The two statements which I have enclosed in brackets were added in 1876. In 1882 Sars places the Dulichiidae as the twenty-second and last family of the Gammarina, with the four genera included in it by Boeck. The later definitions of the family by Carus and Gerstaecker are quoted in the remarks on the genus *Platophium*. All writers who have defined the family have not unnaturally laid stress on the want of the full number of the segments in the pleon. Spence Bate considers that the sixth segment is wanting. Haswell, in describing "*Cyrtophium (?) hystrix*," which he afterwards transferred to *Lætmatophilus*, speaks of "the absence of the fourth segment of the pleon." Gerstaecker regards the fourth and fifth segments of the pleon as coalesced. Of the three opinions this seems the most probable, but the further alternative, that the fifth segment is wanting, may have better claims to acceptance than any of them. However that may be, it is not so much the position of the missing segment, as the fact of its absence or indistinguishable coalescence, that causes a very great difficulty as regards classification. In the genus *Platophium*, as will be seen, the number of segments is complete, and yet in other respects this genus bears so close a relationship to *Lætmatophilus*, that it cannot be satisfactory to classify them in different families. In speaking therefore of the Dulichiidae as having only five segments and five pairs of appendages to the pleon, the convenient expression plerumque, *for the most part*, ought to be added.

Genus *Platophium*, Dana, 1852.

1852. *Platophium*, Dana, Amer. Journ. Sci. and Arts, ser. 2, vol. xiv.
 1852. " Dana, U.S. Explor. Exped., vol. xiii. pt. ii. pp. 831, 837, 1441.

 1882. " (*pars*), Haswell, Catal. Australian Crust., p. 271.
 1885. " Carus, Prodromus Faunae Mediterraneæ, pars ii. p. 390.
 1885. *Dexiocerella*, Haswell, Proc. Linn. Soc. N.S.W., vol. x. pt. i. (extr., pp. 13, 15, 16, 17).
 1886. *Cyrtophium*, Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 494.

For the original definition of the genus, see Note on Dana, 1852 (p. 257). For *Dexiocerella*, see Note on Haswell, 1885 (p. 566). Spence Bate united *Platophium* and *Cyrtophium* under the latter name, and Mr. Haswell re-divided the genus into *Dexiocerella* and *Cyrtophium*, giving the former name to species which will properly fall under Dana's *Platophium*. Carus in defining the "Tribus, Crevettina," gives as a character, "pedum abdominalium paria tria (stili caudales) bene formati, saepe elongati." He places immediately after this the following definition of "1. Fam. DULICHIIDÆ Cls. Corpus lineare, thoracee valde elongato 6-articulato, articulis 2 ultimis connatis, abdomine 5-articulato, snbtus inflexo, sine stilis caudalibus; antennæ I. ramo secundario parvo, II. post superiores insertæ; glandulæ pedum III. et IV. nullæ." Of this family he makes Dana's *Cyrtophium* the first genus, including in it Dana's *Platophium*. But after giving to the tribe three pairs of uropods (stili caudales) well developed, and leaving the family without any, he describes the genus as having the last pair rudimentary, and for the species *Cyrtophium darwini*, Spence Bate, he makes mention of three pairs ("uropoda penultima præcedentibus multo breviora, ramis inæqualibus, ultima rudimentaria"). Some words have perhaps been omitted from the definition of the family, the presence of which would have cleared up the confusion, but it is important to observe that two other statements in that definition exclude both *Platophium* and *Cyrtophium* of Dana, for in both those genera the peræon has seven distinct segments and the pleon its full number of six.

Gerstaecker thus defines the family "Dulichidæ, Dana;"—"Both pairs of antennæ with strongly elongated peduncle and short flagellum. Head extended, in front obliquely truncate. First segment of the peræon shorter than the following, the sixth and seventh generally completely coalesced. First, third, and fourth [pairs of] limbs short, the three hinder pairs elongate and slender; the two anterior pairs subchelate. The fourth and fifth segments of the pleon coalesced; of the three pairs of uropods one wanting." In defining "*Cyrtophium*, Dana (*Platophium*, Dana)" as the fourth genus of

this family, Gerstaecker expressly says that "the last two segments of the peræon are *not* coalesced." But the impediment remains that in both *Platophium*, Dana, and *Cyrtophium*, Dana, the fourth and fifth segments of the pleon are not coalesced, and no one of the three pairs of uropods is wanting. The requisite alteration of the definition of the family has been already discussed.

Platophium danæ, n. sp. (Pls. CXXVIII., CXXIX.).

Head without a rostrum, the lateral lobes angled; below and behind them each side of the head deeply emarginate for the insertion of the lower antennæ; in the middle of the back of the head there is a large upstanding process; each of the segments of the peræon and of the first two of the pleon is armed with a medio-dorsal carinate tooth or process, which on the first segment of the peræon is small and supplemented by a second; the tooth on the second segment is also small, larger on the third and fourth, and again considerably larger on each of the following five segments; the lateral margins of the third, fourth, fifth, and sixth peræon-segments are tridentate, the edges of all the peræon-segments more or less projecting beyond the side-plates; the seventh of the peræon has a tooth on the hind margin on each side below the dorsal process; in this the first and second pleon-segments resemble it; the postero-lateral angles of these and the third segment are rounded; the third has a transverse dorsal depression; the fourth pleon-segment is narrow and elongate, tending to cylindrical, with a transverse dorsal depression near the base; this segment is perfectly distinct from, and has the dorsal margin raised above, the fifth segment; the fifth and sixth segments are together much shorter than the fourth. The pleon from the fourth segment is strongly flexed. The skin in many parts is furred with short hair.

The Eyes very prominent, hemispherical, projecting just behind and partially on the lateral lobes of the head; the ocelli numerous.

Upper Antennæ.—The first joint rather thick, not so long as the head, with slender spines, chiefly at the lower apex; the second joint thinner, twice as long, with a dozen pairs of long, slender, slightly feathered spines; the third joint rather shorter and thinner than the second, with ten pairs of the like spines; the flagellum of nine or ten joints, together not so long as the first and second of the peduncle united, apically carrying groups of cylinders and some spines much shorter than those of the peduncle; the first joint much longer than the rest, with three or four groups of cylinders; the secondary flagellum of one joint, narrow, slightly tapering, not so long as the first of the primary, armed with a few setules.

Lower Antennæ much longer than the upper. The first two joints very short, the gland-cone very small, acute; the third joint considerably longer than the combined first and second, widening distally, with some slender spines on the lower margin; the fourth

joint three or four times as long as the third, the lower side fringed with two rows of spines, the upper margin having a few short ones; the fifth joint thinner, very much longer than the fourth, fringed with two rows of short spines; the flagellum of four joints, together about equal to the fourth joint of the peduncle, the first much longer than the other three united, the fourth minute, the first three fringed below with many short spines in two rows.

Upper Lip.—The distal margin bilobed, not quite symmetrically; the central part of the distal margin finely furred.

Mandibles.—The cutting edge divided into four teeth and a denticle; the secondary plate having three or four teeth on the left mandible, two slenderer teeth and a denticle on the right mandible; on the left mandible the spine-row has three strong, more or less curved, denticulate spines and a small one; on the right mandible only two strong ones and an attendant small one; the molar tubercle prominent, with a dentate crown, and upon the side, not the edge, of the tubercle, a small laminar process; the process above the tubercle is broad-headed, not reaching the base of the palp; the first joint of the palp narrow in the middle, more than twice as long as broad; the second joint stouter, twice as long as the first, or more, the hind margin a little convex, the front margin tending to eave except at the extremities, along the lower part having a row of five spines, the uppermost the longest, and above these seven long feathered spines at intervals, with other similar spines along the surface; the third joint is rather longer than the first, considerably shorter than the second, like the other two widening distally, but in a greater degree, the distal margin set round with about twenty spines, most of them very long; on the outer surface there is a transverse row of four a little below the apex of the convex outer margin, below these are two, and below the two there are three in single file.

Lower Lip.—The lobes both of the inner and outer plates are rather small, and not conspicuously ciliated; the mandibular processes are not large.

First Maxillæ.—The inner plate appears to be small and smooth; the outer plate not broad, with nine short and rather thin spines on the truncate distal margin, none of the spines apparently having more than a single minute lateral denticle; the first joint of the palp very short, the second long, reaching beyond the outer plate, widening a little distally, with six slightly serrate spine-teeth on the dentate distal margin, this series continued by some slenderer spines, two to four in number, a little way down the inner margin; another series of six or seven slender spines is ranged across the surface, from the distal part of the inner margin towards the apex of the outer.

Second Maxillæ.—The inner plate shorter and narrower than the outer, with a row of plumose setæ beginning at about the middle of the inner margin, and keeping near it, and a row of spines beginning a little higher up and passing round to the outer apex, the convex outer margin being unarmed; the outer plate widens from about the middle and

has long spines round the broad serrate distal margin, which is oblique on the outer side.

Maxillipeds.—The inner plates small, not reaching the distal end of the palp's first joint, with a row of seven plumose setæ beginning high up on the inner margin and passing on to the surface near the apex; the distal margin is broad, with three short spine-teeth and several slender feathered spines; there is another spine-tooth submarginal to the inner apex; the outer plates scarcely reaching beyond the middle of the palp's second joint, with seven spine-teeth spaced along the serrate inner margin, and six spines round the serrate distal margin, of which two might count as long teeth, the others being setiform; the first joint of the palp short; the second considerably more than twice as long, with many groups of long spines along the inner margin, and at the apex on both margins; the third joint about as long as the first, oval, with oblique rows of spines on the surface and many spines about the apex; the finger, if the spine-like nail be included, is even longer than the third joint; its basal part is scarcely so long as the serrate nail, near the root of which, on the inner margin, it has several spines of various sizes, one very similar to the nail, and not much shorter or narrower.

First Gnathopods.—The side-plates of a breadth much less than the length of the segment, the depth less than the breadth, the front margin forming a sharp angle with the lower, the hind margin having a small pointed apex. The first joint almost free from the side-plate, its front margin nearly straight, and unarmed, with an inner margin that has a row of spines round the apical curve; the convex hinder margin has a spinule here and there and near the apex some long setiform spines; the second joint short, with spinules on the front lobe, and a brush of very long setiform spines near the apex behind; the third joint not very long, with convex margins converging to a pointed apex, and many groups of long spines on or near each; the wrist widest where it becomes free from the third joint, subequal in length to the hand, most of the free hind margin fringed with long spines, of which there is a group numbering six or seven across the inner surface, and others near the distal margin; the hand attaining its greatest breadth close to the base, then narrowing to the apex, with five or six long rows of spines encircling the convex front margin; the hind margin, all but a small piece at the base, tending to concur and forming the palm, fringed with long spines, of which also the inner surface carries several groups; the finger long and broad, reaching nearly to the end of the palm, the inner margin divided into many slender teeth. In the female the spines are much fewer and shorter, the wrist and hand are stouter compared with their length, the hind margin or palm of the hand is convex.

Second Gnathopods much larger than the first, and the segment is dilated to suit this great increase. The side-plates larger than the preceding pair, their breadth not equalling the length of the segment, the lower margin presenting a bilobed or trilobed appearance. The first joint almost entirely free from the side-plate, narrow at the neck, widening

distally, much shorter than the hand, the hind margin convex, carrying a few spinules, the front straighter, with long plumose setæ on the lower part projecting from the surface; the second joint short, with some spinules on the front lobe, a few setæ behind; the third joint with convex front and hind margins, the distal margin squarely trunecate, all three surrounded by long feathered spines or setæ; the wrist very little longer than the third joint, somewhat triangular, narrower than the hand, with long spines on the hind margin and inner distal margin; the hand of great length, three times as long as the wrist, with a few spines on the long slightly convex front margin; the almost equally long hind margin is thickly fringed with groups of long feathered setiform spines, supplemented by numerous similar groups planted on the surface at a little distance from the margin; the finger is broad, about half the length of the hand, the inner margin seemingly smooth, but bordered with very numerous submarginal setules, and closing over one or two tooth-like processes of the hand's hind margin or palm, at a little distance from that margin's apex; the hand is about three times as long as broad, and is not compressed along the front margin. In the female the spines are comparatively few, the first joint is short, the wrist small, not longer than the third joint, the hand broadly oval instead of elongate, the palm longer than the remaining part of the hind margin, which is separated from it by a sharp apieal tooth, within which is a strong palmar spine, against which the broad curved finger impinges, having but few setules at the smooth inner margin.

First Peræopods.—The side-plates smaller than the preceding pair, the segment which carries them being narrower not only than the preceding, but to some extent than the succeeding segment; the lower margin of the plate almost tridentate; the first joint nearly free from the side-plate, narrow, little longer than the fifth joint, with some spinules along the hind margin and lower part of the front, and three small spines at the top of the front margin; the second joint longer than broad, with spinules on the front lobe and small spines on the apex behind; the third joint widening distally, a little shorter than the fourth, with a spinule and four groups of small spines behind, three spinules and three groups in front; the fourth joint a little shorter than the fifth, with six groups of spines behind, three or four in front; the fifth joint with five groups of spines behind and three in front; the finger rather long and slender, three-fourths the length of the fifth joint, with a short sharp nail, and a dozen short setules or hairs along the convex outer margin.

Second Peræopods scarcely differing from the first, but with the first joint shorter.

Third Peræopods.—The side-plates bilobed, the front lobe rounded, nearly as deep as the preceding pair, the hind lobe shallow. The first joint of the limb shorter than the fifth, not much expanded, the frontmargin nearly straight, with a little spine here and, there, and an apieal group of short spines, the hind margin forming a lobe at the top, distally dividing into two margins, each of whieh carries two or three spines; the second joint has some short spines at the front apex; the third joint a little longer than the

fourth, subequal to the fifth, widening distally, with a group of rather long spines on the somewhat decurrent hinder apex, and smaller spines at three points of the hinder and four of the front margin; the armature of the fourth joint similar; the fifth joint with spines at five points on each margin, the front ones the stronger, and, as on the preceding joint, a little curved towards the margin; the finger about three-quarters as long as the fifth joint, at first straight, distally curved, with a short sharp nail, hairs along the hind margin, and a dorsal cilium close to the hinge.

Fourth Peræopods.—Side-plates as in the preceding segment, but rather smaller. The limb like that of the third peræopods, but longer, and with the first joint rather wider.

Fifth Peræopods.—Side-plates not bilobed; the limb like that of the fourth peræopods, but with the first joint rather larger.

Pleopods slender; coupling spines stout, a little bent, with two pairs of retroverted hooks, the pair below the apical being the larger; the eleft spines appear to be a series of five on the first pair, of three on the second and third; the joints of the rami numbering from eleven to thirteen. The figure *plp.sp.* shows two of the coupling spines of one peduncle interlocked with one from the peduncle of the opposite side.

Uropods.—Peduncles of the first pair about as long as the inner ramus, having five spines on one of the upper margins, and a longer spine on the lower apex; the outer ramus normally shorter than the inner, but on one side of the specimen figured nearly equal to it; the proportions seem to be not quite constant; both rami have spines on the margins and an apical group; the inner ramus has a dozen spines on the inner margin, five or six on the outer, a long and short one at the apex, with two of more equal length above, this arrangement of the apical group applying to both rami in this and the following uropods; peduncles of the second pair much shorter than the inner ramus, the outer ramus shorter than the inner, both with marginal and apical spines; the third uropods resembling the bowl of a spoon, with the cavity turned towards the telson, beyond which they project a little, the margin set round with six or seven spines, of which the inner are somewhat setiform.

The Telson scarcely longer than broad, with a narrowly rounded end, at a little distance from which, on either side, is a group of three small cilia; on the upper surface, at about the middle, begins a bluntly conical, minutely furred projection, not reaching quite to the distal margin, carrying two prominent spines on the upper margin of its apex.

Length.—The length along the back of the peræon and first two segments of the pleon, of the specimen which supplied figure D, was two-fifths of an inch.

Locality.—Nine specimens, including males and females, were obtained at Kerguelen, some, probably all, from Station 149H; off Cumberland Bay; Jan. 29, 1874; depth, 127 fathoms; bottom, volcanic mud.

Remarks.—The specific name is given in honour of the founder of the genus *Platophium*. The description refers to the male, except where the contrary is expressly stated. This species bears a strong resemblance to the Australian species which Mr. Haswell at first named *Cyrtophium dentatum*, and afterwards *Dexiocerella dentata*. He has very kindly sent me specimens. There are not the same number of dorsal teeth in the Australian as in the Kerguelen species.

Platophium cheloniæ, n. sp. (Pl. CXXX.).

The lateral lobes of the head small, rounded ; the back rounded, dorsally broad at the middle of the pereon ; the postero-lateral angles of the first three pleon-segments rounded ; the fourth segment longer than any of the other segments, distinct from the fifth, and much longer than the fifth and sixth united ; the pleon not quite so strongly flexed as in *Platophium danæ*. The skin having in many parts dark stellate markings or round spots, sometimes crowded together, sometimes few and far between.

The Eyes round, near the lateral lobes.

Upper Antennæ.—The first joint much thicker than those which follow, not much longer than broad, with some slender feathered spines on the lower margin ; the second joint scarcely once and a half as long as the first, with three groups of spinules on the upper margin, six or seven of feathered spines on the lower, many of them long ; the third joint thinner and a little shorter, similarly equipped ; the flagellum stout like the peduncle, of four joints, together scarcely longer than the second of the peduncle, the first not quite so long as the next two united, all carrying feathered spines, spinules, and cylinders.

Lower Antennæ not elongate, longer than the upper. The first two joints broader than long, the gland-cone scarcely produced ; the third joint subequal to the first two united, with a lateral distal lobe, and groups of spines upon this and on the lower margin ; the fourth joint stout, longer than the preceding three united, widening distally, with feathered spines at six or seven points of the lower margin, and several groups of spines upon the surface and at the distal lobes ; the fifth joint rather longer, similarly armed, but with the marginal spines shorter and fewer ; the flagellum of three joints, the first longer than the second and third united, the three together not so long as the fourth joint of the peduncle, all tipped with strong curved spines as well as slender spines and spinules.

Upper Lip.—The outer plate with its distal margin rather deeply incised so as to form two somewhat narrow finely furred lobes, one slightly in advance of the other.

Mandibles.—The cutting edge divided into six teeth ; the secondary plate with four small sharp teeth on the left mandible, and with a denticulate edge rather than teeth on the right, this plate being as usual slighter on the right than on the left mandible,

but in this species not stout on either ; the spine-row consists on the left mandible of three, on the right of two, short, moderately broad spines tapering distally and much denticulated; the molar tubercle moderately prominent, with a very small laminar process on the edge; the first joint of the palp a little longer than broad, widening distally ; the second joint wider than the first at the base and widening distally, about twice as long as broad, with about eighteen feathered spines on the surface near the front margin ; the third joint wider and a little longer than the first, but narrower than the second, not twice as long as broad, with about sixteen long feathered or pectinate spines round the distal margin, a row of four on the surface below the apex near the outer margin, and another row of two or three below these.

Lower Lip.—The principal lobes distally rounded, scarcely broader than the distal part of the inner lobes ; the mandibular processes produced to a narrow but not acute point, with the inner margins tending to concave, the outer a little convex.

First Maxillæ.—The inner plate if rightly observed is small, with a small seta or two at the apex ; the outer plate not elongate, narrowing from the middle to the trunecate distal margin, which carries nine spines, some with one lateral denticle, some with two, none, I think, with more ; the first joint of the palp very short, the second reaching beyond the outer plate, narrower at the two ends than in the middle, the distal margin dentate, carrying four spine-teeth with little denticles on the middle of their outer edge ; there are five slender spines close to the upper part of the inner margin, two submarginal to the apical border.

Second Maxillæ.—The inner plate a little shorter and a good deal narrower than the outer, the inner margin smooth till near the apex, then serrate and furnished with plumose setæ ; the apex narrow, fringed with spines, some of which also are arranged alongside of the setæ ; the broader apex of the outer plate in like manner carrying numerous long spines, crowded on the inner part, spaced on the outer slope.

Maxillipeds rather short. The inner plates narrow, reaching beyond the first joint of the palp, the inner distal angle occupied by feathered setæ, with a bent spine-tooth just below the apex, the distal margin a little sinuous, with three (or two) spine-teeth and several slender feathered spines ; the outer plates reaching beyond the middle of the second joint of the palp, with twelve spine-teeth along the inner margin, a thirteenth on the distal margin, followed by three setiform spines ; the first joint of the palp very short, with some spines on the inner apex ; the second joint about twice as long as the first, with the slender spines on the inner margin not very numerous ; the third joint as long as the first, widening distally, with long feathered spines about the distal half ; the finger not as long as the third joint, unless the pectinate ungual spine be included : this spine is attended by others inserted near it on the inner apical margin of the finger, one of the three spines being similar to the nail, and nearly as long.

First Gnathopods.—Side-plates wider below than above, the front margin nearly

straight, directed obliquely forwards, joining the straight lower margin by a narrowly rounded corner, the depth less than the greatest breadth. The first joint nearly free from the side-plate, narrow at the neck, almost unarmed; the second joint short, with a spinule at the front lobe, and some slender spines on the apex behind; the third joint a little longer than the second, wider above than below, with a group of spines near the middle of the front margin, and several spines round and near the curve which joins the convex hinder with the sinuous distal margin; the wrist about as long and as broad as the hand, narrowest at the two ends, the front margin convex, with three small groups of spines near it, the hind margin fringed with many feathered spines, of which the surface has various groups; the hand broad-oval, with six or seven groups of rather long spines along the convex front margin, which is almost continuous with that of the wrist; the hind margin, most of which may be regarded as a palm, is fringed with many feathered spines, and there are various groups of spines on the inner surface; the finger is short, curved, and broad, a good deal stouter than the hand, with a small dorsal cilium near the base, the inner margin having a sharp decurrent tooth beyond the middle, and a longer one at the base of the sharp nail.

Second Gnathopods.—The side-plates small, broader than deep, with a spinule at the front corner of the lower margin. Branchial vesicles oval, much larger than the side-plates, as long as the first joint, and much broader. The first joint nearly free from the side-plate, rather larger than in the first gnathopods, about as long as the hand, with four spines on the convex hind margin; the second joint with two or three spines at the apex behind; the third joint with convex front and hind margins, the latter carrying at the rounded apex a group of three or four spines, above which are two other groups; the wrist shorter than the third joint which completely overlaps it behind, a little wider than long, distally eup-like, but with the distal margin convex, with a few spines round the apical part before and behind; the hand large, broad oval, much wider than the wrist from the very base, with spines singly or in groups at six or seven points round the front margin, at several points along the inner surface, at a little distance from and others near the hind margin, which has three or four groups on the proximal part, and is then distinguished from the palm by a minute tooth or notch, near to which are planted two palmar spines; the palm itself, which forms more than half the convex hind margin, has no spines actually on the rim, though many submarginal; the finger is broad, as long as the palm, with a small decurrent tooth on the inner margin at the base of the nail; and five minute spine-teeth at intervals of the otherwise smooth inner margin, with a few submarginal setules.

First Peraopods.—Side-plates and the branchial vesicles as in the preceding segment. The first joint almost free from the side-plate, narrow at the neck, then expanding on both sides, the hind margin having spines at two or three points of the upper half, and at the apex, the front margin convex, forming a winged expansion, fringed with six or seven

spines, the inner surfacee with a distinct front margin almost parallel with the hinder, and therefore to some extent concave; the second joint with one or two little spines on the front lobe; the third joint widened distally, as long as the fourth and rather wider, with very slight spines at two points of the straight hind margin, and stronger spines at three or four points of the convex front; the fourth joint shorter than the fifth, with three groups of spines on the convex front, three on the straight hinder margin, and some spinules on the hinder slope of the distal margin; the fifth joint with four groups of spines on each margin; the finger more than half the length of the fifth joint, broad at the base, much curved, distally acute.

Second Peræopods similar to the first, but with the first joint rather shorter and broader, and having spines at five points on the hind margin of the fifth joint.

Third Peræopods.—The side-plates less deep than the preceding pair. The branchial vesicles similar to the preceding pair, and like them directed forwards. The limb resembling in form the two preceding pairs of peræopods, but with the third, fourth, and fifth joints longer. The first not longer than in the preceding pair, with a few small spines within the margin at the upper part in front, four spines on the hind margin of the wing, one near the apex of the inner hind margin; the second joint with two or three small spines on the hind lobe; the third joint widening distally, not quite so long as the fourth, with small spines at three points of the front margin, and five points of the convex hind margin; the fourth joint shorter than the fifth, with spines at three points in front and four behind; the fifth joint with four groups in front and five behind; the finger not half the length of the fifth joint, broad at the base, distally strongly curved and acute, with two slender setules near the base of the nail, and another a little further off.

Fourth Peræopods.—The side-plates smaller than the preceding pair, very shallow. The limb like the preceding pair, but with all the joints longer, and the spines stronger; the first joint with its hind margin less convex and with only two spines.

Fifth Peræopods similar to the fourth but longer; the first joint narrowed below.

Pleopods.—Instead of the usual pair of coupling spines on each peduncle, there is here a row of nine, each with an apical pair of hooks, and a second rather larger pair just below it; whether any of the spines on the inner margin of the first joint of the inner ramus are cleft, I have not been able to determine; the interlocking apparatus of the coupling spines is so strong that the assistance of cleft spines may be unnecessary; the joints of the rami number from thirteen to fifteen. In *Cyrtophium minutum*, Haswell, I find a row of six coupling spines.

Uropods.—The first pair reach beyond the second; the peduncles equal in length to the inner ramus, which is considerably longer than the outer; the peduncles and rami have many lateral spines, and the blunt apices of the rami have each a group in which one of the spines is long; the peduncles of the second pair shorter than the inner, a little longer than the outer, ramus; the rami armed as in the first pair; the third

uropods having only an oval plate not so long as the telson, but reaching a little beyond it, with some spinules on the border.

The Telson rather broader than long, very much rounded, with a broad laminar projection on the upper surface beyond the centre, not reaching the distal margin, carrying two spines.

Length.—The specimen, in the position figured, measured, in a straight line from the front of the head to the back of the third pleon-segment, a little over one-fifth of an inch.

Locality.—The single specimen, perhaps not adult, was labelled as obtained from *Chelonia imbricata*, Atlantic.

Remarks.—The specific name is taken from the animal on which the specimen was found lodging.

This species differs from *Platophium danæ* in having the palps of the mandibles and the maxillipeds less elongate, as well as in other points of more obviously specific value, but the general character of the mouth-organs and antennæ, together with the agreement in the structure of the pleon, seemed to warrant its being placed in the same genus.

Platophium inconspicuum, n. sp. (Pl. CXXXI.).

Rostrum inconspicuous; the outer corners of the front of the head rounded; back of the animal broad at the centre of the pereon; pleon closely flexed; first three segments of the pleon with the postero-lateral angles rounded; the fourth segment of the pleon longer than any other segment, very much longer than the fifth and sixth segments united; dark pigment-flakes retaining their colour in the spirit-preserved specimen.

Eyes broad oval, comparatively large, with numerous short ocelli.

Upper Antennæ.—First joint rather thick, shorter than the head, carrying a few slight spines. The remaining joints broken off.

Lower Antennæ.—First joint a little expanded, the first and second joints short, the gland-cone small; the third joint thick, little longer than broad, with a few slender spines; the other joints missing.

Upper Lip unsymmetrically bilobed.

Mandibles.—The cutting edge narrow, sharply toothed with five or six teeth; the secondary plate with four or five teeth which are thin and sharp; the spine-row with two rather broad dentieulate spines; the molar tubercle broad, with strongly dentate crown, and a small laminar distally denticulate process on the edge of it; the first joint of the palp much longer than broad, narrow at the base, widening distally; the second joint about twice as long as the first, with three or four spines on and near the front

margin, and an oblique row of four long ones on the surface near the apex ; the third joint intermediate in length between the first and second, widening distally, with seven pairs of long pectinate spines round the apical border, three spines a little below the apex near the outer margin, and another set below these.

Lower Lip.—The principal lobes rather narrowly, the inner lobes rather broadly, rounded distally.

First Maxillæ.—Inner plate not observed ; outer plate with nine spines, none of them stout or with strong lateral denticles ; two of the outermost appear to have three small lateral denticles, and three of the shorter spines show each a single denticle on the outer side ; the first joint of the palp short, the second reaching beyond the outer plate, widening distally, on the dentate apical margin having four slender denticulate spine-teeth, and a more slender spine (perhaps belonging to this series) at the top of the inner margin ; there are three or four other slender spines on the surface.

Second Maxillæ resembling those of *Platophium cheloniæ*.

Maxillipeds.—Inner plates broad, about reaching the distal end of the palp's first joint, in armature nearly as in *Platophium cheloniæ* ; the outer plates reaching beyond the middle of the palp's second joint, with four distant spine-teeth on the crenate distal part of the inner margin, and four or five other spines, forming the usual gradation, round the serrate distal margin ; the palp nearly as in the species just mentioned, but the basal part of the finger very short, only a little longer than broad, and carrying at the apex a pectinate spine much more than twice as long as itself, besides a group of shorter spines, which are also longer than itself.

First Gnathopods.—The side-plates broader below than above, produced below towards the front of the head in a narrow rounded point which carries a setule in a notch. The first joint nearly free from the side-plates, very little longer than the wrist, widening distally, the margins almost unarmed, except apically ; the second joint short, with a group of long slender spines near the apex behind ; the third joint scarcely longer than the second, the front and hind margins convex, the inner surface carrying some groups of long spines and the hinder margin likewise ; the wrist a little longer and narrower than the hand, narrowing distally, the front margin with spines at the apex and one or two above it, the hind margin fringed with many long spines planted on or near it, the surface also carrying some more remote from the margin ; the hand widening distally, the front margin convex, with some strong spines at various points on and near it, the surface also carrying spines at different points, the hind margin very slightly convex, smooth till near the palm, then having a long spine followed by a short one, and at the apex a palmar spine, which is succeeded by two or three others ; the palm forming an obtuse angle with the hind margin is convex, pectinate, bordered with many submarginal spines, long and short, and has close to the hinge of the finger an appearance of a laminar process or broad tooth (not figured) ; the finger is short and broad, not reaching beyond the palm,

with a row of eight setules of different lengths set close together near the base of the sharp curved nail.

Second Gnathopods.—The side-plates broader than deep. The branchial vesicles more or less oval, not very large. The marsupial plates of great size, much longer and very much broader than the first joint of the limb, narrowing distally, surrounded by setæ not so long as the breadth of the plate. The first joint larger than in the first gnathopods, but not so long as the hand, widening distally, with a few small spines on each margin; the second joint as in the first pair; the third joint a little longer than the second, with spines at two or three points of the hind margin and a group at its apex including two short spines, the distal margin straight; the wrist very small, scarcely as long as the third joint, which overlaps it, broader than long, with a long spine on the narrow hinder apex; the hand large, abruptly wider than the wrist, distally narrowing, with spines at four points of the convex front margin, the hind margin very short, carrying two slender spines and forming an apical tooth beyond this. The very oblique, slightly convex, deeply toothed or serrate palmar margin completes the distance required to match the long front margin; the serrations are occupied by a series of seven or eight strong palmar spines, other slender spines projecting from the surface; the finger is broad, of a length to match the long palm, the outer margin greatly curved, and having five or six submarginal setules; the inner margin is nearly straight till the narrow, acute, and inward curving nail is reached; at the base of this there are three or four setules close together, others being dispersed along the margin, and some extremely small triangular spine-teeth at intervals.

The Peraopods were unfortunately all missing. The second pair of marsupial plates were similar to the first, but more regularly oval. None of the branchial vesicles were very large.

Pleopods.—The coupling spines two in number, each having two pairs of retroverted hooks; there were no *discernibly* cleft spines; the joints were seven in number in each ramus, the terminal joint being unusually stout.

Uropods.—The first pair reaching back much beyond the second, the peduncles as long as the outer, shorter than the inner ramus, with four spines on the outer margin, and a large spine on the lower apex; the outer ramus with three or four marginal spines, and an apical group of four, of which one is very long; the inner ramus with seven spines along its slightly peeltinate inner margin, three or four on the outer, and the apical group; the peduncles of the second pair very short, as long as the outer ramus, which has one submarginal spine and the apical group of four, including as in the other cases one very long one; the inner ramus is a little longer, with two spines on the outer margin, three on the inner, and the apical group; each of the third uropods is represented by a small inward-bent oval plate, shorter than the telson and not nearly reaching the end of it; these plates are covered by the telson except for a small strip of the outer margin;

they have a spinule on the inner side of the distal end. In the figure *ur.2.*, the line is incomplete which should have separated the inner ramus from the peduncle.

The Telson seems to be rather longer than broad, much rounded distally, with two spines on the surface at about the centre; whether these are planted on a raised process as in the companion species, I could not definitely ascertain.

Length.—The specimen measured, in a straight line from the front of the head to the back of the second pleon-segment, one-fifth of an inch.

Locality.—The single incomplete specimen, a female, was labelled as obtained at Port Jackson, 2 to 10 fathoms.

Remarks.—The specific name refers to the small size of the creature, and its want of conspicuous armature.

It is separated by the structure of the gnathopods from the species which Mr. Haswell has named *Dexiocerella lobata* and *Dexiocerella lavis*. These are only partially figured in Mr. Haswell's paper, and I have not seen specimens.

Genus *Læmatophilus*, Bruzelius, 1859.

- 1886. " (pars), Norman, Museum Normanianum, pt. iii. Crustacea, p. 17.

For the original definition of the genus, see Note on Bruzelius, 1859 (p. 312). Boeck gives the following definition:—

“ Sixth and seventh segments of the peræon coalesced.¹

“ *Upper Antennæ* attached to the great frontal process; flagellum not many-jointed; accessory flagellum wanting.

“ *Lower Antennæ* equal to the *Upper* in thickness and length.

“ *First and Second Gnathopods* with subeheliform hands; the *Second* pair the larger.

“ *First and Second Peræopods* alike in shape, very strong; the third joint very short, the fourth and fifth elongate.

“ The last three pairs of *Peræopods* alike in shape; the *Fourth* longer than the *Third*, the *Fifth* than the *Fourth*.

“ The *First Uropods* biramous; the outer ramus shorter than the inner.

“ The *Last Uropods* tubercular in form.”

¹ This is not the case in the species now to be described.

Lætmatophilus purus, n. sp. (Pl. CXXXII.).

The front of the head somewhat produced, with a small pointed process in advance of the eyes on each side; the lower part emarginate for the insertion of the lower antennæ to the rear of the upper; the head with a small dorsal depression to the rear; the first five segments of the pereon each with a dorsal depression, giving the back a corrugated appearance; the third segment has a small ventral process at about the middle, and the second segment is a little produced ventrally, but not into a definite process; the fourth segment of the pleon is a little longer than any of the preceding segments, narrow, cylindric; the following segment is very short. None of the side-plates are deep; the branchial vesicles on the second to the sixth pereon-segments are strongly bent forward, the pair attached to the second gnathopods being much smaller than the following pairs.

Eyes round, prominent on special lobes; retaining a dark colour in the specimen mounted in Canada balsam; the outer ring of ocelli contained thirty.

Upper Antennæ.—The first joint shorter than the head; the second thinner but much longer, the under margin fringed with long setiform spines; the third joint a little shorter and thinner, similarly furnished; the flagellum of three joints, together not quite so long as the third joint of the peduncle, similarly armed, the first joint much longer than the other two united, the second twice as long as the third.

Lower Antennæ stouter and much longer than the upper; the first two joints short, the gland-zone small; the third joint not long, rather thick; the fourth joint thinner than the preceding, as long as the second joint of the upper antennæ, with slender spines on the lower margin, some shorter and stronger spines on the upper, and some lateral groups; the fifth joint considerably longer than the fourth, with many spines on the lower margin; the flagellum practically of one thick joint, narrowing only near the apex, a little more than half the length of the fifth joint of the peduncle, with short spines of various thicknesses distributed about it, including two curved ones on the apex; the apex under a high power appearing to consist of two minute joints scarcely distinct from the large one.

Upper Lip.—The distal margin is here, if I am not mistaken, rather deeply but not broadly emarginate; but in *Lætmatophilus tuberculatus* Boeck says that the upper lip is distally rounded (paa Enden afrundet).

Mandibles not well observed; molar tubercle prominent, palp nearly as in *Platophium danæ*.

Lower Lip.—Principal lobes broad, the convex distal and sinuous inner margins meeting in a small projecting lobe; the mandibular processes rather long, divergent, apically narrowed.

First Maxillæ.—Inner plate inconspicuous; outer plate apparently with nine spines

on the distal margin, the lateral denticles of the spines few and not prominent; the first joint of the palp short, the second joint long, with six rather long spine-teeth, the outermost longest, on the distal margin, and two or three slender spines at the inner corner; some longer setiform spines on the surface.

Second Maxillæ.—The inner plate shorter than the outer.

Maxillipeds.—The inner plates reaching about to the apex of the first joint of the palp, with feathered setæ on the inner margin, and on the broad distal margin some feathered spines and two short spine-teeth which are set wide apart; the outer plates broad, reaching beyond the middle of the second joint of the palp, having on the inner margin several spine-teeth not set very closely together, and followed on the apical margin by some longer curved spines; the first joint of the palp short, the second twice as long, not very strongly armed, the third a little longer than the first, extended over the base of the very short and small conical finger, the truncate tip of which carries some spines which are longer than the body of the finger.

First Gnathopods.—The first joint almost free from the side-plates, as is usual with all the limbs of the peræon in this genus; equal in length to the wrist or the hand, but narrower than either, narrowest at the neck, the margins almost entirely unarmed. The second joint longer than broad, with a few setiform spines on the lower part of the hind margin, and a group of three spines on the surface near the upper part of the front margin; the third joint broader than the second but not longer, tending to diamond-shaped, the convex hinder margin fringed with long peetinate spines, the surface having two groups; the wrist subequal in length to the hand, with two or three groups of long spines on the surface near the long front margin, and a few other groups elsewhere on the surface; the convex, gently crenate hind margin fringed with long feathered spines, twenty or more; the width of the wrist is greatest where it becomes free from the third joint, and lessens very gradually till quite at the distal end; the hand, starting from a narrow neck, widens immediately to its greatest breadth, and thence narrows gradually till at the distal end it is as narrow as at the base; there are several groups of long spines on and adjacent to the convex front margin, and on various parts of the surface, especially near the apex; at the greatest breadth, and therefore not far from the base, the long, crenate, slightly convex palm margin begins, and is bordered with a great number of long feathered spines, but also it is ornamented and armed by a row of ten palmar spines with serrate edges, set close together, not on the margin, but so far within the surface that the tips of most of them project beyond it; the long and strong finger matches this margin and has the distal half of its inner margin set with about a dozen slightly decurrent spine-teeth, its tip being formed by a small curved nail; the outer margin is convex.

Second Gnathopods much larger than the first. The first joint narrow at the neck, then widening so as to be much broader though it is not longer than the first joint in

the preceding pair; the hind margin convex at the upper part, then straight, carrying a setule here and there; the front margin double, nearly straight till the apex, which is produced on each border forwards rather than downwards in a pointed process; the second joint short, not longer than broad; the third joint rather longer than the second, the front and hind margins convex, the lower narrow, concave, the hinder with some small groups of spines, and a sharply pointed apex; the wrist diminutive, not so long as the third joint and not broader than long; the hand much longer than the four preceding joints united, and more than twice as broad as the first joint; it widens at once on both sides of the wrist, and has a convex front margin, on and near to which there are several groups of tolerably stout spines; the front margin is almost straight, till near the apex, when it forms a narrow, blunt process or tooth and immediately beyond this a broad process, sharp at one end, but flattened towards the hinge of the finger; the surface near the hind margin is set with many groups of slender spines, and the hind margin with its processes is fringed in like manner; the very long and strong finger presses in closing against the acute points of the processes, and then, leaving a small interval between its smooth inner margin and the margin of the hand, rests its apical part against the side of the hand, not far from the base; there is no appearance of a nail; the greatest width of the hand is nearly at the level which the tip of the finger reaches, and is not equal to half the length.

The First and Second Peraopods were missing.

The Third, Fourth, and Fifth Peraopods were scarcely distinguishable from one another. The first joint a little longer than the third, but much shorter than the fourth or fifth, the front margin a little convex, carrying here and there a spinule, the hind margin having a little lobe near the top, the lower part nearly straight, carrying one or two strong spines, and apically acute; the second joint as long as broad; the third widening distally, the front straight, with one or two setules, the hind margin having a few strong spines near the middle, and a large group on the blunt decurrent apex; the fourth joint long, widening distally, the front margin straight, with a few setules, the hind margin serrate, with groups of spines at three or four points; the fifth joint still longer, of almost even width throughout, the front margin almost unarmed, the hinder with spines at four points, these spines being less stout than those of the preceding joints; the finger strong, not half the length of the fifth joint, distally very much curved, with a short sharp nail, the dorsal cilium short, close to the hinge.

Pleopods.—The peduncles shorter than the rami; the coupling spines in the first pair were seven in a row, and six or seven in the other pairs, short, with a single pair of retroverted hooks at the apex; the joints of the rami number from eleven to thirteen, the first joint in each ramus being long and slender, except that the upper part on the inner ramus was dilated on the outer side. I could not detect any cleft spines.

Uropods.—The peduncles of the first pair as long as the outer ramus, a little dilated

distally, with five spines on the outer margin and one or two on the inner; the outer ramus with five spines on the outer margin, one or two on the inner, and an apical group, including one spine much larger than the others; the inner ramus broader and very much longer than the outer, with seven spines on each margin, not in pairs, and an apical group of five including one long one; the terminal uropods consist of a pair of narrow oval plates, which reach beyond the telson when extended, but not nearly to the end of the peduncles of the first pair; when directed, in what seems to be their natural position, so that their apices touch, they are almost completely covered by the telson; on the inner side there seems to be a slight constriction before the apex is reached, and a little way above this a small spinule finds its place.

The Telson seems to be almost circular, with a very thin distal edge.

Length.—The specimen, in the position figured, measured, from the front of the head to the extremity of the uropods, just upon a quarter of an inch.

Locality.—The single specimen, no doubt a male, was mounted in Canada balsam during the voyage, and labelled “*Caprella purus*, on Brissops lyrif. 18 Dec. 73.” The date corresponds with Station 142, lat. $35^{\circ} 4'$ S., long. $18^{\circ} 37'$ E.

Remarks.—The specific name adopted is that which was found on the label, and which perhaps referred to the transparency of the specimen.

The species evidently bears a strong resemblance to *Lætmatophilus tuberculatus*, Bruzelius, but in that species the upper and lower antennæ are described and figured as nearly equal, and the hand of the first gnathopods is said to be shorter but broader than the wrist, statements which do not suit the present species, in which moreover the peræopods and branchiæ differ from those figured for the other species.

Family ICILIDÆ, Dana, 1849.

In 1849 Dana established the Iciliidæ as fourth family of the subtribe Gammaracea, placing in it the genera *Icilius*, Dana, and *Pterygocera*, Latreille; in 1852, in the preliminary account of his own collections, he upholds the family with the genus *Icilius* containing the single species *Icilius ovalis*. For his definition of the family, see Note on Dana, 1852 (p. 255). In the same year Dana relinquished the family and made the Icilinæ the third subfamily of the family Corophidæ, with the genera *Icilius* and *Pterygocera*, *Icilius ovalis* being now named *Icilius ellipticus*. For his definition of the group as a subfamily, see Note on Dana, 1852 (p. 257). After a long interval of neglect the title was revived in 1886 by Gerstaecker, who in his “Divisio II., Gammarina,” “Tribus I. Corophiina,” places “Fam. 4. Icilinæ, Dana,” containing the genera “*Icilius* Dana,” “*Iridium* Grube (*Pereionotus* Sp. Bate),” “*Phlias* Guér.”

For this group Gerstaecker gives the following definition :—“ Body broad, depressed, head transverse, widened forwards, the eyes projecting laterally beyond the outline of the head, the upper antennæ without accessory flagellum. The two front pairs of limbs [first and second gnathopods] not differing in character (nicht formell abweichend) from those which follow [the peræopods], with the penultimate joint narrow and the terminal small, unguiform.” Upon this it must be remarked that both in *Icilius australis*, Haswell, and in the new species, *Icilius danæ*, there is a small accessory flagellum to the upper antennæ ; in *Pereionotus*, Bate and Westwood say that “ the hands of the first two pairs [of legs] are subchelate,” and so they are in the new genus *Chosroës*, while in at least one species of *Icilius* the third joint in the gnathopods is as usual distinguished from the third joint in the peræopods by its different position in relation to the fourth joint. The strongly developed third uropods in *Chosroës* distinguish it strikingly from the other genera. In *Icilius* and *Chosroës* the upper antennæ are much shorter than the lower, while in *Iceridium*, *Pereionotus*, and *Phlias* the upper are the longer. In *Icilius* and *Chosroës* the mandibles have a well-developed three-jointed palp, while in *Iceridium*, Grube states that the mandibular palp must be either closely concealed or absent. For *Iceridium* also, Grube, whether rightly or wrongly, denies the existence of a telson. On the mouth-organs of *Phlias* and *Percionotus* nothing, I think, has yet been published. Under these circumstances I provisionally accept the family Iciliidae for the two genera which have come under my own notice, both of which have the body broad and depressed ; the eyes lateral, prominent ; the mandibles with dentate cutting edge and secondary plate, strong molar tubercle, and three-jointed palp ; the upper antennæ much shorter than the lower ; the telson not cleft.

Genus *Icilius*, Dana, 1849.

- 1886. , Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 497.

For the original definitions of the genus, see Notes on Dana, 1849 (p. 229) and 1852 (p. 257). At page 844 of his great work Dana gives a third definition of the genus as follows :—

“ Body much compressed. Antennæ elongate, and having long flagella ; the inferior pair longest. Feet not prehensile, all vergiform and unguiculate. Caudal styles six, fureate.” In the specific description he explains that “ the branches of the last pair [of

stylets or uropods] are quite unequal," a character which, in view of *Chosroës*, might be included in the definition of the genus. In the expression "body much compressed" he is evidently not referring to lateral compression, but to that between the dorsal and ventral aspects of the animal, for which the more usual phrase would now be—body much depressed.

Icilius danæ, n. sp. (Pl. CXXXIII.).

Head and pereon not compressed laterally, rostrum small, the pereon widest at the fourth and fifth segments; the seventh segment dorsally produced backwards in a central tooth or angular process; the first and second segments of the pleon produced in like manner, the fourth segment of the pleon much longer than the fifth and sixth united, but from the doubling over it of the third segment its length is not perceived until it is separated from the third segment; the first three segments have the lower margins convex, the hinder sinuous, the postero-lateral angles acute; the sixth segment broader distally than at the base, a little upturned. The skin in many parts covered with rows of little denticulate scales (see fig. gn.1).

The Eyes set on the sides of the head are prominent, almost spherical, the ocelli of which they are composed being long, narrow, and very numerous.

Upper Antennæ.—The first joint not so long as the head, a little longer and thicker than the second joint, the third thinner and much shorter than the second; all three carrying several groups of slender spines; of the flagellum there are fourteen unequal joints remaining, the first the longest, some, perhaps all, having long apical spines, and being a little dilated distally at the insertion of the slightly feathered spines; the secondary flagellum has a single slender joint, not so long as the first of the primary, but it appears to have one or more joints missing.

Lower Antennæ.—The first and second joints short, the gland-eone narrow and small, not extending along the third joint; the third joint scarcely so long as the united first and second, carrying spines in pairs at two or three points; the fourth joint about three times as long as the third, with several groups of spines; the fifth joint more than once and a half as long as the fourth, with numerous groups of spines along the lower margin and along the side; of the flagellum there are thirty-eight joints remaining, those at the distal end very long and narrow, the whole number together much longer than the long peduncle.

Upper Lip.—There is a shallow emargination in or near the centre of the distal margin, the middle of which is smooth, but has on either side a fur of close-set short cilia directed towards it, the more remote cilia being longer and not closely set.

Mandibles.—The cutting edge with six teeth; the secondary plate with four, this plate forming a thin lamina with very sharp teeth on the right mandible, while on the

left it resembles the principal plate in general structure ; the spine-row of nine denticulate spines ; the molar tubercle prominent, with a strong circlet of teeth round the crown, the outside of which is strongly ciliated ; a round-headed process rises not far from the base of the palp ; the first joint of the long palp longer than broad, with convex outer margin, the second joint long, strongly fringed with numerous pectinate spines on both margins, the groups being planted chiefly on the outer surface ; the third joint long, curved, shorter than the second joint, fringed for almost the whole length of both margins and at the narrow apex with groups of spines, the concave inner margin having a close row of short spines, besides the less closely set long ones.

Lower Lip.—The principal lobes distally broadly rounded and loosely ciliated ; at the junetion with the inner margin there are two minute spines, making a kind of apex ; lower down on the inner margin are two more ; the inner margin is not strongly ciliated, except at the basal part, where the crowded cilia become almost spine-like ; the inner lobes are distally broadly rounded and closely furred ; the mandibular proeesses moderately prominent, a little divergent, the apex rounded.

First Maxillæ.—The inner plate narrowing to the rounded apex on which there are four plumose setæ, one smaller than the other three ; the broad outer plate has on the slightly convex distal margin eleven spines, of which seven are rather long and slender, with two or three lateral denticles on the inner side, the innermost spine having two or three little denticles also on the outer side ; the other four spines are shorter, with a fureate appearance, the apex bending inwards and having on the outer side two unequal lateral teeth ; the first joint of the palp is short, the second is long and broad, reaching beyond the outer plates, broader distally than at the base, with a series of twenty or more spines passing round the broad distal margin and some little way down the inner, those on the inner margin being slender, the others being spine-teeth ; submarginal to these are about fifteen slender spines ; eight or nine slender spines fringe the eonvex outer margin, the surface carrying six or seven more.

Second Maxillæ.—The plates broad ; the inner shorter than the outer, nearly as broad, with plumose setæ along most of the straight inner margin, and some on the surface near the apex, which is broadly rounded, fringed with short spines which stop short of the outer slope ; the outer plate is wider distally than at the base, the spines beginning below the middle of the inner margin, one series passing round within the broad rounded distal margin, another passing round the margin, some of the spines being very long, though a few at the outer extremity are comparatively short.

Maxillipeds.—The inner plates broad, not reaching beyond the first joint of the palp, the inner surface having a triangular spaee covered with spines, the distal margin broad and flat, carrying three spine-teeth and many slender spines ; the outer plates not nearly reaching the end of the second joint of the palp, the inner margin carrying about a dozen slender spine-teeth, and the apical margin half-a-dozen ; there are besides

many longer spines planted submarginally in groups or singly; the apical margin forms an obtuse angle with the inner; the convex outer margin is quite smooth; the first joint of the palp is broad, with two or three groups of spines near the rounded outer apex; the second joint is not quite twice as long as the first, very broad, with three groups of spines adjacent to the outer margin, the convex inner margin crowded with long spines till near the apex, and at this part the rows of spines are set on the inner surface a little way from the margin, beyond which they greatly project; the third joint rather longer than the first, widening from the base, with the distal half on the front margin and over the inner surface, especially at the apex, set thickly with long spines; the finger slender, tapering, little curved, subequal in length to the third joint, a small spine-like nail forming the acute tip; the dorsal cilium at a little distance from the base.

The *triturating organs* of the stomach show on one side a row of short stout acute spines, within which is a longer row of about twenty-five longer spines, stout, apically denticulate, in a semicircle, the opposite side of the semicircle (or oval) occupied as usual by numerous slender spines, and some of this character rise from the intermediate surface.

First Gnathopods.—The side-plates small. The first joint almost entirely free from the side-plate, shorter than the wrist or hand, with a long spine near the centre of the hind margin; the second joint short, with a large group of long spines at the apex of the hind margin; the third joint rather longer, with several groups of spines along the serrate hind margin and the oblique distal margin, which has an acute apex in front; the wrist longer and broader than the elongate hand, narrowing a little distally, with six or seven groups of small spines near the smooth, slightly convex front margin; the hind margin tending to concave, set all along with groups of spines, about fourteen groups or pairs of groups, the spines of different lengths in each group, some near the apex of the joint of very great length, finely pectinate; the hand long and narrow, curved, with ten groups of spines on the concave serrate hind margin, the spines varying in length, many of great length and pectinate; the convex front margin has some spines near the apex, and at the apex a group of very long and strong spines, strongly pectinate; the finger is slender, half the length of the wrist, as long as the apical spines of the hand, curved towards the apex, with setules at five or six points of the inner margin, a group near the base of the nail, a dorsal cilium near the hinge, and also three or four setules along the front margin.

Second Gnathopods.—The side-plates rather larger than the preceding pair. The branchial vesicles a little longer and considerably broader than the first joint, much longer than broad. Marsupial plates much longer and broader than the branchial vesicles, and like them with one margin nearly straight, the other convex, the end rounded; there are long setæ all round, but none equalling the greatest breadth of the

plate. The limb closely resembles that of the first gnathopods, but the joints are rather longer and broader, and the spines on the hand are stronger and more numerous.

First Peræopods.—The side-plates broader than the preceding pair, the hind margin ending in a slightly produced point. The branchial vesicles about as long and broad as the first joint. The marsupial plates more than twice as long as the branchial vesicles, with a breadth more than half the length, the longest of the surrounding setæ scarcely equal to half the breadth. The first joint almost free from the side-plate, the front margin a little sinuous, with some spines near the apex, a second margin in front forming a lobe at the lower part of the joint, on the lower rim of which there are spines; the hind margin has three or four groups of spines; the second joint is short, with three spines at the apex behind; the third joint is much shorter than the fourth, widening a little distally, with spines at the apex in front, and at two points of the hind margin; the fourth joint as long as the first, shorter than the fifth, with four groups of spines on the front and three on the hind margin; the fifth joint with several groups of spines on both margins; the hind margin interrupted at a little distance above the apex, and armed with some stout spines, of which one is very prominent, fitted for the impinging of the finger; the apex itself has a stout spine and some small ones; the finger is short and stout, little more than a third the length of the fifth joint, the nail curved, acute; there are small setules along the outer margin and some submarginal to the inner border. There is no appearance of gland-cells in the limb or of any opening in the finger-tip.

Second Peræopods.—The side-plates broader than the preceding pair, with convex front margin ending in a rounded apex, the hind margin produced more deeply in a triangular apex, the lower margin between these two apices being concave. The branchial vesicles rather larger than in the preceding segment. The marsupial plates distally of immense breadth, the surrounding setæ short. The limb is broken; the three remaining joints are similar to those of the first peræopods; it can here be seen that the apex of the front margin in the third joint is emarginate.

