male gezeigt." He finds the statements of de la Valette on the first developmental stages in *Gammarus pulex* very like what he has himself observed in the eggs of species of *Orchestia*, but 1. the latter undergo "wenn auch einer sehr oberflächlichen und kurzen doch einer echten Furchung;" 2. "bei den Orchestien . . . treten aus dem Inneren des Eies nur vier grosse amöboide Zellen, die nur nach mehrfacher Theilung und Wanderung auf der Oberfläche des Eies in ruhende Blastodermzellen übergehen; während der Wanderung der amöboiden Zellen auf der Oberfläche des Eies wird außerdem der Nahrungsdotter wieder einer Art oberflächlicher Segmentation unterworfen;" 3. "bei den Orchestien ist es möglich gleich nach der ersten Theilung der vier grossen aus dem Inneren des Eies angetretenen amöboiden Zellen den Pol zu unterscheiden, an welchem das Blastoderm angelegt wird und der später der Bauchfläche des Embryo entsprechen wird."

In Bessels's paper in 1869 and Dohrn's in 1870, Ulianin says, "das kugelförmige Organ wird mit dem Rückenstachel der Zoëa homologisiert," but, he thinks, without good reason. Sars' opinion that the organ in question was of service for the nourishment of the embryo, he considers quite untenable. He himself agrees with those who regard it as an inherited organ, having no special physiological function, but of high morphological importance. It is, he says, "als eine lokale Einstülpung des Ektoderms angelegt; die Zellen dieser Einstülpung scheiden eine Cuticula aus, die mit der zur selben Zeit von der Oberfläche

des Embryo ausgeschiedenen Cuticularhaut im Zusammenhange steht." It has, he continues, the most striking resemblance to "der sogenannten Schalengrube der Mollusken."

Having previously observed that, "vorausgesetzt das bei den Orchestien, ähnlich dem, was bei anderen Crustaceen beobachtet wurde, die das Zerfallen des Dotters in Dotterschollen hervorrufenden Zellen zum Aufbaue des Mittel-darmes verbraucht werden, nimmt das Entoderm seinen Ursprung von den Zellen des kugelförmigen Organes," Ulianin thus concludes:—"ähnlich wie bei anderen Crustaceen entsteht bei den Orchestien das Mesoderm durch Zersplitterung des Blastoderms, während das Entoderm aus vom Ektoderm abstammenden und in den Dotter einwandernden Zellen zusammengesetzt wird. Die Thatsache, dass die in den Dotter einwandernden Zellen von den Zellen des kugelförmigen Organes abstammen, kann uns auch nicht sehr befremden: das kugelförmige Organ ist, wie oben gezeigt wurde, ein ererbtes verkümmertes Organ, das seine frühere Bestimmung mit der Zeit verloren hat und dem im Laufe der Zeit neue Funktionen bei der Bildung des Entoderms aufgelegt wurden."

1881. WRZEŚNIOWSKI, AUGUST.

Goplana polonica nowy rodzaj i gatunek skorupiaka obunogiego z okolic warszawy opisał August Wrześniowski. Warszawa, 1881.

A very useful comparative table is given of the terms used by nine authors in describing the mouth-organs and external parts of Amphipoda, omitting mention, however, of the *labrum* or upper lip. The *labium* or lower lip is called *languette* by G. O. Sars, *zunge* by Dybowsky, *Paragnathen* by Claus, but *Unterlippe* is used by Dybowsky for the second maxillæ, and by Claus (as an alternative) for the maxillipeds. Dybowsky is here said to call the uropoda *Schwimmbeine* and *Springbeine*, but that does not quite accurately represent him, since in reality he calls the three pairs of pleopoda *Schwimmbeine*, the first two pairs of uropoda *Springbeine*, and the last pair *das Steuerbein*. It is a mistake also to say that Dybowsky gives *metacarpus* as an alternative for the "Handwurzel" or wrist of the gnathopods; in fact he gives the word *carpus*, as might be expected, though for the corresponding joint in the first two pairs of peræopods he gives "Afterhandwurzel (*pseudocarpus*)," and in the last three pairs "Fusswurzel (*metatarsus*)."
According to the lists here given, *tarsus* is used by Claus and Heller as an alternative for *carpus*, by Dybowsky as an alternative for *Fusstück* (the name which he gives to the hand in the last three pairs of peræopods), and by Milne-Edwards, in the form *tarse*, as an alternative for doigt or dactylopodite.

The structure of *Goplana polonica* is illustrated by Plates X. and XI., of which the explanation is given in French as well as in Polish.

1882. CHILTON, CHARLES, born 1860 (Chilton).

Additions to the New Zealand Crustacea. (Read before the Philosophical Institute of Canterbury, 13th October 1881.) On some Subterranean Crustacea. (Read before Phil. Inst. Cant., 3d November 1881.) Art. XXIV., XXV. From the Transactions of the New Zealand Institute, Vol. XIV. 1881. Wellington, 1882. pp. 171–180. Pl. VIII. fig. 3a, 3b. Pl. IX. X.

Art. XXIV. points out the resemblance of the first gnathopods of *Microdeutopus maculatus*, G. M. Thomson, to those of *Aora gracilis* and *Aora typica*. Art. XXV. describes and figures the new well-shrimps *Crangonyx compactus*, *Calliope subterranea*, and *Gammarus fragilis*.

1882. FAXON, WALTER.

Bibliography to accompany "Selections from Embryological Monographs" compiled by Alexander Agassiz, Walter Faxon, and E. L. Mark. 1. Crustacea. By Walter Faxon. Bulletin of the Museum of Comparative Zoölogy. At Harvard College. Vol. IX. No. 6. Cambridge, 1882.

1882. HASWELL, W. A.

Catalogue of the Australian Stalk and Sessile-Eyed Crustacea. The Australian Museum. Sydney. 1882. pp. xvi-xx, 212-275, 310-314, 325. Pl. IV.

This important work gives in the Introduction a general account of the structure of the Amphipoda. The accounts of Mr. Haswell's own species are reproduced from his earlier publications already noticed. Among the *addenda et corrigenda* at the end of the volume, he remarks that "the species on which the genus *Neobule* was founded belongs to the *Orchestidae*, and is allied to the form afterwards named by me *Aspidophoreia*." He had previously placed *Neobule* in the subfamily Stegocephalides. The name *Glycera* is now altered to *Glycerina*, *Glycera* being preoccupied. The species *Icilius punctatus* is recognised as only a variety, and therefore a synonym, of *Icilius australis*.

1882. HAY, O. P.

Notes on Some Fresh-water Crustacea, together with Descriptions of Two New Species. The American Naturalist. February, 1882. Vol. XVI. No. 2. Philadelphia. pp. 143-146.

Crangonyx lucifugus, n. sp. "a small, rather elongated species, that was obtained from a well in Abingdon, Knox county, Illinois," "appears to resemble *C. tenuis* Smith, but is evidently different. In that species, as described by Prof. S. I. Smith, the first pair of feet are stouter than the second, and have the palmar margin of the propodite much more oblique. The reverse is true of the species I describe. Nor do I understand from the description of *C. tenuis* that the posterior caudal stylets each consist of a single segment. There are some minor differences. From *C. vitreus*, judging from Prof. Cope's description in AMERICAN NATURALIST, Vol. vi. p. 422, it must differ in the caudal stylets. 'Penultimate segment, with a stout limb with two equal styles,' is a statement that will not apply to my species, whichever the 'penultimate' segment may be."

Mr. Hay next describes "*Crangonyx bifurcus*, n. sp.—General form and appearance those of the Western variety of *C. gracilis*." "This species," he says, "differs from *C. gracilis* more particularly in the form of the telson, and in the length of the outer ramus of the posterior stylets as compared with the peduncle. From *C. antennatum* Packard (AMERICAN NATURALIST, 1881, p. 880), it differs in the form of the telson, and in the much greater size of the eyes." Found in a rivulet at Maeon, Miss. "The three species, *C. gracilis*, *C. bifurcus* and *C. lucifugus* present an interesting gradation in the form of the posterior caudal stylets. In the first-named the outer ramus is twice the length of the peduncle, and the inner ramus is present, but rudimentary. In *C. bifurcus* the outer ramus is but two-thirds as long as the peduncle, while it is doubtful whether there is anything whatever to represent inner ramus. In *C. lucifugus* both the outer and inner rami are absent, and the peduncle itself is much reduced."

1882. HOEK, P. P. C.

Die Crustaceen, gesammelt während des Fahrten des "Willem Barents" in den Jahren 1878 und 1879. 75 pp. mit 3 Taf. Separ.-Abdruck aus dem "Nied. Arch. für Zool." Suppl. Band I. 1882.