Third Peræopods.—The side-plates broader than the preceding pair; the front lobe somewhat squared, but with a convex front and sinuous lower margin; the hind lobe tending to triangular, the combined front and lower margin carrying some spinules, the hind margin sinuous. The branchial vesicles greatly dilated, nearly as broad as long. The marsupial plates, or at any rate one of them, much narrower than the branchial vesicles, not once and a half as long. The first joint of the limb not winged, but tolerably broad, the front margin convex, with five groups of spines, the hind margin double, one smooth, and slightly concave except at the top, the other carrying two groups of spines; the second joint short; the third similar to that of the preceding peræopods, and having, as they also appear to have, a lobe behind higher up than the apex; the other joints missing.

Fourth Peræopods.—The side-plates narrower than the preceding pair, the front lobe

with several slender spines at the top of the front margin and shorter ones below and on the rounded corner, the lower margin straight; the hind lobe of about the same depth as the front, with one or two small spines; the lower margin makes almost a right angle with the hind margin. The branchial vesicles oval, about as broad as the first joint, rather shorter, the neck bent. The three first joints of the limb similar to those of the third peræopods, but with some long spines projecting from one of the hind margins, and the third joint rather longer than in the preceding pair; the other joints missing.

Fifth Peræopods.—Side-plates small, not bilobed. Branchial vesicles very small, oval, with a triangular attachment, the upper end the broader. The first joint a great deal longer and broader than the branchial vesicle, with four groups of spines on the convex front margin, winged at the back, the hind margin of the outer surface being lobed at the top, acutely pointed below and produced so as to overlap the second joint; a smaller less acute process of the oblique lower margin also a little overlaps the short second joint; the third joint is longer than in the preceding pair, and has spines at some four points of each margin, those behind being the stronger; the other joints are missing.

Pleopods.—The coupling spines small, straight, the slender shaft springing from an abruptly broader base and carrying on one margin three or four hooks in a row below the apical one, on the other about seven little teeth or serratures; the large first joint of the inner ramus has from eleven to thirteen plumose setæ along its inner margin, of which in one pair the two uppermost, in another three, in another five, are not cleft, while the following two or three become cleft spines with very unequal arms, and the remainder have flexible terminations; it is here, not as usual the shorter, but the longer arm of the cleft, which has the termination like the hand of a cloek, though the expansion is very slight; the joints of the rami are twelve to thirteen for the inner, fourteen to fifteen for the outer, which is also rather the longer ramus.

Uropods.—The peduncles of the first pair longer than the rami, with many marginal spines, and pectinate edges; the outer ramus shorter than the inner, both fringed with several spines along both margins, those on the inner the longer; both with a group of apical spines and with the edges pectinate except near the base; the second uropods like the first, their peduncles and inner ramus reaching nearly equally far, the outer ramus of the second pair rather shorter than that of the first, the peduncles not quite so long as the inner ramus; the peduncles of the third pair longer than the telson, shorter than the outer ramus, not reaching so far back as the other peduncles, the margins carrying some little spines or spinules, the inner produced much beyond the outer, with the apex rounded; the outer ramus is a little longer than the outer ramus in the other pairs, with five spines on one margin, six on the other, and one or more on the apex; the inner ramus is missing in our specimen, but the muscles of the peduncles testify to its existence.

The Telson is small, about as broad as long, the sides parallel for more than half the

length, then converging to a broadly rounded apex, with a setule on either side; each lateral margin carries a small seta and setule where the convergence begins, and there are two setæ and a setule upon the surface not far from each straight lateral margin.

Length.—The specimen, in the position figured, measured, from the front of the head to the extremity of the uropods, half an inch.

Locality.—Station 161, off Melbourne, April 1, 1874; depth, 33 fathoms; bottom, sand. One specimen, female, with the eggs in a forward state of development.

Remarks.—The specific name is given in honour of the distinguished founder of the genus *Icilius*, with a view also to call attention to the resemblance between this species and the type-species *Icilius ellipticus*. From *Icilius australis*, Haswell, this species is distinguished by the produced dorsal point of the seventh peræon-segment and the first two pleon-segments, by the length of the hand in the first peræopods, and other particulars. In regard to the third uropods, Mr. Haswell says, “Inner ramus of sixth pleopoda foliaceous, outer small, long ovate.” The figure¹ of these uropods would in some degree correspond with the third uropods of the present species, if the figure of those appendages in Pl. CXXXIII. were reversed and the outer ramus thus made the inner, with a minute outer ramus supplied; but the uropods in my figure are, I think, drawn in their natural position, and the cavity in the produced end of the peduncle suggests the attachment of something more than a minute ramus.

From Dana’s *Icilius ellipticus*, two lines long, “brought up on corallines in thirty-one fathoms” at Balabae Passage, north of Borneo, the present species differs in not having a produced point on the third pleon-segment, in having the head less produced in front and at the sides, the maxillipeds much more strongly unguiculate, if this may be judged from the fact that Dana’s figure of the maxillipeds does not show a nail at all. Dana regards the upper antennæ as “non-appendiculatæ”; but it is possible that he overlooked the small secondary flagellum, or that it was accidentally missing. He describes the second joint of the upper antennæ as “a little longer than third,” and figures it in accordance with the description; he figures the second and third joints of the mandibular palp as subequal, and gives only two setæ to the inner plate of the first maxilla. Of the uropods he says, “The three pairs of stylets are rather long, and extend back some distance. The branches of the last pair are quite unequal.” In his figure these branches are indistinct, the inner shorter than the outer, but not minute.

Genus *Chosroës*, n. gen.

Near to *Icilius*.

Upper Antennæ without secondary appendage.

The third joint of the mandibular palp longer than the second.

¹ Catalogue of the Australian Stalk- and Sessile-eyed Crustacea, pl. iv. fig. 4, 1882.

Outer plates of the *Maxillipeds* not reaching beyond the middle of the palp's second joint.

Hands of both pairs of *Gnathopods* subchelate, not linear.

The *Third Uropods* with long equal or subequal rami.

The generic name is that of an Armenian king, of whom an account may be found in Gibbon's Decline and Fall of the Roman Empire.

Chosroës incisus, n. sp. (Pls. CXXXIV., CXXXV.).

Rostrum minute; body broad-backed, especially at the centre of the peræon, thence narrowing towards the pleon, the last three segments of which are ventrally flexed; the fifth segment of the pleon shorter than the sixth.

Eyes broadly oval, with many scores of narrow ocelli; their position is close to the lower margins of the head, and very near the two lateral points where the front margin, which is concave on each side of the rostrum, joins the convex lower margins.

Upper Antennæ.—The first joint much thicker than the second, not so long as the second and third united, with a small spine on the lower apex; the second joint longer and thicker than the third; the flagellum much longer than the peduncles, with thirty-four joints remaining, the joints not long, widening a little distally, each having several small narrow caleoli, at intervals armed with groups of long and broad cylinders; the second and third joints of the peduncle likewise having caleoli, there being not fewer than a dozen round the apex of the third joint; the appearance presented by the caleoli being as if four stalked cups were planted one within the other, the basal cup smaller than the next, and the two following smaller than the basal.

Lower Antennæ.—The first two joints very short, the third also short, widening distally, the fourth longer than the third, and the fifth than the fourth, all three having a few spines and small caleoli; the flagellum stout, with twenty-four short broad joints remaining, furnished with small caleoli.

Upper Lip.—Distal margin evenly convex, as observed in the small specimen.

Mandibles.—The cutting edge angled, divided into seven teeth; the secondary plate of the left mandible divided into a row of five teeth, the plate on the right mandible smaller, appearing in profile to have two narrow teeth, but in a broadside view rather to end in two laminæ, one much wider than the other; the spine-row of five spines; the molar tubercle prominent, with long teeth round the dentate crown, cilia on the side, and a plumose seta; there is a process near the base of the palp, such as is found in so many genera; the palp very large, the first joint short, the second both broad and long, with many spines along the front margin, including five in a row near the base, of which the uppermost is the longest, and a group of about fifteen set in a curve on the distal part of the outer surface, the central the longest; there are others between these

groups, most or all being feathered ; the third joint is longer but narrower than the second, much curved, nearly the whole extent of the concave front margin being closely fringed with long and short feathered or pectinate spines, the longer ones being submarginal in origin ; there is a dense group of not very long spines on and below the narrow trunecate apex, and close to the base of the outer margin there are two on the outer surface.

Lower Lip.—The principal lobes broad, distally rounded ; the inner lobes appearing to be scarcely separated from the principal ; the mandibular processes small.

First Maxillæ.—The inner plate with two strong plumose setæ on the narrow oblique apical margin just below the pointed apex, on which, in the small specimen, one maxilla has a third seta ; the inner margin much ciliated ; the outer plate having eleven strongly dentieulate spines on the apical margin, one row of five with numerous small denticles, from four to seven in number, the other row of six rather stouter with stronger denticles, two or three in number ; the first joint of the palp a little longer than broad, the outer margin longer than the inner, the second joint reaching considerably beyond the outer plate, with very convex outer margin, the distal margin carrying seven serrate spine-teeth, the outermost the longest, and one submarginal setiform spine ; in the small specimen there are only four spine-teeth.

Second Maxillæ.—The outer plate shorter than the inner, each with numerous strongly feathered spines round the apical margin ; a few shorter spines are on the outer margin of the outer plate below the apex, and some larger plumose setæ longer than the spines on the inner margin of the inner plate.

Maxillipeds.—The inner plates not nearly reaching the distal end of the palp's first joint, with plumose setæ on the inner margin, three spine-teeth and some feathered spines on the distal margin ; the outer plates scarcely reaching the middle of the second joint of the palp, the inner margin without spine-teeth, but fringed with some eighteen pairs of slender submarginal spines ; without break in the series of spines, beyond the apex of the inner margin, the distal margin has its curve set with eight strong feathered spines ; the first joint of the palp is not especially short, and has several groups of spines on the inner margin, and a group at the apex of the outer ; the second joint is not twice as long as the first, densely fringed with spines on the inner margin, having also two groups on the inner surface, and three on the outer margin ; the third joint is narrower but nearly as long as the second, the distal half buried in successive rows of spines ; amidst those round the apex a short finger with a short sharp nail dimly appears with several spinules along its inner margin near the nail. In the fig. *mrp.*, on Pl. CXXXIV., the palps appear to have five joints, but the line which divides the outer plate from its base, though it represents an actual thickening of the joint along the line of the muscles, should have been omitted, as it is misleading.

The *triturating organs* of the stomach show an outer row of short, strong, acute,

slightly bent spines, within which is a row of longer spines, straight and strong, and apically dentieulate, the series being continued by spines that are much more slender.

First Gnathopods.—Side-plates small, directed a little forwards, with a spine on the lower margin. First joint reaching much beyond the side-plate, not much longer than the hand, the distal half wide, the front margin nearly straight, the inner surface having a few long setæ, each apex carrying some slender spines; the second joint of equal length and breadth, with one or two slender spines at the middle of the hind margin, and a long row round the apex of it; the third joint rather longer, with several groups of spines round the hind margin and across the pointed apex, and one on the convex front margin; the wrist subequal in length to the hand, but not so broad, broadest at the centre, with spines at the apex of the front margin, the hind margin closely fringed with numerous spines, the inner surface carrying two oblique rows, one composed of three or four groups passing from the hind margin to the distal; the hand oval, narrowest at the base, with six groups of spines along the serrate hind margin, the front margin with two or three groups, and the inner surface having seven or eight large groups distributed about it; the palm gently convex and slightly oblique, joining the hind margin by a gentle curve, a row of about ten palmar spines being set, some on the inner, some on the outer, surfaces at the junetion; the palm is fringed with submarginal slender spines; the finger tolerably broad, with smooth inner edge fitting evenly over the smooth edge of the palm, and not projecting beyond it; a small dorsal cilium near the base; almost all the spines that have been mentioned, except those of the palm, are finely pectinate.

Second Gnathopods.—Side-plates deeper than the preceding pair, with the lower margin evenly convex and carrying a spine at the hinder corner. (They are twisted out of their true position in the figure.) The branchial vesicles elongate, widening distally, longer than the first joint. The marsupial plates extensive, far wider and longer than the branchial vesicles, surrounded by setæ, not as long as the greatest breadth of the plate. The limb closely resembling that of the first gnathopods, but more elongate, the wrist longer than the hand, and the numerous spines of its hind margin showing in many cases a far stronger peetination.

First Peræopods.—The side-plates much broader than the preceding pair, broader below than above, with the hind margin concave, a spine on the rounded lower corner. The branchial vesicles a little longer than the first joint. The marsupial plates as in the preceding segment. The first joint reaching much below the side-plate, with the hind margin smoothly convex, carrying a few apical spines, the front margin dilated into a winged lobe near but not at the apex, with two spines at its distal end, the inner margin a little dilated at the upper part, then straight, with an apical group of spines; the second joint short, with spines at the apex behind; the third joint much shorter than the fourth, widening distally, with two small groups of spines on the hind margin, stronger spines at

two points of the front margin, and a group on its decurrent apex; the fourth joint shorter than the fifth, rather wider above than below, with small spines at three points of each margin; the fifth joint slightly curved, with small groups of spines at three points of the concave hind margin, spinules at four points of the convex front, and spines at its apex; the finger short, with a strongly feathered dorsal cilium close to the base.

Second Peraopods.—The side-plates broader than the preceding pair, the front margin very convex instead of almost straight, the long lower margin straight, the hind margin deeply excavate, the rounded lower portion carrying two spines. The marsupial plates of great breadth, with one margin almost straight, the other very convex, and the distal end somewhat truncate. The limb as in the first pair so far as observed; the fifth and sixth joints missing.

Third Peraopods.—The side-plates much broader than deep, the front and hind margins convex, the two lobes very distinct, of about equal depth, the front one with a spine at the front corner, its lower margin rounded, the hinder with an irregularly angled lower margin carrying two spines. The branchial vesicles longer than the first joint but not so broad. The marsupial plates a little smaller than the preceding pairs, with broadly rounded distal margin. The first joint a little longer than broad, the front margin carrying three groups of pectinate spines, the hind margin at the upper part convex, slightly notched for a few setules, below the middle having as it were a triangular piece cut out; the lower margin sinuous, projecting behind considerably beyond the second joint; apart from the wing the hind margin on the inner surface is nearly straight and would give a broad joint narrowest at the top and there fringed with several long spines; the short second joint has some apical spines; the third joint is much shorter than the fourth, with a narrow neck, then much widened, having on the front two groups of several small spines, and behind three or four large groups, that on the slightly decurrent apex including very many spines; the fourth joint, with the margins nearly parallel except at the base, has four groups of spines on each, those behind being the longer; the fifth joint a good deal longer and narrower than the fourth, has five groups of spines on each margin; the finger is short and narrow, not a third the length of the fifth joint.

Fourth Peraopods.—The side-plates not so broad as the preceding pair, the front margin nearly straight, with a spine at the apex, the lower margin of the front lobe convex; the hind lobe produced below the front one, with its hind margin straight, its inner nearly so, and the lower angled, carrying two spines. The limb broken, the three remaining joints like those of the third peraeopods, but larger, the inner hind margin of the first joint forming an obtuse angle and showing no spines, the third joint having five groups of spines on the hind margin.

Fifth Peraopods.—The side-plates smaller than the preceding pair. The limb apparently similar to that of the fourth peraeopods. A fragment of a limb, probably

belonging to this pair, had on the hind margin of the fourth joint seven groups of spines and five on the front; the more slender and not much longer fifth joint had eleven groups behind and six in front; the finger not a fourth the length of the fifth joint.

Pleopods.—Coupling spines small, the apex sharp, its retroverted hook distally broad; there is another hook below it still broader; in each case the hook seems to stretch across the shaft, instead of forming a pair of lateral hooks, as is more usual; there are five cleft spines on the pair of pleopods examined, the same pair having nineteen joints to the outer ramus and eighteen to the inner.

Uropods.—The peduncles of the first pair considerably longer than the rami, with a spine at the apex of one of the upper margins and three on the distal part of the other; the outer ramus shorter than the inner, each with numerous spines along the margins, and a group at the blunt apex; the peduncles of the second pair subequal in length to the inner ramus, with spines at five points of one of the upper margins, one, two, or three together; the outer ramus shorter than the inner, with five spines along the inner margin and five elongate groups along the outer margin, numbering three, five, six, six, two, in the respective groups; there is besides an apical group; the inner ramus has seven spines along the inner margin, eight groups along the outer, and an apical group; the peduncles of the third pair are shorter than the rami, reaching beyond the peduncles of the other pairs, with a group of spines at the outer apex; the rami broad, lanceolate, equal in length, a little shorter than the inner ramus of the first pair, longer than the other rami, the inner with numerous spines and feathered setæ along each margin, the outer with spines and setæ along the inner margin, and groups of spines intermingled with some single spines along the outer margin; both with serrate margins and the apex acute.

The Telson elongate, about as long as the peduncles of the third uropods, widest at the base but almost immediately narrowing, not twice as long as the greatest breadth, but more than twice as long as the breadth below; the apical border with a triangular emargination, a little way above which on either side a dentate line upon the surface carries four large spines with accessory threads and a cilium; of the apices on either side of the emargination one is rounded and has two submarginal spines, the other is more acute and shows but one spine.

Length.—The specimen, in the position figured, measured, in a straight line from the rostrum to the middle of the third pleon-segment, seven-twentieths of an inch.

Locality.—Station 314, near Cape Virgins, January 21, 1876; lat. $51^{\circ} 35' S.$, long. $65^{\circ} 39' W.$; depth, 70 fathoms; bottom, sand; bottom temperature, 46° . One specimen, female.

Station 313, off Cape Virgins, January 20, 1876; lat. $52^{\circ} 20' S.$, long. $67^{\circ} 39' W.$; depth, 55 fathoms; bottom, sand; bottom temperature, $47^{\circ} 8'$. One small specimen, young.

Remarks.—The young specimen is the subject of Pl. CXXXV.; its length, from the rostrum to the extremity of the second segment of the pleon, is less than one-tenth of an inch; the figures will, I think, sufficiently show, without a detailed description, that the differences between the smaller and larger specimens are only such as might be expected between a very young specimen and an adult; in the young the spines are fewer on the palp of the first maxillæ, on the maxillipeds, gnathopods, uropods, &c.; the telson is much shorter in proportion to its length; the pleopods have a single cleft spine, and only four or five joints to the rami; the third uropods are not lanceolate. The latter difference recalls the still more remarkable divergence between the third uropods of the young and of the adult in *Amathilla homari* (Fabr.), better known as *Amathilla sabini* (Leach), a divergence which was pointed out by Bruzelius in the Skand. Amph. Gamm., p. 51, 1859, and further noticed by Buchholz, in Die zweite deutsche Nordpolarfahrt, in 1874.

The specific name refers to the peculiar hind margin of the first joint in the third and following peræopods. It is a curious coincidence that, after the capture of a single specimen of the young of this new species at one station, at the very next station, but much more than a hundred miles away, a single specimen of the adult should have been obtained. The two large specimens of *Andania gigantea* from far greater depths present a similar coincidence that is even more striking.

Family H E L A I D Æ.

In 1872 Boeck named the Helainæ as second subfamily of the Corophiidæ, and in 1876 defined it as follows:—

“Mandibles with the third joint of the palp shorter than the second.

“Maxillipeds with the outer plate armed on the inner margin with few but strong teeth.

“The body slender, depressed; the side-plates tolerably small.

“Antennæ?¹

“Legs rather elongate; First Gnathopods larger than the Second.

“Last three pairs of Peræopods graduated in length, the hinder the longer; the first joint not dilated, linear; the fourth joint very small.

“First and Second Uropods biramous, the Third uniramous.”

This definition Boeck had given in 1870 as that of the genus *Hela*, and in his later work, the definition of the subfamily is allowed to stand for the character of the single genus contained under it. Sars in 1882 relinquishes the subfamily Helainæ altogether, including its one genus under the family Corophiidæ.

¹ Both pairs very long; upper with secondary flagellum, see Hansen, *loc. cit.*

Genus *Neohela*, S. I. Smith, 1884.

 1887. *Neohela*, Hansen, Malacostraca marina Groenlandiae oecidentalis, p. 168.

For the original description of the genus, see Note on Boeck, 1860 (p. 325). S. I. Smith, in substituting a fresh name for the preoccupied *Hela*, does not give an independent definition of the genus, but supplies some notes on the new species *Neohela phasma*. "The antennulæ," he says, "are much longer than the rest of the animal; the first segment of the peduncle is nearly as long as the width of the head; the second segment is much more slender than the first and more than three times as long; the third segment is more slender than the second and considerably longer than the first; there is a well-developed secondary flagellum, as long as the third segment, and composed of about nine slender segments; the primary flagellum is very slender and about one and a half times as long as the peduncle. The third segment of the peduncle of the antenna just reaches the distal end of the first segment of the peduncle of the antennula; there is a small spiniform tubercle on the outside of the first segment, in line with the lateral spine of the head and the spiniform anterior angles of the first and second epimera. The distal portion of each antenna is wanting in the single specimen examined."

The very imperfect specimen, which I have provisionally named *Neohela serrata*, leaves me unable to speak with anything like decision on the proper position of the group.

Neohela serrata, n. sp. (Pl. CXXXVI.).

Rostrum short; lateral lobes of the head small, not produced so far as the rostrum; the animal elongate, somewhat compressed, the back rounded; the side-plates all shallow; the first three segments of the pleon much longer than any of the peraeon-segments, the postero-lateral angles of the first with a scarcely perceptible point, of the second more decidedly acute, of the third prominently so; the first five segments of the pleon have the hind margin dorsally dentate with sharp teeth, for the most part alternately longer and shorter, numbering about ten on the first segment, six on the fifth, and fifteen on the other three which have a prominent central tooth, particularly strong on the third pleon-segment; there are setules between the teeth; the fourth segment is longer than any of the peraeon-segments; the sixth is produced backwards into long sharp points below on either side of the telson.

Eyes doubtful, apparently small, round, composed of few ocelli, situated on the lateral lobes of the head.

Upper Antennæ.—First joint rather thick, longer than the head, narrowing a little distally, and carrying a few spinules; the second joint longer and thinner, with a comparatively long spine high up on the surface and another at the apex, and having the surface, at least on one side, studded with rows of spinules, besides having in common with the first joint a generally roughened hairy appearance all over. The other joints missing.

Lower Antennæ.—First two joints very short, the gland-eone short, decurrent; the third joint rather stout, longer than the united first and second, carrying a few spines and spinules. The other joints missing.

Upper Lip with the distal margin not quite symmetrically emarginate, the round tract on either side of the emargination carrying some short spine-like cilia directed inwards.

Mandibles.—The cutting edge divided into six or seven teeth, the most prominent not being the outermost; the secondary plate of the left mandible (on the right of the Plate) is divided into four strong teeth; on the right mandible this plate is less stout, with small teeth; the spines of the spine-row vary in number from seven and eight on one specimen to ten and eleven on the other, all appearing linear when seen edge-ways, but those near the cutting plates having in reality a broad shaft, widening for some distance from the base, and then rather abruptly narrowing to a serrate linear termination; the molar tubercle large and prominent, with some strong teeth round part of the rim of the dentate crown, a plumose seta and (observed only in one specimen and only in the right mandible) a small dentate process on the outer side of the trunk of the tubercle; the palp is long, the first joint short, scarcely longer than broad; the second joint elongate, with many lightly feathered spines along the inner margin and on the surface; the third joint shorter than the second, but nevertheless elongate, with the outer margin convex, the inner nearly straight, carrying long feathered spines at intervals, the almost acute apex having two or three; there are also spines along the surface, most of which are smaller than the marginal spines.

Lower Lip.—The outer and inner lobes and mandibular processes not showing any striking peculiarities, but not well enough observed for description.

First Maxillæ.—The inner plate with nine or ten very long plumose setæ on the sinuous inner margin; the outer plate with ten spines on the truncate distal border, the innermost spine straight, with some minute lateral teeth, the next shorter, with a small denticle on the outer side, the following pair similar to these two; in the centre there are two, which each have a short and a long lateral denticle on the inner margin, while between them in the adjacent row is a longer spine which has only little teeth if any; of the three outermost spines, which as usual are rather stronger than the rest, one

has a single lateral denticle, one has some minute teeth, and one appears to be unarmed; the first joint of the palp is short; the second joint widens distally and on the dentate distal margin carries seven spine-teeth, and has seven setiform spines submarginal to these.

Second Maxillæ.—The outer and inner plates nearly equal both in length and in breadth; the inner with twelve plumose setæ in a series beginning near the base of the inner margin and curving towards the outer apex, also having a series of spines beginning below the middle of the inner margin and passing most of the way round the apex; the outer plate with longer spines round the apex, except the three outermost which are slight, the subapical series beginning a very little way down the inner margin.

Maxillipeds.—The inner plates reaching beyond the first joint of the palp, having plumose setæ on the inner margin, three strong spine-teeth and several feathered spines on the rather broad dentate distal margin, and a hooked spine-tooth near the apex of the inner margin; the outer plates reaching beyond the middle of the second joint of the palp, the lower part of the inner margin smooth, though having the slender spines on the surface projecting beyond it, the distal part gently crenate, set with six spine-teeth, the distal margin almost truncate, serrate, with four spines, of which the outermost is setiform; the first joint of the palp unusually short, with a setiform spine on the inner apex; the second joint long and slender, not very broad, with a setiform spine on the outer apex, and many such spines along the inner margin; the third joint twice as long as the first, with spines round the inner and apical margins and on the distal part of the surface and outer margin; the finger slender, not so long as the third joint, with a long spiniform nail and two setæ at the base of the nail on the inner side; the dorsal cilium very long, close to the hinge.

The *triturating organs* of the stomach do not appear to have any of the spines very strong.

First Gnathopods.—Side-plates below much broader than the depth, the lower margin nearly straight, serrate, forming with the oblique front margin a strongly produced acute angle. The first joint attached at the lower hind corner of the side-plate, with spines along both margins, set at a little distance from the edge; the second joint short, with some spines at the apex behind, the third joint longer than the second, with spines at four points of the straight hind margin, and groups across the distal margin, some of the spines in which are both long and strongly pectinate on two edges; the wrist about as long as the first joint and except at the two ends much wider, the long front margin slightly convex, having five or six groups of spines on it or closely adjacent; behind, the wrist attains its greatest width abruptly on leaving the third joint, and then, at an angle with the smooth margin by which this is attained, the convex and irregularly denticulate hind margin runs to the junction with the hand, the wrist gradually narrowing, bordered with long and strong pectinate spines, and having others planted

singly or in pairs along the surface; the hand, a narrow oval, as long as the wrist but not so wide, with six groups or rows of long pectinate spines adjacent to the front margin; the hind margin a little serrate, with a few long slender spines and some spaced palmar spines; at a little distance from the hind margin are some slender feathered spines, the groups being close set near what may be reckoned as the palm-border, of which the portion nearest the hinge is almost straight or tending to concave; the finger is slender, about half the length of the hand, the outer margin convex, with a long dorsal cilium close to the hinge, the inner margin nearly straight as far as the nail and set with several setules, the nail about one-third the length of the basal part of the finger.

Second Gnathopods longer than the first, but with a narrower wrist. The side-plates with the breadth and depth equal. The first joint longer than in the preceding pair, but scarcely so wide; the second and third joints narrower than in the preceding pair, the third with fewer spines and the apex acute; the wrist very elongate, yet scarcely so long as the first joint, its greatest width much nearer the distal end than the base, with spines at seven points of the slightly convex front margin, and five or six large groups of long pectinate spines on the serrate hind margin, besides slighter spines on the surface, and on the oblique distal part of the hind margin; the hand in general form is a long narrow oval, shorter than the wrist, but longer than the hand of the first gnathopods, which it much resembles in armature, though the front margin is more lightly spined, the hind margin is not serrate or scarcely so, and the palm is pretty distinctly marked by a shallow concavity, over which the finger curves, leaving a narrow elliptical space between its inner margin and the palm; the finger resembles that of the preceding pair, except in having its inner margin more concave.

First Peræopods.—The side-plates like the preceding pair. The marsupial plates narrow, shorter than the elongate first joint of the limb.

Second Peræopods.—The side-plates rather broader above than in the preceding pair. The first joint long and narrow, with some slender spines at intervals along the hind margin, and some spinules on the front; the second joint quite short, with some small spines at the apex behind; the third joint thinner than the first, but very little shorter, with spines of very different lengths and spinules at seven or eight distant points of the slightly concave and serrate hind margin, and at five points of the slightly convex front; the fourth joint very elongate, but thinner and shorter than the third, with spines and spinules at six points behind and five in front; the fifth joint elongate, thinner than the fourth, carrying some spinules; the length not determined, the joint being broken.

The other peræopods were missing. One or two of the branchial vesicles were observed to be broadly oval.

Pleopods.—The peduncles long, distally produced in a small acute process which seems to coalesce with the first joint of the outer ramus; the peduncles, at least in the

third pair, had numerous marginal spines; the coupling spines are long and slender, with a sharp apieal pair of retroverted hooks, another slender pair just below, and a little further down two more hooks unsymmetrially placed; the cleft spines were observed to be five in a series on the first pair, four on the third, with long unequal arms, the inner margin of the longer arm distinctly serrate; the joints of the rami number from twelve to fourteen; the outer ramus is perhaps slightly the longer.

The Telson is long and narrow, deeply eleft, the outer lateral margins converging, but the apiees being broken it could not be determined what aeuteness was attained.

The Uropods were all broken.

Length.—The specimen, in the position figured, measured, in a straight line from the rostrum to the extremity of the broken telson, three-tenths of an ineh.

Locality.—Station 149H, off Cumberland Bay, Kerguelen Island, January 29, 1874; depth, 127 fathoms; bottom, volcanic mud. Two specimens. One of the speeimens was eertainly a female, as the marsupial plates were present. From this the figures marked A in the Plate were taken; the remainder from the other specimen.

Remarks.—The specifie name refers to the ornatmentation of the pleon.

In the imperfect state of the speeimens the genus must remain to a certain extent doubtful, but there is suffieient likeness between this speeies, so far as it can be made out, and *Hela monstrosa*, Boeck, to justify their being, at least provisionally, placed side by side. Boeek says of his speeies that the mandibular palp is short, and that the spine-row eonsists of two spines.

Family LYSIANASSIDÆ (see p. 606).

Genus *Kerguelenia*, n. gen.

Mandibles with the long three-jointed palp attaeched to the extreme front of the trunk; cutting plates, spine-row, and molar tuberele wanting.

First Maxillæ.—The inner plate apparently rudimentary or wanting; the outer plate carrying five short spines; the palp broad, two-jointed.

Maxillipeds.—The inner and outer plates small, the palp four-jointed, very long and slender.

Lower Antennæ.—The third joint of the peduncle as long as the fourth.

First and Second Gnathopods slender, having the second joint and wrist elongate; the first gnathopods neither chelate nor subchelate; the second gnathopods minutely chelate.

The *Third Peræopods* with the first joint seareely expanded; the *Fourth* and *Fifth Peræopods* with that joint expanded widely.

The *First* and *Second Uropods* biramous, the first extending much beyond the second; the *Third Uropods* small, uniramous.

Telson doubtful, probably very small, undivided.

The name of the genus is taken from Kerguelen Island, which the Challenger Expedition has shown to be a locality of notable interest with regard to the Amphipoda. From Boeck's definition of the Lysianassinae this genus differs in the formation of the mandibles, the tenuity of the maxillipeds, the want of the brush on the first joint of the flagellum of the upper antennae; in not having the first joint of the third pereiopods dilated, and in having the fifth pereiopods shorter instead of longer than the fourth. But in the maxillipeds it agrees with the new genus *Sophrosyne*, next to which for this reason I propose to place it; it agrees with *Menigrates obtusifrons*, Boeck, in the character of the upper antennae, so far as can be judged from Boeck's own description and figure, and with the same genus in the relative length of the two last pairs of pereiopods. From *Acontiostoma*, of which it is in respect to the gnathopods and some other points suggestive, it is widely removed by the character of the maxillipeds and the position of the mandibular palp. The general character of the antennae, the peculiarities of the gnathopods, the shape of the deep side-plates, as indeed of the whole animal, and the pereiopods, all clearly point to the inclusion of the genus in the family Lysianassidae, although the structure of the mandibles must give it rather the air of an intruder.

Kerguelenia compacta, n. sp. (Pl. XVA.).

A compact little species, discovered among the Hyperina too late for the description to be inserted in its proper place; in outward appearance it resembles the Stenothoidae even more than the Typhidae; of the pereion-segments the fifth is the longest and deepest; the third pleon-segment has the postero-lateral angles almost right angles, the fourth pleon-segment is elongate, as long as the third; the fifth is very short, the sixth narrow, longer than the fifth. Colour of the specimens preserved in spirits, a light brown.

Eyes not perceived, but not certainly absent.

Upper Antennae.—The first joint thick, not much longer than broad, carrying three feathered cilia; the second joint rather longer than broad, much narrower and shorter than the first, carrying one feathered cilium; the third joint shorter and narrower than the second; the flagellum of five little joints, successively narrower, together not so long as the first joint of the peduncle, the second with an apical filamentary cylinder, the last with some minute setules; the secondary flagellum consisting of three joints, which are rather longer than the first three of the primary.

Lower Antennae.—The first joint a little expanded, closely coalesced with the second,

of which the gland-eone is minute; the third joint a little bent, widest at the base, longer than the two preceding united; the fourth joint narrower than the third, which it equals in length, somewhat bent; the fifth joint shorter than the fourth; the flagellum tapering, of four or five joints, successively shorter, all of them together not equal to the last two joints of the peduncle.

Mandibles.—The trunk somewhat curved, narrowing to the distal end, at which the palp is attached, and apparently not fitted to serve any other purpose than that of holding the muscles which move the palp; first joint of the palp very short, second long, unarmed, third more than half the length of the second, with five setiform spines on the distal part and apex of the inner margin.

First Maxillæ.—The outer plate carrying on the oblique apical margin five very short spines or spine-teeth, serrate on the inner edge; the palp far outreaching the outer plate, its first joint as broad as long, more than half the length of the second joint, which has two little spines on the broad slightly indented apical border.

Second Maxillæ.—The inner plate shorter and narrower than the outer, with four setæ on the rounded apex; the outer plate similar in form to the inner, with twice as many setæ or spines on or near the apical margin.

Maxillipeds.—The inner plates reaching about to the middle of the first joint of the palp, the apical margin sloping outward, carrying two little spines; the outer plates reaching about to the end of the first joint of the palp, with four setules or spinules on the inner and apical margins; the first joint of the palp rather elongate yet less so than any of the three following joints, which are subequal in length, but the third rather longer than the second or the narrow tapering fourth; two or three apical setules constitute the whole armature of the palp.

First Gnathopods.—Side-plates deep, the anterior margin an arc of a circle with the hind margin for its chord. The first joint attached rather above the centre of the hind margin of the side-plate, not reaching the lower border, its margins nearly parallel, unarmed; the second joint more than half the length of the first, as long as the wrist; the third joint shorter than the second, its hind margin much longer than the front, ending in a pointed apex closely adpressed to the wrist; the wrist a little longer than the hand, its front margin longer than the parallel hinder one; the hand narrow, tapering, with two or three tiny setules on the distal part of the hind margin; the finger very small, a little curved, having in a serration of the hind margin a feathered setule as long as the finger itself, standing out at an angle from it, and followed by a much smaller setule in another serration.

Second Gnathopods.—Side-plates a little longer and rather less broad than the preceding pair. The first joint attached as in the first gnathopods, but longer than in those, about reaching the lower border of the side-plates, the lower half wider than the upper; the second joint more than half as long as the first, not quite so long as the

wrist; the third joint much shorter than the second, flask-like, with the bulb at the distal end; the wrist much longer than the hand, with numerous setæ on and near both margins; the hand not so long as the second joint, an elongate oval, distally sharpened so as to form a little blunt palm process from which a setule projects, and against which lies the minute finger with its strongly bent tip, forming a microscopic chela; the sides of the hand are furred with numerous tufts of setæ, and at the distal end of the front margin there are the spines usual in the Lysianassidæ overarching the finger. These spines were damaged, so that the pectination which might be expected could not be observed.

First Peræopods.—Side-plates broader and deeper than the preceding pair, the hind margin slightly concave. The first joint attached considerably above the centre, not nearly reaching the lower border of the side-plate, widening a little from the base; the second joint short, the third distally widened, longer than the fourth, the front apex a little produced downwards; the fourth joint abruptly narrower than the third, at the hinder apex of which it is attached, slightly curved, with three spinules on the concave hind margin; the fifth joint a little curved, subequal in length to the third, with a spinule at the hinder apex; the finger more than half the length of the fifth joint.

Second Peræopods.—The side-plates rather deeper and immensely broader than the preceding pair, the excavation behind being about half the depth, and more than half the breadth of the plate, the hind margin below the excavation rounded. The limb very similar to the preceding pair, the third joint scarcely so much expanded distally, the fourth with a single spinule on the hind margin, the finger rather stouter and much shorter.

Third Peræopods.—Side-plates with the hind lobe deeper than the front, the breadth slightly greater than the depth of the hind lobe. The marsupial plates very narrow, with two apical setæ. Marsupial plates were not observed attached to any of the other limbs. One pair of oval branchial vesicles was seen, but it was not ascertained how many more pairs there were. First joint attached just above the distal margin of the front lobe of the side-plate, a little wider but not longer than the first joint in the preceding peræopods, with a pair of apical spinules on the nearly straight front margin, and a row of three a little higher up, the hind margin convex; the second joint short, with a few spinules on the front margin; the third joint longer and much more dilated than in the preceding peræopods, with four spinules on the front and three on the much bowed hind margin, besides one or two at each apex; the hinder apex acute, completely overlapping the narrow fourth joint, which has a spinule at the middle of the front margin and two at its apex; the fifth joint longer than the fourth, similarly armed, shorter than the corresponding joint in the preceding peræopods; the finger rather more than half the length of the fifth joint; the nail small.

Fourth Peræopods.—The side-plates much deeper than broad, the margins nearly parallel, the hinder longer than the front. The first joint wider than the side-plate, rather longer than broad, the front margin convex, with some spinules along the lower

half, the hind margin nearly straight, carrying a few cilia; the rest of the limb very similar to that of the third peræopods, the finger rather longer.

Fifth Peræopods.—The side-plates a little broader but not quite so deep as in the preceding segment, the hinder margin convex, much longer than the front, the lower margin very convex. The first joint greatly expanded, a little longer than broad, the front margin nearly straight, with two or three spinules on the lower part, the hind and lower margins smooth, curved; the second joint very short, with two or three spinules on the front margin, behind overlapped by the first joint; the third joint much smaller than in any of the other peræopods, with spinules at three points of the front margin, and one on the hind margin, of which the sharp decurrent apex quite overlaps the small fourth joint; the fifth joint shorter than in the preceding pair, but considerably longer than the fourth joint; the finger more than half the length of the fifth joint.

Pleopods.—The peduncles rather widely separated at the bases, with two little oval processes projecting between them. The coupling spines small, with slender shafts, having three or four retroverted teeth on each margin; a single cleft spine on the inner ramus; the inner ramus seemingly with five, and the outer with six, joints.

Uropods.—The peduncles of the first pair longer than the rami; the rami acute, the lower and outer longer than the upper and inner, the lower having two small spines, the upper having one on the proximal half; the peduncles of the second pair about equal in length to the rami, which resemble in shape those of the first pair, but are unarmed, reaching very little beyond the peduncles of the first pair, the lower and outer rather longer than the other; of the third pair the peduncles were not clearly discovered and must in any case be very short; the single ramus of each uropod curved in towards the other, being broader distally than at the base, the two lying apparently under a shallow transparent telson.

Telson not clearly distinguished, seemingly very small, wider than its length, forming a small arc of a circle.

Length from the front of the head to the back of the third pleon-segment, in the position figured, about one-seventh of an inch.

Locality.—Station 149H, off Cumberland Bay, Kerguelen, January 29, 1874; depth, 127 fathoms; bottom, volcanic mud. Two specimens.

Remark.—The specific name explains itself.

Family PARDALISCIÆ, Sars (see p. 990).

Synopioides macronyx (see p. 1000).

A second specimen of this species, which, like that already described, had been mounted in glycerine during the voyage, was labelled "Tow net at trawl, Nov. 1875, 2025 fms., South Pacific." It may be presumed that this belongs to Station 293,

lat. $39^{\circ} 4'$ S., long. $105^{\circ} 5'$ W.; bottom temperature, $34^{\circ} 4'$; while the other specimen came from lat. $38^{\circ} 7'$ S., long. $94^{\circ} 4'$ W., the bottom temperature there being $35^{\circ} 3'$.

Length, without the antennæ, nine-twentieths of an inch, from the front of the head to the extremity of the first uropods, the second uropods being broken, and the last uropods missing.

Remarks.—While the specimen from Station 295 was a female, the specimen from Station 293 appears to be a male, and the difference of sex may account for certain variations which might otherwise be regarded as of specific value. In the present specimen there is a clearly defined, only slightly depressed, rostrum, with the convex lateral margins meeting in a pointed apex; the third joint of the mandibular palp is not very elongate; the first gnathopods have the wrist almost as long as the hand; the first and second pereiopods have a slight convexity of the hind margin of the fifth joint, and the finger almost linear; the peduncles of the first pair of uropods are considerably longer than the rami. Should the foregoing differences be thought to require the institution of a separate species, I propose for it the name *Synopioides secundus*. The following particulars are in all probability common to both forms, although they were not observed or could not distinctly be made out in the specimen first described; the third segment of the pleon is dorsally produced at the centre of the hind margin into a short blunt tooth; the fourth segment a little in advance of the hind margin has a longer acute tooth or process, but the back of this segment being depressed along the centre, a lateral view showing the raised outer margin and the projecting central process gives a bidentate appearance to the segment. The *maxillipeds* have much greater resemblance to those of *Pardalisca* (see Pl. XCHI.) than, from their condition in the first specimen, I was able to perceive; the inner plates are a little less rudimentary than in *Pardalisca*, but they are very small, conical, without spine-teeth, carrying three setæ, one of these being very long and planted on the apex; there are also some setæ on the outer apex of the joint to which the inner plates belong; the following joint is very large, with two setiform spines apart from one another on its outer margin; the outer plates where free from the basal part of the joint are small, not quite reaching to the apex of the first joint of the palp, the outer margin smooth, the apical margin carrying three spines at intervals, curved, graduated in size, the largest outermost; the inner margin has six slender spines distant from one another; the first joint of the palp is longer than broad, with smooth margins; the second is about one and a half as long as the first, with long, plumose spines or setæ, not very numerous, on the inner margin; the third joint is about as long as the second, with setæ on both margins, chiefly near the distal end; the finger is long and tapering, with a setule at the base of the nail; this description of the *maxillipeds* must be taken in correction of that given on p. 1001. The *trituration organs* are of rather peculiar shape, narrow at one end and broad at the

other, the inner margin as it approaches the widened end being set with six or more powerful, strongly projecting spines, graduated in size, the largest at the broad end of the organ, the rounded apieal part being set with a fan-like arrangement of slender spines. The fourth pereopods in this specimen were preserved, although, unfortunately, in an imperfect condition; they have the first joint intermediate in size between that of the third and fifth pairs; the third joint much longer than in the third peræopods, rather shorter but broader than in the fifth; the fourth joint longer than the third and longer than in the fifth pair, with spines at five or six points of the front margin, and smaller spines at seven or eight points of the hind margin; the fifth joint is nearly as long as the two preceding together, and, therefore, of very great length; the slender sixth joint was broken; the distal part being broken in each of the last three pairs of peræopods, it can only be stated with the necessary reserve, but still as almost a matter of certainty, that the fifth are longer than the third, and the fourth longer than the fifth.

CONCLUDING OBSERVATION ON THE GAMMARINA.

In 1876 Dr. v. Willemoes Suhm writes with regard to Tristan da Cunha, that they there found "Gammarus everywhere under stones." It is possible that specimens were not thought worth collecting, but at any rate I have not found in the collection of Amphipoda entrusted to me any shore specimens from Tristan da Cunha.

Tribe II. AMPHIPODA CAPRELLINA.

Head in general with the boundaries marked, but otherwise coaleseed with the first segment of the peræon; exceptions rare (*Platycyamus*).

The second to the seventh segments of the *Peræon* as a rule distinct; occasionally two of them coaleseed (*Platycyamus thompsoni*, *Protella haswelliana*).¹

Pleon degraded, consisting of one, two, or (*Cercops*) five small segments.

Eyes two.

Antennæ, two pairs; the upper larger than the lower, without accessory flagellum.

First Maxillæ with the inner plate undeveloped.

Maxillipeds with (Caprellidæ) or without (Cyamidæ) two² pairs of plates, and generally with the palp four-jointed; the palp rarely one-jointed (*Platycyamus*).

The side-plates of the peræon never largely developed.

Pleopods wanting; *Uropods* never more than two³ pairs, and those more or less rudimentary.

In 1813 Leach established the Caprellini as sixteenth family of the Class Crustacea, and fourth family within the tribe Gasteruri, giving for it the following brief definition—"Body six-jointed, all the articulations except the second and third bearing feet. Two oars on each side, placed on the sides of the second and third joint." As he assigned to this family the two genera *Caprella* and *Cyamus*, it is practically equivalent to the Amphipoda Caprellina. In 1814 Leach changed the name Caprellini into Caprellides, which he called the fourth tribe of Gasteruri, including in it the new genus *Proto*. In 1815 and 1816 he took what must be considered a backward step, since in the third section of the legion Edriophthalma he united this group with the Isopoda. He made it the first division of its section, improving the classification by forming two subdivisions, the first for *Proto* and *Caprella*, the second for *Larunda* [*Cyamus*], but erroneously assigning "Pedes 14" as a general character of the division.⁴ See Notes on Leach, 1813 (p. 84), 1814 (p. 86), 1815 (p. 90). In 1817 Latreille established the order Læmodipoda to receive this group, which he had previously, under the name Cystibranchia, combined with the Isopods. See Notes on Latreille, 1817 (pp. 95, 99). For further definitions

¹ In *Platycyamus thompsoni* (Gosse) Lütken says that the branchiferous segments, that is, the third and fourth, in the female though not in the male, are coalesced for the greater part of their breadth; in *Protella haswelliana*, Mayer says that the sixth and seventh segments are coalesced.

² In *Cercops* Krøyer observed only one pair of plates, but thought that the second pair had by its small size escaped his observation.

³ The "two very small, oval or vesicular organs" at the base of the first uropods in *Cercops*, which Krøyer figures and describes, cannot, with respect to their form and position, be regarded with any probability as representing either pleopods or uropods.

⁴ In the Encyclopædia Britannica, Art. Annulosa, p. 423, he says without qualification, "Division I. Body with all the segments bearing legs." In the *Trans. Linn. Soc. Lond.*, vol. xi., he says of the legs, "*paria tertium et quartum sæpius spuria*," no doubt in allusion not to rudiments of the actual legs but to the branchiæ.

of the Læmodipoda, see Note on Desmarest, 1825 (p. 123); Latreille, 1825 (p. 125), 1829 (p. 138); Burmeister, 1837 (p. 171); Milne-Edwards (Caprellines), 1838 (p. 174); Milne-Edwards, 1840 (p. 184); Krøyer, 1843 (p. 202). In 1828 Zenker included this group in the Leptomeræ, which he made the second family of the Isopods. In 1852 Dana made this group, under the name Caprellidea, the first subtribe of the Amphipoda, with the two families Caprellidæ and Cyamidæ; see Note on Dana, 1852 (p. 256). Spence Bate in 1856, drawing up his system of classification in concert with Westwood, divided the Amphipoda into "Group A. Normalia," and "Group B. Aberrantia," the latter containing the single family Caprellidæ; in 1857 he added to this group the family Dyopeditidæ, and in 1862 he retained the group unaltered, except that the name Dyopeditidæ was changed into Duliehidæ, and the family Caprellidæ was divided into Caprellidæ and Cyamidæ. This arrangement is also followed by Bate and Westwood in the British Sessile-eyed Crustacea. Boeck in 1870 made the Caprellidæ the fifth family of the Gaminaridæ, with two subfamilies, the Caprellinæ and Cyaminæ; in 1872–1876 he made the Amphipoda Caprellina the third division of the Amphipoda, with the two families Caprellidæ and Cyamidæ. Sars in 1882 and 1885 follows this arrangement with the unimportant alteration of calling the Caprellina the third tribe instead of the third division. Mayer in 1882 reverts to the Læmodipoda as the name of one of the three principal groups, whether to be called subtribes or divisions, of the Amphipoda, including in it the two families, the Caprellidæ and Cyamidæ. Carus in 1885 adopts the same terminology, except that he calls the Læmodipoda the first tribe of the Amphipoda. Gerstaecker in 1886 calls the Læmodipoda the second suborder of the Amphipoda; for the definition see Note on Gerstaecker, 1886 (p. 579). Bovallius in 1886 makes the Caprellidea the fifth tribe. An objection may be raised to the name Caprellina, on the ground of its calling attention too exclusively to one only of the families, and that not the one which embraces the oldest genus in the group, namely *Cyamus*, Latreille; on the other hand the term Læmodipoda has been criticised as implying an attachment of the first gnathopods to the head, which is in no case actual, and in *Platycyamus* not even apparent; there is also, I think, an advantage in having the names of the three divisions or tribes of the Amphipoda terminating alike.

Family CAPRELLIDÆ, White, 1847.

Mandibles with dentate cutting edge and secondary plate; with or without three-jointed palp.

Maxillipeds with two¹ pairs of plates and the palp four-jointed.

Body narrow, more or less cylindrical; side-plates often present, though rudimentary.

¹ See note on *Maxillipeds* in the character of the tribe.

The Peræon seldom or never¹ carrying seven pairs of fully developed limbs.

Branchial Vesicles on the second, third, and fourth, or only on the third and fourth, segments of the peræon.

Pleon with one, two, or five segments.

Uropods.—Two pairs, one or both being sometimes scarcely appreciable.

The name Caprellidæ for this family appears first, so far as I remember, in White's List of the specimens of Crustacea in the collection of the British Museum, 1847; in 1857 White gave the following definition:—

"Body elongated, cylindrical, and very narrow. Four well-developed antennæ. Legs long and slender. Coxæ fused with the body of the animal. Animals not parasitic."

For Krøyer's definition of his equivalent subdivision, Caprellina, see Note on Krøyer, 1843 (p. 202). For Mayer's definition of the family Caprellidæ, see Note on Mayer, 1882 (p. 535). Mayer describes the genera known to him in the following order, *Cercops*, *Proto*, *Caprellina*, *Protella*, *Ægina*, *Æginella*, *Caprella*, *Podalirius*. Accepting this order as far as the older genera are concerned, I insert the genus *Dodecas* after *Proto*, change the name *Caprellina* into *Caprellinopsis*, provisionally placing the new genus *Caprellinoides* immediately after it, and following this by the new genus *Protellopsis*, finally allowing the preoccupied name *Ægina* to be absorbed in *Æginella*.

For the original definition of the genus, see Note on Leach, 1814 (p. 86).

It is thus defined by Mayer, though not verbally as follows, yet to this effect:—

"The *Peræon* with seven pairs of completely developed legs.

"The *Mandibles* with a palp.

"*Branchial Vesicles* on the second, third, and fourth segments of the peræon.

"*Pleon* one-jointed, having in both sexes two pairs of two-jointed *Uropods* (Fussstummel).

"*Lower Antennæ* without motor-setæ (Ruderhaare), the flagellum in the adult animal consisting of more than two joints."

The *Third Peraopods* may on the one hand be regarded as completely developed, inasmuch as they have the full number of joints, but, on the other hand, compared with the elongate limbs which precede and follow them, they have a dwindle appearance that might well be attributed to incomplete development.

Proto novæ-hollandiæ, Haswell, 1880.

 1882. " " Mayer, Die Caprelliden, p. 26.
 1885. " " Haswell, Proc. Linn. Soc. N.S.W., vol. ix. pt. iv. (extr. p. 5).

Head and body without spines ; the very short first segment of the peraeon intimately coalesced with the head, the following segments successively longer to the fifth, the sixth as long as the fourth, shorter than the fifth, the seventh very short ; the second segment dilated at about the middle in the male, but more proximally in the female, in each case at the point of attachment for the second gnathopods.

Eyes rather large, dark in specimens preserved in spirits, not regularly rounded, the ocelli numerous, as many as a hundred and fifty to each eye.

Upper Antennæ.—First joint not as long as the head with the first segment ; the second joint much thinner than the first, not twice as long ; the third joint intermediate in length between the first and second ; the flagellum of seven slender joints, carrying short cylindrical filaments, these joints together not as long as the peduncle ; the second and third joints of the peduncle and the joints of the flagellum with the margins minutely tuberculate in the male, but not, or almost imperceptibly, in the female, in which the flagellum is of six joints.

Lower Antennæ much slighter than the upper, the peduncles of which they equal in length ; first and second joints very short ; third a little longer than the preceding two together ; fourth a little shorter than the fifth ; fifth about equal in length to the third joint of the upper antennæ ; flagellum of three very slender joints, together not equal to the fifth joint of the peduncle in the male, but equal to it in the female, in which this joint is not longer than the fourth.

Mandibles.—The cutting edge with five unequal teeth on one mandible and six on the other, of which one is more prominent than the rest ; the secondary plate with four teeth on one mandible, probably on both ; there are also some laminar spines, not seen with sufficient distinctness for particular description ; the second joint of the palp with the spines few and scattered, the third with two at the apex and several at a little distance from the apex on and near the oblique ciliated apical or inner margin.

First Maxillæ.—The outer plate with six slender spines on the distal margin, only weakly denticulate ; the palp with the apical margin not expanded, carrying four

little teeth or spines, and a spinule or two on a little indent near the top of the inner margin.

Maxillipeds.—Inner plates small, not reaching the apex of the first joint of the palp, not strongly armed; the outer plates small, reaching little beyond the inner, about level with the apex of the first joint of the palp, the distal part of the inner margin serrate, armed with a few spinules; the first joint of the palp scarcely longer than its distal breadth; the second joint about twice the length of the first, broad, with slender spines on the inner margin; the third joint not much shorter than the second; the finger as long as the third joint.

First Gnathopods.—First joint as long as the hand, but narrower, widening a little distally; third joint a little longer than the second, with half-a-dozen slender geniculate spines across the inner surfacee, the middle of the convex hind margin furred, the front apex acute, resting on the wrist; the wrist much longer than the third joint, shorter and much narrower than the hand, the front margin smooth, the hinder furred, the inner surface carrying many slender spines; the hand widening from the base to the apex of the short hind margin, which is partly furred, the adjoining surfacee being mieroscopically marked with lines of peetination, the apex itself forming a strong denti-culate tooth-proeess carrying setules and a palmar spine; from the eavity of this proeess rises on the inner surfacee a much smaller triangular process, also carrying a palmar spine; from this point to the narrowed apex of the hand the long convex palm, whieh almost usurps the place of the hind margin, is planted with numerous small spines and a few setules; the front margin is smooth, not very eonvex, with four transverse rows of long graduated spines on the adjoining surfacee; the finger is as long as the palm, slender, curved, with a very small dorsal cilium close to the base, and some cilia or hairs near the smooth inner margin.

The Second Gnathopods much larger than the first, espeecially in the male, in which the hand is immensely dilated; in structure the second gnathopods much resemble the first, except in regard to the wrist, which is here scarcely longer than the third joint, almost coalescent with the hand, to which it forms a very narrow base; the finger is bulky in some proportion to the size of the hand, having in the Challenger specimen of the male a small incurving of the inner margin near the base. The male specimen was defective beyond the second segment of the peræon.

First Peræopods.—Side-plates small, but very distinct, much broader than deep. Branchial vesicles small, a narrow oval. Marsupial plates large, the fringing setæ small. The limb very slender, first joint nearly as long as the segment; second slightly narrower than the first, little longer than broad; third longer than the fourth, the two together about as long as the first; the fifth a little longer than the fourth, searcely narrower; the finger slender, tapering, curved at the aeute tip, nearly as long as the fourth joint.

Second Peræopods as nearly as possible like the first peræopods, both pairs being without armature, except a few microscopic hairs or cilia.

Third Peræopods missing; the muscles running to this pair and the place of articulation are rather behind the centre of the segment.

Fourth and Fifth Peræopods missing, articulated at the extremities of their respective segments.

Length of female, without the antennæ and hind limbs, a fifth of a inch; length of the second gnathopod of the male, with the finger open, more than a tenth of an inch.

Locality.—Port Jackson, Australia; depth, 2 to 10 fathoms. Three defective specimens, an adult male, a female with the marsupial plates fully developed, and another female of the same size with the marsupial plates quite small.

Remarks.—It seems in the highest degree probable that this is the species described by Mr. Haswell as *Proto novæ-hollandiæ*, but his account of the first and second peræopods does not agree, being as follows:—"First pair of pereiopoda slender, as long as the second and third segments of the pereion, with a slight tooth on the posterior margin of the propodos. Second pair much larger than the first or third, rather longer than the cephalon and the first two segments of the pereion, the carpus, propodos, and dactylos short, the propodos armed with four spines and a row of serrations on its anterior border." These observations may be true of the male, and yet not apply to the female, but it seems unlikely that the second peræopods should differ so much from the first, since in the other known species of the genus these two pairs, so far as they have been described, are in close agreement.

Genus *Dodecas*, Stebbing, 1883.

1883. *Dodecas*, Stebbing, Ann. and Mag. Nat. Hist., ser. 5, vol. xi. p. 207.

Mandibles with an elongate three-jointed palp.

Lower Antennæ with a flagellum of more than two joints.

The *First and Second Gnathopods* and *Fourth and Fifth Peræopods* fully developed; the *First and Third Peræopods* feebly developed, the *Third* not having the full number of joints; the *Second Peræopods* wanting.

Branchial Vesicles on the second, third, and fourth segments of the peræon.

Pleon undivided.

Uropods two-jointed.

The generic name is derived from the Greek δωδεκάς, a set of twelve, this genus being distinguished from the rest of the Caprellidæ by having twelve limbs (in six pairs) attached to the peræon.

With regard to the three systems of arrangement proposed by Mayer in his "Caprelliden," pp. 18, 19 (1882), *Dodecas* in the first will stand after *Proto* and *Protella*, in the other two between *Proto* and *Caprellina*.

Dodecas elongata, Stebbing, 1883 (Pls. CXXXIX., CXL.).

1883. *Dodecas elongata*, Stebbing, Ann. and Mag. Nat. Hist., ser. 5, vol. xi. p. 207.

Body smooth, sometimes more or less speckled, very long and slender; the first and second segments of the pereon very long and slender in the male, much shorter and rather thicker in the female, in both sexes the first broadest at its junction with the almost completely coalesced head, and narrowest at its junction with the second segment, which is broadest at the part where the limbs are attached; the third and fourth segments are shorter in the male, and much shorter in the female, than the fifth and sixth; in the female the third is widened distally, the fourth proximally; in both sexes the seventh segment is very short.

Eyes prominent, round or a little oval, situate near the top and front of the head, small, but with the ocelli very numerous.

Upper Antennæ large and long, the first joint of the peduncle stout, about as long as the head, the second joint more slender, from two and a half to three times as long, the third more slender and a little shorter than the second; the flagellum showing in different specimens seven, eight, or nine joints, of which the first is much the longest, with setules at three or four points of the lower margin, the remainder having each an apical setule, all except the last being a little dilated distally, the whole flagellum much shorter than the fifth joint of the peduncle.

Lower Antennæ very slight in comparison with the upper, the flagella of which they do not greatly exceed in length, nor in thickness at all, except at the base, the first and second joints appearing to be completely coalesced, the gland-cone minute, the third joint a little longer and more slender than the preceding two, the fourth joint nearly twice as long as the three preceding together, the fifth nearly as long as the third and fourth together; the flagellum of three, four, or five very slender joints, together not so long as the last joint of the peduncle.

Upper Lip distally rather deeply divided into two unequal lobes, the margin smooth.

Mandibles.—Cutting plate divided into five strong unequal teeth, of which the lowest is bifid, the others sometimes assuming the same appearance from wear; in one specimen the right mandible had but four teeth, not showing any signs of loss or breakage, while the new growth displayed the usual five; the secondary plate on the left mandible nearly as large as the primary, its broad distal edge divided into five or six teeth; on the right mandible this plate is less powerful, its distal edge broad and

nearly straight, with a small tooth at the top, which is evidently liable to be worn down, the remainder of the edge perhaps finely serrate; on each mandible there are two plates similar in form to the secondary plate of the right mandible, but successively smaller; these are followed by a group of backward curving spines, nine or more in number on the left, perhaps less numerous on the right, mandible; there does not appear to be any dentate molar tubercle; the first joint of the palp is about half the length of the second; the second, which has seven or eight slender spines distributed over it, is very little longer than the third joint; of this the front margin is clear for nearly the first half, the remainder carrying a series of from ten to thirteen spines, one at either end being more than twice as long as the rest; the apex of the joint is acute. The figure which Hoek¹ gives of the mandible of "*Leptomera pedata*," in many respects resembles the mandibles just described, and a similar arrangement is observable in *Caprellina longicollis*, Nicolet, judging from a specimen sent me from New Zealand by Mr. G. M. Thomson.

Lower Lip.—The principal lobes pretty widely dehiscent, their rounded distal margins finely ciliated; the inner lobes large and prominent, distally rounded; the mandibular processes apically narrowed.

First Maxillæ.—Inner plate wanting or at most rudimentary; outer plate carrying six spines on the trunecate distal margin, the innermost and three following pectinately feathered, but not strongly, the two outermost having each a strong lateral tooth on the inner side and a very slight pectination of the margin near it; the first joint of the palp not longer than broad, the second long, with several pectinate spines on the dentieulate apex, and setæ or setiform spines along much of the inner margin.

Second Maxillæ.—The inner plate short, but a little broader than the outer, with about fourteen slender spines round the apical margin, the series slightly descending the inner margin; the outer plate similarly armed, but with the margin less convex and the spines very unequal in size, none on either plate being strongly feathered or pectinate.

Maxillipeds.—The inner plates not reaching the apex of the first joint of the palp, having four setiform spines crossing the distal end of the outer surface, the apical border concave, with two little teeth at its outer corner, a small spine-tooth inserted below the inner corner, the margin itself near to this corner bearing an arrangement of three large, closely-set spine-teeth, two with their serrate edges facing one another, the third and largest intermediate, overlapping and out-topping the other two, with its serrate edge facing outwards; the distal part of the very convex outer margin is a little serrate; the basal part of the joint carrying these plates rises on the outer surface to a divided apex, each half carrying five setæ in two sets; the outer plates are smaller than the inner, and reach just to the apex of the first joint of the palp, the inner margin serrate, armed with setiform spines, the outer margin convex, smooth except for some microscopic

¹ Carcinologisches, Taf. viii. figs. 1, 1a, 1879.

serration apically; the first joint of the palp is not much longer than broad, with two or three setæ near the apex of the almost straight inner margin; the second joint nearly twice as long as the first, the inner margin fringed with setæ, of which there are also groups on the inner surface, the third joint widening from the base, the apical margin oblique on the inner side and fringed with setæ, on the outer side carrying a setule, and with its rounded edge overlapping the base of the fourth joint; the fourth joint longer than the third, curved, pointed, a little ciliated, and having a small dorsal cilium very near the base.

Triturating Organs.—These are small, not regularly oval, apparently without any armature except a row of seven or eight rather broad, slightly pectinate spines, along a margin which slightly projects.

First Gnathopods attached just where the segment coalesces with the head, close to the base of the maxillipeds; the first joint narrow at the base, widening distally, not greatly longer than the hand in the male; the second joint rather longer than wide; the third not much longer than the second, somewhat rhomboidal, with a group of spines at the slightly furred hinder apex, and others on the surface; the wrist narrow at the base, then widening, shorter than the hand, with numerous setiform spines on the surface and along the hind margin; the hand abruptly wider than the wrist, tending to oval, narrowest distally, with several groups of spines on the surface near the front margin, the hind margin, as distinct from the palm, short, ciliated; the palm-border long, convex, fringed on both sides with short spines and setules, the cavity at its junction with the hind margin of the hand being set round with five unequal palmar spines, larger than those along the border; the finger large, curved, matching the palm, with some small cilia on the inner margin, and a very small dorsal cilium near the hinge. The hand in the female is rather smaller than in the male.

Second Gnathopods.—Attached, in the male, close to the hinder end of the segment, which is here abruptly dilated, and bulbous in the lateral view; in the female the attachment is near to the front end of the segment, which from this point of considerable dilatation narrows backwards; the first joint narrow, widening a little distally, of great length in the male, more than twice as long as in the female, being nearly three and a half times as long as the branchial vesicle in one sex to once and a half in the other; the second joint short; the third in the male about twice as long as the second, but scarcely so much in the female; narrow at each end; the wrist narrow, of very great length in the male, sometimes even longer than the first joint, though sometimes shorter, in the female shorter even than the third joint, almost triangular; the hand oval, long and stout, the base in the male a little narrowed, the front margin almost unarmed, as likewise the much shorter hind margin; the long convex palm beginning with an emargination, of which the tips are serrate, and on either side of which large palmar spines are planted; beyond this the border is fringed

on both sides with numerous short spines and occasional setules, and apically forms a small tooth or projection, between which and the hinge of the finger it is crenulate, the fringe of spines not being interrupted; the finger is large, curved, acute, matching the palm.

First Peraopods.—Attached a little behind the centre of the segment, which is here a little dilated in the male, and greatly in the female. Branchial vesicles narrow and elongate, about two-thirds the length of the limb. Marsupial plates much longer and enormously broader than the branchial vesicles, in some specimens adorned with numerous dendritic colour-spots. The limb extremely slender, and smooth; the first joint longer than the third and fourth together; the second longer than broad; the third a little shorter than the fourth and fifth together; the fourth and fifth subequal; each of the five joints having a setule at or near the apex of the hind margin; the finger more than half the length of the fifth joint, with convex front margin, broad at the centre, the tip acute, near which the hind margin has a row of about six small spines, the bases of which are broad. The relative proportions of the joints vary to some extent with age and sex.

Second Peraopods wanting. The branchial vesicles are attached at the centre of the segment, which in the male is here very slightly dilated, while in the female as usual the anterior part of the segment is broad, the posterior narrow; the branchial vesicles scarcely so large as the preceding pair.

Third Peraopods.—Attached behind the centre of the segment, small and degraded, with only four distinct joints; from the shape of the first of these it may be supposed that it represents the second and third coalesced; it about equals the length of the next, or fourth joint; the following or fifth joint is about equal to the two preceding united, and is rather stouter, somewhat curved; the finger is half the length of the preceding joint, strongly curved, acute.

Fourth Peraopods.—Attached at the distal end of the segment, which is here dilated; the first joint elongate, like all the others except the second, distally a little widened, rather longer than the fifth joint; the second joint scarcely longer than broad; the third joint rather shorter than the fourth, widened a little distally; the fourth subequal to the fifth, having a spine near the base on the front margin; the fifth joint having a pair of spines near the base and several single spines along the course of the front margin and some setules on the hind margin, the spines simple except for the accessory thread on the outer side; the finger curved, acute, as long as the fifth joint.

Fifth Peraopods.—Attached at the distal end of the short seventh segment, similar in general to the preceding pair, but the first joint much shorter, the fourth, fifth, and finger considerably longer than in that pair. In the relative proportions of these joints there is some amount of variation, whether it be from individual difference or due to age or sex.

Uropods.—Of these small appendages the first pair are the longer; in each case the first joint is much longer than the second, and its fringe of spinules on the concave side much stronger.

Length.—The longest specimen is figured at the top of Pl. CXXXIX., to the right. From head to pleon, in the position figured, this measures an inch and a half; the upper antennæ in front are more than an inch long, and the hinder pereopods are capable of extension to the length of half an inch, giving a total extensibility of at least three inches; the second gnathopods in this specimen are an inch in length; more than any other Crustacean, with the exception perhaps of *Rhabdoneetes*, this animal suggests the geometrician's definition of a line, as length without breadth. The females, which do not appear to attain so great a length as the males, are as usual broader in the marsupial region.

Localities.—Station 149F, Rhodes Bay, Kerguelen Island, January 27, 1874; depth, 95 fathoms; bottom, volcanic mud. A male and three females (mounted in Canada balsam); also a great entangled mass of specimens of both sexes.

Station 149G, off London River, Kerguelen Island, January 29, 1874; depth, 110 fathoms; bottom, volcanic mud. One specimen, female, and two mounted specimens.

Kerguelen; 100 fathoms; two mounted specimens, female (Stations 149G or 149J).

Genus *Caprellinoides*, n. gen.

Mandibles with a three-jointed palp.

Lower Antennæ with a flagellum of (probably) more than two joints.

The *Third Peraopods* with only three distinct joints, of which the last is not unguiform; the *First* and *Second Peraopods* wanting.

Branchial Vesicles only on the third and fourth segments of the *Peraon*.

Pleon one-jointed.

The generic name alludes to the likeness between this genus and *Caprellina*, G. M. Thomson. The name *Caprellina*, having been earlier applied to the whole group, cannot, I think, be used for a genus within the group, and I have therefore proposed in the Note on Nicolet, 1849 (p. 233), to change it into *Caprellinopsis*, being under the impression at the time that Note was written that the species for which a new genus is now instituted would fall under Mr. Thomson's *Caprellina*. *Caprellinopsis*, however, differs from *Caprellinoides*, in that the mandibles have, besides several slender spines, two broad laminar spines like those in *Dodecas elongata*, and that it has three pairs of branchial vesicles, and the degraded third pereopods ending in a strong claw.

In Mayer's first system *Caprellinoides* will stand between *Caprellinopsis* (= *Caprellina*, Thomson) and *Podalirius*, in his second perhaps between *Proto* and *Caprellinopsis*,

and in his third along with *AEGINA* and *AEGINELLA*. In the arrangement which Mayer adopts for his own work *Caprellinoides* might provisionally follow *Caprellinopsis*, but the doubtfulness of the lower antennæ and the uropods prevents any certain decision.

Caprellinoides tristanensis, n. sp. (Pl. CXLI.).

Body smooth, slender; the rather skull-like head with the closely coalesced first segment of the peræon together shorter than the second segment of the peræon; this much shorter than the third, the third shorter than the fourth, the fourth about half the length of the narrow and elongate fifth, the sixth not quite so long as the third, the seventh not longer than broad; the second segment is dilated anteriorly and narrow distally, the third and fourth, as usual in the female (which sex alone was available for investigation), much dilated, the third narrow for a very short space in front, the fourth abruptly narrowed and tapering for the distal third of its length. The pleon has the appearance, viewed laterally, of consisting of two very small joints, the second much smaller than the first, but such an appearance is explained by Mayer¹ to be due to the valve at the opening of the intestinal canal.

Eyes not clearly made out.

Upper Antennæ.—First joint stouter than the second, but not so long; second joint twice as long as the third; the third a little widened distally; the flagellum longer than the peduncle, of four elongate joints, the first as long as the second joint of the peduncle, with two cylindrical filaments, each of the other joints with one such filament; there are a few setules or cilia on the peduncle as well as on the flagellum.

Lower Antennæ not much longer than the peduncle of the upper, the first two joints very short, the gland-cone small, decurrent; the third joint about as long as the coalesced first and second; the fourth joint longer than the three preceding united; the fifth joint rather longer than the fourth; of the flagellum only two joints remaining, the second considerably longer than the first, the appearance of its distal end indicating that a third joint had probably been broken off.

Upper Lip apically cleft.

Mandibles.—The cutting plate divided into five teeth; the secondary plate, at least on one of the mandibles, nearly as broad as the primary, and likewise divided into five teeth; on this mandible a small prominence was visible, looking like a short double-headed spine; the first joint of the palp short, the second scarcely so long as the third, with a setule near the middle of the inner margin, the third joint with five slender spines on the oblique apical margin. *Caprellinopsis longicollis* (Nicolet) from New Zealand has a somewhat similar palp, but with the second joint rather longer than the third, carrying five setiform spines, the third joint having four unequal spines on

¹ Caprelliden, p. 95.

the apical margin, and at the actual apex a short stout spine pectinate on two edges and with a slender curved tip.

First Maxillæ.—Inner plate absent or rudimentary; outer plate not broad, apically carrying five or (perhaps) six small spines; the first joint of the palp more than half the length of the second, the second having a few spinules or setules on the more or less denticulate apical margin.

Second Maxillaæ.—The inner plate very small, with two small setæ or slender spines on the rounded apex; the outer plate apically rather narrower than the inner, with three or four spines or setæ, the outer margin bowed out below.

Maxillipeds.—The inner plates very small, not reaching even to the base of the palp, having a setule on the inner margin and two on the rounded apex; the outer plates narrow, reaching about to the centre of the second joint of the palp, with four spinules along the inner and apieal margin; first joint of the palp the shortest, the seeond not twice as long, with a small spine on the inner margin near its apex, the third joint about equal in length to the second, with three spinules near the inner apex and a setule near the outer, the finger as long as either of the preeeding joints, with a cilium near the acute curved tip.

First Gnathopods attaehed close to the maxillipeds. The first joint little longer than the hand, a little widened distally; the second joint rather longer than broad, the third joint longer than the second, as long as the wrist, narrow at the neck, the hind margin longer than the front, nearly straight, the broad apex having two setules, the surface one; the wrist small, four-sided, earrying a couple of setules, the front margin the longest, convex; the hand much larger than the wrist and abruptly wider, between oval and triangular in shape, narrowing to the distal end, the front margin convex, with some apical setules, and a row of setiform spines on the surface near its distal half; the short hind margin almost at right angles to the front margin, while its place is practically taken by the long, nearly straight, palmar margin, which has a row of four spinules and another of four setules adjacent to it, the edge itself being microscopically ciliated or pectinate; the long, curved, acute finger matches the palm, its tip closing down between two small palmar spines, its inner edge strongly pectinate.

Second Gnathopods attached close to the proximal end of the segment. The first joint similar in shape to that in the preceding pair; the second joint longer than broad, longer than the third joint; the third joint very short, front and hind margins almost equal, narrow at the neck, the distal margin flat; the wrist very small, triangular, shorter than the third joint, with only the front margin free; the hand similar in structure to that of the first gnathopods, but less narrowed apieally, the palm margin entirely taking the place of the hind margin, from which it is marked off by a small projection with a strong palmar spine planted on it; the palm margin, besides having some spinules and setules at intervals along it, is finely but irregularly denticulate,

with two small teeth breaking the line of denticles in the distal half; the long and powerful finger has a sharp tip, which closes down between and beyond the large palmar spine and a smaller one on the surfacee ; its inner edge is smooth.

First Peræopods wanting, or only represented by the small joint, at the extremity of which the branchial vesicles are attached. Branchial vesicles small and almost round, a little narrowed at the point of attachment. Marsupial plates enormously larger than the branchial vesicles, oval, the distal end the larger, the rim crenulate, fringed with setæ.

Second Peræopods in the same condition as the first. The branchial vesicles and marsupial plates nearly as in the preceding segment, but in this the marsupial plates are directed forwards instead of backwards ; they are, like the others, fringed with setæ.

Third Peræopods three-jointed, attached above the centre and at the broadest point of the very narrow elongate segment ; the first joint attaehed to the distal border of a small laminar projection which may be regarded as representing a side-plate, the joint not twice as long as broad, distally widened ; the following joint more than twice as long, armed with two or three setules ; the third joint as long as the first, slightly tapering, with a setule at the apex, and one on either side a little way above it. There is little or nothing to indicate what joints are homologically represented by these three ; it may be supposed that the last represents the hand or fifth joint, and that the penultimate represents the fourth, or the third and fourth combined.

Fourth and Fifth Peræopods.—Of these nothing was left but the stumps, but the muscles running to them indicated that they are probably of the average size and strength in proportion to the size of the animal.

Uropods.—There was nothing about the pleon to indicate whether the uropods were naturally or accidentally wanting.

Length.—The specimen, in the position figured, measured without the antennæ one-seventh of an inch. Fully extended it would have been rather more.

Locality.—Station 135c, off Nightingale Island, Tristan da Cunha, October 17, 1873 ; depth, 110 fathoms. One specimen, female.

Remark.—The speefie name refers to the place of capture.

Genus *Protellopsis*, n. gen.

The *First* and *Second Peræopods* rudimentary, consisting of two joints.

Uropods of the first pair reaching beyond the pleon, two-jointed, the second joint comparatively long and narrow ; the second pair short, tapering.

In other respects this genus is like *Protella*, Dana.

In Mayer's arrangement of the Caprellidæ this genus will stand immediately in front of *Protella*.

Protellopsis kergueleni, n. sp. (Pl. CXLII.).

The Head smoothly rounded above; the first segment of the peraeon longer than the head, with a single dorsal upright tooth at the distal end; the second (first free) segment with two dorsal spines inclining forwards at about the centre, and a single larger and more upright one at the distal end; the hinder part with its lower margin overlapping the base of the next segment; the third segment rather longer than the second, having at the distal end a tooth broader than high; the fourth segment a little shorter than the third; the fifth longer than either, and longer than the sixth and seventh together, having a projecting tooth on either side near the base, widening to the attachment of the limbs, then abruptly narrowing; the sixth segment much longer than the seventh, distally widened. There are no ventral spines. The animal is sometimes speckled with dendritic markings on almost all parts.

Eyes round, retaining colour in the specimen mounted in Canada balsam.

Upper Antennæ.—The first joint rather shorter than the head and its accompanying segment, with a pair of spinules above the centre of the upper margin, and three or four on its distal end; the second joint thinner and longer; the third about half the length of the first, widening a little distally; the flagellum longer than the peduncle, of thirty distinct joints, the first as long as the following three together; the joints tipped with small setules, the distal joints long and thin compared with the proximal, excepting the first.

Lower Antennæ thinner and little longer than the peduncle of the upper, the first two joints short, the gland-eone of the second tolerably acute and prominent; the third joint as long as the two preceding united, with a few spinules near the distal end; the fourth joint subequal in length to the first of the upper antennæ, and the fifth a little shorter than their second; the two-jointed flagellum is little more than a third as long as the fifth joint of the peduncle, its first joint having spinules at four points of each margin, the longer ones below; the second joint is tapering, a third the length of the first, with two little curved spines and some setules at its apex.

Mandibles.—The cutting plate divided into five large unequal teeth; the secondary plate on the left mandible with a general similarity to the principal plate, against which it lies so closely that the teeth of the two plates could not be distinguished; the secondary plate on the right mandible apart from the principal plate, much smaller, with its distal edge cut into numerous denticles; the spine-row on the left mandible consisting of three large pectinate spines, the first the more tapering, the other two the more curved; the number of spines in the spine-row on the right mandible was not clearly ascertained; the molar tubercle prominent, with circular strongly denticulate crown; the palp longer than the trunk of the mandible, the first joint considerably longer than broad, the second joint not longer than the third, slightly

curved and widening a little distally, carrying three slender unequal spines ; the third joint distally tapering, on the inner margin of this part carrying a row of about eighteen short spines, and at the apex a long pectinate spine, with a short stout one beside it on the outer side ; it also carries three spines on the outer surface at the other end of the row, two that are long and pectinate, and a shorter one.

Lower Lip.—The principal lobes wide apart, not very broad nor strongly ciliated ; the inner lobes rather broad, occupying much of the vacant space between the principal lobes ; the mandibular processes small and narrow.

First Maxillæ.—The inner plate seems to be entirely wanting ; the outer plate has seven spines on the apex, of which the innermost are more or less minutely denticulate, the outer three appear to be almost smooth ; the first joint of the palp is a little longer than broad, its outer margin longer than the inner ; the long second joint much overtops the adjacent plate, and on a strongly dentate apex carries four spine-teeth, and has a couple of setiform spines on the surface below these.

Second Maxillæ.—The inner plate broader and shorter than the outer, with some eight or nine setiform spines on the oblique apical border ; the outer plate with the like number round its apical border, the chief part of which slopes outwards, while that of the inner plate slopes entirely inwards ; the spines on these plates are scarcely plumose.

Maxillipeds.—The inner prismatic plates very small, scarcely reaching beyond the base of the first joint of the palp ; the apex of the inner margin projects a little, the apical border carrying a little imbedded spine-tooth and two curved setiform spines, two larger setiform spines being on the inner surface not far from the apex ; the outer plates are a little longer and reach a little beyond the first joint of the palp, with the inner margin straight, the outer convex, the armature consisting of a row of four or five spines spaced along the outer surface, and two marginal spines in notches, one on either side of the apex ; the first joint of the palp short, with two slender spines on the inner margin ; the second joint the longest, with several spines on and near the inner margin, the third joint rather longer than the first, with numerous spines about the slightly widened apex ; the fourth joint as long as the third, curved, the inner margin pectinate, the dorsal cilium close to the hinge.

First Gnathopods attached close to the maxillipeds ; the first joint much longer than the hand, narrow at the point of attachment, the front margin straight ; the second joint a little longer than wide ; the third rhomboidal, with a narrow neck, having a group of spines on the surface near the front and another at the lower angle behind ; the wrist longer than the third joint, as long as the hand, widening distally from a narrow base, set with numerous spines on the surface and round the hinder and apical margins ; the hand irregularly oval, the surface set with numerous groups of spines ; the hind margin much shorter than the front, the difference being made up

by the oblique palm, which is bordered with setules, having at the commencement two stout palmar spines, between which the long curved finger closes down. Most of the spines on this limb are strongly pectinate.

Second Gnathopods attached rather above the middle of the segment. The rudimentary side-plates very inconspicuous; the first joint long and narrow, rather longer than the hand, distally a little widened, at the extremity having the front margin rounded on the outer side, while on the inner side the front margin is produced into a sharp tooth; the second joint scarcely longer than broad; the third joint lageniform, three times as long as the second; the wrist a narrow triangle, little more than half as long as the third joint; the hand large and long, more than twice as long as the greatest breadth, which is at the produced setiferous tooth, with which the oblique hinder margin ends, and the long, somewhat convex palm begins; the palm margin is fringed with spinules and setules and forms another (not outstanding) tooth, not far from the hinge of the finger; the slightly convex front margin forms a very small produced tooth at its apex; the finger is long to match the palm, and, except at its apex, broad; the outer margin has some distant hairs, the inner is faintly crenulate, with the appearance of small canals running from the new growth to the raised points of the existing margin.

First Peræopods attached rather behind the middle of the segment. The branchial vesicles oval, large and long, attached by a short, narrow neck, which has almost the appearance of a joint. The limb very much smaller than the branchial vesicles, not a third of the breadth, and little over a third of the length. The first joint, attached to a small hinge-piece, is shorter than the second and widens distally; the second joint is narrowed at the apex, where it carries a few small hairs.

Second Peræopods similar to the first.

Third Peræopods attached on the ventral surface a little above the distal extremity of the segment. The first joint the longest, distally a little widened, with small groups of spines at three points of the front margin; the second joint scarcely longer than broad, with an apical group of spinules in front; the third joint longer than the fourth, widening to the distal end, with spinules along the front and at the apex behind; the fourth joint similarly armed, less narrow at the base; the fifth joint longer than the third, with a strong tooth projecting from the front margin close to the base and armed with small spines, the rest of the front border fringed with very small spinules; the convex hind margin has setules at three points; the powerful finger, broad except at the curved apex, is of a length to reach the projecting tooth of the front margin.

Fourth Peræopods attached on either side of the widened distal end of the segment, not materially differing from the preceding pair, but a little stronger.

Fifth Peræopods attached on either side of the distal end of the segment, similar

to the preceding pair, but rather stronger, the fifth joint longer; the little prominence on the front margin near the base of the fourth joint is rather more marked in the fourth and fifth than in the third peræopods.

Uropods.—The longer first pair are two-jointed, the first joint short, with a group of slender spines standing stiffly out from the outer distal angle, and a short spine at the inner distal angle; the second joint long, slender, somewhat curved, pectinate with small teeth at right angles to the concave inner margin, the convex outer margin having some spinules near the centre; the corner of the pleon just above the uropods has a group of slender spines; the much shorter second uropods are perhaps one-jointed; the terminal joint; whether solitary or not, is tapering, a little curved, smooth.

Length.—In the position figured, the specimen measured from head to pleon two-fifths of an inch.

Locality.—Station 149E, off Greenland Harbour, Kerguelen Island, January 21, 1874; depth, 30 fathoms; bottom, volcanic mud. Two specimens, males (one mounted in Canada balsam).

For the original definition of the genus, see Notes on Dana, 1852 (pp. 256, 265). It may now be defined as follows :—

Mandibles with a three-jointed palp.

Lower Antennæ with a two-jointed flagellum ; devoid of motor-setæ (Ruderhaare).

The two pairs of *Gnathopods* and three hinder pairs of *Peræopods* well developed ; the *First* and *Second Peræopods* rudimentary, consisting of a single joint.

Branchial Vesicles only on the third and fourth segments of the peræon.

Pleon two-jointed.

Uropods rudimentary, neither pair produced beyond the end of the pleon.

The definition given by Mayer has been a little enlarged with a view to the new genus *Protellopsis*. Haswell, in describing *Protella australis* in 1885, says that the flagellum of the lower antennæ "is composed of six articuli," without noting that this is contrary to Mayer's definition of the genus, which he apparently accepts.

Protella gracilis, Dana.

1852. *Protella gracilis*, Dana, U.S. Explor. Exped., vol. xiii. pt. ii. p. 812, pl. liv. fig. 2, *a-f*.

 1880. " *australis* (?), Haswell, Proc. Linn. Soc. N.S.W., vol. iv. p. 276, pl. xii. fig. 4.
 1882. " " Haswell, Catal. Australian Crustacea, p. 311.
 1882. " *gracilis*, Mayer, Die Caprelliden, p. 31.
 1885. " *australis* (?), Haswell, Proc. Linn. Soc. N.S.W., vol. ix. pt. iv. p. 5 (separate copy), pl. xlvi. figs. 2-4.

A female specimen ; the head and body smooth ; the convex dorsal line of the head longer than the dorsal, equal to the ventral, line of the ecaleseed first segment of the peræon ; the second segment of the peræon about equal in length to the third, the third a little longer than the fourth, the fifth longer than any of the three preceding, considerably longer than the next two united, the sixth dorsally little if at all longer than the seventh ; the pleon extremely short and small.

Eyes round, not very large, but with from eighty to a hundred ocelli in each.

Upper Antennæ.—The first joint longer than the head ; the second joint more than twice as long as the first, smooth-edged ; the third about as long as the second, narrower, slightly notched for setules ; the flagellum slender, not so long as the third joint of the peduncle, of about twenty-one joints, each carrying an apieal filament (the last joint perhaps excepted) and some setules.

Lower Antennæ not nearly so long as the peduncles of the upper, but longer than the

first two joints of those peduncles; the first and second joints short, the second with a very small decurrent gland-cone; the third joint longer than the preceding two together; the fourth longer than the first of the upper antennæ, fringed with slender rather distant setæ; the fifth joint longer than the preceding, fringed like it, not nearly so long as the second joint of the upper antennæ; the flagellum little more than half the length of the fourth and not nearly half the length of the fifth joint of the peduncle, the first joint about three times as long as the second, having spinules at four points of each margin, the second joint having one or two setules at its apex.

Mouth Organs.—As far as could be observed the mouth-organs are in near agreement with those of *Protella phasma* (Montagu), as figured by Mayer.¹ The specimen was mounted in Canada balsam by Willemoes Suhm on the voyage, and I have not dissected it.

First Gnathopods attached close to the base of the maxillipeds; the first joint a little longer than the hand, narrow at the neck, widening distally, having a single spine on the surface at a distance from the apex of the hind margin, one at the apex of the front margin, one at its centre, and a smaller one higher up; the second joint a little longer than broad, with some apical spines behind; the third joint longer than the second, with a group of slender spines near the rounded hind corner, the front apex acute, resting on the wrist; the wrist a long triangle, as long as the hand, with apical spines in front, and five groups of slender spines along the distal half of the breast; the hand more or less oval, wider at the base than distally, and wider at the base than the distal end of the wrist, with five rows of spines on the surface near the front margin; the palm occupying almost all the hind margin, fringed with setules interspersed with some slender spines; the elongate finger matching the palm, its curved tip reaching even beyond the small palmar spine.

Second Gnathopods attached not far from the proximal end of the segment; the rudimentary side-plates deeper in front than behind; having just in advance a small piece bulbous at the base and distally spine-like, the distal part seemingly adnate to the first joint of the limb; the first joint shorter than the hand, narrowing a little below the proximal end, then widening for the distal half which is channelled in front; the second joint scarcely longer than broad; the third joint little longer than the second, distally rounded, this like the two preceding joints having a slender spine at the hinder apex; the wrist very small, triangular, about as long as, and lying close beside the third joint; the hand large, more or less oval, more than twice as long as broad, with small spines distantly spread along the convex front margin; the hind margin apart from the palm short, carrying a few small setæ; the palm long, defined by a tooth or projection carrying a palmar spine, fringed by setiform spines and spinules, an excavation at a little distance from the finger hinge forming a narrow tooth on one side, and on the side nearer the hinge an angular point rather than a tooth; the finger large and long, its curved apex closing

¹ Die Caprelliden, Taf. v. figs. 19–21.

down beside the palmar spine, its inner margin having a few hairs, the dorsal cilium minute, close to the hinge.

First Peræopods attached behind the centre of the segment. The branchial vesicles large, oval. The marsupial plates much larger than the branchial vesicles; the free margin fringed with setæ. The limb consisting of a long slender joint attached by a small hinge, the length about two-thirds, the breadth about one-third, that of the branchial vesicles, the rounded apex carrying several setules.

Second Peræopods attached in front of the centre of the segment, the details similar to those of the preceding pair, except that no setæ were perceived on the marsupial plates.

Third Peræopods attached nearly at the distal end of the segment, with the little smooth-rimmed oval genital-valves projecting from the ventral surface of the segment just in advance of them. The side-plates as usual quite small; the first joint widening a little distally, with some spines at the apex and one or two spines higher up on the front margin; the second joint scarcely longer than broad, with some apical spines; the third joint not quite so long as the first, widening a little distally, with apical spines and a small group of spines near the middle of the front margin; the fourth joint as long as the first, with spines at four points of the front margin and many round the apex; the fifth joint about as long as the fourth, with spinules at various points of the hind margin, the front margin smooth for the first fourth of its length or a little more, then forming an advanced point, on which are fixed a pair of rather slender spines apically serrate; below these the margin is bordered with spines of various lengths and thicknesses, and setiform spines are set round the sloping sides of the apex; the finger is strong, curved, capable of reaching the pair of spines on the advanced point of the hand, its inner margin carrying a few hairs.

Fourth Peræopods attached quite at the distal end of the segment, similar in armature and general structure to the preceding pair, but the second joint longer than broad, the third joint rather longer than the fourth, the fourth considerably shorter than the first, the fifth longer than the first.

Fifth Peræopods attached at the distal end of the segment, resembling the preceding pair in structure, but exceeding these and the third pair in size, to some extent in length but especially in breadth.

Uropods.—Viewed laterally the diminutive pleon presents the appearance of a basal joint, the distal margin of which is (laterally) emarginate, having a pair of small oval appendages attached at the upper end of the emargination, and folding back so as nearly to reach its lower end. There are some minute setules at the apex in these appendages.

Length.—In a slightly bent position the mounted specimen measures, from the front of the head to the pleon, a quarter of an inch.

Locality.—The label gives “Caprella, 28 fathoms, Arafura Sea.” On the glass slide there is the monogram **S**.

Station 188, Arafura Sea, September 10, 1874; depth, 28 fathoms; bottom, green mud. One specimen (mounted).

Remarks.—Dana's specimens were "from thirty-one fathoms water, in Balabac Passage, attached to a Plumularia and a Gorgonia." He gives the colour as "pale yellowish." In Mr. Haswell's figures and descriptions of *Protella australis* I can find little to distinguish it from Dana's species, except in "the presence of a pair of short, acute, forwardly directed spines on the head."¹ But in the earlier account² he says "Cephalon armed above with a single short, anteriorly directed spine," and again "the cephalic spine is sometimes rudimentary." In the statement that the flagellum of the lower antennæ "is composed of six articuli,"³ which I have already noticed as contrary to the generic character of *Protella*, there must, I think, be some misapprehension. In the original account⁴ Mr. Haswell only says "flagellum very short." One point, however, remains: Mr. Haswell says, "the branchiæ are long oval; the corresponding appendages are distinct, between a third and a half the length of the branchiæ."⁵ In Dana's figures and in the Challenger specimen the rudimentary pereopods are much longer in proportion to the branchial vesicles than in Mr. Haswell's description of his species; but in Dana's figures the legs are proportionately much larger than in the Challenger specimen, so that probably these appendages are very variable in size within the species. The other details given by Mr. Haswell agree so well with Dana's figures and with the specimen here described, that they strongly tend to confirm the opinion expressed by Mayer⁶ that *Protella australis* is a synonym of *Protella gracilis*.

 1887. „ Hansen, Oversigt over de paa Dijmphna-Togtet indsamlede Krebsdyr.

Since the name *Aegina* given by Krøyer was preoccupied, and Mayer has shown that in all probability Boeck's genus *Aeginella* is identical with *Aegina*, the latter name will take the place of the earlier. For Krøyer's definition, see Note on Krøyer, 1843 (p. 202), and for Boeck's, see Note on Boeck, 1860 (p. 325). The definition will at present stand as follows :—

- Mandibles* with a three-jointed palp.
Lower Antennæ with a two-jointed flagellum.
First and Second Peræopods wanting, the other limbs of the peræon normal.
Branchial Vesicles only on the third and fourth segments of the peræon.
Pleon one-jointed.

The only distinction drawn by Boeck between *Aegina*, Krøyer, and his own *Aeginella* was that in the former the first uropods were two-jointed, and in the latter one-jointed. Mayer thinks that this distinction may have been due to an error of observation. In any case it may, I think, be allowed to rank as not more than a specific difference. In the new species here assigned to the genus the uropods were not present.

Aeginella tristanensis, n. sp. (Pl. CXLI).

Head with the dorsal margin rounded in front; behind the middle there rises a little blunt tooth, directed slightly forwards, and having a cilium at its base behind; the first segment of the peræon is intimately coalesced with the head, its dorsal margin shorter, its ventral longer than the head; the second segment shorter than the third, dilated in front except at the neck, with a minute tubercle dorsally in front of the centre; the third segment longer than the fourth; the fourth than the fifth; the fifth than the second; the sixth longer than the seventh, these two together not quite so long as the second. Pleon as in *Caprellinopsis tristanensis*.

Eyes small, round, with about eighteen ocelli, not all of the same size, nor set very close together.

Upper Antennæ.—First joint nearly as long as the top of the head; second nearly as long as the first and third together; third more than half the length of the first, widening distally; flagellum rather longer than the peduncle, consisting of seven elongate unequal joints, each except the first with a slender apical filament and some cilia, the first joint the longest, longer than the third joint of the peduncle, the second joint the shortest, less than half the length of the first.

Lower Antennæ very little longer than the peduncle of the upper antennæ, the first two joints closely coalesced, the gland-cone small, scarcely decurrent, the third joint very little longer than the two preceding united; the fourth joint considerably longer than the three preceding together; the fifth a little longer than the fourth; the flagellum not so long as the fourth joint of the peduncle, the first joint longer than the second, each carrying apical cilia or setules, the second not by any means rudimentary, as would be required by Krøyer's definition of the genus *Aegina*.

Mandibles.—The details not clearly made out; the cutting plate cut into several teeth; the palp elongate, the first joint a good deal longer than broad, the second more than twice as long as the first, with one or two setules near the centre of the front margin; the third joint rather longer than the second, with four or five setæ or slender spines on the oblique apical margin.

First Maxillæ.—The outer plate with five or six small spines on the apical margin; the palp with three or four spinules on the apical margin of the second joint, and one or two setules on the surface or outer margin.

Second Maxillæ.—Inner plate small, much shorter than the outer, with four or five apical setules; the outer plate with five or six apical setules or slender spines, longer than those on the inner plate.

Maxillipeds.—Inner plates very small, scarcely reaching the base of the first joint of the palp, with a couple of setules on the rounded apex; the outer plates reaching a little beyond the first joint of the palp, with two setules on the apex and three on the inner margin; the first joint of the palp the shortest, the second longer than the third, the third with setules about the apex, the fourth not much, if at all, shorter than the second, curved, acute.

There is a great resemblance between the mouth-organs of this species and those of *Caprellinopsis tristanensis*, but the minuteness of the specimens made a thoroughly satisfactory comparison of the details impracticable.

First Gnathopods attached close to the maxillipeds. The first joint about as long as the hand, widening a little distally, the front margin nearly straight; the second joint scarcely longer than broad, with a cilium near the apex behind; the third joint longer than the second, with two spines and a seta at the tolerably broad apex; the wrist about as long as the third joint, widening distally, and on the lower margin armed with three spines; the hand much longer and broader than the wrist, more or less oval, the front margin nearly three times as long as the hind margin without the long oblique palm, which is defined by some very small palmar spines and fringed with a few setules; there are two or three small groups of setiform spines on the surface near the front margin; the finger is long, curved, acute, matching the palm, carrying a dorsal cilium near the hinge, and a couple of cilia at the base of the short nail or nail-like tip.

Second Gnathopods.—As with the other limbs there is a rudimentary side-plate.

The attachment is very near the proximal end of the segment, the first joint subequal in length to the hand, little widened distally; the second joint little longer than wide; the third joint slightly longer than the second, with a rather broad, flat, distal margin, having a cilium near its hinder apex; the wrist very small, triangular, shorter than the third joint, with only the front margin free; the hand large, twice as long as its greatest breadth, the position of the hind margin entirely occupied by the palm, which is defined by a slightly projecting point, within which a palmar spine is planted; the palm border is smooth except for a tooth below the centre pointing towards the hinge; there are setæ or setules at various points on either side of the edge of the palm; the finger matches the palm, and is therefore long; it is also broad, except at the acute tip, thin-edged, and smooth, except for a few microscopic hairs or cilia; the dorsal cilium is not very close to the hinge.

First and Second Peræopods wanting. The branchial vesicles small, oval, closely attached to their respective segments a little behind the centre.

Third, Fourth, and Fifth Peræopods all missing from the specimen, with the exception of the rudimentary side-plates and the broken hinges. The place of attachment in each case is at the distal end of the segment. In the lateral view of the pleon, fig. *Pl.*, the letters *prp.*⁵ refer to the place of attachment of the missing fifth peræopods.

Uropods missing. On the ventral side of the very minute pleon there is a cilium. There is an appearance of a very small second joint partially telescoped within the broader first joint, but this I imagine to be the abdominal valve, which, according to Mayer, has often been mistaken for a second joint.

Length.—The specimen, in the position figured, measured without the antennæ about one-seventh of an inch.

Locality.—Station 135c, off Nightingale Island, Tristan da Cunha, October 17, 1873; depth, 110 fathoms. One specimen.

Remark.—The specific name refers to the place of capture.

For the original definition of the genus, see Note on Lamarek, 1801 (p. 66); Mayer characterises it as follows:—

“The third and fourth segments of the *Peræon* are without legs.

“The *Mandible* is without a palp.

“There are only two pairs of *Branchial Vesicles*, these being attached to the third and fourth segments of the peræon.

“The *Lower Antennæ* have a two-jointed flagellum.”

He adds that the dimorphism, so strongly developed in many species of the genus, to which Krøyer called attention, is brought about by the circumstance that in the male during growth an enormous elongation of the front part of the body often takes place, sometimes bringing the second gnathopods not only near to the distal end of their own segment, but sometimes to the middle of the animal's body. In this change the females and young males are not concerned. He considers that Haller has pointed out a useful distinction between species which have on the lower antennæ motor-setæ (Ruderborsten), and those which have sensitive setæ (Sinnesborsten). Another mode of grouping species he finds in the distinction between those which in the adult male have the first joint of the second gnathopods very long, and those in which it remains short. Of minor and less decisive distinctions, he refers to the length of the upper antennæ and the number of joints that they have in the flagellum, and to the position of the palmar spines on the last three pairs of peræopods.

¹ Spence Bate and Mayer both refer for this species to the Voy. en Scand., pl. vi. fig. 15, but there is no species so named on that Plate or in any part of the work referred to. The reference in the Brit. Mus. Catal. Amph. Crust., p. 362, was probably intended for a reference to the *Naturh. Tidsskrift*, which Mayer gives correctly.

A few notes are added in regard to this widely distributed and often described species for the identification of the Challenger specimens.

Upper Antennæ with the peduncle stout, the third joint longer than the first, each of these shorter than the second; the flagellum abruptly narrower than the peduncle, of twelve joints, almost all of which are distally expanded, and all of them together not nearly as long as the third joint of the peduncle. In the female specimen examined the flagellum was less conspicuously narrower than the third joint of the peduncle and exceeded that joint in length.

Lower Antennæ.—The flagellum nearly as long as the fourth or the fifth joint of the peduncle, strongly fringed like them, with short curved spines on the distal part of the long first joint, which is six or seven times as long as the second, this terminal joint being very narrow as well as short. In the female the flagellum is quite as long as the fifth joint of the peduncle.

Upper Lip bilobed.

Mandibles.—Cutting edge divided into five strong but very unequal teeth; secondary plate of the left mandible strong, divided like the principal plate; secondary plate of the right mandible slighter, with a prominent slender distal tooth, and the upper edge only slightly divided into two or three inconspicuous denticles; spine-row on the left mandible of three, on the right of two, stout curved feathered spines; molar tubercle strong, with a powerful tooth on the front border, giving the crown a very irregular outline.

Lower Lip.—Principal lobes strongly dehiscent, only a little advanced in front of the inner lobes which are fully as large as the outer, and fill up almost all the gap between them, but the inner lobes about halfway from the base become coalescent with one another, and their outer margins not very far from the rounded apical borders seem to lose themselves on the sides of the principal lobes; the mandibular processes not divergent, apically narrow.

First Maxillæ.—Inner plate undeveloped; the outer plate smaller than the palp, with the dentate distal margin carrying seven spines, all of them having one or more strong lateral denticles; the first joint of the palp short, the second widening towards the dentate obliquely convex distal margin, which is fringed with thirteen slender spines, none very long, the outermost the longest, the innermost six slenderer than the rest; on

the surface near the apical margin and the distal part of the inner margin there are fourteen slender spines of greater length than those on the apex.

Second Maxillæ.—Inner plate shorter and more oval than the outer, with many slender spines round the apical margin and descending the inner margin for some distance; the outer plate oblong, with many long spines on the apical margin, of gradually greater length as they approach the outer corner, where there is one short spine; the apical margin for the most part truncate, but with an oblique portion where it joins the inner margin.

Maxillipeds.—The inner plates small, scarcely reaching beyond the base of the first joint of the palp, widening distally, with two long slightly feathered spines near the distal part of the inner margin, and seven on or near the broad slightly denticulate distal margin, which also carries two or perhaps three distant spine-teeth; the angle where the distal and inner margins meet is finely but irregularly pectinate; the outer plates small, reaching little beyond the first joint of the palp, with eight rather long spine-teeth on the straight but denticulate inner margin, and on the oblique denticulate apical margin a spine-tooth at the inner corner, and a long curved spine at the outer; the first joint of the palp short and stout, with spines on the inner margin, and one below the centre of the outer; the second joint stouter than the first, scarcely twice as long as broad, the inner margin fringed with long spines, of which there are two near the outer apex; the third joint intermediate in length between the second and first, its distal half crowded with spines, especially on the inner surface; the finger abruptly narrower, not very much shorter, than the third joint, with a short dorsal cilium near the hinge, its surface covered with rows of minutely pectinate scales or appearances that may be so described; there is a setule on the inner margin at the base of the slightly narrowed furred tip.

The limbs are in close agreement with the figures and descriptions given by Mayer for this species.

Length.—Some of the male specimens were about an inch long from the rostrum to the pleon, with the gnathopods inserted behind the centre of the body; in these specimens the upper antennæ were more than half an inch long, the total outstretched length including the antennæ and hinder pereopods not being less than an inch and three-quarters.

Locality.—“Screw of ship, off Cape of Good Hope, 18 Dec. 1873” (corresponding with Station 142; lat. $35^{\circ} 4'$ S., long. $18^{\circ} 37'$ E.). Several specimens of both sexes and of various sizes.

Samboangan, Philippines, February 18, 1875; lat. $2^{\circ} 56'$ N., long. $134^{\circ} 11'$ E. One specimen, male; total length about seven-tenths of an inch.

 1884. " *attenuata* (?), Miers, Report on Zool. Coll. H.M.S. "Alert," p. 320.

In regard to the above-given synonymy I accept Mayer's conclusion that the minute *Caprella nodosa* of Templeton is no doubt the young of *Caprella scaura*; whether it is the female form is perhaps not easy to determine in regard to so small a specimen as that which Templeton describes. Mayer is strongly inclined to make Dana's *Caprella attenuata* a synonym of *Caprella scaura*. Dana's species was found at Rio de Janeiro, and Mayer has received specimens both from Rio and from Australia (Port Jackson). Templeton's species was found at Mauritius; the Challenger specimens came from the neighbourhood of Japan, and agree so closely with the figures and descriptions given by Templeton and Dana for the male and by Mayer for both sexes, that there can be no further doubt about the identity of *Caprella attenuata* with *Caprella scaura*, the species evidently having a very wide distribution. As Mayer's figures of the two sexes have already shown, there is in this species the curious peculiarity that the female is spiny or tuberculated, while the male except for the cephalic tooth or horn is very nearly smooth. In the species which Boeck calls "*Caprella californica*, Stimpson," taken in the neighbourhood of San Francisco, there is the same peculiarity, and allowing for a certain amount of variation, such as is almost certain to occur where one sex is smooth and the other spiny, Boeck's description seems to justify the addition of *Caprella californica* to the synonymy of *Caprella scaura*. It is to the following effect:—

"The animal's length is in the ♂ from head to pleon 16^{mm}, in the ♀ 13-14^{mm}. The body is as in *C. lincaris* Lin. (*C. lobata* Müll.) very different in ♂ and ♀. In the former it is

¹ Krøyer, Naturh. Tidsskr., R. 1, Bd. iv. p. 504, 1843, refers to *Caprella scaura* and *Caprella nodosa* in a footnote.

especially elongate, the head is above armed with a strongly forward curved horn. The first and second segments of the body are about equally long, the latter somewhat thickened towards the hinder end, where the second gnathopods are fastened. The two following segments are very short, of equal length, and together as long or slightly longer than the second segment; the fifth segment is longer than the preceding, but shorter than the two preceding together, and much longer than the two last segments together. In the younger ♂ on the other hand the first and second segments of the body are not so long, yet longer than the third segment. In the ♀ the first segment is tolerably short, much shorter than the second segment, which is thickest in the front part, where the first [second] gnathopods are fastened; the third and fourth segments together are much longer than the other segments and furnished with a large brood-pouch. The three hinder segments are in the female sometimes furnished with spines, which were not found in any adult specimen of the ♂, but only in a younger one. The *upper antennæ* are in the male especially elongate, and when bent back reach the fifth segment of the body. The first joint of the peduncle is more than a third shorter, but much thicker than the second and about as long as the very thin third joint. The flagellum is longer than the third joint of the peduncle and consists of 16 joints in the ♂ and 10 in the ♀. The *lower antennæ* are in the ♂ much shorter than the upper, and reach to somewhat beyond the middle of the second joint of the peduncle of the upper antennæ; the third and fourth [? fourth and fifth] joints are about equally long, and the flagellum, the second joint of which is scarcely a fourth of the length of the first joint, is slightly longer than the last joint of the peduncle. The antennæ are furnished with long groups of setæ on the lower margin. In the ♀ on the other hand the antennæ, especially the upper, are much shorter than in the ♂ and when bent back do not reach the fifth segment of the body; the second joint of the peduncle is not much longer than the first, and the third is much shorter. In the younger ♂ also the third joint of the peduncle is shorter than the first. The *lower antennæ* are in the ♀ as compared with the ♂ much longer and reach beyond the third joint of the peduncle of the upper antennæ. The *first gnathopods* are alike in both sexes and completely agree with those of *C. linearis*. The *second gnathopods* are in the male especially elongate. The first joint is nearly as long as the segment of the body to which it is fastened, and is prolonged downwards on the front apex in a strong spine. The hand is as large as the first joint, becomes broader outwards and is nearly club-shaped and rounded at the outer extremity; the upper half of the hinder margin is armed with three teeth, the two uppermost small, while the third is broad, triangular. The finger, which is attached at the end of the hinder margin, is very strong and armed with a little tooth at the upper part of the hinder margin. In the younger ♂ the first joint of the gnathopods is shorter than the second segment of the body and shorter than the hand, which is not so narrow. In the ♀ these gnathopods

are very short; the first joint is much shorter than the second segment of the body, and much shorter than the oval hand, which is only armed on the hinder longer margin with two small teeth. The branchial vesicles are of an elongate oval form. The three hinder pairs of feet are successively longer, and are shorter, with much broader joints, than in *C. linearis*. That pair, which is attached to the fifth segment of the body, is the shortest; its first joint is only a little longer than broad, and the lower hinder angle is outdrawn into a spine; the fourth joint is about as long as broad. The hand is somewhat shorter than the preceding joints together and is somewhat more than double as long as broad. The palm is furnished with setæ. On the last legs the joints are much longer and narrower." With this should be compared the description given as follows by Stimpson:—

"The body in this species is slender. The antennæ are exceedingly variable in their proportions; the flagella of the superior ones 10–15 articulate; inferior ones subpediform. A more or less developed spine, which curves forward, and is sometimes of considerable length, is placed upon the dorsal surface at the anterior extremity of the first thoracic segment. Hand of the second pair of feet generally three-toothed on the inner surface; teeth (in full-grown specimens) about equal in size, and placed mostly toward the outer extremity of the palm. Two or three sharp tubercles along each of the sides of the branchiferous segments; and a short dorsal spine on each of the three posterior segments. Hands of posterior feet slender. Color, variable. Length, one-inch; breadth, about 0·03 inch. Found on seaweeds, etc., below low-water mark in San Francisco Bay, near its entrance."