The part concerning the Amphipoda, beginning at p. 41, describes the new species, *Socarnes ovalis*, Taf. III. fig. 29-29r., given as a link between *Socarnes* and *Ichnopuss*, but recognised by G. O. Sars, in 1885, as a synonym of *Socarnes bidenticulatus*, Sp. Bate (sp.); *Anonyx debruyndii*, Taf. III. fig. 30-30x., noted as having much in common with *Anonyx ampulla*; *Haploops laevis*, Taf. III. fig. 31; *Podocerus tuberculatus*, Taf. III. fig. 32. Brief observations are made upon *Onesimus leucopis*, G. O. Sars; *Tryphosa höringii*, Boeck; *Acanthozone cuspidata*, Lepechin (with criticism of the figure given by Buchholz, in 1874); *Gammarus locusta*, Linn.; *Ampelisca eschrichti*, Kröyer, and others. A short appendix refers to Stuxberg's recently published Evertebratfaunan i Sibiriens Ishaf. There is a Literatur Verzeichniss, pages 71-73.

A species closely resembling Hoek's Arctic *Podocerus tuberculatus* was taken by the Challenger near New Zealand.

1882. LENZ, HEINRICH.

Die Wirbellosen Thiere der Travemünder Bucht. Theil II. Vierter Bericht der Commission zur wissenschaftlichen Untersuchung der deutschen Meere, für die Jahre 1877 bis 1881. VII. bis XI. Jahrgang. I. Abtheilung. Berlin, 1882. pp. 169-179.

On pp. 174, 175, *Corophium longicorne*, Latr.; *Bathyporeia pilosa*, Lindstr.; *Calliope larviuscula*, Krøy.; *Melita palmata* (Mont.); *Gammarus sabinei* (Leach); *Talitrus locusta*, L., are mentioned, with notes as to their occurrence, and on p. 178, in a summary of the investigations in this region, nine Amphipoda are recorded.

1882. MARTENS, EDUARD VON.

Crustacea. The Zoological Record for 1881; being Volume Eighteenth of the Record of Zoological Literature. London, M.DCCC.LXXXII. pp. 1-38.

1882. MAYER, P.

Die Caprelliden des Golfs von Neapel und der angrenzenden Meeres-abschnitte. Fauna und Flora des Golfs von Neapel und der angrenzenden Meeres-abschnitte herausgegeben von der zoologischen Station zu Neapel. VI. Monographic: Caprelliden von Dr. P. Mayer. Mit 10 Tafeln in Lithographie und 39 Zincographien. Leipzig, 1882.

It is safe to affirm that for a long time to come this work will be absolutely indispensable to every genuine student of the Caprellidæ. The scope and comprehensiveness of it may be inferred from the principal headings in the long table of contents. Under "Systematik,"

are given, historical review; special classification; alphabetical table of the genera and species. These are followed by "Geographisch Verbreitung." Under "Anatomie und Histologie," are given, general form of the body, segments, limbs; integument; glands; nervous system; organs of sense; muscles; connective tissue; organs of respiration; circulatory apparatus; organs of nutrition; sexual organs. Next come "Entwickelungsgeschichte," "Biologie," "Phylogenie," under which the structure of the Cyamidae is considered, and lastly "Literaturliste." The various topics are handled with great thoroughness, and the opinions of earlier writers are minutely and carefully criticised.

Mayer thus defines the family Caprellidae:—

"Læmodipoden mit schmalen, auf dem Querschnitt annähernd kreisrundem Körper. Kopf und 1. Brustsegment zu einem Cephalothorax verschmolzen, 2.-7. Segment frei. Epimeren fehlen. Kiemcn am 2., 3. und 4. oder nur am 3. und 4. Brustfusspaare, schlauchförmig. Abdomen aus höchstens 5, wenigstens 1 Segmente zusammengesetzt, mit höchstens 3, wenigstens 2 stark rückgebildeten Beinpaaren. Vorderfühler stets länger als Hinterfühler. Füsse an Zahl verschieden; die nicht rückgebildeten sind bengliedrig, ohne Scheere, aber mit einschlagbarer Klaue."