It is probable that by "the anterior extremity of the first thoracic segment" Stimpson intends the head. Boeck did not find in his specimens the sharp tubercles on each side of the branchiferous segments, and does not consider that Stimpson's description of the hand of the second gnathopods agrees with his own.

Guérin-Méneville's *Caprella tuberculata*, 1836, and Lockington's *Caprella spinosa*, 1875, if the types are accessible, may eventually be found to belong to this species, or to be varieties of it.

As observed in the Challenger specimens, the male of this species attains a very considerable length, measuring a good deal more than one inch without the antennæ and hind peræopods. The forward-directed horn on the short head is small; the proportions of the segments vary as usual with the size of the specimen; in the longest specimen the first segment measured not less than three-tenths of an inch and was even longer than the second segment, though these proportions in other specimens were reversed; the suture between the head and the first segment seems to be almost or quite continuous; the second segment is much longer than the third; the third is subequal to the fourth, the two together longer than the second, and each having a small dorsal tooth at the extremity, though in some specimens this, especially on the

third segment, is evanescent; these two segments have also one or two lateral teeth or tubercles behind the place of attachment of the branchial vesicles; the fifth segment is longer than the fourth, with some very inconspicuous raised points on the back; the sixth and seventh segments are subequal, about as broad as long, together shorter than any one of the preceding segments, inconspicuously tubercled on the back.

Eyes small, round, situated on the advanced lateral lobes of the head.

Upper Antennæ in the largest specimen about seven-tenths of an inch in length; the first joint of the peduncle thicker than the second, more than half its length; the second joint with the distal part rather abruptly thicker than the proximal; the third joint thinner than the second, in the longest specimen subequal to it in length, in others intermediate in length between that and the first, widened at the distal end; there are setules and cilia scattered over the whole peduncle; the flagellum a little shorter or a little longer than the third joint of the peduncle, with twelve joints in a dissected specimen, of which the first was the stoutest, nearly equal in length to the remaining eleven together; of these the first nine are widened distally, each carrying an apical filament and setules, the serrate lower margin of the first joint being similarly furnished at nine points.

Lower Antennæ not reaching the end of the second joint of the peduncle of the upper antennæ; in structure as in the female.

Mouth Organs as in the female.

First Gnathopods as in the female.

Second Gnathopods attached almost at the distal end of the narrow second segment, which is there a little widened; the first joint of great length, sometimes longer than the segment as well as longer than the hand, though these proportions, like others, vary in different specimens; there is a little widening of the joint at the distal end, and as in the female a small apical prolongation of the front margin; the second joint is not broader than long; the third joint is a little longer than the second, with scarcely any free front margin, the hind margin almost semicircular, with a setule here and there; the very small wrist is scarcely distinct from the very narrow base of the hand; the hand very long, nowhere very broad, widening gradually for about half its length, that is, from the base to the beginning of the palm, which is defined by a small projecting tooth carrying a palmar spine and setules; thence the palm margin, fringed with a spine or two and some spinules and setules, but otherwise smooth, runs a little obliquely so as to narrow the hand till it projects in a prominent narrow tooth, followed by a small cavity beyond which a broad tooth or process leads up to the hinge of the finger; the finger is greatly curved, of a length to match the palm, broad, especially where the inner margin swells out with a prominence that bites against the large tooth-process of the palm.

The Branchial Vesicles of the third and fourth segments are very long and narrow, subequal in length to their respective segments.

The Peræopods resemble those of the female in general, but the serrated palmar spines are placed a little lower down, and the front surfaces of the hand above these presents a more conspicuous set of spinules; the dorsal margin of the finger is set round with a series of eilia or setules, which are perhaps only accidentally absent from the female specimen described.

The following description refers to the female specimen figured on Pl. CXLIV. :—

The lateral lobes of the head scarcely project so far as the frontal process; the suture is deep between the head and the first segment of the peræon, which is about equal in length to the head, and carries almost at the distal end a dorsal tooth, bent very slightly forwards, and, like the other dorsal processes, slightly ciliated; the second segment is longer than the head and first segment united, longer also than the third segment, dorsally carrying a pair of teeth in front of the centre and a single tooth at the distal end, where there is also a small tubercle on either side; the third segment has a rather larger pair of lateral tubercles near the base, and two dorsal tubercles, the larger behind the centre, the smaller at the distal end; the fourth segment is not shorter than the third, and has a couple of dorsal teeth at about the centre and one tooth at the distal end; the fifth segment is a little shorter than the fourth, and has a tubercle on each side not far from the base, a pair of dorsal teeth at the centre, and another pair not far behind these; the lateral borders are distally emarginate for the insertion of the peræopods and are acutely produced both at the upper and lower ends of the emargination; the sixth segment, which like the fifth and seventh is widened distally, is short, subequal in length to the seventh, and, like it, carrying a pair of dorsal tubercles.

Eyes small, situated on the lateral lobes of the head, with numerous very small ocelli.

Upper Antennæ.—The first joint stout, longer than the head; the second joint longer than the first, the third thinner than the second, as long as the first; the flagellum of fourteen joints, of which the first is much the longest, the second the shortest; all have apical setules and all but the last an apical cylindrical filament.

Lower Antennæ.—First two joints short, the gland-zone not produced along the side of the third joint; the third joint about twice as long as broad; the fourth joint as long as the third joint of the upper antennæ, with motor-setæ at about a dozen joints, longer as they approach the distal end; the fifth joint rather thinner and a little longer than the fourth, with similar setæ; the flagellum nearly as long as the fourth joint of the peduncle, the first joint carrying feathered setæ and setules like those on the fourth and fifth joints of the peduncle, and apically a pair of spines, which indeed are like the feathered setæ except in being shorter and slightly thicker; the second joint not quite a third as long as the first, with a similar pair of apical spines amidst numerous apical setules.

Upper Lip distally bilobed a little unsymmetrically, strongly ciliated.

Mandibles.—The cutting plate divided into five or six strong teeth, of which one or two are much more prominent than the rest; the secondary plate on the left mandible similar to the principal, divided into four or five teeth; on the right mandible the edge of this plate seems to be rather denticulate than cut into regular teeth, but this may be an effect produced by wear in the actual specimen examined; spine-row consisting of three serrate spines on the left mandible, of two on the right; the molar tubercle powerful, ciliated, apparently not strongly denticulate, presenting an angular prominence on the side near the spine-row.

Lower Lip.—The principal and inner lobes strongly ciliated; the mandibular processes narrow.

First Maxillæ.—Inner plate wanting; outer plate carrying seven strong spines, of which four are fureate with some serration of the edges, the others are more or less denticulate; the first joint of the palp is short, with a seta at the outer distal angle; the second joint is long, widening distally, and there cut into seven or eight teeth between which are planted six spines, the outermost the longest; on the inner margin and the distal part of one surface there are several setæ.

Second Maxillæ.—The inner plate shorter, but at the base wider, than the outer, fringed with spines of various lengths round the apical margin and about to the centre of the inner; the outer plate with longer spines on the apical margin, and none on the straight inner margin.

Maxillipeds.—The inner plates narrow at the base, not reaching the apex of the first joint of the palp, with numerous feathered setæ on the inner surface between the centre of the inner margin and the centre of the apical; the apical margin broad, irregular, sloping inwards, carrying numerous feathered setæ, and near the outer corner a spine-tooth, together with one or perhaps two such near the inner corner; the outer plates small, just reaching beyond the apex of the first joint of the palp, the inner margin serrate, carrying some setæ and five rather distant spine-teeth; distally there is an emargination which may be reckoned either to the inner or apical margin, carrying two slender spines, the distal one stronger than its neighbour; the first joint of the palp shorter than any of the three following, with setæ on its inner margin; the second joint stoutest near the base, not twice as long as the first, fringed with slender setæ on the inner margin, the third joint almost as long as the second, with numerous long setæ or setiform spines, especially about the inner margin and apex; the finger as long as the third joint, curved, ending in a very sharp point, the inner margin forming a small tooth just in advance of the apex, its whole course finely pectinate, the surface also showing two or three series of little curved markings pectinate on the lower convex side.

First Gnathopods attached close to the maxillipeds. The first joint not longer than the hand, with the front margin straight, the hinder convex, carrying some apical spines; the second joint with some spines a little above the hinder apex; the third joint not

much longer than the second, with slender spines at two or three points of the straight hind margin, and several long ones on the inner surface near both the front margin and widened apex; the wrist rather broader than long, the rounded process behind not produced at all downwards, fringed with spines; the hand much longer than the wrist, narrowing distally, the lower border straight, the whole hind margin occupied by the palm which is finely cut into little bifid and trifid denticles, bordered with setules and defined by a couple of palmar spines; there are several setiform spines about the surface of the hand; the broad curved apically acute finger reaches over the full extent of the palm, the nail passing the palmar spines; the inner margin has a tooth just before reaching the nail, its whole extent being finely though irregularly denticulate, and, the inner part of the finger being channelled, there is a second more strongly denticulate margin.

Second Gnathopods attached near the front of the segment. First joint not so long as the hand, widened a little distally, and with the front apex a little produced; second joint not longer than broad, with a group of spinules above the hinder apex; third joint small, a little longer than broad, with a few small spines about the hind margin; the wrist broader than long, but of quite insignificant dimensions, forming rather a narrow base to the hand than acting as an independent joint; the hand large, twice as long as broad, the long convex front margin carrying a few small distant spines, the setiform spines of the surface not numerous, the hind margin short, oblique; the palm long, convex, fringed with many small spines and spinules, the margin very faintly crenulate, having a small acutely angled prominence not far from the hinge of the finger, while at the other extremity there is a bold tooth followed by a rather deep cavity with palmar spines above and below, between which the acute tip of the long broad slightly curved finger closes down; the inner edge of the finger is sharp and almost smooth; there are small setules on the surface within the inner margin, and there is a small dorsal cilium at some distance from the hinge.

First Peræopods.—Rudimentary side-plates very indistinct, behind the centre of the segment. Branchial vesicles elongate oval, the hinge joint very small. Marsupial plates large, with some short setæ about the front and long ones about the hinder margin.

Second Peræopods.—The diminutive side-plates at the centre of the segment. The branchial vesicles like the preceding pair. The marsupial plates without setæ.

Third Peræopods.—The small plate or joint within which (as seen from the ventral side) the first joint of the limb is socketed, is produced downwards and outwards to an acute apex. The first joint widening distally from a narrow neck, scarcely longer than broad, with some spines at each apex, the outer apex prominent, a little blunted; the second joint short and narrow, with spines at the inner apex; the third joint nearly as long as the first and nearly as broad as long, with some slender spines about the distal margins; the fourth joint as long as the third, but narrower, the spines on the inner

margin more numerous, and at two points of the outer margin; the fifth joint subequal in length to the three preceding together, at a distance from the base of about a fourth of its total length carrying two palmar spines delicately serrate for more than the distal half of their inner margin; below these the joint is abruptly narrowed, and fringed with slender spines; the outer margin has groups of slender spines at five or six points; the finger is strong, curved, mateling the palm, with a short dorsal cilium not far from the hinge.

Fourth Peraopods like the third but longer.

Fifth Peraopods like the two preceding pairs, but with all the joints decidedly longer, the third joint much longer than broad, and considerably longer than the fourth joint.

The *Pleon* appeared to consist of a dorsal plate and a ventral plate, each more or less semi-oval; between these appeared to lie the rounded distal margins of the anal opening, and projecting at either side was a one-jointed uropod.

Length, in the position figured, from the rostrum to the pleon, nearly nine-twentieths of an inch.

Locality.—Station 233A, off Kobé, Japan, May 19, 1875; lat. $34^{\circ} 38'$ N., long. $135^{\circ} 1'$ E.; depth, 50 fathoms; bottom, sand. Four specimens male; two specimens female.

Cuprella danilevskii, Czerniavski (Pl. CXLV.).

 1882. „ *Danilevskii*, Mayer, Die Caprelliden, p. 54.
 1885. „ *inermis*, Haswell, Proc. Linn. Soc. N.S.W., vol. ix. pt. iv. p. 8 (separate copy).

Czerniavski gives the following deserption:—

“ *Mas*.—Corpus gracile, aculeis tuberculisve non ornatum, segmento 2-do valde longo, triplum vel quadruplum longiore quam lato, 3-io et 4-to vix brevioribus, 5-to oblongo. Caput segmento 1-mo fere duplo brevius. *Antennæ superiores* $\frac{2}{3}$ corporis breviores, flagello 9–10-articulato, $\frac{2}{3}$ pedunculi breviore, articulis in apice filum olfactarium vel duo quibusque gerentibus, a. 1-mo e duobus composito vel simpliei. *Antennæ inferiores* fere pedunculum superiorum longitudine æquantes. *Branchiæ* elongate-elipticæ. *Pedes paris* 1-mi manu pyriformi, palma in angulo subbasali spinam obtusam gerente, ungue curvato, in margine posteriore denticulato; *p. 2-di* manu elongatissima, fortissima, quadruplum longiore quam lata, margine anteriore fere recto, palma in dimidio apicali inter duos dentes obtusos rotundinaliter excavata, ungue curvo, margine posteriore in medio incrassato; *p. posteriores* 3 breviores, articulis abbreviatis, tarso planulum curvato, æque lato vel in basi latiore, ungue

crasso, sub apicem curvato. Color rubescente vel viridescente-brunneus. Long. corp. ad $8\frac{1}{2}$ mm.; manus 2-da long ad 1,8 mm.

"*Femina*.—Corpus segmentis 4 primariis permulto minus elongatis, 1-mo dorsaliter breviore, 2-do nec duplo longiore quam lato, 3-io et 4-to paulo longioribus. Caput segmento 1-mo duplo longius. *Pedes 2-di paris* 1-mo minores, manu simili, paulo breviore, sed latiore, palma dente obtuso subbasali, duas spinas subtrorsum gerente, armata, ungue curvato, laevi, 1-mo debiliore. Corpus rubrescente-brunneum, maculis roseis, rariter viridescente-brunneum. Long. usque ad 8,2 mm.

"*Mas junior*, *Pedes 2-di paris* 1-mo non maiores, manu ad formam feminæ transunte, ungue laevi."

In the Challenger specimen of the male the dorsal line of the head is as long as the dorsal line of the first segment, though considerably shorter than its ventral line; the third and fourth segments of the pereon are decidedly shorter than the second; the lower antennæ are fully equal in length to the peduncle of the upper; the hand of the second gnathopods is scarcely more than three times as long as the greatest breadth, but neither is it in Czerniavski's figure fully *four* times as long.

In the Challenger specimen of the female the second gnathopods are larger instead of smaller than the first, and have the hind margin (as distinguished from the palm) longer than in Czerniavski's figure, but they well agree with the figure which Czerniavski gives for the second gnathopods of the young male, so that the very unusual circumstance which he attributes to the female, of having the second gnathopods smaller than the first, was probably accidental.

Of *Caprella inermis* the following account is given by Haswell:—"Cephalon terminating anteriorly in a minute mesial tooth. Neck very long; first segment of the body longer than the head and neck, the rest shorter. Superior antennæ as long as the cephalon and first segment of the pereion; flagellum shorter than the last two segments of the peduncle. Inferior antennæ a little longer than the peduncle of the superior pair; flagellum shorter than the two last segments of the peduncle. Anterior gnathopoda short; propodos ovate, palm longitudinal, undefined. Posterior gnathopoda very large; propodos elongated, narrow; palm excavate, uniformly concave, occupying about one-third of the entire length of the propodos. Branchiæ sub-cylindrical. Last pair of pereiopoda longer than the others. Colour green. Length $\frac{7}{10}$ ths of an inch. *Hab.* Port Jackson."

This account obviously refers to a male specimen, and agrees so closely with the Challenger specimen of the male as to require no comment, except the remark that the length attributed to the neck or first pereon-segment agrees better with Czerniavski's than with the Challenger specimen. Mr. Haswell in his Revision of the Australian Læmodipoda retains the name *Caprella inermis*, and offers no opinion upon Mayer's suggestion that it may be identical with *Caprella danilevskii*, probably from want of opportunity to consult Czerniavski's work.

On points not mentioned by the preceding authors quoted the following details may be added :—

The animal is in many parts covered with a very short fine down.

Eyes round, small, but with numerous ocelli.

Lower Antennæ having the flagellum armed with motor-setæ, which are shown in the figures given both by Czerniavski and Haswell.

Upper Lip unequally bilobed, the apical part of each lobe furred.

Mandibles.—The cutting plate strongly produced, divided into about five teeth, the actual breadth of the plate not easy to ascertain without breaking the mandible; the secondary plate also rather elongate, apically divided into four teeth, stronger on the left than on the right mandible; the spine-row containing on the left mandible three, on the right mandible two, feathered spines, in each case the one nearer the cutting plates the stouter, the hind one longer, curving backwards; the molar tubercle strong, prominent.

Lower Lip.—The outer lobes a little dehiscent, well ciliated; the inner lobes oval, well developed, strongly ciliated; the mandibular processes divergent, apically narrow.

First Maxillæ.—Inner plate not developed; outer plate carrying on the truncate distal margin seven strongly denticulate spines and some cilia; the first joint of the palp scarcely so long as broad, the second joint long and broad, its apical margin carrying four spine-teeth, of which the outermost is the longest; there are also numerous setiform spines on the surfaces, some of them of considerable length.

Second Maxillæ.—The plates small, the inner shorter than the outer, with slender spines fringing the scarcely rounded apex and descending on the inner margin for a short distance, and there mixing with one or two slightly feathered setæ; the outer plate having the distal margin still more squared, faintly crenulate, and fringed with rather stronger and longer spines, with which short ones are mixed; one or two of the long spines might be regarded as belonging to the inner margin; on the outer margin there are a spinule and some cilia.

Maxillipeds.—Inner plates reaching little beyond the base of the first joint of the palp, narrow at the base, thence widening, the distal margin broad, indentured, sloping inwards, carrying three distant spine-teeth and several feathered spines planted on or a little below the margin; the inner border straight, unarmed; the outer border very convex beyond the neck; the outer plates not reaching the apex of the first joint of the palp, small, the inner margin faintly serrate, fringed with slender setiform slightly feathered spines, at the apex presenting an oblique emargination with a strong spine-tooth at one end and a long spine at the other (the distal end); in the female the inner margin showed two other emarginations below the apical, each with a spine-tooth; in the male there was one additional spine-tooth on one side of the maxillipeds. The broad distal

margin is ciliated; on the outer surface of the plate towards the base there is a row of unequal slender spines; the first joint of the bulky palp is broad, and a little longer than broad; the second is not once and a half as long as the first, broad, the inner margin fringed with slender spines, many of which are very long; the third joint much narrower than the second, but as long, with fringes of long spines on either side the inner margin and at the apex; the fourth joint rather longer than the first, its inner margin finely pectinate, its nail short but extremely sharp.

The first pair of marsupial plates in the female have long setæ on the free margin; the second pair (as seen in the smaller specimen) have setæ also, but these are not long.

Fourth Peræopods a little longer than the third.

Fifth Peræopods much longer than the fourth, the increase of length applying to all the joints, but in a marked manner to the third and fourth, which in the preceding pairs are very short, although in both the third joint is longer than the first. In all three pairs the hind margin of the first joint is produced downwards in a small point; in all three, as Mayer has observed and as Czerniavski's figures show, the hand is devoid of the clasping-spines (Einschlagdorne) so usual in the Caprellidæ; the third pair have some tolerably stout spines a little above the centre of the front margin, and all the pairs have such near its distal end, but all these spines have flexible terminations. The fingers have the inner margin minutely serrulate, and carry some cilia on both margins.

The Uropods appear to be one-jointed, not reaching beyond the trunk of the pleon.

Length of the male specimen, from the front of the head to the end of the pleon, in the position figured, three-tenths of an inch; of one of the female specimens, a little over a quarter of an inch, of the other about a fifth of an inch; the latter one has eggs in the pouch.

Locality.—Bermudas.

Remarks.—The name *Caprella inermis* was preoccupied, so that should this species by any chance prove to be distinct from Czerniavski's, it would fall to Mr. Haswell to select another name for it.

The following Table, adapted from Mayer, Die Caprelliden, p. 17, will illustrate the arrangement of the Caprellidæ here adopted :—

Genus.	Flagellum-joints of Lower Antennæ.	Mandibular-palp.	Peræopods.			Branchial Vesicles to Peræon-segments.	Pleon-segments.	Pairs of Uropods distinguishable.
			1st.	2d.	3d.			
<i>Cercops</i> , . .	2	+	0	0	+	2d 3d 4th	5	3
<i>Proto</i> , . .	More than 2	+	+	+	+	2d 3d 4th	1	2
<i>Dodecas</i> , . .	More than 2	+	+	0	r	2d 3d 4th	1	2
<i>Caprellinopsis</i> , .	More than 2	+	0	0	r	2d 3d 4th	1	2
<i>Caprellinoides</i> , .	More than 2?	+	0	0	r	3d 4th	1	?
<i>Protellopsis</i> , .	2	+	r	r	+	3d 4th	2	2
<i>Protella</i> , . .	2	+	r	r	+	3d 4th	2	{ ♂ 1 ♀ 0
<i>Eginella</i> , .	2	+	0	0	+	3d 4th	1	2
<i>Caprella</i> , . .	2	0	0	0	+	3d 4th	1	{ ♂ 1 ♀ 0
<i>Podalirius</i> , . .	2	0	0	0	r	3d 4th	1	{ ♂ 1 ♂ 0

The symbol + means *present*, 0 *absent*, r *rudimentary*.

The name *Podalirius*, having been already used for two genera before its adoption by Kröyer, may be altered to *Pariambus*, from the Greek παρίαμβος, a metrical foot of two short syllables, in allusion to the structure of the third peræopods in this genus.

Tribe III. AMPHIPODA HYPERINA.

Head not coalesced with the first segment of the peraeon.

Peræon generally of seven distinct segments; the number not unfrequently reduced by the more or less complete coalescence of the first two, rarely of more than two.

Pleon of five distinct segments severally carrying appendages, the fifth segment¹ being formed by the coalescence of two segments, and with rare exceptions carrying two pairs of appendages, sometimes being itself in coalescence with the telson.

Eyes two, almost always very large,² each eye sometimes subdivided into an upper and a lower group of ocelli, with distinct pigment-masses, the upper group sometimes widely separated externally from the lower (*Phronima*, *Phronimella*), at other times contiguous with it (*Platyscelus*, *Thyropus*).

Antennæ, two pairs; the lower pair often obsolete in the female, rarely rudimentary in the male (*Cystisoma*); the upper pair without accessory flagellum.³

Maxillipeds, with a single inner plate, and a pair of outer plates, rarely the three plates coalesced (*Paraphronima*); without palps.⁴

The limbs of the *Peræon* of very diversified pattern in different genera, and sometimes in the individual animal; the side-plates generally small; the *Gnathopods* subordinate in size to some or all of the *Peræopods*.

Pleopods generally having on the inner margin of the peduncle two, rarely more than two, small coupling spines, and on the first joint of the inner ramus one, but never more than one, eleft spine, whieh is very rarely absent (*Cystisoma*, *Dairella*).

From the Amphipoda known as the "Normal Hyperina," a large group has been separated under the title of "Anomalous Hyperina," designated Platyseelidae by Claus. The two salient peculiarities of this group consist in the generally zigzag-folded lower antennæ of the adult male and the widened first joints of the third and of the fourth pereopods, these laminar joints being more or less adapted to act as opereula. The family of the "Hypérines" was instituted by Milne-Edwards in 1830. For the definition whieh its author gave of it in 1840, see Note on Milne-Edwards, 1840 (p. 185). For Dana's definition of the equivalent Hyperidea, see Note on Dana, 1852 (p. 256). For a definition of the Hyperina by Claus, see Note on Claus (trans. by Sedgwick), 1884 (p.

¹ Dana sometimes, but with doubtful accuracy, figures the fifth and sixth segments as separate, and of *Dithyrus faba* he says—"the suture between the fifth and sixth is distinct." Bovallius finds these segments separate in some species of *Vibilia*.

² In *Lanceola* very small.

³ *Hyperopsis*, Sars, is a doubtful exception, since it is not clear that the genus belongs to this group.

⁴ The suggestion has been made that the outer plates correspond with the palps of the other two tribes, but that would imply that the joint which elsewhere develops the outer plates was lost in the Hyperina, and there is the further objection that these plates are never in any way palpiform, while their general shape, and to some extent their armature, corresponds with that of the outer plates elsewhere.

553). For a definition of the "Amphipoda Hyperiidea," see Note on Bovallius, 1887 (p. 587); and for notices bearing more or less directly on the definition of the group, see Notes on Claus, 1879 (pp. 487, 490) and 1887 (p. 596).

Family SCINIDÆ.

Dana in 1852 placed the genus *Clydonia* in a subfamily of the Corophidæ which he constituted to receive it, and named Clydoninae; Bovallius, having in 1885 established the identity of the genus *Clydonia* with the earlier *Tyro*, in 1887 changed the subfamily into a family, and named it the Tyronidæ; since *Tyro* itself falls to the earlier name *Scinæ*, it will be convenient to name the family Scinidæ. The definition given by Bovallius¹ for the family is as follows:—

"Head small. Eyes small as in the Gammarids. First pair of antennæ straight, styliform. Second pair of antennæ angularly bent, fixed at the inferior side of the head. Mandibles without palp. The seventh pair of pereiopoda [fifth peræopods] not transformed. The inner ramus of the uropoda coalesced with the peduncle."

In the *Systema Entomologiæ*, p. 399, J. C. Fabricius in 1775 defines the Agonata as having "Os palpis quatuor, aut sex. Maxilla inferior nulla." Among these he

¹ Arctic and Antarctic Hyperids, p. 551.

includes the genus *Astacus*, and at p. 415 he gives the following definition of *Astacus crassicornis* :—

“7. A. antennis posticis bifidis, thorace articulato, pedibus sexti paris longissimis.

“Habitat in Oceano americano. *Mus. Banks.*

“Corpus parvum, rubescens. Thorax oblongus, subcylindricus, dorso carinatus, antice retusus absque rostro, articulatus; articulis octo subæqualibus. Antennæ anticæ corpore longiores, setaceæ, crassiusculæ. Abdomen angustatum, quinque-articulatum. Pedes utrinque octo, omnes simplices; sexto duplo longiori, femoreque serrato. Cauda stylis sex exsertis, filiformibus.”

By Herbst in 1796 this species is called “Das Dickhorn. Cancer (*Gammarellus*) *crassicornis*” (see Note on Herbst, p. 61), but, though he correctly places it in the midst of Amphipoda, he leaves it in so much obscurity that later writers have not accepted it as an Amphipod. By the expressions “antennis posticis bifidis,” and “pedes utrinque octo,” it seems to be entirely excluded from this group, but fortunately there is in the Museum Banksianum, under the care of Dr. Günther in the British Museum at South Kensington, a figure of *Cancer crassicornis*, signed “Sydney Parkinson pinxt. 1768,” to which the description by Fabricius clearly refers. The bifid hinder antennæ were perhaps assigned to it as a matter of course on the presumption that the species belonged to the genus *Astacus*; the eight segments attributed to the thorax probably include the head, and possibly the lower antennæ of a male specimen were counted as the first pair of legs, by this means making the total number of legs eight pairs, and the longest pair the sixth in order instead of the fifth; if these or some equivalent explanations be accepted, it will then, I think, be readily admitted that the *Astacus crassicornis* of Fabricius is the earliest described species of the genus since successively named *Scinà*, *Tyro*, *Clydonia*, while it is beyond all question that Sydney Parkinson’s figure of *Cancer crassicornis* is the earliest known representation of any species of that genus.

The first intelligible description, however, of a species of *Scinà* appears to have been that given by Milne-Edwards in 1830 of *Hyperia cornigera*, which in 1840 he made the type-species of the genus *Tyro*. In the meantime Prestandrea in 1833 had described the genus *Scinà*. For the curiously worded definition, see Note on Prestandrea, 1833 (p. 151). The difficulties introduced into that definition by misprints and bad Latin will disappear on a comparison of it with the specific description which Prestandrea gives of *Scinà ensicorne*, and which for facility of comparison with the other generic accounts I here reproduce in English :—

“Body triangular, with the lower surface broader than the lateral, five lines long, dorsally carinate; lateral margins prominent; the colour of the body is deep orange-red, although in the middle there are one or two segments whitish. Head truncate, depressed, with two raised divergent lines, which starting from the beginning of the carina, where they form an acute angle, terminate at the base of the upper antennæ. Upper antennæ

sword-shaped, triangular as far as the half of their length, with the lower angle denticulate at the base, three and a half lines long, flesh-coloured with two lines of orange-red dots; they are supported on a short cylindrical peduncle. Lower antennæ filiform, white, much longer than the upper, formed of six joints, the first of which is much longer than the rest. Eyes very small, round, orange-red, placed on the outer side at the base of the upper antennæ. Thorax of seven segments, which increase gradually in width to the fifth; the sixth and seventh are narrower. Abdomen of four rings, narrower, but longer than those of the thorax, so that the whole of the animal appears as if divided into two portions, the anterior half wider, the hinder abruptly narrowed. Seven pairs of legs properly so called, simple, slender, which in their length preserve the order of the segments of the thorax;¹ the fifth pair, the longest of all, is denticulate on the outer side through the whole length of the second joint, which on the inner side is prolonged beyond the articulation in an acute point. The tail carries six very slender stiles; four inserted on the same line, and the other two lateral, somewhat lower and longer than these."

It is possible that the notes of colouring² given by Prestandrea may suffice to determine whether his species be the same as *Tyro marginata*, Bovallius, which is also from the Mediterranean, but in the latter species the eyes are said to be very large. *Tyro cornigera*, Milne-Edwards, agrees with Prestandrea's species in having "face supérieure de la tête garnie de deux petites crêtes obtuses et divergentes."

For the original definition of the genus *Tyro*, see Note on Milne-Edwards, 1840 (p. 189). It will be noticed that Milne-Edwards says that "the lower antennæ are extremely small," while Prestandrea says that they are much longer than the upper, but the apparent discrepancy can be explained by a reference to the description of *Clydonia borealis*, in which Sars states that "the lower antennæ of the female are altogether rudimentary, almost inconspicuous, those of the male elongate, very thin, filiform, geniculate." For the definition of the genus *Clydonia*, see Note on Dana, 1849 (p. 229). The identity of this genus with *Tyro*, Milne-Edwards, was pointed out by Bovallius in 1885, but Bovallius does not describe the lower antennæ in any of the nine species which he refers to this genus. It is therefore probably from the male of *Clydonia borealis*, as described and figured by Sars, that, in the diagnosis of the family Tyronidæ, he draws the character of the lower antennæ as "angularly bent, fixed at the inferior side of the head." The definition which Bovallius gives of the genus is as follows:—

"Head truncated anteriorly. First pair of antennæ very robust, long, occupying with their basal joints the largest part of the anterior side of the head. First two pairs of periopoda [first and second gnathopods] simple, not cheliform. Fifth pair [third

¹ The meaning no doubt is that the shorter legs are attached to the shorter segments and the longer legs to the longer segments, but at any rate in some of the species, if not in all, the fourth segment is longer than the fifth, while the limbs of the fifth are longer than those of the fourth, and in *Tyro clausii*, Bovallius, the short sixth segment has the limbs longer than those of the longer fifth segment.

² The colouring of an unpublished figure by Sir J. D. Hooker agrees well with that of Prestandrea's species.

pereopods] strongly developed. Inner rami of the uropoda coalesced with the peduncles. Peduncles very long and broad."

To this may be added the seemingly unique character, that the first maxillæ have the outer plate apically divided.

The specimens belonging to this genus were all hard and more or less shrivelled, as though by some accident they had become dry before being put into spirit. Hence some of the details have been made obscure or doubtful. There seems to be a minute rostrum ; the back of the pereon is rounded and probably also that of the pleon, but, if appearances may be trusted, the centre of the back is angled throughout except at the head and telson ; of the pleon-segments the first two appear to have the postero-lateral angles but little rounded, while in the third these angles seem to be more strongly rounded ; the fifth and sixth segments are completely coalesced, except that the fifth is sufficiently wider than the sixth to admit the attachment of a uropod on either side to the projecting hind margin ; the following uropods occupy the whole hind margin of the sixth segment.

The Eyes are small, situate on the sides of the head, composed of nine ocelli.

Upper Antennæ very large, a little less than two and a half times as long as the elongate first uropods ; the peduncle consists of one thick cylindrical joint, nearly as broad as long ; the flagellum, at its base nearly as broad as the peduncle, tapers gradually to the distant apex ; in section it is almost prismatic, the two lateral edges and the lower one being all armed with little spine-like teeth ; on the inner margin at the proximal end there are some cilia or thread-like spines ; at the distal end there is a faint show of division into three or four joints, but in the condition of the specimens this cannot be spoken of with any certainty, being probably only due to cracking or shrivelling. In the male, fig. a.s. A., the proximal half of the flagellum joint has a tolerably strong brush of filaments.

Lower Antennæ in the female very small and slender, placed close behind the upper, the base being a broad joint more or less adherent to the wall of the head, accompanied by a tolerably conspicuous gland-cone ; the next joint is small, cylindrical, a little longer

than wide, and is followed by a terminal joint much narrower but immensely longer, tapering so far as its initial narrowness permits, which may be regarded as the flagellum; how diminutive are these lower antennæ compared with the upper, may be judged from the figures of both in the Plate, which are drawn to the same scale. In the male it is probable that here, as in *Scinà borealis* (Sars), the lower antennæ attain a much greater development; successive steps are seen in the figures *a.i. B.*, *a.i. C.*, and *a.i. A.*, from three different specimens; the coalesced first and second joints of the peduncle are to some extent free from the wall of the head and show a small blunt gland-cone; the third joint is rather longer than broad; the fourth longer than the third; the fifth longer than the preceding two together, more or less bent except in the earliest stage; the first joint of the flagellum at first shorter than the last of the peduncle, then equal to it, and eventually perhaps exceeding it in length; this is succeeded in the different specimens by three, four, and five joints respectively. In fig. *a.i. C.*, these antennæ are shown in their position as folded back round the mouth organs. The flagellum-joints of specimen A were seen to be microscopically scabrous near the convex margin, with little groups of spinules.

Upper Lip unequally bilobed.

Mandibles without palp, spine-row, or molar tubercle; the trunk shallow, attached along the straight upper border, the front terminating in a small cutting edge, which is more or less triangular, striated in appearance, and minutely denticulate; the secondary plate of the left mandible is similar to the principal plate, but rather smaller, the denticles fewer, about fourteen in number.

First Maxillæ.—The inner plate appears to be rather broadly oval, distally hairy; the outer plate slender, a little curved, its outer margin convex, at some distance from the apex interrupted and capped by a spine, the remainder of the plate being triangular, with smooth outer margin, the inner carrying three denticles and a spine, the narrow apex completely occupied by a spine; the concave inner margin ends in a similar but smaller triangular piece, with some minute denticles on either side and an apical spine; this plate therefore presents the very unusual feature of a cleft termination, and in some positions the spine on the outer margin together with the two terminal triangles gives it a tridentate appearance;¹ the palp, consisting of a single joint, is broader and a little longer than the outer plate, its outer margin a little convex, the inner a little concave, with some spinules adjacent, the distal margin nearly straight, with a spinule near the outer apex, and a little tooth at the inner apex. The figure of these maxillæ is taken from the South Atlantic specimen, in which the principal apex of the outer plate shows five denticles.

Second Maxillæ.—The inner plate shorter and much narrower than the outer, distally furred with numerous spines of various thicknesses but none large, the distal margin narrow but truncate and having a blunt tooth on the inner corner; the outer plate rather broad, but not long, somewhat bent, furred with rather stronger spines than

¹ In *Clydonia borealis* G. O. Sars describes this plate as "angusto, incurvato, indistincte tridentato."

those of the inner plate, the distal margin truncate and having a blunt tooth at each end, each tooth having beside it a comparatively long spine.

Maxillipeds.—The inner plate is very much narrower and shorter than the outer; the outer plates have the straight inner edges scarcely at all dehiscent, the adjacent ridge of the inner surface armed with a few small spinules, the outer edge convex, very lightly furred; the distal half in these plates is much narrower than the proximal, each ending in a narrowly rounded apex.

First Gnathopods.—The side-plates shallow, broader than deep. The first joint almost entirely free from the side-plate, evenly broad throughout except at the extremities, with one or two setules near the apex behind; the second joint short, the surface speckled with tiny spicules, the hinder apex having some small curved spines; the third joint, very little longer than the second, with a pointed apex lying against the wrist, the hinder surface furred with spicules; the wrist not so long or so broad as the first joint, but broader and much longer than the hand, widening a little distally, the hind margin fringed with very slender spines, of which there are some also along the surface and at the front apex; the hand narrow, without palm, having the front margin gently convex, the hinder nearly straight, scabrous, both fringed with slender spines, those on and adjoining the hind margin more numerous than those in front, the surface also carrying many groups of spines; a slender, nearly straight finger, slightly pectinate on the inner margin, is attached between the two front slightly produced and rounded apices, and in length about equals half the hand.

Second Gnathopods.—Side-plates a little broader than the preceding pair. Branchial vesicles seemingly about as long as the first joint, widening below. The limb similar in general character to the preceding, the first joint a little longer, with a few setules on the hind margin; the second and third a little thinner and less scabrous, with slender spines near the hinder apex, the wrist shorter and with fewer spines, the hand longer so as to be nearly as long as the wrist, also with fewer spines and a somewhat less breadth; the finger not quite half the length of the hand.

First Peræopods.—The side-plates shallow. The first joint as in the preceding pairs; the second joint considerably longer than broad, widening from a narrow neck; the third joint a little shorter than the fourth, a little longer than the fifth; the fourth as broad as the third, but much broader than the fifth; the fifth narrow, broadest near the base; the finger very slender, slightly curved, not quite half the length of the fifth joint; the armature of the limb very slight, the hind margin of the third, fourth, and fifth joints, and of the finger at its upper half, being faintly pectinate.

Second Peræopods scarcely differing from the first, but having the third and fourth joints a little longer.

Third Peræopods.—The side-plates rather deeper than the preceding pair, narrowly produced both before and behind and carinate. The first joint of great

length, of prismatic section like the upper antennæ, its three sharp edges serrate, the hinder one forming the strongest teeth; the front margin is produced into a thin pointed process, which in most of the specimens is broken or crumpled; the second joint is very small, serving as a hinge between the somewhat expanded end of the first joint and the base of the third which folds back closely against it; the third joint is rather shorter than the fourth; these two together reach back beyond the first joint when folded against it, but the first joint including its distal process almost equals or occasionally exceeds their united length; the fifth joint is slender, and no doubt owing to its feeble structure, the great length of the limb, and the prominent position which it appears to assume, this joint is in many instances damaged; its length is less than half that of the fourth joint, its front margin being like that of the third and fourth joints very faintly serrulate; the finger curved, minute, with bulbous base, apically slender.

Fourth Peræopods.—The first joint longer than in the first and second peræopods, which this pair in many respects resembles; the second joint small, but larger than in the third pair; the third joint longer than the fourth; the fourth a little longer than the fifth; the fifth a little narrower than the fourth, but wider than the corresponding joint in the first and second peræopods.

Fifth Peræopods slender; the first joint shorter than in the preceding pair, widest near the base; the second small, a little longer than broad; the third longer than the fourth or fifth; the fourth a good deal shorter and a little wider than the fifth; the finger very slender, curved, not half the length of the fifth joint.

Pleopods.—The coupling-spines short, with two rows of retroverted teeth and a bent apex; the cleft spine is short, the arm with the backward serratures being scarcely, if at all, longer than that with the subapical dilatation; the joints of the inner ramus number from seven to nine, of the outer from nine to eleven, the inner ramus being rather the shorter.

Uropods.—The first pair reach beyond the second and as far as the apices of the first or nearly so; on the straight inner margin they have some small distant teeth, on the more convex outer margin the dentation is coarser and continuous, especially along the lower half till near the acute apex; an interruption near the middle of the outer margin is occupied by a spine-like rudiment of an outer ramus; the second pair reach beyond the outer ramus of the third pair, the straight inner margin for most of its length ornamented with little teeth at intervals, the spaces between being filled with a succession of much smaller teeth of great slenderness; the outer margin is interrupted near the middle, about on a level with the interruption in the first pair, and there carries a similar spine-like rudiment of an outer ramus, which may be regarded as marking the commencement of the coalesced inner ramus; the third pair at about the middle has a free outer ramus, reaching about halfway to the end, and having its inner margin finely toothed; the outer margin of the coalesced ramus is more coarsely toothed.

The Telson is minute, triangular, nearly once and a half as long as broad.

Length, without the antennæ, two-fifths of an inch.

Locality.—The label “September 29, 1873,” refers this species to the South Atlantic, off the coast of Brazil, lat. $19^{\circ} 6'$ S., long. $35^{\circ} 40'$ W. Six specimens, two of them males.

“October 5, 1873, South Atlantic, surfacee, night;” between lat. $26^{\circ} 15'$ and $29^{\circ} 35'$ S., long. $32^{\circ} 56'$ and $28^{\circ} 9'$ W. One specimen, male..

A specimen labelled “New Hebrides, August 23, 1874,” does not seem distinguishable from this species, although coming from a very distant locality, between lat. $15^{\circ} 58'$ and $14^{\circ} 7'$ S., long. $160^{\circ} 48'$ and $153^{\circ} 43'$ E. It has, however, a shorter wrist to the first gnathopods, and the outer ramus of the third uropods is more than half the length of the inner ramus.

Remarks.—Whether this be really Milne-Edwards’ briefly described species from the Atlantic must perhaps remain a little uncertain. He describes the upper antennæ as longer than the body, but whether by this he means the peræon and pleon without the head and the uropods is not clear. “*Tyro Sarsii*” of Bovallius is very near to, if not identical with, the present species, but there seems to be little to separate that species from *Tyro cornigera*. Dana’s *Clydonia gracilis* agrees with the present species in so minute a particular as having “eyes small, nine lenses”; the description of *Astacus crassicornis*, Fabricius, is too vague and erroneous to entitle the specific name to the honour of priority.

Family VIBILIDÆ, Claus, 1872.

In 1840 Milne-Edwards formed the “Tribu des Hypérines gammaroides,” to receive the single genus *Vibilia*. In 1852, Dana placed this tribe in the family Hyperidæ, as “Subfam. 1. Vibilinæ.” Claus changed the subfamily into the family Vibiliidæ. This is changed into Vibiliidæ by Carus in 1885, but written Vibiliidæ by Gerstaecker in 1886, and by Bovallius in 1887. None of these writers increase the number of genera in the family. In the table of generic divisions belonging to his “Famille des Hypérines,” Milne-Edwards, in 1830, attributes to *Vibilia*, “pattes-mâchoires présentant des rudimens de tiges palpiformes.” These he figures in his later work, pl. xxx. fig. 2. Dana in 1852, and Carus in 1885, retain these rudimentary palps of the maxillipeds as a character of the group, but it is almost certain that the original mention of them was due to some error of observation; Marion in 1874 expressly denies their existence either in adult or young of *Vibilia jeangerardii*, Lucas. Bovallius in 1887 gives the following character of the family :—

“Head small, not tumid; eyes medioere, resembling those in the Gammarids. Both pairs of antennæ fixed at the anterior side of the head. First pair with the first joint

of flagellum very large, compressed; the rest of flagellum minute. Second pair filiform, angulated. Mandibles with palp. Daetyli of seventh pair of pereiopoda [fifth pereiopods] transformed [not normal]."

For the original definition of the genus, see Note on Milne-Edwards, 1830 (p. 142). The account of *Dactylocera* given by Latreille in 1831 (see p. 144) is of no importance. For *Thaumalea*, see the description of the species *Thaumalea depilis*, in Note on Templeton, 1836 (p. 167). Bovallius in 1887, gives the following definition of *Vibiliia*:

" Head small, almost quadrangular. Eyes small, ovate or bean-shaped. First pair of pereiopoda [gnathopods] simple, not chelate, second pair with a more or less produced carpal process. Femur of seventh pair [first joint of fifth pereiopods] shorter [than] or as long as the following joints together. Telson broad, well developed."

¹ Costa does not describe the genus, but since its name means—with expanded antennæ—and since Costa subsequently named a species *Vibiliia speciosa*, and does not again mention *Elasmocerus*, it may be presumed that he had discovered that his *Elasmocerus speciosus* was a *Vibiliia*.

In regard to the eyes it may be noticed that Bovallius attributes to the species *Vibilia gracilenta* "eyes large," and to the species *Vibilia macropis* "eyes very large, occupying almost the whole sides of the head." The gnathopods and the first four pairs of peræopods in this genus have the first joint arranged for containing gland-cells. Many of the species, according to Bovallius, have the fifth and sixth segments of the pleon free, not coalesced.

Vibilia propinqua, n. sp. (Pl. CXLVII.).

Back round, smooth; rostrum minute, sharp; first segment of the peræon very short, with the front corners a little projecting forwards; the postero-lateral corners of the first three segments of the pleon rounded, very finely serrate; the fifth and sixth segments of the pleon completely coalesced dorsally, but less completely ventrally.

Eyes long oval, vertical, narrowing below, wide apart; the ocelli small, numerous.

Upper Antennæ.—Peduncle very short; the first joint broader than long, on the inner side overlapping the other two, which are very short; the flagellum longer than the peduncle, its broad flat joint scarcely narrowing till near the apex, where it is still broad; the length about twice the breadth; along the centre of the inner surface are two rows of filaments, in numerous small groups, not reaching to the apex, and round the edge spinules are placed at regular intervals, the lower margin distally more or less oblique, its tip concealing two minute joints.

Lower Antennæ inserted in a small notch of the head, very much narrower than the upper and but little longer, with six free joints, the first about as long as broad, the second not twice as long as the first, the third slightly longer than the second, the fourth slightly longer than the third, the fifth equal to the first, the sixth nearly twice as long as the fifth; of these the first three are no doubt homologous with the third, fourth, and fifth joints in the Gammarina, the first two joints of the peduncle being here obscured by coalescence with the head, the opening of the gland-cone being at some distance from the first free joint; the last three joints, constituting the flagellum, are armed with spinules on the upper margin and taper to an almost acute apex, near which the spinules are close set.

Upper Lip.—Epistome broader than deep; the distal border of the lip with a deep but narrow emargination, from which two narrow rounded not quite symmetrical lobes result, the cilia on the sides of the emargination overlapping; the inner plate has a broad nearly straight edge, furred with short cilia.

Mandibles.—Cutting edge a little convex, with about fourteen little teeth; the secondary plate of the left mandible triangular, the distal edge cut into about a dozen small denticles, resembling those of the principal plate; the secondary plate of the right mandible narrow, strap-shaped, apically divided into a very few teeth; in the spine-row

the first two spines are fureate or tridentate, and though not longer are stronger and more horny-looking than the rest, which include four of moderate length and two or three that are very short; there is also a group of almost hair-like spines; the molar tubercle is strong, with numerous sharp teeth round the oval crown; the long palp has the first joint longer than broad, a little widened distally, the second joint narrower but much longer, much curved, the front margin convex, the hinder very concave; the third joint thinner and longer than the second, curving in the opposite direction, at first narrowing and then widening again slightly, its concave front margin almost smooth, the convex hinder margin furred, except near the base, with many small spines; the apex forming an acute point.

Lower Lip.—The outer corner of the distal margin of the principal lobes prolonged into a tooth, the slightly convex distal and outer margins on either side of this tooth fringed with cilia; the mandibular processes as usual in this genus with the ends scarcely free.

First Maxillæ.—Inner plate small, oval; outer plate with numerous slender spines on the distal part, the distal margin not very broad, with (not fewer than) eight stout spines, of which the outermost are the longest, some having lateral denticles, the outermost but one the strongest, but without denticles; the palp consists of a single joint, narrower than the base on which it stands, reaching a little beyond the outer plate, having long slender spines on its margins, and on the narrow apex a group of unequal spines rather stouter than the rest.

Second Maxillæ short. The basal part with very convex outer margin, the inner plate much narrower than the outer, curved, apically narrowed, with spines along the distal part of the outer margin and at the apex, besides many hair-like spines in other parts; the outer plate short and broad, the outer margin carrying many hair-like spines, except at the base, apically produced into a rounded point, which is tipped and flanked with many spines; the inner margin and inner part of the distal margin are united by a curve and appear to be smooth.

Maxillipeds.—The inner plate, of which the length and breadth are about equal, has a convex distal margin divided into five flat-topped teeth in the centre, the three central scarcely distinct from one another; the flat teeth are followed on either side by five sharp denticles, the first two forming a single tooth, the other three separate; the inner surface shows five spinules down the centre, not symmetrically arranged, and a great many scattered cilia; the outer plates are much longer than broad, with three or four spinules not symmetrically arranged on the convex outer margins; the inner margins dehiscent till near the convex distal part, irregularly cut into several sharp teeth, with one small spine or sometimes two inserted at the base of the tooth, but not quite reaching its apex; on the convex distal part the teeth and spines are small and crowded together; seven or eight denticles overlap one another on the apical part of the

outer margin; the inner surface has many cilia or hair-like spines near the inner margin, and the outer surface carries a curved row of about a dozen small spines at some distance from the inner margin.

First Gnathopods.—Side-plates small, broader than deep, with rounded front. The first joint long and broad compared with the rest of the limb, the margins smooth, the hinder more evenly convex than the front which bulges a little above the centre, the distal margin carrying two or three small spines; the second joint not longer than broad, with some spines near the apex of the hind margin; the third joint very little longer than the second, almost triangular, with a strong spine at the apex of the hind margin and a smaller one above; the wrist a little longer and wider than the hand, the hind margin nearly straight, with a spine at the apex and a smaller one near it above, the front margin with a group of small spines at the apex, the distal margin sinuous, minutely pectinate; the hand widening a little from the base, then narrowing to the apex, with three spines on the distal half of the very convex front margin, the hind margin nearly straight, pectinate for most of its length with little teeth; the finger narrow, curved, acute, a little more than half the length of the hand, the proximal half of the inner margin pectinate. Almost all or all the spines are more or less feathered or dentieulate.

Second Gnathopods.—The side-plates much broader than deep, the front rounded. The branchial vesicles very large, much longer and broader than the first joint, narrowing to a rounded tip; the marsupial plates nearly as long as the first joint, rounded oval, very broad, finely saclike. The first two joints similar to those of the first gnathopods, but rather larger, the second with two spines on the hind margin; the third joint longer than the hand, overlapping a large part of the wrist on the inner side, the hind margin carrying eight spines, those at the distal part the longest, feathered; the distal margin trunecate, armed with five or six stout spines that have hooked tips, and are more or less dentieulate; the wrist is broader than the hand, and longer even without the narrow acute process by which it overlaps more than half the hand's hinder margin; the front margin has an apical spine; the process is dentieulate on one of its inner edges and finely pectinate on the other, the two edges not being in view together; the hand and finger are as in the first gnathopods, except that the hand is scarcely so broad, the spines of its front margin are more slender, and the finger is not more than half the length of the hand.

First Peræopods.—Side-plates rather broader than deep, like the two preceding pairs narrower in front than behind, the front margin flatter. The branchial vesicles and marsupial plates large. The first joint with sinuous front margin, convex above, concave below, the hind margin convex, except at the base; the second joint short; the third longer and broader than the fourth; the fourth with a straight hind margin, the front convex, the distal margin of the inner surface pectinate; the fifth joint narrower than the

fourth, about as long as the third, curved, pectinate, but not closely, on the concave hind margin, the adjacent surface scabrous with little spines; the finger narrow, curved near the base, where on the inner margin it has a trace of incipient pectination, the length not half that of the hand. There are some minute distant spinules on various parts of the limb.

Second Peræopods.—The side-plates deeper than the preceding pair. The branchial vesicles and the limb similar to those of the first peræopods, but with the third, fourth, and fifth joints of the limb longer. Both the first and second pairs of peræopods are very considerably larger than the gnathopods.

Third Peræopods.—The side-plates with a front lobe much broader than deep, and a narrow hind lobe descending below the front one; hexagonal markings are conspicuous on these plates. The branchial vesicles broad, irregular in shape; the marsupial plates large. The first joint narrow at the base and nowhere much expanded, two or three times as long as broad, the margins nearly parallel, the front one with four spines at the distal part; the second joint short; the third joint longer than the fourth, shorter than the fifth, rather narrower than the third joint of the preceding pair; the fourth joint has a small spine at the pectinate distal end, besides having like the two preceding joints some minute spinules here and there; the fifth joint is slightly curved and has the concave front margin closely pectinate; this and the preceding joint exceed in length the corresponding joints both of the second and those of the fourth peræopods; the finger about a third of the length of the fifth joint.

Fourth Peræopods.—The side-plates about equally broad and deep, the hind lobe deeper than the front one. The branchial vesicles smaller than the preceding, but otherwise very similar. The first joint wider and longer than in the preceding pair, with five spines on the lower part of the front margin; the third joint rather shorter than in the third pair, with two spines at the distal end of the front margin; the fourth joint with the front margin pectinate except at the base, and carrying six spines at intervals, the apical margin also pectinate; the fifth joint armed as in the preceding pair; the finger similar.

Fifth Peræopods very considerably shorter than the fourth, yet much more than half the length. The side-plates rounded behind, and there free only for a short space from the segment's upper part. The first joint expanded, somewhat oblong, the front margin not very convex, a little scabrous below, the hind margin very slightly convex, completely overlapping the short second joint with a narrow rounded lobe; the third joint bent forward at the base, the proximal part of the hind margin being convex, the rest straight, having a small spine near the apex, and having like the other joints some pectination of the distal margin; the front margin nearly straight, with a small apical spine; the fourth joint longer than the third, slightly curved; the fifth joint narrower but rather longer than the fourth, also slightly bent; the finger not acute, shorter than

the fifth or the fourth joint, the apical part slightly widened and spoon-shaped, edged with spines, and having on the surface near the front margin a row of spines with their points directed upwards, the surface being also set with lines of spinules in little curved groups, which are found also near the front margins of the two preceding joints.

Pleopods.—The peduncles broad, not so long as the rami; the two coupling spines very short, apically broad and bent, with two or three retroverted teeth; the cleft spine stout, with slender unequal arms, each having a very slight subapical dilatation; the joints of the rami broad, numbering from eleven to fourteen, the inner ramus the broader, its joints generally one less in number than those of the outer ramus.

Uropods.—The peduncles of the first pair longer than the rami, and reaching beyond those of the second pair, the outer margin cut into small teeth; the rami almost equal, the outer slightly the shorter, both margins cut into teeth, those on the inner side the larger, the apex acute; the inner ramus with the outer margin cut into teeth, the lower half of the outer into four or five distant teeth, the apex acute; the peduncles of the second pair a little longer than the rami; the inner ramus the longer, armed like that of the first pair, the outer ramus having its inner margin cut into teeth, and the lower half of the outer; the peduncles of the third pair broad, longer than the rami, reaching much beyond the first peduncles, the edges smooth, the inner converging to near the apex of the telson, and then running near together with a slight convexity; the inner ramus rather broader and longer than the outer, its outer margin and lower part of the inner finely pectinate; the outer ramus with the inner margin and lower part of the outer pectinate; the apices acute.

The Telson shortly pear-shaped, about as broad as long, rather more than half the length of the peduncles of the third uropods, the narrow apex rounded.

Length.—The specimen, in the position figured, measured, in a straight line from the front of the head to the back of the second segment of the pleon, just over one-fifth of an inch.

Locality.—“April 4, 1875; Pacific Ocean, off Volcano Island; surface.” Lat. $25^{\circ} 30' N.$, long. $138^{\circ} 0' E.$ Four specimens were obtained, that from which the details are drawn being of the same size as that of which the full figure is given.

Remarks.—The specific name refers to the evident proximity of this species to *Vibilia peronii*, Milne-Edwards, and *Vibilia robusta*, Bovallius. The notices hitherto published of those two species, both of them found in eastern waters, do not seem to me to suffice to discriminate them the one from the other. The present species is distinguished from both by having the fifth and sixth segments of the pleon coalesced, not free. The rami of the second and third uropods also are unequal, not equal as in *Vibilia robusta*.

Vibilia milnei, n. sp. (Pl. CXLVIIIA.).

This species does not differ greatly in general appearance and structure from *Vibilia propinqua*. The points of difference displayed by the specimen will be described, it being understood that no specific value can be attached to the characters of the lower antennae and the mandibular palp, since they vary with the age of the animal.

Upper Antennæ.—The large flagellum joint oval, with almost entirely smooth margins, the upper more flattened than the lower; at the rounded apex the two minute terminal joints rest upon the surface, the apical much the smaller and just projecting.

Lower Antennæ about as long as the flagellum joint of the upper, but much narrower. The first free joint short, the second longer, the third intermediate; the single flagellum joint tapering, nearly as long as the three preceding together, tipped with a spinule.

Mandibles.—The secondary plate of the right mandible distally divided into three irregular teeth; the molar tubercle very prominent; the third joint of the palp not very slender, the apex abruptly acute.

Maxillipeds.—The inner margin of the outer plates nearly straight, with only a single small spine to each denticle; the upper part of the outer margin carrying a single spinule.

First Gnathopods.—The first joint without spines, the second and third joints each with one spine; the wrist not longer than the hand; the hand with a single spine within the convex front margin, the hind margin irregularly pectinate, with few teeth; the finger not more than half the length of the hand, slightly pectinate.

Second Gnathopods.—The third joint has five spines on the hind margin, and four on the distal margin, these being straight, not hooked, at the tips; the process of the wrist is very acute, its margin facing the hand not strongly pectinate; the hand not closely pectinate, carrying some little spinules dispersed over the breast.

The first four pairs of pereiopods are of shorter, stouter build than in *Vibilia propinqua*, and in the fourth pair the fifth joint is longer instead of shorter than the corresponding joint of the third pair; the front margin of the fourth joint of the fourth pereiopods has four spines.

Fifth Pereiopods little more than half the length of the preceding pair. The first joint broadly oval, not very much longer than broad, widening at once from a narrow neck, the hind margin rather more convex and shorter than the front, not produced at the back of the short second joint, which is bent up close to it; the third joint longer than the second, little longer than broad; the fourth slightly longer and slightly narrower than the third; the fifth a little longer and a good deal narrower than the fourth; the sixth almost as long as the fifth, a little narrower, round-ended, with some minute armature round the margin, the other joints being quite smooth or with armature requiring a very high microscopic power for its discernment.

Plcopods.—The joints of the rami numbering from ten to eleven.

The Telson small, nearly circular, but flattened at the base.

Length.—The specimen, with the after part of the pleon flexed, measured a fifth of an inch.

Locality.—The single specimen, a male, was taken at the surface in the South Atlantic, on the night of October 5, 1873.

Remarks.—The specific name is taken from the first part of the name of the distinguished French naturalist, the second part of his name having been applied to another species in this genus. The species differs from *Vibilia macropis*, Bovallius, which is also from the South Atlantic, by the smaller size of the eyes, by the flagellum of the upper antennæ not being “elongate lanceolate,” and by the rami of the uropoda being much serrate, and in the second and third pairs not equal. It has a shorter telson than *Vibilia gracilis*, Bovallius, from the Pacific, though it agrees with that species in having a round telson and in some other noticeable characters.

Vibilia sp. (Pl. CXLVIII B. figs. C, D).

Rostrum minute, back smoothly rounded.

Eyes oval, the lower end the smaller.

Upper Antennæ.—The distal end of the large flagellum joint a little narrowed.

Lower Antennæ.—Two stages of the development of the flagellum are shown in the figures *a.i.* C. and *a.i.* D. respectively.

Mouth Organs differing little from those of *Vibilia propinqua*. In the molar tubercle of the mandible the teeth along the flattened side of the crown were here observed to be long and slender, and apically bidentate or tridentate.

First Gnathopods nearly as in *Vibilia propinqua*, but the wrist scarcely so long as the hand, and with only one spine on the apex of the hind margin.

Second Gnathopods.—The third joint has seven spines on the hind margin, six on the apical margin, all with sharp tips, the front spine much the smallest.

Peræopods like those of *Vibilia propinqua*. In the fourth pair the fourth joint has seven spines on the front margin, and in the fifth pair the first joint is rather more widely expanded than in the species compared.

Uropods.—In one specimen the inner ramus of the third pair was considerably longer than the outer ramus, see fig. *ur.3.* C., but in another specimen the difference was less.

Length, from the front of the head to the back of the second segment of the pleon, three-tenths of an inch.

Locality.—“March 10, 1876, South Atlantic, surface.” Lat. $37^{\circ} 29' S.$, long. $27^{\circ} 31' W.$ Six specimens.

Remarks.—It seems probable that this form may be one of the numerous species from the Atlantic which have already received names, otherwise the differences scarcely suffice to separate it from the eastern species, *Vibiliа propinqua*.

Vibiliа viator, n. sp. (Pl. CXLVIIIe. fig. E).

The dorsal depression deep where the fifth and sixth segments of the pleon coalesce, but with no separation between them.

Eyes large and dark.

Upper Antennae with the upper margin of the large flagellum joint much longer than the lower, the end of the joint being obliquely truncate.

Lower Antennae.—The flagellum in this specimen exhibiting six joints.

Upper Lip.—The smaller of the distal lobes distinctly serrate, neither strongly ciliated.

Mandibles.—The cutting edge divided into sixteen teeth; the strap-like secondary plate of the right mandible having four little slender teeth at its apex, one much longer than the other three; the first two spines of the spine-row on each mandible much widened distally and there cut into several little teeth, not so strong as those of the secondary plate on the left mandible, but stronger than the teeth of that plate on the right mandible.

First Gnathopods.—The first joint with the front margin not bulging, the hinder apex set about with five spines; the second joint with three spines about the hinder apex; the third joint with three spines on the hind margin; the wrist wider, but not longer, than the hand, having a spine at the apex of the convex front margin, and three at and near the apex of the straight hind margin; the hand with two spines adjacent to the convex front, the pectination of the straight hind margin continued round the slightly prominent apex; the finger more than half the length of the hand, the upper half of the inner margin pectinate.

Second Gnathopods not very different from those of *Vibiliа propinqua*, but perhaps not quite in the normal condition, since in one the third joint is unusually short, and in the other the process of the wrist is very short and apically rounded, instead of acute as in the companion limb.

First Peraopods.—The third joint is narrow at the base, and then widens greatly, with very convex front margin, the length a little exceeding that of the fifth joint; the fifth joint is longer than the fourth, scabrous along the hind margin; the finger elongate, subequal in length to the fifth joint.

Second Peraopods similar to the first. The remaining pairs differing little from those of *Vibiliа propinqua*, the fingers broken.

Pleopods.—Joints of the rami eleven in number in the pair examined.

The *Uropods* and *Telson* are in very close agreement with those of *Vibilia propinqua*.

Locality.—“Cape York,” September 1874. One specimen.

Remarks.—The specific name is chosen to indicate the close agreement between this species and *Vibilia viatrix*, Bovallius, from the Atlantic, from which, however, it is separated by not having the fifth and sixth segments of the pleon distinct from one another.

Vibilia australis, n. sp. (Pl. CXLIX.).

Head with an acute rostrum which does not reach beyond the first joint of the upper antennæ; the lateral emarginations deep to correspond with the thickness of the peduncle of the upper antennæ; the first segment of the peræon dorsally the shortest, widened below, being produced at the rounded front corners; the first three segments of the pleon long and deep, the postero-lateral angles of the second segment squared, those of the first more rounded, those of the third more acute; the coaleseed fifth and sixth segments not quite equalling the length of the fourth.

Eyes remarkable, in general form a long irregular oval, not quite parallel to the lateral margins of the head, the ocelli in three rows of about thirteen or fourteen each, forming a compact eye, but with this peculiarity, that as well the crystalline cones in the rows as the rows themselves stand apart from one another; the cones appear to be rather spherical than conical, or each of the component halves, which can be very clearly distinguished, may be a little more than a hemisphere; those at the ends of the rows are of diminished size.

Upper Antennæ stout; the peduncle short, the first joint broader than long, longer than the next two together, these being very short, but almost as broad as the first; the first joint of the flagellum more than twice as long as the peduncle, tapering at first very gradually, at the end more abruptly; at the outer side this joint has a rounded and smooth surface, forming on the inner side two sharp edges between which the inner surface or breast bulges a little, being set with a long brush of short setæ or cylinders in two series, the rows composing which number about thirty, with from one to five cylinders in each row; the edges near the end are serrate, and carry each about a dozen little tufts of small cylinder-like setæ; the almost acute apex of this large joint is tipped with two minute joints, the first scarcely longer than the second but considerably broader, and a little decurrent; the apex of each has a pair of setules.

Lower Antennæ very small (at least in our specimens). The first joint short, bent, not appearing beyond the margin of the head; the second longer than either the first or third; the third rather longer than the first, narrower than the second, slightly tapering,

with three distant serrations on the lower and seven or eight not distant on the upper side, all, as well as the tip, armed with setules.

Upper Lip.—The epistome a little arched above; the outer plate of the upper lip of a squared shape, with the distal margin unequally bilobed; the inner plate shorter, with the distal margin rounded.

Mandibles.—The cutting edge small, oblique, with eight teeth; the secondary plate narrower than the principal at both proximal and distal ends, but especially at the proximal; on the right mandible its teeth are extremely fine, and the plate is more widened distally than in some other species of this genus; the spine-row containing a few small but stout spines amidst others that are hair-like; the molar tubercle with the dentate crown moderately prominent; the palp three-jointed, longer than the trunk of the mandible, set a little behind the molar tubercle; the first joint short, the second more slender, more than twice as long; the third slender, tapering, longer than the other two together, with a series of small spinules or setules all along it, except quite at the base.

Lower Lip compact; the inner lobes small; the mandibular processes having an attachment close to the rounded distal end, which makes it difficult to separate the lip from its surroundings.

First Maxillæ.—The outer plate has several strong unequal spines at the distal end, amidst numerous hair-like setæ; the single joint of the palp is short, with the convex outer and nearly straight inner margins meeting in a narrow apex, and distally fringed with many hair-like setæ or spines.

The Second Maxillæ not made out with sufficient certainty for description.

Maxillipeds.—Inner plate or tongue short, the distal margin having the corners rounded and in the centre two little embedded spines; the outer plates not meeting at the base, the inner margin at first straight, serrate with six teeth, at each of which there is a little spine, the distal part oblique and finely denticulate; the outer margin very convex, with two or three little spines on the distal part; there is also a row of six or eight spinules on the outer surface, near the inner margin.

First Gnathopods.—Side-plates shallow, much broader than deep. First joint as long as the next four together, the breadth greatest just above the centre, the front margin being convex above and concave below; the second joint about as long as its breadth, with a spine at the apex of the hind margin, and a smaller one just above; the third joint not larger than the second, with a spine at the apex of the hind margin, the distal margin angled; the wrist nearly as long as the two preceding joints together, the lower half of the hind margin armed with about ten little teeth; the hand oval, a little longer than the wrist, abruptly narrower but not much, the front apex a little produced and finely pectinate, the hind margin less convex than the front, armed with many little teeth, the surfaces near the hind margin being also microscopically seaceous; the finger

more than half the length of the hand, its hind margin nearly straight, armed with a few small teeth, the front margin convex, the apex acute.

Second Gnathopods.—The side-plates rather deeper than in the preceding pair. The branchial vesicles oval, narrowed at each end, about as long as the first joint. The first joint longer than in the first gnathopods, but less wide, sinuous, widest distally; the second joint short, with a distal spine; the third joint longer than the second, five-sided, with two spines on the apex of the joint, and two others just below the end of the hind margin; the wrist longer than the hand, being produced behind it in a slightly divergent process, of which the oblique distal or inner margin is denticleate with about twenty teeth; the hand and finger are as in the first gnathopods, but the hand is a little narrower.

First Peraopods.—Side-plates much broader than deep, rather deeper behind than in front. Branchial vesicles as long as the first joint, and broader. The first joint a little sinuous, the front margin for the most part concave, and the hinder convex; the second joint a little longer than broad; the third considerably longer than the fourth, which is narrower than the third but broader than the fifth; the fifth nearly as long as the third, a little curved, the lower part of the concave hind margin pectinate, the apex also minutely pectinate; the finger slender, not strongly curved, acute, not half the length of the fifth joint, its inner margin a little pectinate.

Second Peraopods very similar to the first, but the third joint more decidedly longer than the fifth.

Third Peraopods.—Side-plates with the hind-lobe deeper than the front. Branchial vesicles of irregular form. The first joint pretty evenly expanded, at no part widely; the second joint about as broad as long; the remaining joints slender; the third much longer than the fourth, the front apex pectinate; the front margin of the fourth pectinate, but less strongly than the apical margin; the fifth joint not shorter than the third, the slightly concave front margin closely pectinate; the finger nearly straight, not nearly half the length of the fifth joint, with the upper part of its inner or concave margin pectinate, as in the other peraeopods, the lower teeth of the pectination being much the longest.

Fourth Peraopods similar to the third, but the side-plates less broad, with the hind-lobe much deeper than the front, the branchial vesicles longer, the first joint rather longer and broader, the third and fifth joints rather shorter, and the fourth joint as strongly pectinate as the fifth.

Fifth Peraopods.—Side-plates not bilobed, a little broader than deep. First joint wider than in the preceding pairs, wider above than below, the front margin straight except at the top, the hind convex, slightly erenate, produced with rounded apex below the front; the second joint short, not reaching below the hind lobe of the first joint; the third joint twice as long as the second, widening from the base, both margins and the apices minutely serrate or pectinate; the fourth joint abruptly narrower than the third

and slightly longer, bent at the base; the fifth joint not as long as the preceding two together, but much longer than either, its front margin straight, and like the hinder minutely peetinate; the finger a little longer than the fourth joint, constricted just below the base, thence widening and from the middle again narrowing to a blunt apex, the armature of the margins being exceedingly minute. The whole limb is about two-thirds the length of the fourth peræopod.

Pleopods.—Coupling spines exceedingly minute; cleft spine stout, with the arms slender, unequal in length; the joints of the rami eight in number, the outer ramus narrower than the inner.

Uropods.—The peduncles of the first pair scarcely so long as the rami; the rami equal, lanceolate, reaching just beyond those of the third pair, each cut into five or six sharp teeth on the inner margin and nine or ten on the outer, the apex long, acute; the peduncles of the second pair reach as far as those of the first, the rami are as long as the peduncles; the inner ramus has the inner margin nearly smooth, the outer peetinate; the outer ramus is a little longer and has its outer margin cut into six teeth, the inner with the upper part peetinate, the lower part cut into three teeth, the apex long, acute; the peduncles of the third pair, which are set apart, reach much beyond those of the other two pairs, and are a good deal longer than the rami; the outer ramus has its outer margin smooth, the inner pectinate; the inner ramus the reverse; ventrally the distal margin in the various peduncles is peetinate.

Telson rather longer than broad, triangular, with a well-rounded apex, reaching more than half-way down the peduncles of the third uropods.

Length.—The specimen, in the position figured, measured one-fifth of an inch in a straight line from the apex of the upper antennæ to the back of the third pleon-segment.

Locality.—“March 9, 10, 1874, surface. South of Australia”; lat. $48^{\circ} 18' S.$, long. $130^{\circ} 4' E.$ Three specimens.

Remarks.—The specific name refers to the southern latitude from which the specimens were obtained. The species agrees with *Vibilia gracilis*, Bovallius, from the Pacific, in having a rostrum and in having a tapering flagellum to the upper antennæ, but here the carpal process of the second gnathopods is strongly instead of “sparingly” serrated, and the telson is not round but triangular.

Vibilia antarctica, n. sp. (Pl. CL.).

Frontal margin of the head shallowly convex; back of the animal broadly rounded, the first two segments of the peræon together shorter than the head; none of the segments either of the peræon or the pleon very long, the terminal part of the pleon having an unusually stumpy appearance.

Eyes not made out.

Upper Antennæ.—First joint of the peduncle broader than long, the two following joints together as long as the first, and each nearly as broad; the first joint of the flagellum longer than the peduncle, having some slender filaments along the inner margin; the minute second joint abruptly narrower than the apex of the first, not embedded in that apex, a little longer than broad, with some apical spinules, the third joint narrower than the second, a little longer, with four apical spinules.

Lower Antennæ not half the length of the upper, close beside which they are planted, the first two joints, which may be supposed to represent the peduncle, not being together so long as the third which represents the flagellum, and is tolerably stout, tapering, tipped with a setule.

Upper Lip pretty strongly ciliated or furred on the distal margin.

Mandibles.—The cutting plate very small compared with the broad trunk, the edge divided into ten or more small but sharp teeth; the secondary plate of the left mandible with about eight teeth along its broad edge; the secondary plate of the right mandible strap-shaped, with three or four apical teeth; behind the plates there is a group of cilia or hair-like spines, among which there are three stouter spines, the first large, distally pectinate; the molar tubercle is prominent, its crown set with very many little teeth, and an outer row of fairly long ones; the palp in the present specimen seemingly not fully developed, its first joint quite short; the second a little longer; the third rather longer than the first and second together, apically blunt.

First Maxillæ.—Inner plate small, oval; the outer plate not quite so large as the palp, distally set with seven spines among a crowd of spinules; the palp apically narrow, with slender spinules along the margins of the distal part, some at the apex a little less slender than the rest.

Second Maxillæ short, the inner plate shorter and apically broader than the outer.

Maxillipeds.—The inner plate broader than long, the convex distal margin a little serrate and crenulate, with two minute spinules embedded at the centre; the dentation of the margin in the new growth is seen to be much sharper than in the plate actually in use; the outer plates have the outer margins convex and smooth except for two little spines near the apex, the inner margins are to some extent concave, the middle part denticulate and carrying little spines, the distal part crenulate and pectinate; there are four or five small spines on the inner surface of each of the outer plates, and four on the inner surface of the joint below the plates.

First Gnathopods.—First joint a little sinuous; second short, like the first smooth and unarmed; third scarcely longer than the second, with one apical spine, which, however, is present only on one of the limbs; the wrist distally widening, broader and a little longer than the hand, with one apically plumose spine on the channelled apex of the hind margin; the hand with smooth convex front margin, the hind margin straight, with a

small spine where it meets the rounded, channelled, distal margin, which as usual in this genus is faintly pectinate and armed with a spinule; the finger is short, tapering from the base to an angle of the hinder margin, and then again tapering to the apex, in which a spine-like nail is inserted; the hand and wrist are both scabrous on and near the hind margin.

Second Gnathopods.—The branchial vesicles oval, small. The first and second joints of the limb similar to those of the first pair but longer; the third joint longer than the second, with a small and a large feathered spine on the hind margin, and at the almost acute apex a large spine with a small one close beside it; the proximal part of the wrist as long as the hand, the narrowly triangular hinder process nearly as long as the hand, scabrous, faintly serrate on its inner or front margin; the hand narrower than in the first pair, more strongly scabrous, and having two little spines at the apex of the hind margin; the finger shorter than that of the first gnathopods.

First Peraopods.—Branchial vesicles larger than the preceding pair, not so long as the first joint of the limb. The first joint broader than in the gnathopods, not sinuous; second joint longer than broad; third joint broader but shorter than the fourth, with one slender spine standing out from the hind margin; fourth joint slightly curved, having like the third a minute spinule a little above the apex of the convex front margin; fifth joint a little longer than the fourth, with a spinule a little above the apex of the hind margin, and another at the apex of the front; the finger not half the length of the fifth joint, tapering from the base nearly to the bent tip, the hind margin a little pectinate.

Second Peraopods like the first.

Third Peraopods like the two preceding pairs, the first joint scarcely more dilated, the fourth and fifth joints and the finger longer, the fourth joint having a little spine at the apex of the front margin, and its distal margin pectinate, the front margin of the fifth joint being faintly scabrous, and having two spinules; as in the other pairs, the termination of the finger is not sharp and strong, though the new growth seems to indicate that it is normally acute.

Fourth Peraopods like the third, but with all the joints except the finger rather longer.

Fifth Peraopods equal in length to the two first joints of the fourth pair, the first joint not broad, fully as long as the following five together, the third a little longer than the second, the fourth than the third, the fifth than the fourth, the fifth having a slender spine at the apex of the front margin; the finger is oval, about as long as the third joint, scarcely scabrous.

Pleopods.—Peduncles scarcely so long as the rami, coupling spines short, with long apical retroverted teeth; the cleft spine represented by a minute rudimentary acute spine near the top of the inner margin of the long first joint of the inner ramus; interlocking process of the outer ramus very short; joints of the inner ramus numbering from six to seven, of the outer from seven to eight.

Uropods.—Peduncles of the first pair a little shorter than the outer ramus, which has four strong teeth on the outer and two on the inner margin near the apex, the upper part being finely pectinate; the rather shorter inner ramus has one or two teeth on each margin; the second pair are similar to the first, but shorter and with fewer teeth; the third pair are shorter than the second, the peduncles set wide apart, broad, longer than the rami, of which the outer is slightly the longer, denticulate on the inner margin and having an apical spinule; the inner ramus is denticulate chiefly on the outer margin.

Telson transversely oval, much broader than long, less than half the length of the peduncles of the third uropods.

Length.—One-fifth of an inch.

Locality.—“Antarctic, surface, February 2, 1874”; lat. $52^{\circ} 4'$ S., long. $71^{\circ} 22'$ E. One specimen.

Remarks.—The specific name alludes to the place of capture; the shape of the telson seems to separate this species from all others within the genus that have been hitherto intelligibly described.

Vibiliia sp.

Where the fifth and sixth segments of the pleon coalesce there is a small groove at the centre of the back, limited to about a quarter of the whole dorsal breadth.

Eyes nearly round.

Upper Antennæ nearly as in *Vibiliia viator*.

Lower Antennæ.—The flagellum with three joints, of which the second is the shortest.

Upper Lip with the distal lobes strongly furred.

Mandibles.—The cutting edge with fifteen or sixteen teeth; the first two of the stouter spines in the spine-row having each one lateral denticle on the outer edge.

Lower Lip.—The outer corner of the principal lobes not flanked by a pronounced tooth, yet with a little irregularity of outline.

First Maxillæ.—Inner plate small, oval.

Maxillipeds with three spinules on the outer margin of the outer plates.

Gnathopods distinguished from those of *Vibiliia australis*, chiefly in the first pair, by having the first joint's front margin a little less bulging, and in the second by having the process of the wrist narrower, reaching nearly to the apex of the hand.

Uropods.—Peduncles of the first pair reaching just to the apex of the telson, a little longer than the rami; the narrower peduncles of the second pair reaching very nearly as far as those of the first, very little longer than the rami; the peduncles of the third pair the broadest, intermediate in length between the other two pairs, longer than the rami, the outer ramus a little shorter than the inner; the rami of the second pair a

little shorter than those of the first, and the third than those of the second, the armature nearly as in *Vibiliа propinqua*.

Telson triangularly rounded, not quite half the length of the peduncles of the third uropods.

Length.—One-third of an inch.

Locality.—“Between Kerguelen and Heard I., February 3, 1874, surface”; lat. 52° 20' S., long. 72° 14' E. One specimen.

Remarks.—There seems to be a close resemblance between this form and *Vibiliа gracilenta*, Bovallius, from the Atlantic, but in that species the hinder corners of the coalesced segments of the pleon are “strongly produced backwards,” and the peduncles of the third uropods are “linear,” neither of which characters suits the Challenger specimen.

The following list shows the localities at which specimens of the genus *Vibiliа* were obtained, arranged in sequence from the North Atlantic round to the North Pacific.

1. “June 18–19, 1873, surface”; between Stations 62 and 63, lat. 35° 7' and 35° 29' N., long. 52° 32' and 50° 53' W. One specimen.
2. “Between Bermuda and Azores, surface”; lat. 32° 29' and 39° 0' N., long. 68° 48' and 27° 0' W. Two specimens.
3. “April 27, 1876, North Atlantic, surface”; between Stations 352 and 353, lat. 10° 55' and 26° 21' N., long. 17° 46' and 33° 37' W. Three specimens.
4. “April 13–14, 1876, off Africa, surface”; near Station 352, lat. 10° 55' N., long. 17° 46' W. One specimen.
5. “October 5, 1873, South Atlantic, surface, night”; between Stations 130 and 131, lat. 26° 15' and 29° 35' S., long. 32° 56' and 28° 9' W. One specimen (*Vibiliа milnei*).
6. “Vibiliа, South Atlantic, November 10, 1873”; Station 140, lat. 35° 0' S., long. 17° 57' E. One specimen, mounted in Canada balsam.
7. “March 10, 1876, South Atlantic, surface”; Station 332, lat. 37° 29' S., long. 27° 31' W. Six specimens.
8. “March 9, 1876, South Atlantic, surface”; Station 331, lat. 37° 47' S., long. 30° 20' W. Five specimens.
9. “February 2, 1874, Antaretic, surface”; Station 150, lat. 52° 4' S., long. 71° 22' E. One specimen (*Vibiliа antarctica*).
10. “Between Kerguelen and Heard I., February 3, 1874, surface”; near Station 150. One specimen.
11. “March 9–10, 1874, south of Australia, surface, lat. 48° 18' S., long. 130° 4' E.”; between Stations 158 and 159. Three specimens (*Vibiliа australis*).

12. "August 23, 1874, New Hebrides," between Stations 179 and 180, lat. $15^{\circ} 58'$ and $14^{\circ} 7'$ S., long. $160^{\circ} 48'$ and $153^{\circ} 48'$ E. One specimen.

13. "August 25, 1874, Api to Cape York, surface"; Station 181, lat. $13^{\circ} 50'$ S., long. $151^{\circ} 49'$ E. One specimen.

14. "Cape York"; lat. $10^{\circ} 30'$ S., long. $142^{\circ} 18'$ E. One specimen (*Vibilia viator*).

15. "Pacific." One specimen.

16. "April 4, 1875, off Volcano I., Pacific, surface"; between Stations 229 and 230, lat. $22^{\circ} 1'$ and $26^{\circ} 29'$ N., long. $140^{\circ} 27'$ and $137^{\circ} 57'$ E. Four specimens (*Vibilia propinqua*).

17. Station 245; lat. $36^{\circ} 23'$ N., long. $174^{\circ} 31'$ E. One specimen.

None of the Challenger specimens are as much as half an inch in length. The largest species yet recorded appears to be *Vibilia edwardsii*, Spence Bate, from the southern Orkneys, the length attributed to this species being three-quarters of an inch. *Vibilia kroeyeri*, Bovallius, from Greenland, has a length of 12 mm. *Vibilia jeangerardii*, Lucas, from the Mediterranean, is 10 mm. long. *Vibilia borealis*, Bate and Westwood, from Banff, is seven-twentieths of an inch in length, but neither the size nor the colour nor any of the details given seem sufficient to distinguish this species from that named by Lucas. The figure and description of *Vibilia affinis*, Spence Bate, from Java, are also, I think, insufficient for any specific determination. Except in the absence of colour markings, the specimens from various stations in the Atlantic differ but little from *Vibilia jeangerardii*, Lucas, and the colour markings may have disappeared during the ten or twelve years that the specimens have been preserved in spirit. *Vibilia edwardsii*, Spence Bate, and *Vibilia longipes*, Bovallius, differ from the rest of the group by the great disparity in length between the second and fourth pereiopods, and *Vibilia pyripes*, Bovallius, from "tropical parts of Atlantic," is distinguished by having the "telson round, very broad, longer than last peduncles."

Family CYLLOPODIDÆ, Bovallius, 1887.

The family is defined by Bovallius as follows:—

"Head globular; eyes large, occupying almost the whole sides of the head. First pair of antennæ fixed at the anterior side of the head, with the first joint of flagellum tumid, conical; second pair fixed at the inferior side of the head, angulated. Mandibles with palp. Dactyli of seventh pair of pereiopoda [fifth pereiopods] transformed."

It may be questioned whether there was any pressing necessity for separating the single genus included in this family from the neighbouring Vibiliidæ, a family which is itself as yet not overcrowded with genera. Mr. Spence Bate indeed is so much impressed with the likeness between *Vibilia* and *Cyllopus* as to say of the two genera, that "had

they been found associated, they might have been supposed to be sexually related."¹ There are objections to that particular inference from the fact, but the fact itself of their being found associated is highly probable, since Mr. Spence Bate records a *Cyllopus* and a *Vibiliia* from the same habitat "near the Powel Islands," and the Challenger specimen of *Cyllopus* bears the same date of capture as specimens of *Vibiliia*.

Genus *Cyllopus*, Dana, 1852.

- 1852. *Cyllopus*, Dana, U.S. Explor. Exped., vol. xiii. pt. ii. pp. 981, 989, 1519.²
- 1862. " Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 305.
- 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk. Akad. Handl., Bd. 11, No. 16, p. 11.
- 1887. " Bovallius, Arctic and Antarctic Hyperids, Vega-Exped., Bd. iv. p. 555.

For the original definition of the genus, see Note on Dana, 1852 (p. 268). Bovallius in 1887 defines it as follows:—

"Head globular; a little tunid. Eyes large, filling almost the whole sides³ of the head. First pair of pereiopoda [first gnathopods] simple or subchelate. Second pair with a more or less produced carpal process. Femur of seventh pair [first joint of fifth peraeopods] much longer than the following joints together. Telson small, rounded."

The epithet "rounded" is scarcely applicable to the telson, since in *Cyllopus lucasii*, Spence Bate, it is said to be lanceolate. Spence Bate notices in regard to the species which he calls "*Cyllopus magellanicus*," that the second joint of the mandibular palp is the longest. This is the case in the Challenger specimen, and if it be a character of all the species it would be convenient to include it in the generic definition. *Cyllopus magellanicus*, Spence Bate, is distinguished by Bovallius from Dana's species of that name, and renamed "*Cyllopus Batei*."

Cyllopus hookeri, n. sp.

Head with a small rostral angle between the upper antennæ; back rounded; first three segments of the pleon with convex lower margins, serrate near the rounded postero-lateral angles; the coalesced fifth and sixth segments have the line of coalescence marked by a slightly convex groove at the centre of the back equal to about a quarter of the dorsal breadth.

Eyes dark, occupying almost the entire surface of the head; many of the multitudinous ocelli are very small, the crystal cone being in some cases spherical.

Upper Antennæ.—The first joint of the peduncle longer than the two following

¹ Brit. Mus. Catal., p. 305.

² It was no doubt by an oversight that Dana omitted *Cyllopus* from the classification of the Hyperidea at page 1442.

together, all three broader than long; the first joint of the flagellum considerably longer than the peduncle, for some distance nearly as thick as the peduncle, then tapering gradually, with a narrowed terminal piece more than a third, but less than half, the length of the joint; the second joint is minute, a little longer than broad, and in our specimen this is the last.

Lower Antennæ.—In the present specimen straight and almost smooth, situated very near one another; the first free joint scarcely longer than broad, the second a little, and the third a good deal, longer than the first; the following joint, which is probably the first of the flagellum, is nearly as long as the three preceding together and longer than the two subequal terminal joints combined.

Upper Lip.—The outer plate distally unsymmetrically bilobed with a not very deep emargination, each lobe having fur directed towards the emargination; the inner plate has a slightly convex distal margin which is hairy.

Mandibles.—The upper margin of the trunk behind the palp is straight; the cutting plate has about nine teeth, of which the lowest stands somewhat apart from the rest; the secondary plate of the left mandible has seven teeth very similar to those of the principal plate; on the right mandible it seems to be rather different, with one long tooth and the rest slighter; besides some ciliation above the plates there is a spine-row, with several strong, more or less denticulate spines among others that are slender and hair-like; the molar tubercle is prominent, cylindrical, with strongly dentate crown, in general appearance recalling the form common in the Gammarina; the first joint of the palp is twice as long as broad, but short compared with the other joints; the second is between two and three times as long as the first, longer and much broader than the third, narrowest at the two extremities, a little bent near the lower end; the long and narrow third joint has some small spines or setules along the convex hind margin of the acute apex.

Lower Lip.—Principal lobes rather broad, ciliated; the rounded apices of the mandibular processes scarcely free.

First Maxillæ.—Inner plate small, oval, smooth; the outer plate with numerous slender spines of various lengths on the surface and margins; the distal margin truncate, carrying eight strong but unequal spines, most of them having one or two lateral denticles; the palp joint is strongly ciliated, its outer margin convex, the inner nearly straight for more than half the distance from the base, the remainder concave, a spine being placed at the junction of the two portions; there are also some small spines on and near the very narrow truncate apex.

Second Maxillæ.—The two plates appear to be coalesced into a single plate with two apices, of which the inner is the larger and more prominent; there are numerous hair-like spines and slender spines about each apex, and a small spine at each apex. In the genus *Vibiliæ* these two plates are seen to be partially coalesced, and here, if my observation is correct, the coalescence is carried a step or two further.

Maxillipeds.—The inner plate nearly as broad as long, the rounded corners of the distal margin serrate, the centre almost flat, with two little embedded submarginal teeth; the outer plates with their bases not contiguous, the inner margin at first smooth, then divided into five or six irregularly serrate teeth with spinules, the distal part convex, irregularly denticulate, the two plates here becoming contiguous; there are five small spines on the outer surface and on the distal part of the outer margin there are three together with some elia.

First Gnathopods.—The first joint most widened near the centre, containing gland-cells, having a subapical spinule to the hind margin; the second joint as broad as the length; the third scarcely longer or wider than the second, with the hinder apex not very acute, resting on the wrist and having a spine adjacent; the wrist a little longer than the hand, broader, the hind margin straight, the front convex, the distal margin very faintly pectinate; the hand with spinules at two points of the slightly convex front margin; the hind margin straight, much of it and the distal margin beset with little groups of little tooth-like spines; the finger curved, tapering, more than half the length of the hand, its inner margin pectinate with little spine-teeth, of which there are also some adjacent to the margin.

Second Gnathopods.—Branchial vesicles as long as the first joint, broad, distally widened. The first joint a little sinuous, with two or three spines at the lower part of the hind margin; the second joint with two spines on the hind margin; the third joint much longer than in the preceding pair and than the second joint, with three spines along the hind margin, the lowest the longest, and three larger spines at the apical margin; the wrist longer than the hand, half of which it clasps with the produced hinder process, its distal margin on the inner surface and round the process being fringed with little teeth; the hand nearly as in the first pair, but with the hind margin a little convex, more strongly pectinate with little groups of teeth, which do not appear to be triple-pointed as described by Spence Bate for his "*Cyllopus Magellanicus*," though the teeth in many of the groups are set extremely close together; the finger as in the first pair.

First Peraopods more bulky than the gnathopods; the side-plates much larger than the preceding pair, broader than deep, with both ends rounded, the lower margin straight. The first joint, as in the gnathopods and the three following pairs of peraeopods, containing gland-cells, with two or three little spines on the hind margin; the third joint broader and very little longer than the fourth; the fifth joint a little longer than either of the two preceding joints, with a setule here and there; the finger about half the length of the fifth joint, a little bent, the upper half of the inner margin pectinate.

Second Peraopods like the first; the third, fourth, and fifth joints a little longer.

Third Peraopods.—Side-plates bilobed, broader than the preceding pair. Branchial vesicles longer than the first joint. The first joint rather shorter than in the preceding pair, but winged, with about six little spines along the front margin; the second joint

scarcely longer than broad; the third joint longer than in the preceding pair, rather shorter than the fourth joint, which has a little spinule at the apex of the straight front margin, and a scarcely developed tendency to pectination; the fifth joint curved, considerably longer than the fourth, the concave front margin with fine decurrent pectination; the finger rather more than a quarter the length of the fifth joint, armed like that of the preceding peræopods.

Fourth Peræopods.—Side-plates bilobed. Branchial vesicles widened above, narrowed below, rather longer than the first joint. The first joint much larger than in the preceding pair, with six spines along the front margin, the hind margin smooth, scarcely convex except at the two extremities; the rest of the limb similar to the preceding pair, except that the fourth joint is more decidedly though very finely pectinate, and the fifth joint is longer. The first and fifth joints being longer, and the others certainly not shorter than in the preceding pair, it follows that the whole limb is longer than that of the third peræopods.

Fifth Peræopods not much longer than the first joint of the fourth. The first joint twice as long as the remaining joints together, broad, looking very like a branchial vesicle, the front margin convex, with four little spines on the lower part, the apex drawn down a little below the hind margin, which is almost straight except at the two extremities; the second joint as broad as the length, with a subapical spine on the front margin; the third joint narrower, not longer, than the second; the fourth a little longer than the second; the fifth narrower than the fourth, not longer than the third; the sixth about as long as the fifth, tapering slightly to a blunt end, the front corner angled, furry, with a minute spinule at the angle.

Pleopods.—Coupling spines small, the apices forming as it appears a circlet of retroverted teeth, below which is another group of smaller teeth; the cleft spine without any considerable dilatation of either arm; the first joint of the inner ramus having three plumose setæ on the inner margin below the cleft spine; the first joint of the outer ramus with a short, broad, interlocking process, apically narrowed, the outer margin of the joint having several plumose setæ; the joints of the inner ramus nine to ten, of the outer ten to eleven. The terminal joint of the outer ramus in two or three instances in this specimen had but one seta instead of two, an anomaly which I have nowhere else observed.

Uropods.—Peduncles of the first pair subequal in length to the rami, the outer margin pectinate, the inner with an acute apex; the rami lanceolate, reaching beyond those of the third pair, the outer a little the shorter, pectinate along the outer margin and having five larger teeth on the lower part; the inner margin with two teeth and a little pectination; the inner ramus very similarly armed, but with four teeth on the inner margin; peduncles of the second pair much shorter than those of the first, shorter than the rami; the rami reaching beyond the peduncles of the third pair, much shorter than

the rami of that pair; the outer the shorter, with a little serration of the outer and not much more of the inner margin, the apex acute; the inner ramus also similar, a little more strongly armed; the peduncles of the third pair set wide apart, a little shorter than those of the first pair, much longer than the rami, the inner apex acute; the rami shorter than those of the second pair, the outer the shorter, the margins only a little dentieulate.

The Telson much broader than long, very short, triangularly rounded, its base occupying the space between the third uropods.

Length, outstretched, about a quarter of an inch.

Locality.—March 9, 1876, South Atlantic, surface; lat. $37^{\circ} 47'$ S., long. $30^{\circ} 20'$ W.; surface temperature, $64^{\circ} 5$. One specimen.

Remarks.—The specific name is given out of respect to Sir J. D. Hooker, among whose numerous unpublished drawings of Amphipoda there is one representing a species of this genus; the colouring represents the head as almost black, evidently occupied almost entirely by the eyes, the body a deep blue, the antennæ a lighter shade of the same colour, and the legs light red. In *Cyllopus armatus*, Bovallius, the first flagellum joint of the upper antennæ is drawn out to a much greater extent, there is a much greater disproportion between the second and third pereopods, the rami of the second uropods are more nearly equal to those of the third, the telson is differently shaped, and the size of the animal much greater. *Cyllopus magellanicus*, Spence Bate, has the rami of the third uropods “scarcely one-fourth of the length of the peduncle,” the telson cylindrieal, and the body of the animal “thickly covered with coarse stellate spots of black pigment,” whereas the Challenger specimen was colourless except as to the eyes. From *Cyllopus magellanicus*, Dana, if the figures of that species can be trusted, the present species is distinguished by having the fifth and sixth segments of the pleon coaleseed instead of free, by having the peduncles of the second uropods much shorter as compared with those of the first, and by having the first joint of the fifth pereopods of greater breadth; to these marks of distinction might be added the fact that the telson is free, not, as in Dana’s figure, coaleseed with the preceding segment, but the figure cannot perhaps be relied on for so minute a detail.

Dr. v. Willemoes Suhm, in a letter from Cape York, September 1874,¹ refers to the capture of a species of *Cyllopus*, but a mounted specimen so named, in his handwriting, with his monogram attached, and labelled as taken on the voyage from “Api to Cape York,” belongs not to *Cyllopus* but to *Paraphronima*.

¹ See Note on v. Willemoes Suhm, 1875 (p. 452).

Family LANCEOLIDÆ, 1887.

Bovallius, who in 1885 had reinstated Say's genus *Lanceola*, in 1887¹ established the family Lanceolidae to receive it, with the following diagnosis:—

"Head small, anteriorly truncated, not tumid. Eyes very small, often indistinct. First pair of antennæ short, high, compressed, fixed at the anterior side of the head. Second pair long angulated, fixed at the anterior side of the head. Mandibles with palp. Three posterior pairs of pereiopoda with retractile dactyli. Seventh pair [fifth peraeopods] not transformed."

In a subsequent work of the same year Bovallius varied the description as follows:—

"Head small, not tumid, anteriorly truncated. Eyes small. First pair of antennæ tumid. Second pair filiform, not angulated, fixed at the anterior side of the head. Mandibles with palp. Seventh pair of pereiopoda [fifth peraeopods] not transformed. Peduncles of uropoda normal."

That the lower antennæ are not folded as in the Platyselidæ is in agreement with the Challenger species belonging to this family, but neither do the dimensions of the lower antennæ in those species agree with the epithet "filiform."

For the original definition of the genus, see Note on Say, 1818 (p. 102). The British Museum Catalogue, in the description of Say's type-species under the name *Vibiliæ pelagica*, speaks of the upper antennæ as "reaching to the extremity of the peduncle of the inferior pair," whereas Say's words are "attaining the middle of the third joint of the inferiores"; in the account of the peraeopods, "third pair longest" is evidently a misprint for—third pair longer. In 1887 Bovallius gives the following definition of the genus:—

¹ Systematical List of the Amph. Hyper., p. 5.

"Head anteriorly concavated, the upper part more or less projecting into a rostrum. Eyes small, like those in the Gammarids, placed uncommonly far down on the sides of the head. First pair of antennæ long, the flagellum more or less lanceolate, tumid; somewhat like that in the Vibiliidae. Second pair are long, filiform, with very long joints. Urus [segments in connection with the uropods and telson] like that of the Hyperiidæ."

In 1885 Bovallius mentions that among his new species of *Lanceola* he has "two totally blind ones," in which case the generic character ought to speak of "eyes small or wanting"; that the lower antennæ are not always filiform has been already observed.

In this genus the ganglionic chain has its two halves clearly distinguishable, the longitudinal commissures being actually separate, in contrast to the genus *Vibia* in which they are closely united. The muscles do not form thick and compact groups, but slender bundles of which the components are easily separable, and in the large segments of the peræon, instead of a single longitudinal group on either side of the back, there are several slender strips of muscle very distinctly separated.

Lanceola pacifica, n. sp. (Pls. CLI., CLII.).

Rostrum small, obtuse, a little depressed; back of the peræon rounded, its third segment the longest, the second and fourth nearly equal to the third; the pleon-segments slightly carinate dorsally, the first three also laterally ridged, having the lower part of the hind margin fringed with spinules and sloping forwards to form an obtuse angle with the lower margin, which is likewise bordered with spinules.

Eyes small but prominent, tending to oval, placed obliquely between the upper and lower antennæ.

Upper Antennæ reaching nearly to the middle of the fourth joint of the lower antennæ; the peduncle short and stout, the first joint not so long as broad, as long as the two following together; the flagellum three times as long as the peduncle, the bulky first joint channelled on one side, and on the other fringed with a brush of short setæ or filaments in many transverse rows; the apex is obliquely truncate and is followed by a very short laminar second joint, with one edge folded, to which succeed two minute terminal joints, much less broadly winged.

Lower Antennæ.—First joint obscure; second joint short, with a small gland-cone; third joint twice as long as broad, very setiferous; the fourth joint two and a half times as long as the third, as long as the whole upper antennæ but not quite so broad, triangular in transverse section; fifth joint as long as the third and fourth together, narrower, tapering to a point, of triangular section till near the apex. It is possible that the fourth joint may represent the fourth and fifth joints of the peduncle coalesced, and that the whole of the tapering fifth joint may be the flagellum; that its apical part belongs to the flagellum can not be doubted.

Epistome prominent, helmet-shaped.

Upper Lip not quite symmetrically bilobed, the emargination between the two lobes being very deep.

Mandibles.—The cutting edge sharp, oblique, more than two-thirds of the breadth of the trunk, the upper angle produced into a tooth; this tooth on one mandible crosses its fellow on the other just above the emargination of the upper lip, under which the cutting edges of the mandibles lie, except at their lower extremities; there is a small tooth on the lower margin a little to the rear of the cutting edge, and to the rear of this tooth there is a row of short spinules and setules; the left mandible has a small tooth-like secondary plate high up on the inner surface; each mandible has on the inner surface a curved diagonal brush of numerous setæ extending from the lower front angle to near the base of the palp; the palp is set very far back, the first joint short, a little longer than broad, the second joint long, apically a little widened, with setæ along one margin and many about the distal end, the third joint shorter than the second, apically pointed, one margin convex, smooth, the other sinuous, furred with cilia.

Lower Lip.—Pl. CLII. shows the two mandibles from the inner side, clipped above by the transversely oval inner plate of the upper lip, and supported below near the outer corners by the mandibular processes of the lower lip. The figure of the mouth organs in Pl. CLI. shows the two mandibles from the outer side clipped above by the outer plate of the upper lip, but the lower lip is concealed by the maxillæ.

First Maxillæ.—The inner plate broad, with sinuous distal margin, both that and the surface carrying very numerous spinules; the outer plate not so broad as the inner, reaching beyond it, with many spinules, especially on and near the inner margin, the somewhat narrowed apex carrying on the inner side a rather slender spine followed closely by a very stout one, with another equally stout but shorter below it on the outer side, and somewhat further down a stout curved spine, followed by another planted on the surface just within the outer margin; there are also a few small spines on the trunk of the joint to which this plate belongs; the palp rather longer than the outer plate, near the middle of the base of which it is attached by a ridge of its inner surface, this attachment causing both the margins of the palp to face inwards; that which appears to be the true inner margin has several distant short spine-teeth spaced along it; between that at the almost acute apex and the next below it there is a marked emargination; on the outer slope of the apex there is a feathered spine; the outer margin is convex, pectinate with little spine-teeth for more than half its length from the apex.

Second Maxillæ.—The inner plate shorter but broader than the outer, with thirteen spines of various lengths planted on and just within the serrate distal margin, the outer and inner margins and one surface having cilia or spinules on the distal portion; the outer plate has eight spines on the truncate oblique apex, the outer and inner margins and one surface armed as in the other plate.

Maxillipeds.—The inner plate short, strongly projecting, cleft far down the middle, the distal margin of each half convex, set with many spinules; outer plates to a certain extent "prismatic," each having two inner margins, one of which carries several long and short spines; the outer margin is convex, smooth, the apical carries three or four unequal spines in notches; the outer surface of the plates is armed with many unequal spines, nineteen or twenty being counted on one plate and thirteen on the other; the basal joint carrying these plates has several spines on each lateral margin, and at the centre of the distal margin a small lobe or plate apically surmounted by two spines.

First Gnathopods.—Side-plates shallow, the lower margin nearly straight. The first joint nearly equal in length to the following four together, the inner front margin fringed with setiform spines, the hinder margin with spines of various lengths; the second joint short, with some spines on the hind margin; the third joint with the front margin on the inner surface longer than that on the outer, the hind margin with several slender spines; the wrist widening distally, much longer and broader than the hand, the front margin much longer than the hind one, each with spines or spinules at intervals, the sinuous distal margin with many spines, especially on the inner surface; the hand almost triangular, broadest at the base, not twice as long as broad, with five or six spines on each serrate margin and four on the inner surface, the narrow apex truncate; the finger very narrow, straight, when complete about half the length of the hand.

Second Gnathopods.—The side-plates shallow, broader than the first pair, the lower margin very sinuous. Branchial vesicles elongate, oval, narrower than the first joint and much shorter. Marsupial plates in an early stage of development, smooth-edged, as wide as the branchial vesicles and rather more than half their length. The first joint as long as the wrist, hand, and finger together, fringed with spines on both margins; the second and third joints nearly as in the first gnathopods, but the second rather longer; the wrist much longer and much narrower than in the first pair, similarly armed, distally widened, but not greatly; the hand shorter and narrower than the wrist, longer but narrower than the hand of the first gnathopod, with seven small spines on the hind margin and three or four on the front.

First Peræopods.—Side-plates broad, shallow, especially in front, the lower margin sinuous. Branchial vesicles much larger than the preceding pair, as long as the first joint and broader. The marsupial plates much narrower than the branchial vesicles and less than half their length. The first joint nearly as in the second gnathopods, but rather broader; the second joint rather longer than broad; the third joint shorter and much narrower than the first, considerably longer than the fourth or fifth; the fourth joint rather shorter but broader than the fifth; the fifth joint narrowing to the apex, slightly curved, having like the two preceding joints several small spines on the hind margin; the third has also several spines on the front margin, and the fourth has two or three;

the fourth and fifth joints are to some extent three-sided, or may be said to have a double hind margin; the finger small, curved, acute, not a fifth of the length of the fifth joint.

Second Peraopods.—Like the first, but the joints a little longer, especially the fifth joint. The branchial vesicles similar to the preceding pair, but much broader; the marsupial plates much narrower than the preceding pair.

Third Peraopods.—The side-plates like the preceding pair shallow, especially in front, and broad. Branchial vesicles larger than the preceding pairs. The marsupial plates similar to the preceding pair. The first joint narrower and longer than in the second peraeopods; the third, fourth, and fifth joints also respectively a little longer than those of the preceding pair, their front margins minutely spined, the hinder margin of the third being also spined; the fifth joint is straight, its hind margin smooth, nearly parallel with the front till the apex, which is rounded, produced behind the insertion of the finger, with oblique front margins, between which the minute, strongly curved, acute claw can be exserted or retracted.

Fourth Peraopods.—Branchial vesicles with the oval outline interrupted below the middle of the hind margin, a sort of suture marking off a narrow region from the base as far down as this interruption, below which the vesicle is narrowed. The first joint of the limb not longer than in the preceding pair, but broader, carrying some small spines along the front margin; the second and third joints longer and stouter than in the third peraeopods; the fourth joint nearly as long as the fourth and fifth together in the preceding pair; the fifth joint narrower than the fourth, but considerably longer, this and the three preceding joints unarmed; the retractile finger very little larger than that of the third peraeopods, with several little unequal spines on the upper part of the front margin, not decurrent.

Fifth Peraopods not half as long as the fourth. The side-plates small, narrower behind than in front. The first joint narrowing a little distally, its front margin carrying some small spines, the convex hinder margins nearly smooth; the third joint a little longer than the fourth, the two together scarcely as long as the first; the fifth joint longer than the third; the retractile finger smaller than in the two preceding pairs, with small spines or teeth on the inner margin directed slightly upwards.

The relative proportions of the peraeopods may be represented by the numbers 40, 44, 48, 66, 36.

Pleopods.—Peduncles stout; coupling spines short and small, each with four or five retroverted teeth on either side; the cleft spine stout, strongly feathered, the acute arm longer than the other, denticulate on two edges; the long first joint of the inner ramus has five feathered setæ below the eleventh spine; there are fifteen joints in this ramus and nineteen in the outer.

Uropods.—Peduncles and rami all more or less prismatic or three-sided in transverse (ZOOL. CHALL. EXP.—PART LXVII.—1888.)

section; peduncles of the first pair much longer than the rami; the inner margin fringed with unequal spines, the outer finely denticulate; the rami narrow, lanceolate, the outer and inner margins denticulate, the ridge of the under surface carrying a few spines, the inner ramus a little longer than the outer; peduncles of the second pair not so long as those of the first but much broader, with some small spines on the three margins, the rami similar to those of the first pair, subequal to them in length, but broader; the peduncles of the third pair not quite so broad as those of the second, much shorter; the rami shorter than the peduncle, similar to those of the second uropods, but not quite so long, and the inner ramus broader.