Up to the date of Mayer's treatise there had been established eight genera, for the arrangement of which various useful tables are given. *Cercops*, *Proto* and *Caprellina* agree in having branchiae on the second, third and fourth segments; the rest have them only on the third and fourth. *Proto* and *Caprellina* have more than two joints to the flagellum of the lower antennæ; the rest have only two. *Caprella* and *Podalirius* are without the mandibular palp, which is present in the rest. *Proto* stands alone in having seven pairs of complete limbs on the pereon; *Protella* has five pairs complete and two pairs rudimentary; *Cercops*, *Ægina*, *Æginella*, *Caprella*, have only five pairs; *Caprellina* and *Podalirius* have four pairs complete and one pair rudimentary. In *Cercops* the pleon has five segments, in *Protella* two, in the rest only one. In *Ægina*, the abdominal feet are jointed, in *Æginella* not jointed. But of *Cercops* and *Æginella* Mayer does not speak from his own observation. Within the genus *Caprella*, the species may be divided, as pointed out by Haller, into two groups, those in which the lower antennæ carry "Ruderborsten," and those in which they carry "Sinnesborsten." They may be otherwise divided into two groups, according as in the male the basal joint of the second gnathopod is very long or is short.

To *Cercops* is assigned the single species "*Cercops Holbölli*, Kröyer." *Proto*, Leach, has the synonymy, *Leptomera*, Latreille; *Naupredia*, Latreille; *Naupridia*, Milne-Edwards; *Proton*, Desmarest. The species assigned to it are, *ventricosa*, O. F. Müller; *brunneocittata*, Haller; "*Nova-Hollandia*," Haswell; and "? *Proto cornigera*," Haswell, for *Caprella cornigera*, Haswell. This last species has three pairs of branchiae arranged as in *Proto*, but the first three pairs of pereopods have not been observed, only the muscles of the body going to them are so little developed, as to produce the impression that the limbs themselves may be rudimentary, in which case Mayer would place the species in a new genus, *Hircella*, a name adopted by Haswell in 1884, without further observation of the appendages in question.

The genus *Caprellina*, Thomson, has the one species *longicollis*, Nicolet, with "Novæ-Zealandiæ," Thomson, and *brevicollis*, Nicolet, for synonyms.

Protella, Dana, has the species *phasma*, Montagu; *gracilis*, Dana, with *australis*, Haswell, as a possible synonym; *echinata*, Haswell, for *Caprella echinata*, Haswell; and "*Haswelliana*," Mayer, n. s., in which the last two segments of the pereon are coalescent. Haswell, in 1885, says of his *Protella australis* that "it is a very well-marked species and quite distinct from *P. gracilis* of Dana, to which Mayer is inclined to unite it, both in the form of the head and of the gnathopoda. The gnathopoda are not unlike those of *P. dentata* [? *C. dentata*] but in other respects the two species are quite different." Mayer remarks

that if Boeck's *Aegina echinata* should prove to be a *Protella*, Haswell's *Protella echinata* might be renamed *echinimana*.

To the genus *Aegina*, Kröyer, Mayer assigns *Aegina longicornis*, Kröyer, with *Aegina laevis*, Boeck, for a synonym; and *Aegina echinata*, Boeck, with the synonymy, *Aegina spinosissima*, Stimpson; *Caprella spinifera*, Bell; *Caprella spinosissima*, Bate, and ? *Caprella spinosissima*, Norman. Of these, however, the first three represent *Aegina spinosissima*, Stimpson, 1854, and the fourth is *Caprella horrida*, Sars (see Note on Sars, 1885). As doubtful species of *Aegina* are mentioned Dana's "A.? aculeata" and "A.? tenella," from the Sooloo Sea, of which Dana thought the former might be the female, the latter the male, of one and the same species. *Aeginella*, Boeck, distinguished from *Aegina* only by having the appendages of the pleon unjointed, has the solitary species *Aeginella spinosa*, Boeck, also marked out by the strong dorsal spine at the beginning of the first pereon-segment. A spine on this segment is to be noted also in *Caprella spinulata*, Couch, 1852.

In regard to the genus *Caprella*, Lamarck, Mayer calls attention, as Kröyer had already done, to the great variability in the species, which has led to the introduction of many needless specific names. He lays down a sort of canon, that "a single specimen of small size can only be determined with any certainty under favourable circumstances." New species ought not as a rule to be established without an opportunity of examining an adult male specimen. Of about ninety named species Mayer has been able to refer ten to other genera of Caprellidae, about ten he has had to leave uninvestigated; of the remaining seventy he has been able to recognise ten as undoubted species, the remainder consisting partly of synonyms, partly of species perhaps good and tenable, partly of such as are absolutely indefinite (unbestimmbar). His ten well-ascertained species are thus classified:—

"A. Hinterfühler mit Sinneshaaren. Dimorphismus bedeutend.

Stamm völlig glatt ; 2. Arm des erwachsenen Männchens laug,
Hand desselben ausserordentlich gross und dick