Telson long and narrow, nearly two and a half times as long as broad, subequal in length to the peduncles of the third uropods, not longer though extending a little beyond them; the nearly acute apex is rounded and microscopically pectinate.

Length.—In the position figured, in a straight line from the rostrum to the back of the third pleon-segment, the specimen measured eleven-twentieths of an inch.

Locality.—Station 241; lat. $35^{\circ} 41' N.$, long. $157^{\circ} 42' E.$; depth, 2300 fathoms; bottom, red clay; bottom temperature, $35^{\circ} 1$; surface temperature, $69^{\circ} 2$. One specimen. Trawled.

Remark.—The specific name refers to the capture of this species in the depths of the North Pacific Ocean; it bears a great general resemblance to *Lanceola sayana*, Bovallius, but in that species from the Atlantic the rostrum is acute, the segments of the peræon are imbricated, and the telson is longer than the peduncles of the third uropods.

Lanceola sp.

Rostrum curved, acute; back of peræon smooth.

Eyes minute, prominent.

Antennæ nearly as in *Lanceola pacifica*; the fifth joint of the lower pair rather less robust, followed by a small joint, scarcely longer than broad, to which succeeds a more slender joint, about twice as long, having a little setule on one side, and at the apex two setules, one of which is longer than the joint.

Mouth Organs and *Gnathopods* closely resembling those of *Lanceola pacifica*. The branchial vesicles of the second gnathopods are elongate oval, shorter than the first joint of the limb. The marsupial plates are strongly dilated like branchial vesicles, much broader and longer than the first joint of the limb, encircled by numerous slender setæ, which are rather long, but not of a length equal to the breadth of the plates.

Peræopods.—The first pair eleven-twentieths of an inch, the second over three-fifths, the third scarcely so long as the second, but still just over three-fifths of an inch,

the fourth three-quarters of an inch, the fifth just under two-fifths of an inch long. The relative proportions may be represented by the numbers 66, 74, 73, 90, 48. In the first pair the branchial vesicles and marsupial plates are larger than in the second gnathopods; in the second pair the branchial vesicles are larger, the marsupial plates smaller than in the preceding pair, the vesicles as long as the first joint of the limb, the plates longer; in the third pair the branchial vesicles are longer and the marsupial plates shorter than the first joint of the limb, the marsupial plates in all the pairs being fringed with setæ.

Pleopods.—Peduncles of the first pair as usual longer than those of the third pair; the inner ramus of the first pair with seventeen joints, outer with twenty-two; inner ramus of the third pair with nineteen joints, outer with twenty-three. First joint of the inner ramus of the first pair with nine feathered setæ below the cleft spine, of the third pair with seven such setæ; the first joint of the outer ramus in the third pair having fifteen plumose setæ along its outer margin.

Uropods scarcely differing from those of *Lanccola pacifica*.

Telson in general appearance like that of *Lanccola pacifica*, a very little longer than the peduncles of the third uropods, and having the lower part of the lateral margins and the apex not minutely pectinate as in the species just mentioned, but by comparison boldly serrate with teeth, of which some are bifid.

Length, about one inch, the antennæ not included.

Locality.—Station 334, March 14, 1876; lat. $35^{\circ} 45'$ S., long. $18^{\circ} 31'$ W.; 1915 fathoms. Trawled. One specimen, female.

Remarks.—Had no other species been described than *Lanceola pelagica*, Say, from the Gulf Stream, there could have been no difficulty in assigning that name to the present form, but the locality is more suggestive of *Lanceola felina*, Bovallius, from Tristan da Cunha; in that species, however, the telson appears to be shorter than the peduncles of the third uropods. From *Lanccola sayana*, Bovallius, an Atlantic species, as well as from the Pacific species, *Lanccola pacifica*, it is separated to all appearance only by minute differences.

Lanccola sp.

Length a little over half an inch.

Locality.—Station 297, November 11, 1875, South Pacific; lat. $37^{\circ} 29'$ S., long. $83^{\circ} 7'$ W.; depth, 1775 fathoms; bottom, Globigerina ooze; bottom temperature, $35^{\circ} 5'$; surface temperature, 57° . Tow-net at trawl. One specimen.

Remarks.—This specimen was mounted in a cell on the voyage, apparently in

glycerine. The second, third, and fourth segments are the longest and by far stouter than those which follow. The segments are imbricated. The relative lengths of the legs do not seem to differ very strikingly from those of the species just described. The telson, so far as appears in the undissected specimen, is a little more than half the length of the peduncles of the third uropods.

Lanceola sp.

The specimen here figured has not passed through my hands. The woodcuts represent two drawings by the late v. Willemoes Suhm, who appended the following notes:—

“Fig. 2. Amphipod. $\times 2$, etwas mehr.

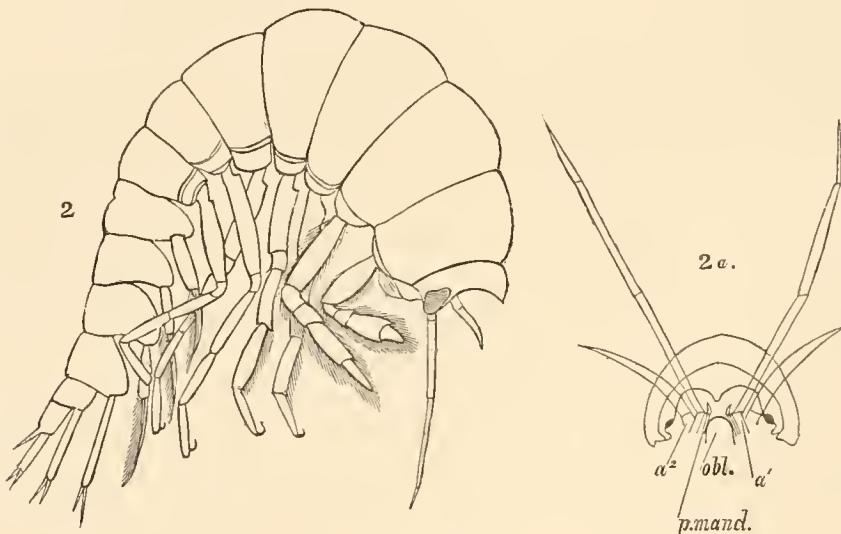

Fig. 27.

“Augen fehlen. Rothe Pigmentflecken ea. $1\frac{1}{2}$ mm. im Dehm. am ersten Ring. Maxillipedtaster fehlen. Länge von Schwanz-Ende bis zur Spitze 2ten Segm. 42 mm.

“Fig. 2a. Starker Vergrösserung des Kopfes von vorn. Augen keine hervorragende Platte sondern eine etwas deprimirte pigmentirte Stelle, wohl ganz ohne opt. Apparat.

“Von No. 194, 29 Sept. 74, off Banda Isl., 360 fs.”¹

Fig. 2a is reduced to half the size of the original drawing. Fig. 2 is a facsimile of the original. So far as can be judged from the measurements given, the total length of the specimen was about two inches. It is probably to this specimen that Pagenstecher refers (see Note, 1879, p. 497) in the words, “Eine Hyperide von 7 em. nur mit rothen Pigmentflecken statt der Augen in grossen Tiefen der Arúsee.” But “7 em.” is the measurement of the figure from the rostrum to the apex of the third uropods, and the

¹ Compare the description of *Erythrocephalus coccus*, Tilesius, quoted at p. 109.

figure represents the specimen in a bent position, magnified to rather more than twice the natural size. Pagenstecher does not give any reference to the source of his information, but it was no doubt obtained in one way or another from the notes of v. Willemoes Suhm himself. The statement that eyes are wanting must be received with reserve. "The red pigment-spots about $1\frac{1}{2}$ mm. in diameter on the first segment," that is on the head, as shown in the figures, correspond in size and position with the eyes as usually met with in this genus, and the crystal cones being in any case few and minute might easily be overlooked by any one unacquainted with the genus but accustomed to the multitudinous ocelli commonly found in the Hyperina. In fig. 2a, a^1 indicates the lower antennæ, a^2 the upper, *obl.* the epistome or Oberlippe.

Lanceola aestiva, n. sp. (Pl. CLIIL.).

Head rather short but very deep, with a very small triangular rostrum; the lateral margin irregular, the front of the head large and flat, with a central carina running between the antennæ which project above the mouth-organs; the central dorsal line of the whole animal scarcely carinate though the back is angled both here and laterally; the first three segments of the pleon with numerous spines or setæ round the convex lower margins.

Eyes doubtful, seemingly minute, prominent.

Upper Antennæ.—The peduncle of three short joints, the second and third successively shorter; the flagellum with its first joint broad, curved, very long, narrow near the base, acute at the tip, its three edges serrate, the convex upper one closely so; just within the apex there is a minute second joint, an apical third joint having probably been broken off.

Lower Antennæ.—Second joint short, with well-pronounced decurrent gland-cone; third joint about three times as long as the second, slightly bent, with three edges; the fourth joint elongate, longer than the whole of the upper antennæ, three-edged, the upper margin minutely serrate; the fifth joint scarcely so long as the fourth, much more slender, at first three-sided, then laminar, strongly tapering, its upper edge finely ciliated; the slender apex divided into two or perhaps three little joints.

Epistome prominent, helmet-shaped.

Upper Lip with the outer plate apically deeply cleft, the inner plate much shorter, transversely oval.

Mandibles similar in structure to those of *Lanceola pacifica*, the triangular secondary plate of the left mandible a little serrate on the edges, the groove or ridge over the spinous region strongly developed, convex; the palp much longer than the trunk, the first joint short, distally widened, the second joint very long with several slender setæ or setiform spines on three edges of the slightly widened distal part; the third joint long

and slender, two-thirds the length of the second, tapering to a point, the outward facing margin closely furred with spinules or setules.

Lower Lip.—The two oval pieces which represent at once the principal lobes and the mandibular processes, are ridged longitudinally; the long footstalks on which they appear to be supported form the lower border of the wide mouth-opening; between these in the figure *l.i.* are seen portions of the mouth cavity itself, a broad line of cilia running right round.

First Maxillæ.—The inner plate very broad, broadest distally, the distal margin nearly straight, this and the surface near it thickly set with spines and cilia which pass along the rounded corners and some way along the outer and inner margins; the outer plate as in *Lanceola pacifica*, the five distal spines similarly arranged and with similar proportions; the palp a little broader and longer than the outer plate, a ridge on its inner surface attaching it to the outer plate near the middle of the base, its own inner margin turned outwards, fringed with twelve minute distant spine-teeth, its convex outline becoming concave between the two distal spine-teeth, the apex blunt, partially serrulate, with a small spine just below it on the outer margin, this margin facing inwards, peetinate with minute spines for scarcely a third of its length from the apex, then smooth.

Second Maxillæ.—The bases broad, the plates long and narrow, on one surface distinct, on the other surface having their bases completely coalesced; the inner plate shorter than the outer, more or less channelled on the outer edge, distally strongly furred with spine-like cilia and carrying twelve long spines; the outer plate ciliated in a similar manner, and carrying ten long spines in two rows. Each pair of plates is in this genus widely separated from the fellow pair.

Maxillipeds.—Inner plate prominent, forming a sort of triangle, decidedly cleft half-way down from the apex, perhaps below this having a suture; the outer margins some way down from the apices fringed with a fur of spinules; the outer plates prismatic, twice as long as broad, with half a dozen little spine-teeth spaced along the inner margin of the outer surface and three closer together on the apical slope; the second inner margin has about eighteen slender slightly feathered spines, most of them very long; the distal part of the outer margin is serrate and carries four spines; the outer surface is armed with twenty or more spines; the base carries numerous slender spines on the outer margin and outer surface, and from the centre of its distal margin rises a thin somewhat triangular plate, of which the apex is somewhat rounded and minutely peetinate, with a minute central emargination.

First Gnathopods.—Side-plates broad and shallow, with sinuous lower border. The first joint narrowest at the neck, very broad, as long as the four following joints together, the outer front margin convex, smooth, the inner fringed with long setæ, the convex hinder margin fringed with slender setiform spines; the short second joint with

three such spines at the apex behind, and three or four on the outer surface ; the third joint with the serrate hinder and distal margins fringed with spines ; the wrist as broad as the first joint, a little longer than broad, with spines along the convex front margin and the parallel ridge and the shorter hind margin, and thickly set on the inner surface of the sinuous distal margin, either end of which is rounded and serrate : the hand much shorter than the wrist, scarcely half as broad, narrowing to a slightly emarginate apex, the margins slightly serrate, the hinder nearly straight, finely pectinate, both fringed with spines ; the inner surface having about thirty flexible spines distributed over it ; the finger nearly straight, slender, more than half the length of the hand, its inner margin a little pectinate.

Second Gnathopods.—Side-plates similar to the first pair. Branchial vesicles oval, about half as long but not nearly half as broad as the marsupial plates. The marsupial plates are similar in appearance to branchial vesicles, much broader than the first joint, but not half its length, smooth, without setæ, of which, however, the eventual production is perhaps indicated by markings round the margin. The first joint longer than that of the first gnathopods, but less broad, not quite so long as the wrist and hand together, with some slender spines along the front margin, the adjoining ridge without spines, the hind margin with a few ; the second joint with some spinules on the hind margin ; the third joint shaped as in the preceding pair, but with fewer spines ; the wrist elongate, widening a little distally, with six small spines on the front margin, two on the straight hind margin, and about ten on the distal margin ; the outer surface has two longitudinal ridges, of which the hinder carries a few spinules ; the hand elongate, narrower and shorter than the wrist, tapering to an emarginate apex, with eight spinules along the front margin, the outer surface with two slight ridges, the inner carrying about a dozen small spines ; the finger slender, not a third the length of the hand.

First Peraopods.—Side-plates broad and shallow, like the preceding pairs narrow in front. Branchial vesicles like the preceding pair. The marsupial plates larger than the preceding pair. The outstretched limb two-thirds of an inch long. The first joint longer than in the preceding limbs, with about twenty-four spines along the hind margin, fewer on the front, the adjoining ridge unspined ; the second joint longer than broad, without spines ; the third joint longer than the fourth, shorter than the fifth, with small spines along three edges ; the fourth joint with spines along both margins, and a row along the under surface, the two longitudinal ridges of the upper surface without spines ; the fifth joint narrower, gently curved and tapering, with two ridges along the upper, and one along the under surface, the concave hinder margin carrying about twenty-seven minute spines, and the inner surface a row of fewer spines ; the finger slightly bulbous at the base, slender, a little curved, about a seventh part of the length of the fifth joint.

Second Peraopods similar to the first, but with the side-plates larger, the branchial vesicles very much larger, equal to or exceeding the size of the marsupial plates, and the

joints of the limb, except perhaps the finger, longer; the third and the fifth joints are subequal in length; the outstretched limb rather more than seven-tenths of an inch long.

Third Peraopods.—Side-plates broad and shallow, especially in front. Branchial vesicles and marsupial plates like the preceding pair. First, third, and fourth joints longer but less broad than in the second peraeopods, the structure in general similar; the fifth joint shorter than in the preceding pair, shorter than the fourth joint, straight, little narrowed distally, apically produced in a narrow lobe behind the finger; the finger extremely narrow except at the base, very small and strongly bent upwards, without teeth on the inner margin; the outstretched limb three-quarters of an inch long.

Fourth Peræopods.—Side-plates not narrowly produced forwards like the preceding pairs, the front lobe the smaller, the hinder produced downwards at the back in a small point. Branchial vesicles large, the oval rather abruptly narrowed some distance above the apex. The outstretched limb more than an inch long; the long first joint has a folding in of the hind margin near the base, fringed with spines; the front margin and the longitudinal ridge of the upper surface near the hind margin carry small spines; the third joint is intermediate in length between the first and fourth, the fifth joint is rather longer than the first, the armature of all these both on margins and ridges being very inconspicuous; the retractile finger is very small, strongly bent, narrowing rapidly from the base to the bend, the inner margin fringed with minute teeth, of which those near the base are inclined backward.

Fifth Peræopods.—Side-plates not very broad. The outstretched limb over two-fifths of an inch; the first joint longer than the following three together, with fifteen spines along the front margin, and nine or ten on the hind margin, the three ridges smooth; the third joint longer than the fourth, shorter than the fifth, which is not so long as the first joint; the finger as in the fourth peraeopods.

The relative proportions of the pereopods may be represented by the numbers 80, 86, 90, 122, 50.

Pleopods.—The two slender coupling spines have each on either margin three or four retroverted teeth below those of the apex; the cleft spine nearly as in *Lanceola pacifica*; the rami are about equal in length, but in the pair examined there are on the somewhat stouter inner ramus only fifteen joints, and eighteen on the outer; the long first joint of the inner ramus has eight feathered setæ on its inner margin below the cleft spine; and on the outer margin of the first joint of the outer ramus the setæ are also numerous.

Uropods very similar in character to those of *Lanceola pacifica*, but the rami of the second pair do not exceed in breadth those of the first pair, or scarcely so, the peduncles of the third pair are less unequal to those of the second pair, and the inner ramus of the third pair is not noticeably shorter than the inner ramus in either of the other pairs.

Telson triangular, about one and a half as long as the breadth at the base, not

nearly as long as the peduncles of the third uropods, but more than half as long, just at the apex in our specimen microscopically and irregularly serrate or notched.

Length.—The length in a straight line from the rostrum to the apex of the third uropods was an inch and two-fifths. The animal when it reached me was broken in two.

Locality.—Station 120; lat. $8^{\circ} 37'$ S., long. $34^{\circ} 28'$ W.; depth, 675 fathoms; bottom, red mud; surface temperature, 78° . One specimen, trawled.

Remarks.—This appears to be the first species of the genus that has been taken within the tropics, and the specific name refers to the surface temperature of its habitat. The specimen, besides being broken, could not in other respects be described as well set up, but the animals of this genus seem liable to present themselves in a dilapidated condition, their integument probably being very little crustaceous. The species comes near to the briefly described *Lanceola felina*, Bovallius, from Tristan da Cunha.

A second specimen, in poor condition, appears to belong to this species.

Telson scarcely half as long as the peduncles of the third uropods.

Length, without the antennæ, three-fifths of an inch.

Locality.—Station 106; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; depth, 1850 fathoms; bottom, Globigerina ooze; bottom temperature, $36^{\circ} 6'$; surface temperature, $78^{\circ} 8'$.

Lanceola suhmi, n. sp.

Rostrum blunt; the second, third, and fourth segments of the peræon the longest, transversely ridged down the sides, the central dorsal line seeming more or less angled from the rostrum to the extremity of the telson, at either end of the animal only faintly, but on the last three segments of the peræon and the first four of the pleon forming a carina, distally produced into a tooth, which on the pleon-segments just mentioned is very pronounced.

Eyes very small according to the figure by v. Willemoes Sulim.

Upper Antennæ.—The three joints of the peduncle very short, the long first joint of the flagellum broad, tapering, curved, strongly ridged below, without any brush of filaments, rather longer than the last joint of the lower antennæ, succeeded by three minute joints, the last of which is acute.

Lower Antennæ.—Fourth joint very long, slightly curved, almost laminar, though a little ridged below, the fifth joint considerably shorter, yet long, straight, tapering to a point, almost laminar.

Mouth Organs (so far as could be seen without dissection and in their dry hard condition) similar to those of *Lanceola pacifica*. As the animal was figured during the voyage, it may be presumed that it had at some period been allowed to become dry, an experience from which the more delicate organs of an Amphipod seldom entirely recover.

First Gnathopods similar to those of *Lanceola aestiva*, but the first joint, the wrist and the hand less broad, the spines on the hind margin of the wrist differently arranged, and the wrist carrying on its outer surface a second ridge with a few spines near to the hind margin ; the spines on the margins and inner surface as numerous as in the species just named.

Second Gnathopods similar to those of *Lanceola aestiva*, but one ridge of the tapering hand set closely with spines, the hand and finger together not so long as the wrist.

Second Peraopods a little longer than the first, the full length thirteen-twentieths of an inch, the first joint not quite so long as the third and fourth together, the third longer than the fourth, nearly as long as the fifth, these three joints having two ridges along the outer surface, the hinder one in all three and both in the fifth joint carrying small spines, which is also the case with the two margins, but the spines are much more numerous on the hind than on the front margin.

Third Peraopods.—The full length sixteen-twentieths of an inch, the first joint the longest, but not greatly longer than the third; the third longer than the fourth, the fourth than the fifth ; the fifth, which like the four preceding joints has two longitudinal ridges on the outer surfaces, is not strongly spined, slightly curved, and a little narrowed towards the apex, this not being very strongly or broadly produced behind the small retractile finger.

Fourth Peraopods very similar to the preceding pair, but broader, almost unarmed ; the full length about nineteen-twentieths of an inch, the excess of length over the preceding pair being chiefly in the first and fifth joints, but more especially in the fifth.

Fifth Peraopods.—The full length half an inch, the joints ridged as in the preceding pairs, the first joint the longest, the third longer than the fourth, the fifth intermediate between the first and the third, the produced apex narrow ; the finger very small, bent, the inner margin without teeth in our specimen.

Pleopods.—Inner ramus in the first pair with sixteen joints, the outer with twenty.

Uropods closely resembling those of *Lanceola aestiva*, although here it appears as if the outer ramus were the longer both in the first and second pairs, and the peduncles are rather more sharply produced at the inner apical angle, especially in the third pair.

Telson long and narrow, very nearly equal in length to the peduncles of the third uropods, triangular, with the sides smooth for some distance from the base, then finely but not closely serrate or irregularly denticulate, the apparently acute apex also being seen under a high power to be cut into a fringe of four tiny teeth.

Length about an inch from the rostrum to the end of the uropods, the head and pereon measuring half an inch, the pleon-segments one-third, and from the base of the telson to the extremity of the uropods nearly one-fifth of an inch.

Locality.—Station 50, off Nova Scotia; lat. $42^{\circ} 8'$ N., long. $63^{\circ} 39'$ W.; depth, 1250 fathoms.

Remarks.—The name is given in honour of the deceased naturalist, v. Willemoes Suhm, who during the voyage made the rough sketch, here reproduced, of this interesting animal. The drawing is said to be magnified to double the size of the specimen, but seems to be rather in excess of that. The species appears to come near to *Lanceola*

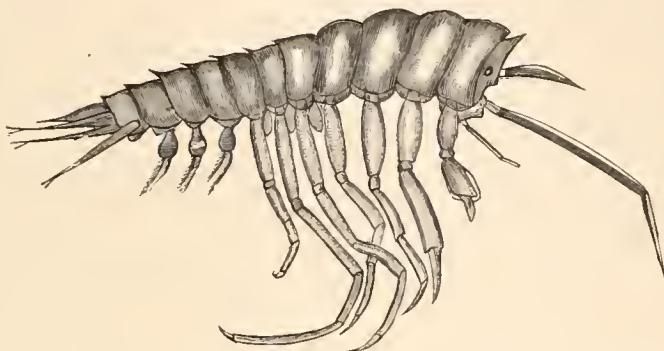

FIG. 28.—*Lanceola suhmi*, n. sp., from a drawing by the late Dr. R. v. Willemoes Suhm.

serrata, Bovallius, "from the mouth of Davis Strait," but in that species the pleon is said to be shorter than half the peræon with the head, and the segments of the peræon are said to be smooth, only the segments of the pleon being mentioned as forming a serrated keel.

Lanceola australis, n. sp.

Head forming an obtuse angle in front, without rostrum; the whole dorsal line of the animal angled; the seventh segment of the peræon has the dorsal line produced backwards in a very small tooth; each of the first three segments of the pleon has a similar but rather larger tooth.

Eyes very small, projecting a little from the surface of the head.

Upper Antennæ as in *Lanceola aestiva*, but with the large flagellum joint more strongly curved.

Lower Antennæ similar to those of *Lanceola aestiva*, but showing no minute apical joints.

Mandibles not very different from those of *Lanceola aestiva*; the tooth on the lower margin behind the cutting edge very minute; the inner groove or ridge extending with sinuous outline from the rear of the cutting plates for almost the whole length of the trunk; the second joint of the palp without setæ at the distal end, not very much longer than the third joint.

Second Maxillæ.—The plates long and narrow, the inner a little shorter and considerably narrower than the outer.

Gnathopods agreeing very nearly with those of *Lancecola aestiva*; the wrist in the first pair less dilated, with the front margin less convex.

Peraopods.—The *First* and *Second* a little under half an inch, the *Third* nearly three-fifths of an inch, the *Fourth* three-quarters of an inch, the *Fifth* one-third of an inch long; the relative proportions may be represented by the numbers 54, 56, 69, 90, 40. In the *Third Peraopods* the fifth joint is longer than in the preceding pair, and not shorter than the fourth joint, differing in these respects from the proportions found in *Lancecola aestiva*.

Uropods differing little from those of *Lancecola aestiva*, except that the peduncles of the second and third pairs are narrower, with the inner apices more acutely produced.

Telson long and narrow, about two and a half times as long as the greatest breadth, not quite reaching the bases of the rami of the third uropods, the central dorsal line angled for a short distance from the base, the apex almost acute, the sides being a little serrate near the apex.

Length, without the antennæ, about nine-tenths of an inch.

Locality.—Station 158, in the Southern Ocean, March 7, 1874; lat. $50^{\circ} 1'$ S., long. $123^{\circ} 4'$ E.; 1800 fathoms; bottom, Globigerina ooze; bottom temperature, $33^{\circ}.5$; surface temperature, 45° . One specimen.

Remarks.—The specific name refers to the place of capture, which makes it improbable that this species should be the same as the large *Lanceola serrata*, Bovallius, from "the mouth of Davis Strait," in which, moreover, "the dorsal side of pereion is smooth." In *Lancecola suhmi*, another North Atlantic species, the dorsal teeth are more numerous and larger than in the present species, and in the third peraeopods the fifth joint is not longer than in the preceding pair and is shorter than the fourth joint.

The following table will show at a glance the remarkable distribution of the genus *Lancecola*, as illustrated by the eight specimens of the Challenger collection:—

1. Station 50; lat. $42^{\circ} 8'$ N., long. $63^{\circ} 39'$ W.; depth, 1250 fathoms (*Lancecola suhmi*).
2. Station 106; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; depth, 1850 fathoms.
3. Station 120; lat. $8^{\circ} 37'$ S., long. $34^{\circ} 28'$ W.; depth, 675 fathoms (*Lancecola aestiva*).
4. Station 334; lat. $35^{\circ} 45'$ S., long. $18^{\circ} 31'$ W.; depth, 1915 fathoms.
5. Station 297; lat. $37^{\circ} 29'$ S., long. $83^{\circ} 7'$ W.; depth, 1775 fathoms.
6. Station 158; lat. $50^{\circ} 1'$ S., long. $123^{\circ} 4'$ E.; depth, 1800 fathoms (*Lancecola australis*).

7. Station 194A; lat. $4^{\circ} 31' 0''$ S., long. $129^{\circ} 57' 20''$ E.; depth, 360 fathoms.
 8. Station 241; lat. $35^{\circ} 41'$ N., long. $157^{\circ} 42'$ E.; depth, 2300 fathoms (*Lanceola pacifica*).

Thus from west to east the genus may be considered as ranging round the world, while from north to south a range is shown of more than ninety degrees, to which may be added about thirty degrees northward, since *Lanceola clausii*, Bovallius, was taken in "Davis Strait, at lat. 72° N." It is remarkable that each of the Challenger specimens was labelled, not, like most of the Hyperina, with the word "surface," but with the number of fathoms of the particular station, indicating that the specimen was supposed to have come from the great depth mentioned. It may be conjectured that the smallness of the eyes and the soft membranaceous character of the integument are connected with residence in the abysses of the ocean, and the latter character perhaps also with a capacity for passing without injury from the bottom to the surface. The pleopods are well developed, so that the animal may be itself a good swimmer, but, to account for the wide distribution of the genus, it may be supposed that the creature often avails itself of extraneous assistance, the retractile claws of the last three pairs of pereiopods being well adapted for giving it a firm hold upon animals of much greater size and speed.

Family CYSTISOMIDÆ, von Willemoes Suhm, 1875.

The name Cystisomidæ was proposed for this family by von Willemoes Suhm in the paper read before the Linnean Society on May 7th, 1874. Under the name Thaumatopsidæ, the family was defined by Bovallius in 1886 as follows:—

"Hyperids with large, tumid head. The eyes large, occupying the upper parts of the head. The first pair of antennæ straight or angularly bent, not tumid. The second pair rudimentary. The mandibles without palp. The seventh pair of pereiopoda [*fifth peræopods*] not transformed. The inner ramus of the uropoda coalesced with the peduncle; the peduncles very thick."

In the Systematical List, 1887, Bovallius gives a similar definition, but omitting all notice of the uropoda, and remarking that the second pair of antennæ are rudimentary *in both sexes*. In the Arctic and Antarctic Hyperids of the same year he gives a third definition, as follows:—

"Head and body very large and tumid. Eyes large, occupying the upper sides of the head. First pair of antennæ straight, not tumid, few-jointed. Second pair rudimentary. Mandibles without palp. Seventh pair of pereiopoda [*fifth peræopods*] not transformed. Uropoda very thick, prismatic, with distinct rami."

The description of the uropods as having "distinct rami" is open to misunder-

standing unless taken in connection with the definition of the genus "*Thaumatops*," given in the same work as follows:—

"Head very large, bordered with a serrated crest around the middle. First two pairs of pereiopoda [*First and Second Gnathopods*] cheliform. Second pair of uropoda are totally wanting. The interior rami are coalesced in both existing pairs of uropoda."

For the original definition of the genus *Cystisoma*, see Note on Guérin-Méneville, 1842 (p. 196); this may be compared with the account of the earliest described species, *Oniscus spinosus*, in the Note on J. C. Fabricius, 1775 (p. 40). For the definitions successively given for *Thaumops*, see Notes on v. Willemoes Suhm, 1873 (p. 423), 1874 (p. 440). The definition of the genus under the name *Thaumatops* given by Bovallius in 1887 has been quoted above; in 1886 he defined it as follows:—

"The body is hyaline, the segments distinctly separated from one another (except the two first pereional segments of *Th. Neptunus* and *Th. pellucida*, which are coalesced). The epimerals are only indicated.

"The head is large, more or less rounded, tumid. The eyes are large, occupying almost all the upper surface of the head.

"Only the first pair of antennæ are developed, straight, few-articulated. The second pair are represented by two small tubercles.

"The mandibles are small, rounded, with a molar tubercle, but without palp.

"The second pair of maxillæ consist of only one lamina.

"The first and second pairs of pereiopoda [First and Second Gnathopods] are cheliform, the following [five pairs of Peræopods] ending with a claw-shaped dactylus.

"The uropoda are very thick, the second pair wanting, the inner rami coalesced with the peduncles."

In the species, however, which have come under my examination, the mandibles are large as compared with the other mouth-organs, and by no means rounded, each has a denticulate cutting edge, the left mandible a denticulate secondary plate, the molar tubercle a long, straight edge set with cilia and minute spine-teeth. The integument of the back appears to be remarkably homogeneous, not as generally in the Gammarina much more flexible and less crustaceous at the folds between each segment, hence I feel some hesitation in adopting as a character of the genus the statement that the first two segments of the peræon are as a rule distinct. The line of coalescence between the two segments being in any case marked by a transverse ridge, a very slight crumpling of the integument behind this ridge would give the same effect of separation as that which in fact marks the division between the following segments.

Head inflated, wider than any part of the body, longer than the upper antennæ, rather broader than long, the upper surface almost entirely mapped out into minute hexagonal spaces in correspondence with the multitudinous ocelli; the lower surface fringed on either side by a row of thirteen or fourteen denticles, the wide space between these rows being occupied by a thin transparent membrane, from which, on either side of the mouth-organs and for a short space above them, project two short rows of denticles, five in each row, the highest pair of denticles being much the longest, and the next pair longer than the three lowest pairs, the lowest approaching the outer angle of the mandibles. The first two segments of the peræon are coalesced into one, which is rather longer than the next following, the seventh is longer than those which precede it, but shorter than the first segment of the pleon; the segments of the pleon diminish in length successively; in breadth the animal tapers from the base of the head to the telson. The segments are all carinate and centrally dentate, except the small (coalesced) fifth and sixth segments of the pleon. The seventh segment of the peræon and the first three of the pleon have each three teeth along the central ridge, the others have two apiece. The segments of the peræon and some of those of the pleon have the hind margin fringed with minute denticles, the composite first segment of the peræon having also a row near the front corresponding probably with the line of coalescence. The joints of all the limbs are prismatic in transverse section.

Eyes (see description of the female).

Upper Antennæ thirteen-twentieths of an inch in length, the first joint the stoutest, short, two or three times as long as broad, seemingly constituting a one-jointed peduncle, the following joint many times as long, of triangular transverse section, tapering, having on the inner side for most of its length a row of small setules not very closely set and scarcely showing beyond the margin, the apex produced into a small tooth on one side; planted within but projecting beyond the tooth is a small narrow tapering third joint.

Lower Antennæ wanting, unless the foremost pair of ventral denticles may be regarded as rudiments of these organs.

Epistome small, unsymmetrically helmet-shaped. In the upper figure of the mouth organs the epistome and upper lip are at the top, the maxillipeds at the bottom, the mandibles projecting on either side; the palps of the first maxillæ meet just over the emargination of the upper lip; the second maxillæ are crossed by the outer plates of the maxillipeds. In the lower figure, the maxillæ and maxillipeds having been removed, the

lower lip and the distal emargination of the upper lip come into view, with the cutting edges and molar tubercles of the mandibles lying under and between them; the trunks of the mandibles being partially released from their attachment are here more widely displayed than in the upper figure.

Upper Lip broader than the epistome, broader than deep, smooth-edged, unsymmetrically bilobed, the cleft in the distal margin being narrow and not very deep.

Mandibles.—The cutting edge narrow, with nine teeth on the right mandible and perhaps one or two more on the left; the lowest tooth in each recedes behind the line of the others, and behind and below it there is a tuft of cilia-like spines, the lower margin beyond being smooth; the secondary plate on the left mandible is quite narrow at the base, but widens out till its distal margin, which is cut into thirteen denticles, is about as wide as that of the principal plate, the edges so closely overlapping that it is not very easy to distinguish the teeth of the one from those of the other; the molar tubercle on each mandible large, with a very long, straight front edge, which is closely ciliated, and carries a row of small projecting teeth or spine-teeth, not quite closely set, more than fifty in number, besides several other rows of smaller teeth; the trunk of the mandible is large, the lower margin forming an obtuse angle at some distance behind the molar tubercle, while some distance further back the extremity of the mandibles forms an acute angle, the long comparatively straight upper margin having in advance of the centre a small triangular process with a broad base extending backwards, this process possibly representing a rudiment of the palp.

Lower Lip.—The outer and inner lobes coalesced, though distinguished by a strong ridge or suture, both dehiscent, the inner a little less than the outer, the inner margin of the outer lobes slightly hairy, that of the inner lobes strongly ciliated; the mandibular processes apically rounded, not divergent.

First Maxillæ.—The inner plate appears to be a smooth thin expansion surmounting the short first joint, but scarcely prominent beyond the inner margin of the long second joint; the outer plate short and broad; some way up on its sinuous inner margin a series of setiform spines begins, which is continuous right round the very broad distal margin, but there is also a series of stronger spines, on the distal part of the inner margin three that are rather narrow, followed by six stronger, a weak one, a strong one, two weak ones, and then a mixed group, in which there are three or four especially large and strong; the single-jointed palp is not so broad as the outer plate, but is rather longer, with some very minute spine-teeth on the inner margin, the apical margin being cut into many very acute little teeth, some still smaller teeth descending a part of the convex outer margin.

Second Maxillæ.—Basal part broad, beyond the centre abruptly contracting on the inner side, the inner margin then running smoothly and almost straight to the apex, but within this margin, before the apex is reached, there is a small linear projection,

distally seabrous, which perhaps represents in rudiment the inner plate of the maxilla ; beyond this there are two or three prickles and a very small spine tooth, which is followed by the sharply double-pointed apex, whence fifteen or sixteen small acute teeth descend the convex outer margin, gradually weakening into faint serrations, all the lower part of the margin being smooth.

Maxillipeds.—The first joint, which in the separate figure *mp* is for the sake of distinctness unfolded, in its natural position is bent at a sharp angle to the second joint, so that when the maxillipeds are separated from the head, the first and second joints naturally close together ; the inner plate strongly prismatic, one edge centrally projecting inwards, this edge starting some way below the distal margin of the second joint ; at its apex there is a small interval between the concave distal margins of the two sides, each of which carries two small separated spine-teeth near the inner and lower end ; the front of the plate also has a concave distal margin, with a small central emargination and two or three little spine-teeth spaced along the slightly serrate margin on either side of this ; the outer surface of the plate is not distinctly marked off from that of the second joint, except that in the centre of what may be considered as its base-line, there is a small conical tooth ; on either side of this are planted the two outer plates, which after widening a little from their bases, narrow to an acute apex ; the outer margin is smoothly convex, the inner carries two spinules at intervals not far from the base, and then is cut into strongly marked teeth as follows, a very small, a larger, a larger still, a rather small, a very large, a less large, a rather small, a large, a small, a moderately large, the apical largest of all, with a small tooth on its inner side ; the two plates, however, are not symmetrical, since that on the right hand in place of the twelve teeth just mentioned has but ten, the first of them, however, being a double tooth.

First Gnathopods.—The side-plate represented by an outward projecting tooth. The limb about eight-twentieths of an inch long, the first joint as long as the next four together, widening a little distally for the strong muscles which are grouped in the distal portion ; the front margin having on one gnathopod six strong teeth and three small ones, on the other having eight less unequal teeth ; the hind margin is nearly smooth, but the apex is produced into a sharp tooth, and above this there are on one gnathopod two, on the other three, small teeth and a spinule ; the second joint much broader than the length of its front, apically produced behind in a strong tooth, at the base of which there is a very small tooth on the hind margin ; the third joint longer than broad, clasping the wrist, with scarcely any free front margin, the surfaces carrying some slender spines, of which there are some on the more or less deeply emarginate apex, and on one gnathopod one on the otherwise smooth hind margin, while the other gnathopod has three ; the wrist with the front margin longer than the hand, apically forming a small tooth, otherwise smooth, triangularly produced behind almost to the extremity of the long apical tooth of the hand ; on the outer surface

there is near the front apex a strong tooth-like spine, and several smaller ones elsewhere besides some setiform spines, of which there are very many on the inner surface of both wrist and hand; the produced part of the wrist has its margins cut into strong teeth, much of the tooth-margins being also pectinately denticulate; on one gnathopod the margin facing the hand has six teeth and the other margin six, the large apical tooth making the thirteenth; on the other gnathopod the margin facing the hand has seven teeth, and the other margin four; the hand is oblong, about twice as long as broad, the front rather thick with two lines of teeth, each comprising from six to eight, not exactly alike in the two gnathopods, but each line in both gnathopods ending with a strongly produced apical tooth; the hinder margin is cut into seven or eight unequal teeth with partially denticulate margin, and there is a similar tooth on the distal margin; the surfaces of the hand are armed like those of the wrist; the finger is rather more than half the full length of the hand, broad at the base, apically curved and acute, reaching, when bent at a right angle to the hand, beyond the apical teeth of the wrist, its inner margin forming a very small spined tooth, much nearer the hinge than the apex, with two or three little spines or denticles between it and the hinge.

Second Gnathopods in general structure like the first. Side-plate represented by a rather stronger spine-tooth than that of the preceding segment. Branchial vesicles consisting of two subequal oval lobes united at the base, a little longer than the third joint. Limb about eleven-twentieths of an inch long, the first joint rather longer than the four following together, with one front edge smooth, the other carrying eight strong teeth, which on one of the gnathopods are supplemented by two small ones, the hinder margin having six teeth, one being the produced apex; the second and third joints nearly as in the first gnathopods, but larger, and the third with the slender spines more numerous; the wrist and hand similar but much more elongate; the wrist has the margin facing the hand cut into eleven denticulate teeth, and the hind margin in one gnathopod into ten, in the other into seven, such teeth, in addition to the long apical tooth; the hand, which is fully three times as long as broad, has the hind margin cut into twelve teeth, and the front margins much as in the first gnathopods, the inner surface with fewer setiform spines; the finger is longer than in the first gnathopods, but with its inner margin similarly armed.

First Peræopods.—Branchial vesicles about three-twentieths of an inch long, consisting of one very small lobe and a large one of the length mentioned. Limb about an inch and three-tenths in length, the first joint nine-twentieths of an inch long, with nine prominent teeth along the hind margin, and about as many small ones on one edge of the thickened front; the short second joint has three teeth along the hind margin, of these the apical being the longest; the third has fifteen larger and smaller teeth on the hind margin; the fourth which is a little longer has fifteen or sixteen; the rather longer but much narrower fifth joint has about thirty minute teeth, the margin in the intervals

as in the preceding joint being finely pectinate ; the three last-mentioned joints have on the surface several transverse rows of slender setæ, which, when the animal is in liquid, stand out on either side and give a feathered appearance to the limb ; these setæ are numerous at the apex of the fourth joint ; the finger is short and slender. In the figure the first two pairs of peræopods are represented facing forwards, as they happened to be in the specimen, but these long slender appendages sway about in all directions, and the normal position of the limbs is, therefore, assumed in the use of the terms—front margin and hind margin—in the description.

Second Peræopods.—Branchial vesicles simple, much larger than the preceding pair, four-tenths of an inch long. Limb two inches long ; first joint nearly as long as the third and fourth together, fourth a little longer than the third, fifth decidedly longer than the fourth, narrowed at the apex, armed as in the preceding pair, the distal part carrying a line of gland-cells ; finger small, acute or almost so, a little curved.

Third Peræopods.—Branchial vesicles rather larger than the preceding pair. Limb all but three inches long ; the first joint the longest, the second very short, the fourth longer than the third, and the fifth than the fourth, the slender fifth joint not much shorter than the first ; the first, third, and fourth joints serrate or dentate on three edges, the fifth along the front margin ; the fifth joint distally having a line of gland-cells ; the finger small.

Fourth Peræopods.—Branchial vesicles rather larger than the preceding pair. The limb nearly two inches and a half long, the armature and relative lengths of the joints nearly as in the preceding pair.

Fifth Peræopods.—Limb an inch and two-tenths long ; the first joint wider above than below instead of the reverse as in the other limbs, as long as the third and fourth joints together, the fourth scarcely longer than the third ; the fifth longer than the fourth, narrowest at the base, not narrowing distally, except where the finger is hinged, behind which on either side it is produced into a little sharp spinous process, while in front the distal end of the joint forms a kind of short oblique palmi-margin with four distant teeth ; the small finger is slightly bent, comparatively thick for the first half, the remainder narrow, acute ; the inner margin of the thick part has a minute denticle. In these and in the first and fourth peræopods, gland-cells probably occur at the distal end of the fifth joint, but they were not distinctly observed.

Pleopods.—The first pair about half an inch long, the peduncles rather shorter than the rami ; the coupling spines minute, with narrow apex and six or eight retroverted teeth on each margin ; there is no cleft spine, but the long and large first joint of the inner ramus carries numerous feathered setæ, in the first pair having as many as twenty-four on the inner margin ; the outer ramus has twenty-seven setæ along the outer margin of the first joint ; the joints of the inner ramus in the first pair are twenty-one, of the slightly longer but narrower outer ramus twenty-four.

Uropods.—The first pair eight-tenths of an inch long, strongly but irregularly toothed along three margins, the outer margin being also pectinate, the coalesced inner ramus broader but very little longer than the outer, its inner edge strongly toothed all along and pectinate near the acute apex, the ridge more lightly toothed, the outer margin not toothed but pectinate, except at the neck; the outer ramus one-fifth of an inch long, with the inner margin pectinate, of the other two, one toothed, the other scarcely toothed but pectinate; the second pair similar to the first, but a little shorter, yet reaching a little further back, seven-tenths of an inch long, the outer margin of the coalesced inner ramus having two teeth near the neck, besides being pectinate, the outer ramus as long as in the first pair.

Telson very small.

Length, without including the antennæ, four inches and one-eighth, the head over an inch long, the peræon an inch and four-tenths, the pleon an inch and nearly three-tenths, the last uropods seven-tenths, the sum total of the parts rather exceeding the entire length of the animal, since there is a certain amount of overlapping.

Locality.—Station 107, south-west of Sierra Leone, August 26, 1873; lat. $1^{\circ} 22' N.$, long. $26^{\circ} 36' W.$; depth, 1500 fathoms; bottom, Globigerina ooze; bottom temperature, $37^{\circ} 9$; surface temperature, $78^{\circ} 8$. One specimen, male. Trawled.

Cystisoma spinosum, ♀ (J. C. Fabricius), 1775 (Pl. CLV.). Specimen B.

The Head and general appearance of the animal as in the male; the dentation of the central keel apparently not differing from that in the male.

Eyes.—In his original description of the present specimen, von Willemoes Suhm observes,¹ “the upper surface of the head is entirely occupied by two contiguous faceted eyes, which are separated from one another by a mesial line, 20 millims. in length (Plate XLIX. figs. 2 & 3). Each eye is 13 millims. in width, and its anterior and lateral borders are limited by a slightly coloured band, which will be referred to when considering the structure of the eyes. The posterior border nearly corresponds with the posterior border of the head, which arches gently over to the first segment of the thoracæ region.” Further on he says,—“THE EYES are contiguous, the line separating them being, however, clearly visible: the length of this line is 20 millims. The eyes thus occupy a rectangular space, the outer edges of which are separated from the spiny borders of the head-shield by a space 6 millims. in width. At the front of the head there is a space of 3 millims. between their anterior borders and the line into which the two antennæ are inserted. Along the sides of the eyes there is a brownish line produced by elongated chitinous appendages, 0·140 millim. long. (Plate L. fig. 8),

¹ *Phil. Trans.*, vol. clxiii. pp. 629, 631.

attached irregularly to the borders of the cornea. These appendages are hollow tubes pointed and closed at the top, and flattened and slightly dentieulated at the base. The cornea of the eye is faceted externally, the facets being hexagonal (Plate L. fig. 7). Beneath the facets we find very elegant slender crystalline bodies, 0·840 millim. long, and at the top 0·147 millim. broad (Plate L. figs. 9, 9a). I have figured two pairs of these, as they are always united together by their slender ends, the point of union being shown at fig. 9a. In their upper part a granulation is to be seen, giving them a slightly brownish colour; and in their tapering extremities there are some clear vesicles, which have some resemblance to the varieosities of a nerve-fibre. The nerve-ends which are present in *Phronima* are absent in this form, and there is no pigment."

In regard to the figures of the ocelli, it may be remarked that their tapering extremities should have been drawn straight, not sinuous; at least I believe that they only assume the serpentine form when detached. The hinder margin of the eyes is not straight, as implied in the above description and as figured in the Plate referred to, but each eye has a curved hind margin, which leaves a small triangular space at the back of the head dividing one eye from the other.

Upper Antennæ.—Of these von Willemoes Suhm says,¹—"At the frontal border, separated by a distance of about 7 millims., there are two antennæ 26 millims. long. The antennæ consist of two elements, of which the proximal is longer than the distal, which is enlarged at the end, and bears a very small recurved claw." These antennæ are therefore longer than the head, instead of shorter as in the male. Unfortunately when the specimen came into my hands the ends of the antennæ were broken and the tips were gone, but from the portions remaining I feel tolerably sure that the articulation of these antennæ has been misinterpreted; the first joint is short as in the male and evidently represents the peduncle, the "recurved claw" is no doubt equivalent to the little terminal joint in the male, while the elongated intermediate joint had, owing to an accidental fracture, assumed the appearance of two joints, one "angulated" upon the other. The appearance of jointing produced by fracture is not uncommon in the limbs of animals belonging to this genus.

Mouth Organs closely resembling those of the male.

Mandibles.—The lowest tooth of the cutting edge is a little more drawn back on the left mandible than in the male specimen; the triangular process on the upper margin of the trunk is more slender.

First Maxillæ.—The distal spines of the outer plate are not in precisely the same arrangement as in the male specimen; thus, the two large spines nearest to the outer group are cleft for more than half their length; but the force of minute differences of detail of this kind is destroyed by the fact already noticed, that in the maxillipeds of the male specimen the two sides are unlike in just such details.

¹ *Loc. cit.*, p. 630.

Second Maxillæ.—On the distal curve of the widest part of the plate, just before its abrupt contraction, there are four little spines. In the male this part of the margin was broken, and probably for that reason no such spines were seen.

Maxillipeds.—The lateral margins of the distal triangle of the inner plate have each three instead of two small spaced spines.

First Gnathopods.—An elongate outward projecting tooth representing the side-plate. First joint about as long as the next four together, with eight unequal teeth along the front margin, one at the apex of the hind margin, and another a little higher up; a long tooth at the hinder apex of the second joint, and a small one higher up; the third joint also nearly as in the male; one front edge of the wrist cut into five large teeth, its triangular process not quite reaching to the extremity of the hand, the margin facing the hand cut into nine teeth, the hind margin into four, the apical making a fourteenth tooth; the hand with the hind margin cut into eight teeth, besides one on the palmar margin; of the two front margins one has seven, the other eight teeth, besides the large apical tooth of each; the finger as in the male.

Second Gnathopods only differing from those of the male specimen in trifling details, as is also the case with the first gnathopods.

Peræopods of the first, second, third, and fourth pairs not materially differing in appearance from those of the male specimen, not exhibiting the striking expansion of the distal end of the fifth joint figured by von Willemoes Suhm, and of which he says,¹—"the enlarged distal terminations of the limbs and of the antennæ are not, like the remaining part of the appendages, transparent, but are of a milk-white colour, produced, I believe, by glands in their interior analogous to the glands in the enlarged claw of *Phronima*." It is possible, I think, that, while the specimen was fresh, the opacity of the termination of the fifth joint, contrasted with the transparency of the rest, produced an optical impression of expansion beyond the reality, but it is even more probable that, during the years the specimen has been in spirit, some of the actual expansion has been lost by a discharge of the contents of the gland-cells.

Fifth Peræopods similar to those of the male specimen except in regard to the fifth joint, which, except at the narrow neck and the narrow place of insertion for the finger, is strongly swollen and closely packed with gland-cells; it widens gradually for about two-thirds of the length, and then narrows very slightly to the distal end, which forms a smooth-edged palm, against which the small bent finger is capable of impinging, though it cannot reach its extremity; the hinder margin is smoothly convex, the front is straight and almost entirely smooth, though here and there bearing very slight traces of a lost dentation; the lateral setæ are as in the male.

Uropods.—The first pair scarcely over six-tenths of an inch long from the base to the extremity of the coalesced inner branch, seven-tenths of an inch to the extremity

¹ *Loc. cit.*, p. 630.

of the outer branch; the outer branch eight-thirtieths of an inch long, or more than half the length of the peduncle excluding the inner branch; the ornamentation is similar to that in the male specimen, except that of the two pectinate margins of the outer branch, both are slightly toothed; this branch is distally a little, but conspicuously dilated, and then rather abruptly narrowed to an acute apex; the second pair similar to the first, the branches equally long, the peduncles shorter.

The Ventral Surface of the animal is remarkable. The description given by von Willemoes Suhm of the genital organs has been already quoted in the Note on that writer (p. 438). The figure here given of the anterior part of the ventral surface of the peræon shows at the top the central spine to which von Willemoes Suhm refers; to the rear of this, what he calls "the genital papilla" is formed by two pairs of plates, the plates of each pair meeting and fitting closely together along the median line of the animal; the opening of these valves seems to be dependent upon the movement of the small second pair of gnathopods, which are very stiffly connected with them; each plate has on the inner side and inner surface a lobe, of which the distal and inner margins are beset with setæ, and which may be supposed to correspond with the marsupial plates of normal Amphipods. Behind the "genital papilla," there is a transverse wrinkling of the ventral surface, and a little to the rear of this, a pair of rudimentary branchiæ, one of which is shown in its relative position on the Plate; behind this there is another transverse wrinkle, and again a little to the rear another pair of rather larger rudimentary branchiæ, one of which is also shown in its relative position; these rudimentary branchiæ may be supposed to correspond to the small pairs of double branchiæ found attached to the second gnathopods and first peræopods in the male specimen. Only the first two joints of the second gnathopod are shown in the figure of the valves, the distal part of that limb being represented in a separate figure at the lower left-hand corner of the Plate.

Length, three inches and three-tenths, or to take the measurement made when the specimen was fresh, "84 mm."

Locality.—Station V., off the Strait of Gibraltar, January 28, 1873; lat. $35^{\circ} 47'$ N., long. $8^{\circ} 23'$ W.; depth, 1090 fathoms; bottom, Globigerina ooze; bottom temperature, $38^{\circ}.5$; surface temperature, 61° . One specimen, female. Trawled.

Remarks.—For the original description of *Oniscus spinosus* from the Atlantic, see Note on J. C. Fabricius, 1775. Fabricius makes a reference in that description to the *Museum Banksianum*. In the cases of this museum, preserved at South Kensington, no such specimen is now to be found, but among the Zoological drawings by Sydney Parkinson in Capt. Cook's First Voyage 1768–1771, which form part of the Banksian Museum, there are three figures undoubtedly representing a species of *Cystisoma*. These figures are signed, "Sydney Parkinson pinxt. 1768," and bear the manuscript

name "*Onidium spinosum*." It may be taken for granted that they represent the species *Oniscus spinosus* of Fabricius; they give a dorsal, a ventral, and a lateral view of the animal, and vary in length from four inches and three-quarters to nearly five inches and a half. Since, with the other Amphipoda which he represents, Parkinson gives life-size figures as well as the enlarged ones, it may be presumed from the absence of any small figure of "*Onidium spinosum*," that five inches was approximately the length of the actual specimen, or not so greatly in excess of it as to be thought to demand a more exact specification of the real size. In general appearance and details, and in particular in the antennæ and uropods, the figures agree with the male specimen brought home by the Challenger, but in the fifth peræopods there is the remarkable thickening of the fifth joint, which has been described for the female only and to which Fabricius no doubt alludes when describing this joint as "articulo ultimo elevato."

The male and female specimens which I have here placed together under the name *Cystisoma spinosum* (Fabr.), are regarded by Bovallius as representing two distinct species, the male being named by him *Thaumatops neptunus* (Guérin-Méneville), and the female *Thaumatops pellucida* (von Willemoes Suhm). In the female, the upper antennæ are longer than in the male, and have the termination of the long second joint swollen, containing a gland; the fifth joint of the fifth peræopods is swollen, smooth-edged, and full of gland-cells; the outer ramus in each pair of uropods is longer than the inner, and swollen near the apex, containing a gland. These make a striking group of differences, outside of those which are obviously sexual, but it will be noticed that there is probably a correlation between the differences, since all are connected with glandular contents of the organs concerned, in the lengthened antennæ at one end of the animal, and the lengthened rami of the uropods at the other, while in the peræopods, midway between these two extremities, it is easy to understand that the dentate edge, useful to a laminar joint, would be of no service to the joint when by the packing with gland-cells it becomes more or less cylindrical. In Parkinson's figure of "*Onidium spinosum*" we find the antennæ and uropods agreeing with the Challenger male specimen, but the fifth peræopods agreeing with the Challenger female specimen. From the perplexity which thus arises, it would be easy to escape by saying that Parkinson's is a third intermediate species between the other two, and future discoveries may prove this to be the true solution, but for the present I am disinclined to ground specific distinction on characters which may turn out to be merely sexual. Moreover, the differences, though striking when discussed on paper, are comparatively trivial when contrasted with the still more striking resemblance, both in general and in detail, which the two fine specimens present.

Cystisoma spinosum (Fabricius). Specimens C, CC.

Specimen C.—*Length*, one inch and eight-tenths; antennæ seven-tenths of an inch, a little longer than those of the very much larger specimen A, and placed much nearer to one another than in that specimen; third pereopods just under an inch and a half, the first joint half an inch, the following two together nine-thirtieths, the fourth and fifth each ten-thirtieths of an inch; the fourth pereopods just under an inch in length, the fourth and fifth joints equal; no trace could be perceived of the small branchial vesicles related to the second gnathopods and first pereopods; the uropods similar in their proportions to those of the specimen from Station 224.

Specimen CC.—*Length*, one inch and eight-tenths; the antennæ not especially near together as in the companion specimen; the small branchial vesicles related respectively to the second gnathopods and the first pereopods, and the three large pairs, similar to those described for specimen A.

Locality.—Station 101, August 19, 1873; off Sierra Leone; lat. $5^{\circ} 48' N.$, long. $14^{\circ} 20' W.$; depth, 2500 fathoms; bottom, blue mud; bottom temperature, $36^{\circ} 4'$; surface temperature, $79^{\circ} 2$. Two specimens. Trawled.

Remarks.—Sir Wyville Thomson (see Note, p. 471), in noticing specimen B, says, “We have since taken several specimens at different stations in the Atlantic,” and “as a small male was in one case captured in the towing-net,” he infers that the animals of this genus occasionally come to the surface. As no especial notice is taken of the occurrence of *Cystisoma* at the remarkable depth of 2500 fathoms, some doubt may have been felt whether the two specimens of Station 101 actually came from that depth. Indeed, as Mr. Murray has frequently pointed out, although the dredge or trawl may have been down to a depth of 2500 fathoms, there is no certainty that many of the animals captured came from that depth, as they may have been taken at any depth between the bottom and surface. Since only four specimens of the genus *Cystisoma* seem to have been taken in the Atlantic, I am inclined to believe that the “several specimens” mentioned may have included some belonging in reality to the genus *Lanceola*.

Cystisoma spinosum (Fabricius) (Pl. CLVI.). Specimen D.

Head with twelve teeth on each lateral margin.

Upper Antennæ.—The distal part broken off, so that the full length could not be ascertained, the remaining portion rather thick, tapering, one-fifth of an inch long. Of the spines on either side of the central line on the under side of the head, there are only two pairs, the upper pair (which possibly represent the *Lower Antennæ*) being

much longer than the other pair; the second pair is not spine-like, but tubercular, blunt-ended, apparently forming the antennary gland-eone with its terminal channel.

Mouth Organs.—It is extremely difficult to say whether the small differences observed between the mouth organs of the present and those of larger specimens are of any specific value; here on the left mandible the cutting edge has nine teeth, and the secondary plate has ten, the cutting edge of the right mandible has nine teeth; the rows of denticles on the crown of the molar tubercle were here seen to number about twenty, forming a serrated mass; the outer plate of the first maxillæ has on its inner margin four setæ, followed by three rather narrow spines; these are followed without interruption on the apical margin by a connected series of spines successively stouter, seven in number, to which succeeds the set of six or seven stout spines grouped round the outer apex; there are also several submarginal setæ; the outer plates of the maxillipeds have five teeth on the inner margin, the one nearest the apex being irregularly jagged.

First Gnathopods less than one-fifth of an inch long; *Second Gnathopods* a quarter of an inch; *First Peræopods* eleven-twentieths; *Second Peræopods* sixteen-twentieths; *Third Peræopods* a little over an inch; *Fourth Peræopods* eighteen-twentieths of an inch; *Fifth Peræopods* nine-twentieths; the relative lengths of the fourth and fifth joints of the various peræopods are like those described for Specimen F from Station 196; the *First Uropods* are six-twentieths of an inch long to the extremity of the narrow outer branch, the length of the branch being two-twentieths; the coalesced inner ramus is slightly shorter; the *Second Uropods* are five-twentieths of an inch long, the outer ramus almost two-twentieths.

Pleopods.—Peduncles as long as the rami; coupling spines very slender, joints of the rami numbering from ten to twelve, the first joint in each ramus very long.

Telson as usual very small and shallow, not so broad as the peduncles of the uropods, not so long as broad, its distal margin rounded.

Length.—The figure at the top of the Plate is intended to represent the natural size, and according to this it would not be more than an inch and a quarter long, but the specimen was in a crumpled flaccid condition, and might possibly have been in life rather longer.

Locality.—Station 170A, July 14, 1874; off the Kermadec Islands; lat. $29^{\circ} 45' S.$, long. $178^{\circ} 11' W.$; depth, 630 fathoms; bottom, volcanic mud; bottom temperature, $39^{\circ}.5$; surface temperature, $65^{\circ}.2$. One specimen, male or young. Trawled.

Cystisoma spinosum (Fabrieius). Specimen E.

This specimen of moderate size was taken comparatively near to specimen G, the distance between their respective localities being about 3 degrees of latitude and 17

of longitude; from the locality of the large specimen A its place of capture was far more remote, the distance being about 6 degrees of latitude and 170 of longitude, yet between these two specimens, obtained at opposite sides of the globe, I could perceive no salient marks of difference, other than the following measurements:—

Length from the front of the head (as with the other specimens not including the antennæ) to the extremity of the uropods, two inches; antennæ just over six-tenths of an inch; first pereopods a little over six-tenths of an inch, second pereopods a little over an inch, third pereopods an inch and a half, fourth pereopods (fifth joint broken) about an inch and one-tenth, fifth pereopods seven-tenths of an inch; in the large third pereopods the first joint is half an inch long, the two following together three-tenths of an inch, the fourth eleven-thirtieths, and the slender fifth ten-thirtieths of an inch; the minute fingers have not been taken into account in the measurements either of this or the other specimens; the first uropods are almost four-tenths of an inch long to the extremity of the coalesced inner branch, the outer branch, which at least in its present condition is a little shorter than the inner, is just under one-tenth of an inch long; the second uropods, which reach just beyond the first, are three-tenths of an inch long, the outer branch as long as the inner, just over one-tenth of an inch long.

Locality.—Station 224, March 21, 1875; between the Admiralty Islands and Japan; lat. $7^{\circ} 45'$ N., long. $144^{\circ} 20'$ E.; depth, 1850 fathoms; bottom, Globigerina ooze; bottom temperature, $35^{\circ}.4$; surface temperature, $81^{\circ}.2$. One specimen, male. Dredged.

Remark.—Whether the small branchial vesicles of the second gnathopods and first pereopods were present in this specimen, I could not determine without dissecting it.

Cystisoma. Specimen F.

Antennæ one inch and one tenth in length, the basal joint not longer than broad, its distal margins slightly convex, the terminal joint minute, acute, the second joint more than an inch long, with the usual slight serration, some slender setæ, which are most numerous near the base, the joint tapering for some distance from its base, but for much of its length narrow and of nearly uniform breadth; just before the narrow apex is reached it shows a slight tendency to thicken.

Mouth Organs, so far as could be seen without separating them from one another, in close agreement with those already described for the species *Cystisoma spinosum*.

First Gnathopods four-twentieths of an inch long; *Second Gnathopods* more than six-twentieths; *First Peraopods* fifteen-twentieths; *Second Peraopods* one inch and two-twentieths; *Third Peraopods* one inch and twelve-twentieths; *Fourth Peraopods* one inch and seven-twentieths; *Fifth Peraopods* a little over fourteen-twentieths of

an inch; in the first pair the fourth joint is a little longer than the fifth, in the second and third they are as nearly as possible equal, in the fourth pair the fifth joint is perhaps slightly the longer; in the fifth pair the fifth joint is longer than the third, and the third than the fourth; branchial vesicles were observed only with the second, third, and fourth pairs, those of the second being decidedly the smallest, those of the fourth apparently the largest.

Uropods.—First pair a little under eight-twentieths of an inch long to the extremity of the coalesced inner branch, a little over eight-twentieths to the end of the outer branch, this branch being about half the length of the peduncle; the second pair about seven-twentieths of an inch to the end of the outer branch, which as in the first pair is a little longer than the inner.

Length.—The specimen was not in good order and the measurement was not taken before it was broken up; the full length was probably not much over two inches.

Locality.—Station 196, October 13, 1874; north of Amboina; lat. $0^{\circ} 48' 30''$ S., long. $126^{\circ} 58' 30''$ E.; depth, 825 fathoms; bottom, hard ground; bottom temperature, $36^{\circ}\cdot 9$; surface temperature, 83° . One specimen, male. Trawled.

Remarks.—If, in view of the great length of the upper antennæ, it be necessary to separate this specimen from the others, I should propose to name it *Cystisoma parkinsoni*, in honour of the artist, who, so far as is known, was the first to delineate any species of this genus. It will be observed that in the antennæ in question the basal joint is shorter than in other specimens where the total length of the antennæ is far less.

Cystisoma. Specimen G.

Head measuring seventeen-twentieths of an inch on the ventral surface from the front to the mouth organs; thirteen teeth on the lateral margin, two pairs of spines on the ventral surface.

Upper Antennæ eight-tenths of an inch long, the tip broken, but probably a very small piece missing.

Third Peræopods two inches and a half in length, the fifth joint decidedly longer than the fourth.

Fifth Peræopods just over an inch in length, the fifth joint cylindrical, packed with gland cells, the front margin denticulate and apically produced into a tooth or process, between which and the narrowed part of the joint where the finger hinges there is a concave palm; the much curved finger touches with its tip the middle of the palm. The two joints here described much resemble the corresponding joints

figured by Bovallius for his *Thaumatops lovéni*, but there the fifth joint is "twice longer than the carpus," while here it is not once and a half as long.

The small branchial vesicles of the second gnathopods and first peræopods are, I think, present in this specimen.

Uropods.—The outer branch is scarcely longer in either pair than the inner, and is not apically dilated.

Length.—Three inches.

Locality.—Station 214, February 10, 1875; off the Meangis Islands, north of Papua; lat. $4^{\circ} 33'$ N., long. $127^{\circ} 6'$ E.; depth, 500 fathoms; bottom, blue mud; bottom temperature, $41^{\circ} 8$; surface temperature, $80^{\circ} 5$. One specimen. Trawled.

Remarks.—Should it be thought necessary to make this a separate species, I would propose for it the name *Cystisoma fabricii*.

It is conceivable that by a diligent counting and comparing of the teeth on various parts of the animal of *Cystisoma spinosum*, and comparative measurements of the limbs, one might make a species of every specimen; on the other hand, among specimens from so many parts of the world some specific variation might be expected, difficult as it is to seize any characters which can be regarded as at once so salient and so constant as certainly to warrant the establishment of any fresh species.

The following table shows the distribution of the Challenger specimens:—

1. Station V, lat. $35^{\circ} 47'$ N., long. $8^{\circ} 23'$ W.; depth, 1090 fathoms.
2. Station 101, lat. $5^{\circ} 48'$ N., long. $14^{\circ} 20'$ W.; depth, 2500 fathoms (surface?).
3. Station 107, lat. $1^{\circ} 22'$ N., long. $26^{\circ} 36'$ W.; depth, 1500 fathoms.
4. Station 170A, lat. $29^{\circ} 45'$ S., long. $178^{\circ} 11'$ W.; depth, 630 fathoms.
5. Station 196, lat. $0^{\circ} 48' 30''$ S., long. $126^{\circ} 58' 30''$ E.; depth, 825 fathoms.
6. Station 214, lat. $4^{\circ} 33'$ N., long. $127^{\circ} 6'$ E.; depth, 500 fathoms.
7. Station 224, lat. $7^{\circ} 45'$ N., long. $144^{\circ} 20'$ E.; depth, 1850 fathoms.

Besides the specimen which Fabricius records from the Atlantic, and that which Guérin-Méneville records from the Indian Ocean, there is a specimen figured by Sir J. D. Hooker, as having been obtained on the Antarctic Expedition at " $33^{\circ} 23'$ S., $7^{\circ} 40'$ E." Bovallius records a specimen 105 mm. long, which he names "*Thaumatops Lovéni*," from the Indian Ocean, a specimen 57 mm. long, which he names "*Thaumatops longipes*," from "off the west coast of Australia," and a second specimen of "*Thaumatops longipes*," 50 to 60 mm. long, "taken just at the southern limit of the Arctic region at lat. $59^{\circ} 38'$ N., long. $5^{\circ} 24'$ W." The genus therefore appears to have a range north and south of more than ninety degrees, and round the world from east to west, as well as a capacity for sounding very considerable depths of the ocean.

Family PARAPHRONIMIDÆ, Bovallius, 1887.

This family is placed by Bovallius between the Cylopodidæ and Thaumatopsidæ [Cystisomidae]. He gives for it the following diagnosis:—

“Head very large, tumid. Eyes very large. First pair of antennæ fixed at the anterior side of the head, with the first joint of flagellum tumid, ovate, the rest of flagellum terminal, few-jointed. Second pair fixed at the inferior side of the head, angulated. Mandibles without palp. Seventh pair of pereiopoda [*Fifth Peræopods*] not transformed.”

To this may be added the special characteristic that the *Maxillipeds* end in a single broad plate, no doubt representing the usual pair of outer plates in coalescence with the inner plate or tongue.

Genus *Paraphronima*, Claus, 1878.

For the original definition of the genus, see Note on Claus, 1879 (p. 488). Claus while placing the genus among the Phronimidae suggests that, with reference to the tube-shaped liver appendages of the intestine, it might be correct to place it among the Hyperidæ. The following definition agrees nearly with that given by Claus.

Eyes.—Each with two closely approximate groups of ocelli, a large and a small.

Upper Antennæ attached at the front of the head, in both sexes having a short three-jointed peduncle and a flagellum with large apically pointed first joint.

Lower Antennæ attached just in front of the mouth organs, with four free joints in the male, the second and third short, these with the long terminal joint in the adult bent downwards; in the female with one conical or stiliform joint and a minute second joint at its apex.

Mandibles without palp in both sexes.

Maxillipeds ending in a single broad concave plate.

The *First Gnathopods* with third joint and wrist distally widened, so as to be in an imperfect fashion complexly subchelate; the *Second Gnathopods* with joints unexpanded, the hand produced distally into two little plates, one on either side the finger.

The *Peræopods* simple, the fifth the shortest, the first four pairs having branchial vesicles; in the female the first three pairs of pereopods and the second gnathopods having marsupial plates.

The three pairs of *Uropods* having the peduncles longer than the lanceolate rami; the outer branch shorter than the inner in the first and second pairs.

Telson very short.

Head large, tumid, squared in profile, deeper than the peræon, the mouth organs projecting backwards from the lower hinder corner; body dorsally compressed.

Peræon narrowing towards the seventh segment, sometimes becoming tumid at the third segment.

The eyes to some extent agree with those of *Phronima*, in that the grouping of the ocelli justifies the expression of divided-eye for each of the pair. In the upper division the ocelli are arranged almost in parallel rows, in the lower and smaller in a radiating manner; in both, as Claus observes, they stand wide apart.

Bovallius is inclined, though not without doubts, to unite the genus *Daira*, Milne-Edwards, 1830, with *Paraphronima*, Claus, while decidedly and with good reason separating both from *Dairinia* [*Dairilia*], Dana. In 1885, to explain his views on these points, he gave parallel descriptions of the three genera mentioned, but in the adaptation of them to a uniform terminology, some obscurity has arisen. The original definition of *Daira* has been already quoted in the Note on Milne-Edwards, 1830 (p. 143). In 1830 Milne-Edwards says that his *Daira gabertii* is probably not adult, that it has but one pair of antennæ, much like the lower antennæ in *Hyperia*, that the first segment of the peræon is extremely short (*étroit*¹) and almost entirely concealed under the second, that the second gnathopods end in a sort of didactyle hand, the movable finger of which extends a little beyond the immovable finger, and is apically armed by a crooked and movable nail, and that the first gnathopods, though similar to the second, have the immovable finger less developed. I cannot therefore see any probability that *Daira* is the same as *Paraphronima*, since in the latter there are two pairs of antennæ in both sexes, the first segment of the peræon is not at all concealed under the second, the second gnathopods are less stout than the first, while neither pair has any immovable finger at all, the second pair not even having any spines which might by chance be mistaken for one. Bovallius, it is true, among the characters in the definition of *Paraphronima*, Claus, gives the following:—"The last joints of the second pair [of gnathopods] forming a didactyle hand, the moveable finger consists only of the last joint, and is longer than the fixed one." Claus' own description, however, contains nothing of this sort, and the "fixed" finger probably refers to the

¹ That *étroit* refers to the measurement of the segment from front to back, not from side to side, seems clear from the description of the peræon, "le thorax point enflé au milieu comme dans l'Hypérie de Latreille, mais diminuant progressivement de volume d'avant en arrière."

little appendages at the apex of the hand which Claus figures. But that Milne-Edwards in describing *Daira* was not thinking of a didactyle hand like this very clearly appears from his remarks on *Themisto*, in which he says, "the second gnathopods are sometimes imperfectly prehensile, the antepenultimate joint being compressed and prolonged anteriorly so as to form a sort of hand and an immovable finger, on the upper edge of which impinges the movable claw, which is conical and formed of the last two joints, an arrangement exactly like that which we have just seen in the genus *Daira*."

Paraphronima cuvis, n. sp. (Pl. CLVII.).

The Head of about equal length and depth, much deeper than the peraeon, nearly equal in length to the first four of the peraeon-segments together; the seventh segment of the peraeon the longest, yet not so long as either of the first three segments of the pleon, which are also much deeper, with the postero-lateral angles rounded; back of the animal, except the head, obtusely ridged, peraeon scarcely, pleon rather more strongly.

The Eyes occupy most of the surface of the head, and may be regarded as two pairs very closely united, the larger pair occupying not only the summit but most part of the sides of the head; the much smaller second pair are near the lower margin, the little ocelli of this pair radiating from a point in advance of the mouth organs.

Upper Antennæ straight, projecting from the triangular groove in the front of the head; the peduncle short, the first joint considerably longer than the other two together, widening distally; the flagellum stout, lanceolate in outline, far longer than the peduncle, the two together as long as the head; the inside of the flagellum carrying a brush of broad filaments and fringed with short setules which project along the lower margin and at the apex; the second joint is minute.

Lower Antennæ inserted close to the mouth-organs, the first and second joints coalesced with the head, but with the opening of the gland-eone distinct; the third joint nearly as long as the head, slender, directed forwards, slightly curved so that the concave upper margin, which is closely fringed with setules, fits into the gently convex channelled lower margin of the head; the next joint is short, though longer than broad, with some setules on the upper margin; this joint bends downwards, the following, scarcely longer and similarly armed, is in line with it, and so is the long straight terminal joint, which perhaps alone represents the flagellum; this is more than half the length of the third (first free) joint, with convex lower or hinder margin, the front or upper pretty closely fringed with filaments, of which the truncate yet almost acute apex also carries a group. It is a question whether the long third joint represents the third, fourth, and fifth joints of the peduncle in coalescence, leaving the three remaining joints for the flagellum, or whether the two short joints are respectively the fourth and fifth of the peduncle.

*The Mouth-Organ*s are placed at the lower hinder corner of the head, projecting backwards below the peræon, and giving a very sinuous appearance to the hind margin of the head.

Epistome arched, broader than deep.

Upper Lip unsymmetrically bilobed by a small cleft of the distal margin, one side of the cleft being minutely furred.

Mandibles.—The cutting edge shows six or seven little teeth; the secondary plate on the left mandible is narrow at the neck, then widening, but not nearly as broad distally as the principal plate, the teeth eight or nine in number; on the right mandible there appears to be a secondary plate with the edge pectinate rather than denticulate; some small spines to the rear of the cutting plate run from the lower margin of the trunk along a small ridge of the inner surface; no molar tubercle or trace of palp could be discovered; the trunk of the mandible is comparatively large.

Lower Lip very small, so far as could be made out.

First Maxillæ.—Inner plate (if rightly observed) smooth-edged, oval; the outer plate appears to have seven or eight spines on the distal margin, the outermost the stoutest; there are also some cilia or setæ on the plate; the palp is broad for some distance from the base, and has three very small spine-teeth and a short slender spine on the somewhat oblique distal margin, and sometimes, if not always, a setule on the outer margin.

Second Maxillæ.—A single plate was doubtfully observed, with cilia on the rounded distal margin and on the inner margin.

Maxillipeds.—The first joint (or chin) short and narrow, the second joint also short, expanding distally, the third joint much wider than the second, transversely oval, like a rather deep dish, of which the width appears to be nearly twice the depth; the distal margin is sinuous, with a little central cleft, on either side of which the margin has three little setules at a distance from one another; there are also two small prominences, one on each side of the central cleft, probably representing the distal margin of the inner plate, which, as already suggested, would seem to be, not as usual distinct, but in coalescence with the two outer plates.

First Gnathopods.—The side-plates are not marked off from the segment, except in so far as there is a narrow projection to which the limb is attached. In this respect all the limbs of the peræon are alike, as also in the possession of gland-cells, to leave room for which the muscles of the first joint are in no case extensive. The first joint wider than any of the other joints and considerably longer than them all together, the margins smooth; the second joint not longer than broad; the third a little longer than the second; with scarcely any free front margin, the hind margin smooth, the truncate distal margin projecting behind the wrist, set round with six strong spines; the wrist as long as the hand and finger together, and more than twice the breadth of the hand, widening a little distally, the convex front longer than the nearly straight hind margin, the hind

margin microscopically pectinate, having a spine at the apex, the distal margin finely pectinate, projecting behind the hand; the hand narrow, finger-like, a little curved and tapering, the distal end rounded, but with a little setule-carrying indent, microscopically pectinate, produced over the base of the small finger in the same way that the trunk of the finger is produced over the base of its own acute nail; the nail is nearly as long as the trunk of the finger.

Second Gnathopods a little longer, but narrower than the first. The first joint narrower, not much longer, than in the preceding pair, as long as the four following joints together; the second joint a little longer than broad; the third a little longer than the second, with parallel margins, unarmed; the wrist not half the length, about half the breadth of the first joint, longer and broader than the hand, nearly straight and smooth; the hand narrow, tapering, longer than the hand of the first gnathopods, produced in two delicate transparent plates beyond the base of the finger's nail, the plates finely serrate on the inner edge, but the serration is not easy to observe; the finger small and slender, the extremely acute nail shorter than the trunk of the finger, with a minute setule at the base on the inner margin. The fingers of the second gnathopods face the mouth-organs, while those of the first have the ordinary position.

First Peræopods.—Branchial vesicles small, oval, not half the length of the first joint. The limb much longer and broader than the second gnathopods, the first joint about as long as the third and fourth together, smooth-edged, the second rather longer than broad, the third about once and a half as long as the second, the fourth nearly three times as long as the third, having some setules along the almost straight hind margin; the fifth joint more slender, slightly curved and tapering, together with the finger equal in length to the fourth joint; the finger small, acute, a little curved.

Second Peræopods.—Branchial vesicles larger than in the preceding pair, the limbs similar.

Third Peræopods.—Branchial vesicles larger than in the preceding pair. The joints of the limb, with the exception of the finger, rather stouter and a little longer than in the second peræopods.

Fourth Peræopods.—Branchial vesicles subequal to the preceding pair, the limb a very little shorter.

Fifth Peræopods.—The limb considerably shorter than the preceding pairs, the difference affecting all the joints except the first, but especially the fourth and fifth, which together are not equal in length to the first, instead of being, as in all the other peræopods, much longer than it; the fifth joint shorter and much narrower than the fourth, curved, tapering; the finger small, nearly straight, acute.

Pleopods.—The peduncles massive, in the first two pairs longer than the rami; the two coupling spines have the base bulbous, the shaft feathered with from three to five retroverted teeth on each margin, and the apex crescent-shaped; in the cleft spine of the

inner ramus it is the shorter arm that is shaped like the hand of a cloek; the joints of the rami vary from five on the inner to seven on the outer ramus; the pair of feathered setæ on each joint are stout.

Uropods.—Peduncles of the first pair scarcely as long as those of the second and much narrower, longer than the rami; the outer ramus much shorter and narrower than the inner, almost completely smooth-edged, acute like the rest of the rami; inner ramus nearly smooth on the inner margin, the outer margin pectinate with thirty or forty very long slender spine-like teeth, and near the apex cut into some strong downward pointing teeth; peduncles of the second pair longer than the rami; the outer ramus shorter than the inner, longer than the outer of the first pair, its outer margin nearly smooth, its inner serrate, less and less closely as it approaches the apex; the inner ramus broadly lanceolate, with both margins denticleate, the outer more closely than the inner; the peduncles of the third pair as long and broad as those of the second, the rami equal in length, not as in the other pairs more, but less, than half the length of the peduncles; the outer ramus with the outer margin almost smooth, the inner denticleate; the inner ramus having eight teeth or serratures on its nearly straight inner margin, and nine or ten stronger teeth on the outer, the proximal part of which is straight and smooth; the peduncles of the second and third pairs have the under surfacee grooved for a short distance from the base backwards.

Telson very small, distally rounded, apparently rather tumid and very thin-walled.

Female.

Upper Antennæ.—First joint cylindrieal, rather longer than broad, second about a fourth the length of the first, narrowing towards the still shorter third joint; the flagellum not quite so broad as the peduncle, but twice as long, with convex margins tapering to an outdrawn point, the inner margin fringed with groups of filaments.

Lower Antennæ shorter than the terminal joint of the upper; the gland-eone is observable on the inner side of the antennæ, but coaleseed with the wall of the head; the third (first free) joint is tapering, followed by a minute terminal joint.

Marsupial Plates much larger than the branchial vesicles, without setæ; a large pair attached to each of the first three pairs of peræopods and a small pair to the second gnathopods.

Pleopods.—The peduncles rather more slender than in the male.

Length of the male specimen, in the position figured, from the front of the head to the extremity of the uropods, three-tenths of an inch; fully extended, the length would be about four-tenths.

Locality.—July 1875; between Japan and Honolulu, lat. 35° N.; surfacee. Seven specimens, male and female.

To this species also belong specimens from the following localities:—

"Phronimid, N. W. Pacific, ♂, ♀." Two specimens mounted in Canada balsam during the voyage.

"Phronimid, ♂, N. W. Pacific;" a specimen in Canada balsam.

"Api to Cape York;" a specimen in Canada balsam.

Station 181, August 25, 1874; Api to Cape York; lat. $13^{\circ} 50'$ S., long. $151^{\circ} 49'$ E.; surface; surface temperature, 80° . This specimen is a young male, with the lower antennæ four-jointed, not so long as the head, the terminal joint the longest, but this and the two preceding short joints still in line with the first joint; the large terminal joint of the upper antennæ has filamentary cylinders only along the distal half.

Station 241, June 23, 1875; east of Japan; lat. $35^{\circ} 41'$ N., long. $157^{\circ} 42'$ E.; surface; surface temperature, $69^{\circ} 2$. Two specimens, female. The four pairs of marsupial plates are partially developed in the larger of these two specimens. It may be noticed that most of the specimens, whether mounted in Canada balsam or preserved in spirit, are yellow, but these two were lighter than the rest.

Station 243, June 26, 1875; North Pacific, east of Japan; lat. $35^{\circ} 24'$ N., long. $166^{\circ} 35'$ E.; surface; surface temperature, 71° . One specimen.

Station 245, June 30, 1875; between Japan and Honolulu; lat. $36^{\circ} 23'$ N., long. $174^{\circ} 31'$ E.; surface temperature, 69° . One specimen, male, with the head much deeper than the peræon, the fourth pair of branchial vesicles unequally developed, the vesicle on one side normal, that on the other very much smaller.

July 4, 1875; North Pacific, between Japan and Honolulu; lat. $36^{\circ} 42'$ N., long. $179^{\circ} 50'$ W.; surface, night; surface temperature, $71^{\circ} 5$. Three specimens. One of the specimens is an adult male; another a young male, as may be judged by the lower antennæ, which are straight, the terminal joint reaching a little beyond the head, a little shorter than the first free joint, which is very slightly curved; the third is probably a young female.

September 1, 1875; North Tropical Pacific; lat. $7^{\circ} 17'$ N., long. $147^{\circ} 20'$ W.; surface temperature, $81^{\circ} 7$. One specimen, male.

Station 352, April 13, 1876; Atlantic, off the west coast of Africa; lat. $10^{\circ} 55'$ N., long. $17^{\circ} 46'$ W.; surface; surface temperature, $77^{\circ} 7$. One specimen, male. This Atlantic specimen shows only the most trifling differences from the Pacific specimens. In the first gnathopods the wrist is a little less broad and has two spines instead of one at the outer apex; in the second gnathopods the wing-like plates, *dactyloptera* of Spencer Bate, at the apex of the hand have the margin more conspicuously pectinate; the inner ramus of the first uropods has its inner margin more decidedly serrate near the apex.

May 7, 1876; Atlantic, south-west of the Azores; lat. $34^{\circ} 22'$ N., long. $34^{\circ} 23'$ W.; surface; surface temperature, $67^{\circ} 8$. One specimen, male, mounted in Canada balsam

during the voyage. This specimen was taken towards the close of the voyage, and appears to agree closely with that last mentioned.

Remarks.—The specific name—meaning *whose you please*—refers to the difficulty of deciding whether the various specimens belong to a distinct species or to one of the five or six specific names with which Claus and Bovallius have endowed the genus *Paraphronima*. None of the species bearing those names have been at all fully described, and there seems some probability that a single name may suffice for them all.

Family PHRONIMIDÆ, Dana, 1852.

For Dana's account of the family, see Notes on Dana, 1852 (pp. 259, 261). For the definition by Claus, see Note on Claus, 1879 (p. 487). Bovallius in 1887 gives the following diagnosis:—

“Head large, tumid, more or less conical, much deeper than the body. Eyes large, occupying parts of the sides and the top of the head. First pair of antennæ fixed at the anterior side of the head; with a multiarticulate flagellum (in the male); second pair fixed at the anterior side of the head, multiarticulate (in the male) or rudimentary (in the female). Mandibles without palp. Seventh pair of pereiopoda not transformed [*Fifth Peraopods normal*]. Peduncles normal.”

From this family Bovallius excludes the Phrosininae and also two of the genera of Claus' Phroniminæ, namely *Paraphronima* and *Phronimopsis*. He adds a new genus, *Dairella*. In the expression “peduncles normal” there is evidently some omission or other error of the press. If, as is probable, the expression intended was—*uropods* normal—the liability of the second pair to become rudimentary should not be left unnoticed.

Genus *Dairella*, Bovallius, 1887.

1887. *Dairella*, Bovallius, Systematical List of Amph. Hyper., Bihang. till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 24.

For the definition of this genus, together with that of the subfamily Dairellinæ, in which Bovallius places it, see Note on that author, 1887 (p. 589). It will be remembered that the expression—“first and second pairs of pereiopoda simple”—refers to the first and second pairs of gnathopods, and that the expression—“all the pereiopoda are simple walking legs”—includes the two pairs of gnathopods, as well as the five pairs of peræopods. That the differences between this branch of the Phronimidae and the family Paraphronimidae are not at the first glance very striking may be inferred from the circumstance that *Dairella californica* was originally named *Paraphronima californica*, before it was made the type of the new genus, but, besides the distinct character of the antennæ, to

which attention is drawn in the diagnoses of the two families, there are also some notable differences in the mouth-organs. The generic character—"peduncles of uropoda very broad"—requires some modification, since the peduncles of the second pair are described as narrow in *Dairella californica*, Bovallius, and are narrow also in the species now to be described.

Dairella bovallii, n. sp. (Pl. CLVIII.).

Head wider than deep, deeper than long, not so long as the coalesced first and second segments, together with the third segment of the peraeon; each of the first three segments of the pleon longer than any of those of the peraeon, and having the postero-lateral angles rounded; the dorsal line of the specimen a little corrugated.

Eyes occupying almost the whole surface of the head as seen from above or in profile; of the four groups of ocelli the lower pair are as large as the upper, which they almost join at the sides of the head; only the lower groups fold round to the front of the head, where they are separated by a wide space.

Upper Antennæ standing wide apart on the upper part of the front of the head. In the male, peduncle short, tumid, the first joint not longer than broad, the two following very short, much broader than long; the first joint of the flagellum broad, narrowing a little apically, much longer than the peduncle, the tumid breast covered with a large brush of elongate filaments; the remainder of the flagellum comparatively narrow, with small and slender filaments at intervals; the second joint little longer than broad, the third twice as long as the second, the fourth as long as the second and third together, but thinner, the fifth a little shorter than the fourth; the remainder broken. In the female these antennæ are slender, the first joint of the peduncle little dilated, the flagellum consisting of a single long joint, slightly curved, of almost uniform breadth, except at the apex which is not very acute.

Lower Antennæ attached much below the upper; the coalesced first and second joints short, broader than long, the third joint smaller than these, the fourth smaller than the third, the fifth longer than the preceding two together and forming an angle with them, wider distally than at the base; the first joint of the flagellum longer and abruptly much narrower than the last of the peduncle, narrowing from the base to the middle, again a little widened at the apex. Remainder of these antennæ missing. In the female the rudiments of these antennæ, if present, were not observed.

Upper Lip unsymmetrically bilobed by a narrow cleft in the distal margin, one lobe being a little less deep than the other.

Mandibles.—Cutting plate small, triangular, with straight, finely denticulate edge; there appears to be a similar secondary plate on the left mandible, but it was not clearly made out; the molar tubercle with broad multidenticulate crown, as usual straight-edged

in profile, the prominent teeth in this view twelve in number, pretty widely spaced ; the surface of the mandible for some distance behind the tubercle seaborous with minute teeth or prickles. There is no trace of a palp.

First Maxillæ.—The pair appear to be connected by a thin membrane ; no inner plate was perceived ; the outer plate distally cut into three very sharp teeth ; the inner margin of the palp straight, serrate, carrying at its apex a small sharp spine-tooth, the outer margin convex, smooth, the distal convex, with slight outward directed serrature ; both plate and palp being so bent that the distal margins of one maxilla may antagonize with those of the other.

Second Maxillæ.—These are obscure, probably small and unarmed.

Maxillipeds.—The base is formed by an oblong plate having a flat distal margin with its corners rounded and a small spinule projecting near each of them ; a little above the middle of this, and not nearly reaching its distal margin, is placed a small triangular inner plate with rounded apex, and above this are placed the two outer plates, which are smooth-edged, apically narrowed, the outer margin convex, the inner carrying three minute spinules. All these organs are small, thin in texture, and transparent.

The heart has very thin and delicate walls, apparently with three pairs of venous ostia ; it reaches just into the sixth or penultimate segment of the pereon.

First Gnathopods.—Side-plates of this and the following segments shallow, but definitely marked, not overlapping ; the coalesced first and second segments having separate side-plates for each segment. The first joint in this and the six following pairs of limbs attached at the lower extremity of the side-plate, longer than the three following joints together, and like them apically encircled with one or two rows of minute denticles, the lateral margins smooth ; the second joint not longer than broad ; the third a little longer than the second, not *under-riding* the fourth ;¹ the fourth joint elongate, a little curved, more than half as long as the first, the hinder margin as in the preceding joint a little furred, the fifth joint more than half the length of the fourth, much narrower, a little curved ; the distal part (as is the case with this joint in the other limbs) speckled as if with scale-markings ; the finger exceedingly small, acute. This and the six succeeding pairs of legs are all arranged on the same plan, and all for the reception of gland-cells, in particular the muscles of the long first and fourth joints being relegated to a mere corner of the distal end, leaving so large a space vacant as to give a rather peculiar appearance to these transparent limbs.

Second Gnathopods.—Similar to the first but longer. Branchial vesicles quite smooth, oval, a little wider than the first joint and about two-thirds as long. The first three joints of the limb rather stouter and slightly longer than in the first pair ; the fourth joint as

¹ The rule laid down by Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 89, footnote, that "the meros *always* overrides the carpos in the pereiopoda and underrides it in the gnathopoda," is of very limited application to the gnathopods of the Hyperina, although so constant in the Gammarina.

long as the third and fourth together of the first pair; the fifth joint also considerably longer than the fifth in that pair.

First Peræopods like the preceding gnathopods except in size and in having the extremities of the first four joints unarmed or almost so. The branchial vesicles larger than the preceding pair in proportion to the greater size of the limb. The first joint wider than in the preceding pair, especially at the distal end; the fourth joint longer than the third and fourth together of the preceding pair, and much wider, its front margin convex, the hinder nearly straight, the distal minutely pectinate; the fifth joint as long as the fourth joint of the first gnathopods, having, as in the gnathopods, some small setules about the apex; the finger very small.

Second Peræopods similar to the first, but a little longer. In the female specimen, the second peræopods have the first joint longer, but the fourth and fifth joints shorter, than the corresponding joints of the first pair.

Third Peræopods.—Side-plates rather broader and branchial vesicles larger than in the preceding pairs, the limbs similar to the preceding pairs but both longer and broader. The first, fourth, and fifth joints are very considerably longer than the corresponding joints in the second peræopods; the fourth joint is but little shorter than the first; the fifth is much narrower than the fourth, and a little over half its length; the finger minute and slender, very little curved, the basal part squared.

Fourth Peræopods.—Side-plates and branchial vesicles similar to the preceding pairs, the limbs shorter. The first joint is a little shorter and above slightly broader than in the third peræopods, the second and third joints similar, the fourth much shorter, not narrower; the fifth shorter and rather broader, the finger similar.

Fifth Peræopods similar to the fourth but shorter, the side-plates not so broad. The first joint not shorter than in the preceding pair, and decidedly wider just below the neck; second and third joints similar, fourth and fifth each much shorter but not narrower; finger similar.

Pleopods.—Peduncles strong, in the first and second pairs longer than the rami, in the third pair about equal to the rami; the coupling spines form a series of from eight to twelve on each pleopod, each spine having only the apical pair of retroverted hooks; there is no cleft spine, this being probably not needed when the coupling spines are so numerous; the first joint of the inner ramus is fringed with the ordinary plumose setæ; the joints of each ramus are eleven or twelve in number, the terminal joints not lengthened. In the female specimen the coupling spines did not exceed five on any pleopod, and the joints of the rami were only six or seven in number.

Uropods.—The peduncles of the first pair are a little longer than those of the third, but not quite so broad; they widen gradually to the distal end; the lanceolate equal rami are about half the length of the peduncle, and where widest about half its greatest breadth; the peduncles of the second pair are shorter than those of the third

and not half as broad; the rami are narrowly lanceolate; the inner about half the length of the peduncle, the outer rather longer; the broad peduncles of the third pair are of almost uniform breadth except near the base; the inner ramus is a third of the length of the peduncle, not twice as long as broad, the outer is rather longer and narrower. All the rami are finely, but more or less irregularly, pectinate on both margins; this is also the case with the inner and distal margins of the peduncles.

Telson small and smooth-edged, broader than long, the sides a little concave, the distal margin rounded, broad, though narrower than the base.

Length, three-tenths of an inch, allowing four-thirtieths of an inch for the measurement from the front of the head to the end of the pereon, and five-thirtieths from the base of the pleon to the extremity of the uropods.

Locality.—April 26, 1876; off St. Vincent, Cape Verde Islands; lat. $16^{\circ} 49'$ N.; long. $25^{\circ} 14'$ W.; surface temperature, $73^{\circ} 2$. Two specimens, male and female.

Remarks.—The specific name is given in compliment to Professor Bovallius, who instituted the genus *Dairella*. From his species *Dairella latissima* of the South Atlantie, the present species is distinguished by the wrist of the first gnathopods not being twice as long as the hand, and by having the peduncles of the first pair of uropods much longer, instead of shorter, than those of the second pair.

In the young ones taken from the mother's pouch, the seven pairs of limbs resemble one another even more closely than in the adult; only the first joint is elongate; in the last three pairs the base of the finger is squared, and the remaining part more slenderly withdrawn than in the preceding pairs; the pleon is strongly flexed against the ventral surface, and several or all of its segments are coalesced, narrowing very gradually to the apex, which is broadly rounded; in this stage no pleopods, uropods, or distinct telson, seem to be developed; no trace of antennæ could be perceived; the mouth-organs occupy nearly the whole breadth of the head, instead of a very small portion of that breadth as in the adult, the outer plate of the first maxillæ shows only a single spine-tooth, and the palp resembles a rounded tubercle.

For the original definition of the genus, see Note on Latreille, 1802 (p. 72), but this definition is less to the purpose than the original description of the type-species, *Cancer sedentarius*, for which see Note on Forskål, 1775 (p. 38). Forskål speaks of ten feet on each side, explaining that of these twenty feet seven pairs belonged to the thorax. Latreille, thinking apparently only of thoracic feet, changed twenty into ten, and the fifth pair of feet into the third, ignoring the two pairs of gnathopods. What Latreille intended by the "salient setaceous palps" is not quite clear. The mandibles in this genus are without palps in both sexes; the lower antennæ are multiarticulate only in the male. For the definition of the genus by Claus, see Note on Claus, 1879 (p. 487).

Claus, in his Text-Book of Zoology, translation by Sedgwick, 1884, says (p. 455) that the female of *Phronima* "lives with its offspring in *Pyrosoma* and *Diphyidae*, Mediterranean." This may throw some light on the mysterious genus *Diphyicola*, Costa, 1862.

 1882. ,, Streets, Proc. U.S. Nat. Mus., vol. v. p. 6, pl. i. figs. 3, 3a.

Postero-lateral angles of the first three pleon-segments scarcely produced or acute, the third segment not so deep as the second.

The *Eyes*, *Antennæ*, and *Mouth-Organ*s agree very nearly with the corresponding parts as figured and described by Claus for *Phronima sedentaria* (Forskål), the differences being of a minute character and in some instances possibly depending only on the particular view obtained of the organs; for example, in our specimen no marginal teeth could be perceived on the finely furred edges of the outer plates of the *Maxillipeds*, but these plates had two little setules at the apex, and two on the outer and one on the inner margin.

First Gnathopods.—First joint nearly as long as the following four, second longer than broad, third scarcely longer than the second, the projecting distal margin straight,

pectinate, with rounded hinder angle; the wrist not longer than the hand, the inner or front margin of the produced hinder apex pectinate; the serrate distal appendages of the hand (*dactyloptera*) nearly reaching to the narrow bent nail of the finger.

Second Gnathopods very similar to the first but longer, the produced apex of the wrist decidedly less than half the length of the hand.

First Peræopods.—First joint armed with two or three setules, one of which is on the minute subapical tooth of the hind margin; the third joint is more than half the length of the fourth, and the fourth is two-thirds the length of the somewhat curved fifth; all these, and the second to some extent also, have the hind margin fringed with hairs; apically the fifth joint is produced into an almost straight pointed process on one side of the minute bent finger.

Second Peræopods.—The branchial vesicles slender, much shorter than the first joint. The marsupial plates much larger than the branchial vesicles. The limb similar to that of the preceding pair, but with all the joints longer and stouter, the first joint having a little projection of the hind margin closer to the actual apex and not produced into a tooth.

Third Peræopods.—Branchial vesicles longer than the preceding pair. The limb shorter than in the preceding pair. The first joint as long as in the second peræopods and a little stouter, distally channelled behind, the hind margin on the outer surface produced into a rather long tooth, which, however, scarcely descends below the front part of the distal margin; the rather broad second joint, which is channelled behind, has the front margin produced into a small apical tooth; the broader and longer third joint has two setules on the very convex hind margin and two on the rather shorter nearly straight front; the massive fourth joint, widening at once from the point of attachment, has a distal breadth more than three-quarters of the length, the hind margin at first very convex, then nearly straight, the front margin slightly sinuous, produced apically into a short curved tooth; between this latter and a second smaller tooth of the distal margin there is a cavity occupying more than a third of that margin, and armed with one setule; a much smaller cavity follows the second tooth, and this is succeeded by a triangular setuliferous margin leading to the hinge of the finger; over this distal border and projecting considerably beyond it closes the finger-like fifth joint, equalling the fourth in length, with convex outer margin and sinuous setuliferous inner or front margin, the convex portion of which partially occupies the larger cavity of the preceding joint; the finger is minute, affixed at the narrow apex of the fifth joint. The form of the fourth joint agrees very nearly with that which Claus figures for the male of *Phronima sedentaria*, except that there the triangular piece of the distal margin near the hinge is subdivided into five little teeth.

Fourth Peræopods.—Branchial vesicles longer than the preceding pair, about as long as the first joint but not nearly so broad. The first joint oval, with the gland-cells

broad, the length of the joint rather less than that of the three following joints together, the little rounded apex of the front margin carrying a setule; the second joint longer than broad, with the distal part of the front margin slightly excavate, having a setule but no tooth at the top of the excavation; the third joint not half the length of the fourth, with an upward directed point at the top of the front margin; the fifth joint longer than the third, shorter than the fourth, straight, slightly tapering, with setules about the apex, which is produced to a point on one side of the finger; the finger minute, with broad base and narrow strongly bent tip.

Fifth Peraopods agreeing with the fourth in the shape of the joints, but differing in their relative proportions; the first joint considerably longer than in the preceding pair, longer than all the other joints together of its own limb, but not so long as the corresponding joints of the fourth peraeopods; the third joint more than half the length of the fourth; the fourth not much longer than the fifth.

Pleopods.—Coupling spines small, with an apieal pair of retroverted teeth, and a pair below the apex; the eleft spine with very slender arms, the serrate one the longer, the other with a very slight subapieal dilatation; the inner ramus with seven joints, of which the first is not very elongate, much excavate at the base on the outer side; the outer ramus with eight or nine joints, the first having a proeess of the peduncle attached to its surface.

Uropods.—Peduneles of the first pair rather longer and narrower than those of the third, twiee as long as the outer ramus, which is a little shorter than the inner; the outer ramus has its inner edge, the inner its outer, finely peetinate; the peduncles of the seeond pair narrow, about once and a half as long as the outer raimus, whieh is shorter than that of the preceding pair, the inner margin finely peetinate; the inner ramus almost smooth, or with the peetination of the inner margin seareely perceptible, narrower than the outer and about half its length; the peduncles of the third pair about twice as long as the outer ramus; the rami as in the first pair, but rather shorter.

The Telson an extremely thin lamina, forming about three-quarters of a eirele, affixed to the preeeding segment in such a position that its apex only just projects beyond the ventral opening of the segment between the bases of the third uropods.

Length.—Three-tenths of an inch.

Locality.—Station 103, August 22, 1873; off Sierra Leone; lat. $2^{\circ} 52'$ N., long. $17^{\circ} 0'$ W.; surface-net, 100 fathoms; surface temperature, 77° . One specimen, female.

Remarks.—It is perhaps a rather signifeant circumstance that the speeimen of *Phronima pacifica* should come from the Atlantie, while the specimens which I have been led to assign to *Phronima atlantica* come from the Pacific.

Phronima atlantica, Guérin (Pl. CLX.).

1836. *Phronima atlantica*, Guérin, Mag. Zool., vi. Cl. vii. p. 7, pl. xviii. fig. 1.
 1836. " " Guérin-Méneville, Icon. du règne anim., Crust., pl. xxv. fig. 4.
 1840. " " Milne-Edwards, Hist. Nat. des Crust., t. iii. p. 93.
 1852. " " Dana, U.S. Explor. Exped., vol. xiii. pt. ii. p. 1001.
 1862. " " Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 318, pl. li. fig. 4.
 1882. " " Streets, Proc. U.S. Nat. Mus., p. 5, pl. i. figs. 1, 1a, 2.

Last segment of the peraeon elongate, a little longer than the first of the pleon, which is much longer than either of the two following; the first three segments of the pleon with the postero-lateral angles produced in the female, the tooth being longer in the second than in the first, and in the third than in the second segment; in the male specimen only the third segment had a tooth and that a small one.

First and Second Peræopods with the hind margin of the first and second joints apically produced to form an acute slender tooth. In the male this tooth seems to be unimportant in size.

Third Peræopods.—First joint very little expanded below, each margin having a pointed apex; the second joint having the front margin produced into a pointed apex, this joint being as long as the third in the male specimen, but much shorter in the female; the third joint little dilated; the fourth considerably longer in the female than the distal breadth, the front margin forming only a small apical tooth, separated by an almost semicircular cavity from a much smaller tooth which projects from the palmar margin almost as far as the front tooth; a second much smaller cavity reaches the centre of the palm, the margin of which beyond this cavity is at first either crenate or cut into two or three little teeth; in the male this joint differs only in being a little broader near the base and shorter in proportion to the breadth; the fifth joint is much bent, almost as long as the fourth, with a slight bulge near the centre of the inner or front margin, the bulge being nearer the apex in the male than it is in the female; the finger as usual minute.

Fourth Peræopods.—Branchial vesicles not quite so long as the first joint. The first joint with the two lines of gland-cells very distinct, each line divided into four elongate packets; the front margin of the joint apically produced into a narrow acute tooth, less developed in the male than in the female; front margin of the second joint produced into a projecting tooth.

Fifth Peræopods similar to the fourth, with the usual differences in the proportions.

Pleopods.—Peduncles elongate, the inner ramus with seven, the outer with eight joints; the first joint in each ramus nearly as long as the rest together.

Uropods in agreement with those of *Phronima pacifica*, Streets, except that in the female the inner ramus of the second pair is much more than half the length of the outer,

with a very fine but obvious pectination; in the male specimen this ramus was smaller, and on one side of the animal little more than a tubercle, though on the other side it was more than half the length of the outer ramus and apically acute.

Telson wider than deep, the curved distal margin scarcely projecting between the bases of the third uropods, the texture so thin as to make its outline difficult to observe. Guérin says that the telson is triangular, but this may refer to the profile view, as in the dorsal view he makes it curved; in both views he draws the fifth and sixth segments of the pleon as separate, and he treats them as distinct in the description; there can be little doubt that this is an error of observation.

Length of the female specimen half an inch, of the male seven-twentieths of an inch.

Locality.—Station 245; June 30, 1876; between Japan and Honolulu; lat. $36^{\circ} 23'$ N., long. $174^{\circ} 31'$ E.; surface temperature, 69° . Two specimens, female and young male.

Remarks.—From the same locality there are two other specimens of *Phronima*, very small, one, by more swollen upper and the budding lower antennæ, shown to be a young male, this scarcely a quarter of an inch long, and the other about one-fifth; in each, the fourth joint of the third peræopods is distally wide, with a narrowly produced incurved apex to the front margin, and two little subequal teeth on the distal margin; the fifth joint bulges a good deal where its inner or front margin meets the cavity of the fourth joint's distal margin.

In Guérin's figure of this species the gnathopods are represented as linear, without any prolongation of the wrist. Milne-Edwards, probably judging only by the figure, says, "pates des deux premières paires grêles et sans élargissement vers le bout." There can be little doubt, however, that Guérin represents them as seen edgewise, and that he left them undescribed because he had not made out the details. In the Brit. Mus. Catal. Amph. Crust., pl. 51, Guérin's figure is reproduced, and close to it is placed a figure marked *4i*, as if to represent the second gnathopods; but this figure has not really anything to do with *Phronima atlantica*, having been accidentally transferred from Guérin's *Oxycephalus oceanicus*. In regard to specimens from the "Atlantic, latitude 7° or 8° north, and longitude about 24° west," Dana only says, "the figure of Guérin represents our specimens correctly in most respects. The moveable finger of the large hand has a low tooth on its inner side, one-third of the distance from its base to its apex; and the immovable finger is longer, with a prominent angle near the articulation with the moveable finger." A species named *Phronima spinosa* by Bovallius in 1887, found in "tropical parts of the Atlantic," does not seem to differ much from Guérin's except that it is said to have the first joint of the fifth peræopods nearly twice as long as that of the fourth pair.

Phronima megalodous, n. sp. (Pl. CLXII., A.).

Seventh segment of the peræon longer than the first of the pleon; postero-lateral angles of the first three segments of the pleon acute. Branchial vesicles respectively longer and broader than the first joints of the limbs.

First Gnathopods.—The produced wrist longer than the hand, its distal margin very sinuous, the produced hinder apex not half the length of the hand, its convex inner or front margin very regularly pectinate; the hand very searous.

The First and Second Peraopods with hind margin in the first and second joints only slightly prominent just above the apex, not at all produced or acute.

Third Peræopods.—As usual the first and second joints are thickened and more or less channelled behind and sharp-edged in front, while in the third joint and in the fourth at its upper part the hinder margin is sharp, the front of these joints being broad. The first joint is large, widening considerably as it approaches the distal end, where the hind margin of the outer surface forms an angle but is not produced into a tooth; the front margin of the second joint forms a tolerably acute apical tooth; the third joint is rather longer than the second, with a narrow neck, below which the hind margin is very convex, the front straight with rounded apex; the fourth joint is as long as the first, twice as long as its greatest breadth, the neck narrow, the front margin sinuous, distally forming a considerable tooth which may be reckoned as about a fourth of the total length of the joint; a deep cavity separates this tooth from one not much smaller occupying the centre of the palm, its front edge smooth, its longer hinder margin being distally divided into five little teeth or eruncate compartments; beyond this the palm has a rather irregular course, but without teeth, on either side of the base of the following joint; the finger-like fifth joint is curved, not so long as the fourth joint, but when closed upon it projecting much beyond the front tooth of that joint, having its front or inner margin a little bulging and erenate for a short space where it begins to emerge beyond the tooth; the finger is as usual minute and strongly bent. On the inner surface of the fourth joint between the bases of the two teeth there is a little rounded process carrying a setule.

Fourth Peræopods.—The first joint considerably shorter than in the preceding pair, as long as the three following joints together, with a minutely produced apex of the front margin; second joint of the front margin strongly bent, and excavate below the quasi-apical angle; the third joint longer but much narrower than the second, the upturned angle at the top of the front margin not strongly produced, the distal margin as usual oblique; the fourth joint considerably more than twice as long as the third, and nearly twice as long as the fifth.

Fifth Peræopods similar to the fourth, but with the first joint much longer, the others shorter, especially the third and fourth; the fourth joint nearly twice as long as the third, and considerably longer than the fifth.

Length, four-fifths of an inch.

Locality.—April 26, 1876; off St. Vineent, Cape Verde Islands; lat. $16^{\circ} 49' N.$, long. $25^{\circ} 14' W.$; surface, night; surfæe temperature, $73^{\circ} \cdot 2$. One speeimen, female.

Remarks.—The speeifie name is derived from the Greek word *μεγαλόδονς*, meaning with a large tooth, and refers to the unusually large tooth on the eentre of the palm in the third peræopods.

Akin to the present species, and perhaps identieal with it, are two speeimens labelled “Pacific, Api to Cape York, surface.”

In the female speeimen the marsupial plates are only slightly developed, and as compared with the Atlantie speeimen just deseribed, the fourth joint in the third peræopods is more elongate, the front tooth much larger than that at the centre of the palm, the fifth joint more stumpy, very much shorter than the fourth. The length more than half an inch.

The male specimen accompanying this female is only a quarter of an ineh long, and far less than a quarter of the bulk of the female, so that it might have been regarded as a young one, but on examination the antennæ proved to be those of an adult, the upper with a long thiek first joint to the flagellum, having a large bush of filaments, and the following joints slender, the lower with numerous filiform joints; in this specimen the fourth joint of the third peræopods is distally as broad as its length, the front apical tooth not very long, the palmar margin having no very deep cavity and at about the centre two separate nearly equal teeth, not very large, inelined towards the hinge of the following joint; the fifth joint has a very slight bulge of its inner margin between the two teeth just mentioned, and with the finger only just reachees the tip of the front tooth of the fourth joint.

A specimen, female, from Station 227, March 27, 1875; between Papua and Japan; lat. $17^{\circ} 29' N.$, long. $141^{\circ} 21' E.$; surfæe temperature, $79^{\circ} \cdot 2$, appears also to belong to this form or speeies.

In the Brit. Mus. Catal. Amph. Crust., pl. 51, fig. 2, a form is represented which shows much resemblance to the present species, and which is there named *Phronima custos*, Risso, although, as Mr. Spenee Bate had not seen the typeal speeimens of that species, he gives the name with some reserve. His figure does not in fact agree with Risso's, which is here copied in the Note on Risso, 1816 (p. 97), and which is also eopied in Desmarest's Consid. gén. sur la elasse des Crust., pl. 45, fig. 1, in Lueas' Hist. Nat. des Crust., pl. 18, fig. 6, and in White's Popular Hist. of Brit. Crust., pl. xi. fig. 4, but by all these authors named *Phronima sedentaria*, without reference to Risso.

Phronima tenella, n. sp. (Pl. CLXI., A.).

Last segment of the peræon not very elongate, longer than the first of the pleon; postero-lateral angles of the first three segments of the pleon seareely produced, those of the third segment forming an aeute point.

Upper Antennæ.—The peduncle short, the first joint not longer than broad, but longer than the two following together; the first joint of the flagellum very elongate, the brush composed of more than forty rows of filaments, the apex of the joint produced to a point which almost reaches the apex of the third joint; the second joint not half the breadth of the first, not longer than broad, carrying three groups of filaments; the third joint narrower, also carrying filaments; the fourth, fifth, and sixth joints successively narrower and longer; the two terminal joints also narrow, neither of them longer than the sixth.

Lower Antennæ.—Although the upper pair are so powerfully developed, the lower, as far as can be seen in the mounted specimen, consist each of a single narrow joint.

The Gnathopods are nearly of the usual character, the wrist not longer than the hand, with the produced portion very short.

The First and Second Peraopods have the hind margin of the first and second joints produced apically into a narrow acute tooth.

Third Peraopods.—There is an acute tooth at the apex both of the front and the hind margin, that on the front the smaller and lower; the second joint has its front margin produced into an acute tooth; the fourth joint is considerably longer than its greatest breadth, the small apical tooth of the front margin not reaching so far as the much smaller tooth within the palm, this tooth being separated from it by a narrow but deep cavity, and followed by a small cavity, beyond which comes the usual erenulate margin leading towards the hinge; the fifth joint is subequal in length to the fourth, curved, with a very slight bulging of the smooth inner margin in one of the limbs, while in the other this margin is simply concave; the finger is minute, of the usual form.

Fourth Peraopods.—The first joint rather longer than the branchial vesicles, not quite so long as the first joint in the third pair, the front margin produced into a sharp narrow tooth; the second joint much narrower than the first, apically produced into a sharp tooth in front; the third joint having a small sharp tooth at the top in front; the fourth joint more than twice the length of the third.

Fifth Peraopods similar to the fourth, with the usual variations in the length of the joints, and the first joint broader than the broad first joint of the preceding pair, the teeth of the first, second, and third joints somewhat more pronounced. The male genital organs which have their opening in the seventh peraeon-segment are fully developed and conspicuous through the transparent integument.

Pleopods.—Peduncles broad; ten joints in each ramus, the first not very long.

Uropods.—The inner ramus of the second pair more than half the length of the outer, not reaching to the apex of the peduncle of the first pair, while the outer ramus reaches beyond that apex.

Length, without the antennæ, rather more than two-fifths of an inch.

Locality.—Station 272, September 8, 1875, Mid Pacific; lat. $3^{\circ} 48' S.$, long.

152° 56' W.; surface net; surface temperature, 79°. One specimen, male, mounted in Canada balsam.

Remarks.—The specific name refers to the delicacy of structure displayed by the specimen, the fourth joint of the third pereopods in especial not having the squareness common in the males of this genus.

Phronima novæ-zealandiæ (?), Powell (Pl. CLXI., B.).

1875. *Phronima novæ-zealandiæ*, Powell, Trans. and Proc. N. Z. Inst., 1874, vol. vii. p. 294,
pl. xxi. figs. 1, 2.
1876. „ „ Miers, Catal. Stalk- and Sessile-eyed Crust. New Zealand,
p. 129.
1886. „ *neo-zelanica*, Thomson and Chilton, Trans. N. Z. Inst., vol. xviii. p. 150.

The specimen which I take to represent Mr. Powell's species has the postero-lateral angles of the first three pleon-segments strongly produced. The first and second joints of the first pereopods are not apically produced. The fourth pereopods agree closely with those figured for *Phronima megalodonis*, Pl. CLXII., A. The third pereopods do not differ to any great extent from those figured on Pl. CLXII., B, for *Phronima sedentaria*, although the front tooth of the fourth joint is less elongated; but, judging by specimens kindly sent me from New Zealand by Mr. G. M. Thomson, that, as might be expected, is not a specific characteristic; moreover, a large specimen taken south of Australia, March 9 and 10, 1874, and presumably belonging to this species, has the front tooth in question elongate. The peduncles and rami of the first uropods are the longest, and respectively nearly reach back as far as those of the third uropods; the inner and the outer ramus in each pair are equal, and have the adjacent margins pectinate; the rami of the second pair are shorter than those of the third, and reach just beyond the peduncles of the first pair. The telson is semicircular.

Length, one inch.

Locality.—Station 158, March 7, 1874; in the Southern Ocean; lat. 50° 1' S., long. 123° 4' E.; depth, 1800 fathoms; bottom temperature, 33°·5; surface temperature, 45°. One specimen, female, containing eggs.

Remarks.—The interest of the specimen does not so much depend on the question of its right to this or that specific name, as on the latitude from which it comes. If it actually came from the depth named, it must be capable of bearing a very low temperature, and it will be observed that even the surface temperature of the station is not very high. The identity, however, of *Phronima novæ-zealandiæ* with *Phronima borneensis*, Spence Bate, and of both with *Phronima sedentaria*, seems well within the bounds of probability.

Phronima sedentaria (Forskål) (Pl. CLXII., B.).

1775. *Cancer sedentarius*, Forskål, Deser. Anim. quæ in itin. orient. observavit, p. 95.
 1776. " " Forskål, Icones rerum nat. quas in itin. orient. depingi curavit., tab. xli. fig. D, d.
 1796. *Cancer (Gammarellus) sedentarius*, Herbst, Naturgesch. der Krabben und Krebse, Bd. ii. p. 136, tab. xxxvi. fig. 8.
 1802. *Gammarus sedentarius*, Schousboe, Skrivter af Naturhist.-Selskabet, Bd. v. Hfte. 2.
 1802. *Phronima sedentarius*,¹ Latreille, Hist. Nat. des Crust. et des Insectes, vol. iii.

A specimen, which seems to agree with this species as well as any in the collection, is figured on the Plate of the natural size. An enlarged figure of the third peræopod is given for comparison with one drawn to the same scale of that peræopod in *Phronima megalodous*. The third peræopod of a young one taken along with the large specimen is also given, drawn to the same scale, and a figure of the terminal portion of the same peræopod much more enlarged.

Length, from the front of the head to the apex of the third pleon-segment, an inch and a quarter; the full length quite an inch and a half.

Locality.—Station 232, May 12, 1875; the *Hyalonema*-ground, Japan; lat. $35^{\circ} 11'$ N., long. $139^{\circ} 28'$ E.; depth, 345 fathoms; bottom temperature, $41^{\circ}.1$; surface temperature, $64^{\circ}.2$. One specimen, female, with young.

Remarks.—From the very extended distribution of the genus *Phronima* there arises a probability that it may include several species, but to establish clear marks of discrimination between the species is likely to require very extended research. Though it is easy to distinguish the adult males from the adult females, there are stages of growth when the two sexes are closely alike, and it is quite possible that some species when full grown present a close resemblance to the earlier stages in other species. The available marks depend to a great extent on the lengthening and shortening, the sharpening or rounding, of this apex or of that, on the question whether one tooth is more or less distant from another, or whether a margin is denticulate or crenulate. But all these marks are liable to so much variation, whether dependent (as may be the case) on the individual, or (as is certainly the case) on age and sex, that determinations of species are of necessity very problematical. Even if the limits of variation within any one species were definitely known, it is quite possible that in some of the stages it might be practically indistinguishable from some stage of a different species. In the young ones a tenth of an inch long, from the specimen taken south of Australia, March 9 and 10, 1874, the dactyloptera of the gnathopods were found to be very short, and the broad fourth joint of the third peræopods scarcely longer than the distal width, armed only with a minute front tooth;

¹ Most of the references given in the synonymy of the genus *Phronima* have to do with *Phronima sedentaria*, Latreille, so that it is scarcely worth while to repeat the list.

on the other hand, young ones from the specimen taken at Station 232 showed the daetyloptera well developed, the fourth joint of the third peræopods considerably longer than the distal breadth, and the distal margin divided as in *Phronima atlantica*, Guérin, Pl. CLX., fig. prp.3, ♀; but then these specimens proved to be a little more than a tenth of an ineh long, and when one was examined that was not more than a tenth of an inch, the distal margin of the fourth joint of the third peræopods was found to be armed only with a minute front tooth, just as in the specimens taken at a distance of 83° to the south. To give a full account of the Challenger specimens would demand a treatise by itself. It may be of interest, here, without the treatise, to mention the various localities at which specimens of the genus were obtained, whatever the species may be to which they respectively belong.

Station 103, August 22, 1873; off Sierra Leone; lat. $2^{\circ} 52'$ N., long. $17^{\circ} 0'$ W. (*Phronima pacifica*, see p. 1348).

Station 106, August 25, 1873; east of St. Paul's Rocks; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; surfacee to 40 fathoms; surfacee temperature, $78^{\circ} 8$. Two speimenes, female.

September 29, off Rio Janeiro; lat. $19^{\circ} 6'$ S., long. $35^{\circ} 40'$ W.; surface, night; surfacee temperature, $74^{\circ} 7$. One specimen.

Station 130, Oetoer 3, 1873; south-east of Rio Janeiro; lat. $26^{\circ} 15'$ S., long. $32^{\circ} 56'$ W.; surfacee temperature, 69° .

Station 131, Oetoer 6, 1873; South Atlantic; lat. $29^{\circ} 35'$ S., long $28^{\circ} 9'$ W.; surfacee temperature, 65° . One male speimen, mounted in Canada balsam. Length, seven-twentieths of an ineh. Flagellum of the upper antennæ with very long first joint, followed by six small joints; flagellum of lower antennæ with twelve long slender joints; of the second uropods the inner ramus almost as long as the outer. The third peræopods have the square form of wrist, with the hand projeeting but little beyond it (? *Phronima pacifica*).

Station 132, October 10, 1873; South Atlantic; lat. $35^{\circ} 25'$ S., long. $23^{\circ} 40'$ W.; surfacee temperature, 58° . One male speimen, mounted in Canada balsam. Length, half an inch. The antennæ and uropods nearly as in the specimen from Station 131; the third peræopods with the wrist longer than broad, like that figured for the female of *Phronima atlantica* on Pl. CLX., the hand projeeting much beyond the wrist.

Station 158, March 7, 1874; in the Southern Ocean; lat. $50^{\circ} 1'$ S., long. $123^{\circ} 4'$ E.; depth, 1800 fathoms; bottom temperature, $33^{\circ} 5$; surface temperature, 45° . One specimen, an inch long, female, with eggs (? *Phronima novæ-zealandiæ*, see p. 1356). A *Phronima*-house.

March 9 and 10, 1874; south of Australia; lat. $48^{\circ} 18'$ S., long. $130^{\circ} 4'$ E.; surface; surfacee temperature, 50° . One large specimen, female, in its house, with numerous young. One empty *Phronima*-house.

Station 159, March 10, 1874; south of Australia; lat. $47^{\circ} 25'$ S., long. $130^{\circ} 22'$ E.; surface temperature, $51^{\circ} 5$.

Station 196, October 13, 1874; north of Amboina; lat. $0^{\circ} 48' 30''$ S., long. $126^{\circ} 58' 30''$ E.; depth, 825 fathoms; bottom temperature, $36^{\circ} 9$; surface temperature, 83° . One large specimen, an inch and a quarter long, female, with young; both the large claws broken off. Two of the *Phronima*-houses.

Station 227, March 27, 1875; between Papua and Japan; lat. $17^{\circ} 29'$ N., long. $141^{\circ} 21'$ E.; surface; surface temperature, $79^{\circ} 2$. One specimen, female (*? Phronima megalodous*).

April 3, 1875; North Pacific, south of Japan; lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E.; surface; surface temperature, $71^{\circ} 5$. One specimen, a fifth of an inch long, male, with the antennæ not fully developed.

April 4, 1875; North Pacific, south of Japan; lat. $25^{\circ} 33'$ N., long. $137^{\circ} 57'$ E.; surface; surface temperature, 69° . One specimen, female.

Station 230, April 5, 1875; North Pacific, south of Japan; lat. $26^{\circ} 29'$ N., long. $137^{\circ} 57'$ E.; surface; surface temperature, $68^{\circ} 5$. One specimen, female (*? Phronima megalodous*).

Station 232, May 12, 1875; the *Hyalonema*-ground, Japan; lat. $35^{\circ} 11'$ N., long. $139^{\circ} 28'$ E.; depth, 345 fathoms; bottom temperature, $41^{\circ} 1$; surface temperature, $64^{\circ} 2$. One specimen, female, with numerous young (*Phronima sedentaria*). Two *Phronima*-houses.

Station 235, June 4, 1875; off Japan; lat. $34^{\circ} 7'$ N., long. $138^{\circ} 0'$ E.; depth, 565 fathoms; bottom temperature, $38^{\circ} 1$; surface temperature, 73° . One specimen, female, more than an inch long.

Station 240, June 21, 1875; east of Japan; lat. $35^{\circ} 20'$ N., long. $153^{\circ} 39'$ E.; surface; surface temperature, $64^{\circ} 8$. One specimen, male.

Station 241, June 23, 1875; east of Japan; lat. $35^{\circ} 41'$ N., long. $157^{\circ} 4'$ E.; surface; surface temperature, $69^{\circ} 2$. One specimen, male, three-tenths of an inch long (*? Phronima atlantica*).

Station 244, June 28, 1875; North Pacific; lat. $35^{\circ} 22'$ N., long. $169^{\circ} 53'$ E.; surface; surface temperature, $70^{\circ} 5$. One specimen, male, about a quarter of an inch long (*? Phronima atlantica*).

Station 245, June 30, 1875; North Pacific; lat. $36^{\circ} 23'$ N., long. $174^{\circ} 31'$ E.; surface temperature, 69° . Five specimens (*Phronima atlantica*, see p. 1351).

July 4, 1875; Mid North Pacific; lat. $36^{\circ} 42'$ N., long. $179^{\circ} 50'$ W.; surface, night; surface temperature, $61^{\circ} 5$. Several small specimens.

July 1875, between Japan and Honolulu; lat. 35° N.; surface. Several specimens of both sexes and various sizes, none very large. Also about the same locality twelve specimens; one an adult female, one inch long, with third peræopods nearly as in Pl. CLXII., B.; of the rest the longest nine-tenths of an inch, six of the specimens being females not adult, the other five males, and of these five two with both pairs of antennæ fully developed.

August and September 1875 ; Pacific Ocean ; lat. $7^{\circ} 35' - 5^{\circ} 54'$ N., long. $149^{\circ} 49' - 147^{\circ} 2'$ W.; surface ; surface temperature, 81° . One specimen, female, seventeen-twentieths of an inch long.

Station 272, September 8, 1875 ; Mid Pacific Ocean ; lat. $3^{\circ} 48'$ S., long. $152^{\circ} 56'$ W.; surface temperature, 79° . (*Phronima tenella*, see p. 1355.)

September 15, 1875 ; Mid Pacific Ocean ; lat. $12^{\circ} 8'$ S., long. $150^{\circ} 13'$ W.; surface ; surface temperature, 75° . One specimen, female.

October 1875 ; South Pacific, between Tahiti and Juan Fernandez ; surface. One specimen, female, agreeing in the shape of the third peræopods very exactly with Guérin's figure, in the Magasin de Zoologie, of *Phronima atlantica*, with bifid tooth on the fourth joint ; this specimen is about three-quarters of an inch long, and has very small marsupial plates, which look like little branchial vesicles, adjoining the second gnathopods and first two pairs of peræopods.

Station 295, November 5, 1875 ; South Pacific ; lat. $38^{\circ} 7'$ S., long. $94^{\circ} 4'$ W.; surface, night ; surface temperature, $58^{\circ} 5$. One specimen, male.

Station 323, February 28, 1876 ; Atlantic, off Monte Video ; lat. $35^{\circ} 39'$ S., long. $50^{\circ} 47'$ W.; surface ; surface temperature, $73^{\circ} 5$. One specimen, young.

March 5, 1876 ; South Atlantic ; lat. $37^{\circ} 32'$ S., long. $42^{\circ} 0'$ W.; surface ; surface temperature, $70^{\circ} 5$. One specimen, male.

Station 335, March 16, 1876 ; South Atlantic, north of Tristan da Cunha ; lat. $32^{\circ} 24'$ S., long. $13^{\circ} 5'$ W.; surface ; surface temperature, $73^{\circ} 5$. One specimen, mounted.

Station 351, April 12, 1876 ; Atlantic, off coast of Africa ; lat. $9^{\circ} 9'$ N., long. $16^{\circ} 41'$ W.; surface ; surface temperature, $81^{\circ} 8$. One specimen, female (*Phronima pacifica*).

April 26, 1876 ; off St. Vincent, Cape Verde Islands ; lat. $16^{\circ} 49'$ N., long. $25^{\circ} 14'$ W.; surface, night. (*Phronima megalodous*, see p. 1353.)

Station 354, May 6, 1876 ; North Atlantic ; lat. $32^{\circ} 41'$ N., long. $36^{\circ} 6'$ W.; depth, 1675 fathoms ; deep trawl ; bottom temperature, $37^{\circ} 8$. One specimen, female, mounted in Canada balsam.

May 7, 1876 ; North Atlantic, south-west of the Azores ; lat. $34^{\circ} 22'$ N., long. $34^{\circ} 92'$ W.; surface, night ; surface temperature, $67^{\circ} 5$. A female, not full grown.

Other labels were given as follows, with the Stations indeterminate :—

“ Atlantic, surface.” Seven specimens, all females, two large ones in their houses, one large one free, about an inch and one-fifth long, the other four smaller, but all of them over three-fifths of an inch.

“ Surface, between Bermuda and Azores.” One specimen, female.

“ Pacific, Api to Cape York, surface.” Two specimens, a male and female (see p. 1354, on *Phronima megalodous*).

“ Phronimid, Pacific, Admiralty Islands to Japan.” One specimen, male. Length, less than a fifth of an inch ; the flagellum of the upper antennæ with the first joint large,

not produced along the second joint, which like the third and last is small; the flagellum of the lower antennæ has a long first joint followed by eight or ten short ones.

"Surface, Sydney to Wellington." One specimen, female. A large *Phronima*-house.

"Japan to Honolulu."

The range of the genus as illustrated by the Challenger specimens is, therefore, between lat. $36^{\circ} 23'$ N. and $50^{\circ} 1'$ S., and over a space of 223 degrees between long. $13^{\circ} 5'$ W. and $123^{\circ} 4'$ E. Specimens from the Shetland Isles obtained by Dr. Fleming and Dr. Johnston (Brit. Sess. Crust., vol. ii. p. 26) carry the range in latitude up to 60° N. in the Atlantic; Dr. Streets extends it to 40° N. in the Pacific; and since Dr. Giles has added the Bay of Bengal to so many other localities from which the genus is known, its range from east to west may fairly be considered as extending all round the world.

Genus *Phronimella*, Claus, 1871.

For what is practically the original definition of the genus as far as Claus is concerned, see Note on Claus, 1879 (p. 487). For the definition of *Anchylonyx*, see Note on Streets, 1877 (p. 470). The definition which Claus gave of the species *Phronima elongata* in 1862 was as follows:—

"Body slender and delicate. The pleon very elongate with three pairs of pleopods and two pairs of uropods. Limbs of the peræon very thin and weak, the third and still more the fourth [First and Second Peræopods] almost whip-like in elongation; the fifth [Third Peræopods] are not chelate but subchelate." He shortly afterwards noted that the first peræopods were longer than the second, and that the second pair of uropods attained to some development in the male; but in the definition of the genus in 1879 these points seem to have been again overlooked. Bovallius in 1887 adds a new species, *Phronimella filiformis*, from the South Atlantic, which may be distinct, but there is nothing in the very brief description to separate it from *Anchylonyx hamatus* as described by Streets in 1877, a species which Streets himself identifies with *Phronimella elongata*.

Phronimella elongata, Claus¹ (Pl. CLXIII.). Specimens A, B.

Male.—The first two (coalesced) segments of the peraeon not longer than the third but deeper; the seventh segment longer than any of the preceding, distally narrowed; the first three segments of the pleon deeper than the last of the peraeon, the first the longest, the second the deepest, the third the shortest, the postero-lateral angles of all produced into a minute tooth, the lower margin in the second and third very convex.

Eyes answering the generic description.

Upper Antennæ.—The peduncle not very long, the first joint the widest, wider than long, the two following joints about equal to one another, together not so long as the first; the first joint of the flagellum of great length, longer than the five following slender joints together, narrowing a little distally, the apex produced to a point beyond the second joint, the whole breast covered with a brush of long slender filaments; the fourth joint longer than the second or third, the fifth longer than the fourth, the two following each shorter than the fifth, all bordered with short filaments at intervals; the remainder of the flagellum missing.

Lower Antennæ.—Gland-eone projecting from the wall of the head, third (first free) joint of the peduncle much narrower than the peduncle of the upper antennæ, longer than broad, a little widened distally, fourth joint shorter, fifth joint narrower than fourth, narrowing distally, as long as the third; flagellum abruptly narrower than the peduncle, very long and filiform, containing in the specimen examined about twelve elongate joints carrying slender filaments, the last joint ending bluntly.

First Gnathopods.—The first joint longer than the others together, the margins smooth and nearly parallel, the muscles occupying only a small space at the distal end of the joint; the second joint longer than broad; the third not longer than the second, distally a little projecting but not produced behind the fourth joint, its convex margin being here faintly scabrous, and carrying one hair or spinule; the wrist elongate, longer than the two preceding joints together, equal in length to the hand, widening a little distally, the front margin almost straight, the hind margin a little before the apex produced into a narrow tooth carrying a spinule, the arched cavity between this and the apex being scabrous; the hand narrow, slightly bent, carrying a few hairs or spinules, the daetyloptera at its extremity of great tenuity, reaching to the middle of the finger; the finger small and curved, not half the length of the hand, narrowing rather abruptly near the base and again at the insertion of the slender nail; the figure gives a ventral view, in which the finger appears almost straight; the daetyloptera are difficult to see in full; they appear to be oval, smooth-edged, with longitudinal markings which may be due to an optical effect of the transparent concave surface.

¹ The references for the species are practically the same as those already given for the genus.

Second Gnathopods similar to the first but longer ; the first, second, and third joints a little longer and very noticeably wider than in the preceding pair ; the fourth, fifth, and sixth joints very decidedly longer ; from the tendency in this pair to turn back towards the mouth-organs, it is not easy to lay them flat for a profile view, and in a ventral view the tooth near the apex of the wrist does not project, so that the joint appears altogether linear.

First Peræopods.—A narrow tooth or process projects from the segment above each of these limbs, which are very much longer and broader than the gnathopods. The first joint not quite so long as the third and fourth together, its front margin straight and smooth, the hind margin with one or sometimes two little teeth ; the second joint longer than broad ; the third more than twice as long as the second, with its hind margin nearly straight, the front a little convex ; the fourth joint not twice as long as the third ; the fifth joint narrow, tapering, almost straight, nearly three times as long as the third, produced into a spine-like process along the proximal half of the minute finger ; there are small setules or hairs at intervals along the hind margin of the limb.

Second Peræopods.—Branchial vesicles narrowly oval, less than half the length of the first joint. The first joint broader and a little longer than in the preceding pair, the hind margin having a tooth at the centre (or, as on one of the limbs, below the centre), another at the apex, and two intermediate ; the second joint with the apex of the hind margin slightly acute ; the third and fourth joints nearly as in the preceding pair, the fifth joint only equal in length to the fourth, otherwise with the finger as in the preceding peræopods.

Third Peræopods.—Branchial vesicles rather larger than the preceding pair. First joint a little longer and much wider than in the second peræopods, the front margin having six or seven little teeth, the hinder margin smooth, but dividing near the apex to form two little apical teeth ; the second joint comparatively stout, with two little teeth on the front margin ; the third joint not twice the length of the second, with convex hind margin, the front margin having three or four teeth, the lowest the largest ; fourth joint less than twice the length of the third, with smoothly convex hind margin, the front margin having six or seven unequal teeth ; the joint widens downwards to the fourth and largest tooth, below this having two or three teeth, on what may be considered as the palm margin ; the anterior distal part of the joint containing gland-cells ; the fifth joint finger-like, slender, curved, about three-quarters the length of the fourth joint, the largest tooth of which could impinge against the fifth joint about at its centre ; the finger minute, sharp-tipped, thick at the base, which is inserted in the narrowed apex of the fifth joint.

Fourth Peræopods.—Branchial vesicles rather larger than the preceding pair. First joint of the limb shorter than in the first peræopods but rather wider, longer than the three following joints together, the margins convex and smooth, the front one having a little

apieal tooth; the second joint not longer than broad, with a front apical tooth; the third joint narrower than the second, not twice as long; the fourth slightly curved, more than twice as long as the second; the fifth slender, nearly twice as long as the third; distally armed as in the first and seeond pairs; the front margin of the third, fourth, and fifth joints seabrous; the finger minute, bulbous at the base.

Fifth Peraopods similar to the fourth, but with different relative proportions, the first joint being rather longer than in the preceding pair, considerably longer than all the following joints together, all of which are inferior both in length and breadth to the corresponding joints in the fourth pereopods, so that in total length these limbs are the shortest of the pereopods, though longer than the gnathopods. Arranged in gradation according to length, the order of the limbs would be *gn.1.*, *gn.2.*, *prp.5.*, *prp.4.*, *prp.3.*, *prp.2.*, *prp.1.*

Pleopods.—Peduneles broadly oval, as usual the second pair shorter than the first and the third than the second; the coupling spines short and tolerably stout, the apex acute, with a pair of retroverted teeth, below which a seeond pair are placed, one tooth occupying each margin; in the first pair of pleopods there are three coupling spines; the eleft spine having the arm with the expanded apex rather the shorter; the rami shorter than the peduneles, with six or seven joints to the inner, and seven or eight to the outer ramus.

Uropods.—The peduneles narrow, longer than the rami, smooth edged; the rami narrowly lanceolate, the outer finely peetinate on the inner margin, the inner on the outer margin; in the first pair the peduneles slightly longer and narrower than those of the third pair, the outer ramus scarcely longer than the inner; the two rami slightly apart at their bases; the peduncles of the second pair much narrower than those of the first, and a little more than half the length, the outer ramus being also much shorter and narrower than the rami of the other pairs, the inner ramus represented only by a produced rather blunt tooth or process of the pedunele; the rami of the third pair almost equal, the outer perhaps a little the longer.

Telson nearly semieireular, of extreme tenuity, and therefore very difficult to perceive, espeeially as, owing to its very small size, it does not project beyond the divided margin of the ventral opening.

Length.—In a straight line from the front of the head to the extremity of the uropods, the specimen measured, in the position figured, three-tenths of an inch.

Female.—The seventh segment of the pereon more elongated than in the male and the dorsal emargination of the distal end more conspicuous; the first three segments of the pleon more elongate in proportion to their depth and differently shaped, widening a little distally, with the postero-lateral angles sharply produced into pronounced teeth, another little tooth standing a little higher up on the hind margin, this tooth being

indeed represented in the male, but standing at a greater distance from the postero-lateral angle and being very faintly marked; in the female there is very little convexity in either the upper or lower margin of these segments.

Upper Antennæ two-jointed, the first joint rather thicker than the second, but not half as long, the second joint widening a little for some distance, then narrowing and carrying three or four pairs of filaments, the apex blunt or truncale.

Lower Antennæ only represented by the semicircular rudiment swelling out on each side of the head just below the lateral eye; from the lower part there is a little projection containing the opening of the gland-eone.

Maxillipeds.—The inner plate rudimentary; the sinuous inner margin of the outer plates carries five conspicuous spaced denticles, followed by two smaller close together, and these again by a finely pectinate tract, while the narrowed apical portion is almost smooth, the blunt end having a setule; there are also two setules on the surface below the apex.

Gnathopods differing little from those of the male.

Peræopods more elongate than in the male; in the first and second peræopods the length of the third joint is much greater as compared with the second joint; the second peræopods are much shorter than the first, the difference in size being very marked in the fourth joint as well as in the fifth.

Third Peræopods.—First joint much longer than in the preceding pair, narrower than in the male, with six teeth on the front margin, and three besides the apical teeth on the hind margin; the second joint with three little teeth or serratures; the third joint twice as long as the second, with five teeth on the front margin; the fourth joint more elongate and slender than in the male, the largest tooth of the front margin being the seventh or eighth, below which are two strong teeth; the fifth joint relatively shorter than in the male.

Fourth Peræopods.—The fourth joint very much longer than the fifth, the front margin seemingly smooth, except for a minute setule here and there.

Fifth Peræopods.—Fourth joint much more than twice as long as the third and considerably longer than the fifth. In this and the preceding pair the gland-cells are very conspicuous in the long first joint.

Pleopods.—Peduncles narrowly oval.

Uropods.—Peduncles rather more slender and elongate than in the male; the second pair rudimentary, consisting of a single lanceolate joint so short that it only about reaches to the base of the telson.

Length rather greater than that of the male specimen.

Locality.—February 6–7, 1875; south of Mindanao, Celebes Sea; lat. $6^{\circ} 20' N.$, long. $123^{\circ} 18' E.$; surface, night; surface temperature, $81^{\circ} 7$. Six specimens, one male, five female.

Remarks.—In one of the female specimens the third peræopods approach those of the male in the comparative shortness of the fourth joint, which has only seven teeth on the combined front and palmar margin; in this specimen one of the branchial vesicles of the fourth peræopods was normal, the other dwindle; small marsupial plates were developed to the first, second, and third peræopods, not overlapping as in the adult female but hanging down like small branchial vesicles; those of the second peræopods were the largest, these and the following pair being attached to the ventral surface of the animal a little in front of the branchial vesicles. Considerable as are the differences between the male and the females, there can be little or no doubt that these specimens all belong to the same species; they were taken together; they all have the same yellowish tone of colouring in spirits, and the intermediate character of the young females corroborates what is on other grounds probable.

It is possible that some of the specimens here described ought to be assigned to new species, but it seems so extremely uncertain whether the differences observed do not belong merely to age, sex, or individual peculiarity, that the distinguishing names originally chosen have been relinquished. Streets, in changing the name of his own *Anchylonyx hamatus* into *Phronimella elongata*, Claus, says that the second uropods are well developed in the male, and figures them with two rami. In no specimen, either from the Atlantic or the Pacific, have I been able to find biramous second uropods, and am therefore unable to say whether the solitary specimen of a male examined by Streets constitutes a separate species, *Phronimella hamata*, or is only one stage of development in the life-history of a species common to the whole circumference of the globe.

Phronimella elongata. Specimens C, D.

Male.—The seventh segment of the pereon and first three segments of the pleon deeper and less elongate than in the female, the fourth segment of the pleon also shorter; the first three segments of the pleon with the postero-lateral angles produced into a tooth, the hind margin a little higher up projecting not into a tooth but a rounded angle.

Upper Antennæ.—The peduncle short, with only two joints, the second shorter than the first; the flagellum eleven-jointed, the first joint large and of great length, the breast unarmed, apically a little produced but not reaching to the end of the joint, which is distally narrowed and carries a row of seven filaments commencing near but not on the distal part of the breast; the remaining ten joints are together shorter than the first and successively narrower, all longer than broad, but by no means linear, the last conical with a little setule at the tip.

Lower Antennæ.—The boss containing the antennary gland has an obtuse-angled

projection for the opening of the duct; of the three joints of the peduncle which follow, the first is the stoutest, the second the shortest, the third about equal in length to the first; the flagellum is nine-jointed, not linear, shorter than that of the upper antennae, but in stoutness equal to its terminal portion, the first joint far the longest, longer than the peduncle, the other joints a little longer than broad.

Gnathopods.—These agree, certainly in all essential details, with those of specimen A. In the female I was able to perceive that the inner edge of the daetyloptera had a fine peetination, a character which may probably belong to all the specimens, though sometimes eluding observation.

First and Second Peræopods as in specimen A.

Third Peræopods.—First joint not greatly widened, with five teeth along the front margin, and two besides the apical teeth on the hind margin; the second joint only having the apical tooth of the front margin; the third joint with two teeth to the front margin; the fourth joint having in one limb the longest tooth the fourth, in the other limb the fifth on the front margin; the fifth joint scarcely so long compared with the fourth as in specimen A, so that the long tooth of the fourth joint would impinge below the middle of the upturned fifth joint.

Fourth and Fifth Peræopods.—The first joint with the front and hind margins almost parallel, much narrower than in specimen A.

Pleopods.—Peduncles long-oval; the eleventh spine not so stout as in specimen A.

Uropods.—Second pair with only one ramus.

Length.—Three-tenths of an inch, exclusive of the antennæ.

Female.—In all parts much more elongate than the male.

Mandibles.—The trunk widest at the base, the cutting edge almost in line with the long narrow body of the trunk and almost as wide, its margin apparently smooth, though the surface just within it is closely striated as if leading up to a dentieulate edge; the upper corner forms a shallow projection rather than a tooth, but the lower corner presents at least one sharp upturned denticle, to the rear of which the lower margin is ciliated; the left mandible has a secondary plate, about half the width of the principal plate, with its distal margin cut into about a dozen little teeth; the molar tubercle appears to be almost laminar, its broad distal margin partially projecting below the body of the mandible, set with numerous little sharp teeth and ciliated; the upper border of the trunk, of which no part is free, is nearly straight, without palp or process.

First Maxillæ.—The outer plate with some slender cilia and one or two that are more spine-like projecting from the inner margin; the oblique distal margin has four spine-teeth rather wide apart, followed by two that are larger and stouter near the outer apex and close beside these a smaller one at the apex; the one-jointed palp over-arches the outer plate, and has some very small spine-teeth on its distal margin.

First Peræopods.—The first joint has three small teeth on the lower part of the hind margin.

Second Peræopods.—The first joint has seven teeth along the hind margin, this joint being nearly as long as the three following together; the third joint is nearly as long as the fifth, while the fourth is noticeably longer than either.

Third Peræopods much longer than the second. Branchial vesicles little more than a fifth the length of the first joint. The first joint with twelve little unequal teeth along the front margin, and six or seven along the hind margin; the second joint with four or five very small teeth on the front, the third joint with six or seven; the fourth joint with the largest tooth the eleventh, below which the palm has three, the lowest blunt; the fifth joint though larger than in the male specimen, is little more than a third the length of the fourth joint, the large tooth of which touches its upturned inner margin a little below the centre.

Fourth Peræopods.—Branchial vesicles longer than the preceding pair, elongate, but less than half the length of the first joint. First joint elongate, much shorter than in the third peræopods, a little longer than the three following joints together, proximal part narrow, distal half widened, with the gland-cells conspicuous, the front margin forming a small apical tooth; the second joint considerably longer than broad, with a small apical tooth in front; the third joint a little more than twice as long as the second; the fourth about twice as long as the third; the fifth scarcely so long as the third.

Fifth Peræopods shorter than the fourth. First joint longer than in the preceding pair and a little more slender, much longer than all the remaining joints together, the second a little longer than broad, the third not more than twice as long as the second; the fourth more than twice as long as the second, less than twice as long as the fifth.

Pleopods.—Peduncles elongate, especially in the first pair.

Uropods more elongate than in the male specimen, except the second pair, which are reduced to a minute oval joint not long enough to reach the base of the telson; at the apex there is a hair or very small setule.

Telson very small, broader than deep, almost too flat-ended to be called semicircular, not reaching clear of the ventral opening.

Length.—The largest of the female specimens measured three-tenths of an inch from the front of the head to the end of the peræon, and four-tenths from the latter point to the extremity of the uropods, in all when fully extended seven-tenths of an inch.

Locality.—Station 230, April 5, 1875; North Pacific, south of Japan; lat. $26^{\circ} 29'$ N., long. $137^{\circ} 57'$ E.; surface; surface temperature, $68^{\circ}.5$. Seven specimens; one male, six females.

Remarks.—Since in the male specimen the first joint in the flagellum of the upper antennæ, though greatly elongated, is without a brush of filaments, it is probable that the animal was not fully adult, and this will in part account for the great difference in size between this specimen and that of the largest female.

Phronimella elongata. Specimen E.

Locality.—August and September 1875; Pacific Ocean; lat. $7^{\circ} 35'$ – $5^{\circ} 54'$ N., long. $149^{\circ} 49'$ – $147^{\circ} 2'$ W.; surface; surface temperature, 81° . Three specimens, female.

Remarks.—The second uropods consist of a conical rudiment. One of the specimens presents an extraordinary spectacle, since it appears to be swarming in every part with a little oval parasite, unique in this respect among all the Challenger specimens of *Phronimella*.

Phronimella elongata. Specimen F.

Locality.—Station 268, August 30, 1875; between the Sandwich Islands and Tahiti; lat. $7^{\circ} 35'$ N., long. $149^{\circ} 49'$ W.; surface temperature, 81° . Two specimens, male.

Remarks.—The upper antennæ in one of these specimens are like those in the male specimen from Station 230, and nearly so in the other, but the narrow termination of the large first joint of the flagellum was ready to divide into smaller joints, and in the lower antennæ the long first joint was similarly ready for subdivision; the second uropods consisted only of a small single joint, about reaching to the base of the peduncles of the third pair.

Phronimella elongata. Specimen G.

Length, from the front of the head to the end of the pereon, five-twentieths of an inch; from the latter point to the extremity of the uropods, six-twentieths of an inch; the coaleseed first and second segments of the pereon are shorter than any that follow; the seventh pereon segment is rather longer than the two preceding together; the first segment of the pleon the longest, a little longer than the last of the pereon, shallow, with the postero-lateral angle forming a tooth, above and a little beyond which the hind margin is roundly angled; the two following segments similar, successively shorter.

Locality.—Station 346, April 6, 1876; Tropical Atlantic; lat. $2^{\circ} 42'$ S., long. $14^{\circ} 41'$ W.; surface; surface temperature, $82^{\circ} 7$. One specimen, female.

Remarks.—In this specimen the sinuous upper outline of the heart could be perceived extending along the first two (coalesced) segments and the three following, in the last of these descending with a steep incline to its narrowed termination in the sixth segment; the three lateral openings could also be seen respectively in the compound segment and the two following. In the third pereopods the first joint is of great length, much longer than the first joint in any of the other pairs, longer than the three following joints together, the second joint has four teeth on the front margin, the third has six, the fourth has the ninth tooth longest with four little teeth to the palmar margin, the fifth joint is little more than a third as long as the fourth; in the fourth pereopods the first joint widens gradually from the base and is subequal in length to the three following joints together, the third joint is rather longer than the fifth, the fourth being much longer than either; in the fifth pereopods the first joint is rather longer than in the fourth, longer than the following joints together; the third is as long as the fifth, the fourth much longer than either, but all of these three much shorter than in the preceding pair; the peduncles of the pleopods like the branchiae are slender, as usual the latter set being successively longer, the former set successively shorter; of the second uropods I cannot see the least trace.

The tenuity of this pellucid specimen might well suggest the specific name *filiformis*, which Bovallius has given to a specimen from the South Atlantic. Among the characters which he assigns to his species he mentions that the second pereopods are longer than the third, and that the second uropods are well developed; these characters, however, I believe to be not specific, but merely sexual, belonging to the male; the other characters which he assigns are, that the second gnathopods are much longer than the first, the processes at the apex of the hand longer than half the finger, and that the first joint is of the same length in the fourth and fifth pereopods; of the value of these relative measurements as specific characters it is very difficult to judge without drawings of the parts and without comparison of numerous specimens.

Phronimella elongata. Specimen H.

Locality.—Station 348, April 9, 1876; Atlantic, off the African coast; lat. $3^{\circ} 10'$ N., long. $14^{\circ} 51'$ W.; surface to 200 fathoms; surface temperature, 84° . Two specimens, female.

Remarks.—The larger of these was in close agreement with the specimen from Station 346, but the body a little more inflated, the colour yellowish, the third pereopods less elongate, having on the second joint three teeth, on the third five teeth, on the

fourth the largest tooth the seventh ; the difference in length between the first joint of the fourth pereopods and that of the fifth is scarcely perceptible ; the angle above the postero-lateral tooth in the first three segments of the pleon is very little rounded ; in the smaller specimen with the marsupial plates not fully developed, the third peræopod on one side of the animal had two teeth to the second joint, four to the third, and the large tooth of the fourth joint fourth in order, followed by four on the palmar margin ; the third peræopod on the other side had three teeth to the second joint, three to the third, and the large tooth of the fourth joint fifth in order, with the palm as in the other limb ; in the first three segments of the pleon the postero-lateral tooth had above it a very decided tooth instead of a more or less rounded angle of the upper margin ; no second uropods could be seen in either specimen.

Phronimella elongata. Specimen I.

Locality.—Station 108, August 27, 1873 ; off St. Paul's Rocks ; lat. $1^{\circ} 10'$ N., long. $28^{\circ} 23'$ W. ; surface ; surface temperature, 78° . Eleven specimens, all female.

Remark.—No trace of second uropods could be seen in any one ; there were variations in the number of teeth on the joints of the third pereopods, and in the shape of the hind margin of the first three pleon-segments.

Phronimella elongata. Specimen J.

Locality.—Station 106, August 25, 1873 ; Mid Atlantic ; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W. ; surface to 40 fathoms ; surface temperature, $78^{\circ} 8$. Thirty specimens, twenty-one females, nine males.

Remarks.—One of the male specimens in some respects, and especially as to the antennæ, agreed closely with that described from south of Mindanao ; the upper antennæ had fourteen joints remaining of the slender part of the flagellum, probably within one of the full number, since the last was very thin ; the upper antennæ were as long as the lower ; the third pereopods had two teeth on the third joint of one limb, and three teeth on that of the other ; the second uropods were reduced to a minute rudiment. Other specimens were similar, with variations as to the number of teeth ; in other specimens again, the male agreed as to antennæ and pleopods with the specimen from Station 230, but with the second uropods a mere rudiment, this being the case with all the male specimens, while the females agreed in having no trace of the second uropods.

The following table will show the range of the genus *Phronimella* as illustrated by the Challenger specimens :—

1. Station 3, February 18, 1873; south-west of Ferro, Canary Islands; lat. $25^{\circ} 45'$ N., long. $20^{\circ} 14'$ W.; surfacee; surfacee temperature, 65° . *Phronimella elongata*, ♀, Claus. One specimen, mounted during the voyage.
 2. Station 348; lat. $3^{\circ} 10'$ N., long. $14^{\circ} 51'$ W. (See p. 1370.)
 3. Station 346; lat. $2^{\circ} 42'$ N., long $14^{\circ} 41'$ W. (See p. 1369.)
 4. Station 106, August 25, 1873; Mid Atlantie; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W. One specimen, female, mounted during the voyage. Thirty speeimens (see p. 1371). Also one speeimen, female, labelled "surface to 4 fathoms."
 5. Station 108; lat. $1^{\circ} 10'$ N., long. $28^{\circ} 23'$ W. (See p. 1371.)
 6. Mareh 1-4, 1876; South Atlantie; lat. $36^{\circ} 1'$ - $36^{\circ} 52'$ S., long. $47^{\circ} 35'$ - $42^{\circ} 47'$ W. One speeimen, female, mounted during the voyage.
 7. Western Paeifie, north of New Guinea. Three speeimens mounted in Canada balsam, and marked respeetively "Phronimella ♀," "Phronimella ♀," "Phronimella ♂."
 8. February 6-7, 1875; south of Mindanao, Celebes Sea; lat. $6^{\circ} 20'$ N., long. $123^{\circ} 18'$ E. (See p. 1362.)
 9. January 9, 1875; China Sea, off Luzon; lat. $16^{\circ} 35'$ N., long. $117^{\circ} 47'$ E.; surfacee; surface temperature, $76^{\circ} 5$. Two speeimens, female.
 10. April 3, 1875; Paeifie, between Papua and Japan; lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E.; surfacee; surfacee temperature, $71^{\circ} 5$. One speeimen, female.
 11. Station 230; lat. $26^{\circ} 29'$ N., long. $137^{\circ} 57'$ E. (See p. 1366.)
 12. Mareh 1875; Paeifie, Admiralty Islands to Japan. One speeimen, female, mounted in Canada balsam.
 13. Station 268, August 30, 1875; Sandwicheh Islands to Tahiti; lat $7^{\circ} 35'$ N., long. $149^{\circ} 49'$ W. (See p. 1369.)
 14. August and September 1875; Paeifie Oeean; surfacee. (See p. 1369.)
- These stations show a range from lat. $26^{\circ} 29'$ N. to lat. 36° or 37° S., but as *Phronimella* is also reoorded from the Mediterranean, its northward extension is carried some degrees higher; its extension from east to west as here exhibited eonfines it to the Atlantie and Pacific Oceans, but, as just observed, it is also found in the Mediterranean, and it has been reeently reported by Dr. Giles from the Bay of Bengal.

Family HYPERIDÆ, Dana, 1852.

For Dana's aeeount of the family, see Notes on Dana, 1852 (pp. 258, 261). For the definition by Claus, see Note on Claus, 1879 (p. 487).

Bovallius, who writes the name Hyperiidæ, thus defines the family in 1887:¹—

"Head large, more or less globular. Eyes large, oecupying the sides of the head.

¹ Arctic and Antarctic Hyperids, p. 559.

First pair of antennæ thick, scarcely tumid (δ with multiarticulate flagellum). Second pair of antennæ almost similar to the first pair, not angulated, fixed at the anterior side of the head. Mandibles with palp. Seventh pair of pereiopoda not transformed [*Fifth Peræopods normal*]. Uropoda normal."

The genera included in the family by Bovallius¹ are *Hyperia*, *Iulopsis*, *Hyperoche*, *Tauria*, *Hyperiella*, *Parathemisto*, *Euthemisto*, *Themistella*, and *Phronimopsis*. Of Dana's *Tauria*, however, Bovallius does not appear to have seen any examples, so that its validity as an independent genus remains more or less conjectural. *Phronimopsis* is withdrawn from the family Phronimidæ, in which Claus placed it, probably on account of the shortness of the head and the possession of a palp by the mandibles. *Cyllopus* and *Cystisoma*, which Claus alludes to as included among the Hyperidæ, are transferred to two separate families by Bovallius.

Genus *Phronimopsis*, Claus, 1878.

- 1878. *Phronimopsis*, Claus, Zool. Anzeiger, Jahrg. i. No. 12, p. 269.
- 1879. " Claus, Der Organismus der Phronimiden, p. 5.
- 1881. " E. von Martens,² Zool. Record for 1879, Crustacea, p. 33.
- 1885. " Carus, Prodromus Faunæ Mediterraneæ, pars ii. p. 424.
- 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 489.
- 1887. " Bovallius, Systematical List of Amph. Hyper., Bilang till K. Svensk. Vetensk. Akad. Handl., Bd. 11, No. 16, p. 23.

For the original definition of the genus, see Note on Claus, 1879 (p. 488). Bovallius in 1887 removed it, without giving any fresh definition, from the family Phronimidæ, in which it was placed by Claus, and made it the ninth genus of the family Hyperiidæ. As the genus now includes three species, the definition may be modified as follows:—

Antennæ of both pairs having multiarticulate flagella in the male, but not in the female.

Mandibles with dentate cutting edge, a secondary plate on the left mandible, a molar tubercle, and, in the male, a three-jointed palp.

The *First Gnathopods* simple, with hairy finger; the *Second Gnathopods* chelate.

The *Peræopods* slender, all narrowly subchelate.

Uropods with long narrow peduncles and narrowly lanceolate rami.

Telson small.

The *Head* short and deep; branchial vesicles attached to the second, third, and fourth pairs of peræopods.

There are in the heart of *Phronimopsis spinifer*, Claus says, three pairs of venous ostia.

¹ Systematical List of the Amphipoda Hyperiidea.

² The index suggests the form *Phronimatopsis*.

Phronimopsis tenella, n. sp. (Pl. CLXIV.).

Head deeper than long, deeper than the peræon; first two segments of the peræon partially coalesced, deeper than the two following, and those two deeper than the three that succeed them; the first three segments of the pleon much longer and deeper than the peræon-segments, the postero-lateral angles rounded, though there is a minute point showing where the convex lower margin and convex part of the hinder margin meet. The skin apparently without pigment-flakes.

Eyes probably having an upper and lower group of ocelli, but in our specimen they were scarcely visible except near the lower margins of the head.

Upper Antennæ.—Peduncle short, tumid, the first joint a little longer than broad, the two following much shorter than their breadth; the first joint of the flagellum about as long as the peduncle, narrowing to the distal end, its broad breast lined with a brush of long filaments, the breast not quite reaching the apex of the joint; the second joint rather longer than broad, the third joint narrower but considerably longer than the second. The remainder missing. The second joint of the flagellum, besides having apical filaments, has a narrow decurrent process, the blunt apex of which is tipped with long filaments.

Lower Antennæ.—Gland-cone broad, projecting from the wall of the head; the third (first free) joint cylindrical, as broad as long; the fourth joint scarcely so large as the third, widened distally; the fifth joint not quite so long as the third and fourth together, distally a little narrowed and produced over the slightly bulbous base of the first joint of the flagellum, this joint being slender, longer than the fifth joint of the peduncle; the remainder missing.

Upper Lip.—I believe it is correct to say that this is unsymmetrically bilobed.

Mandibles.—Cutting plate divided into six or seven teeth forming a convex edge; the right mandible (fig. m.) without a secondary plate, the left mandible having a secondary plate similar to the primary, about equally long; the teeth were not counted as this plate was seen only in profile; the lower edge of the trunk and the upper part of its surface to the rear of the cutting plate are strongly ciliated; to the rear of the ciliated portion is a broad molar tubercle, the crown of which has a sharp, slightly crenate edge; the three-jointed palp is much longer than the trunk, slender, the first joint the thickest, equal in length to the slightly curved third, the second longer than either.

Lower Lip.—The forward margins finely ciliated. The mandibular processes with rounded apices.

First Maxillæ.—Inner plate not strongly developed; outer plate having much of its surface crowded with hair-like setules or spinules, from among which distally a series or group of about seven strong spines emerge; one of the seven appears to be apically

toothed; the palp reaching beyond the outer plate, widening distally, the broad apex set with minute spine-teeth and having a larger spine near the inner angle.

Second Maxillæ.—The inner plate considerably shorter than the outer, with one spine at the apex, the outer plate with two spines at the apex and one on the inner margin below the apex, each of these spines having a lateral tooth; both plates have numerous hair-like setules.

Maxillipeds.—The inner plate large, three-sided, the inner surface constituted by two of the sides which are covered with hair-like setules, the narrow apex carrying two or three spines; the outer plates long and narrow, very finely ciliated, with a small spine at the acute apex, a setule in a notch a little below it on the outer margin, another in a notch rather lower on the inner margin, and a third lower than this on the outer margin; the first joint or elin is short, while the following joint is long, longer than the outer plates.

First Gnathopods.—The side-plates in this species are not jointed. First joint of the limb a little sinuous, not very elongate, wider below than above, smooth-edged, adapted for gland-cells, as seems to be the case in all the six following pairs of limbs; second joint not longer than broad; third joint rather longer, with a spine at the apex of the hind margin and a larger one in the middle of the minutely pectinate distal margin; the wrist a little shorter than the hand, wider above than below, the front margin convex, smooth, the hinder with a spine standing out above the middle, where the joint begins to narrow; the hand not very much shorter than the first joint, narrow, and narrowing distally, the front margin smooth, the hinder ciliated and having a serrature of four points wide apart; the finger curved, not half the length of the hand, armed all along with two or more rows of long, closely set cilia; the nail short.

Second Gnathopods.—First and second joints as in the preceding pair, but larger; third joint longer than the second, without spines; the wrist distally cup-like, not so wide as the hand, much wider than the third joint, but not longer, apart from the long, tapering, partially channelled process into which its hinder margin is produced; the apex of the process, which appears to be a little pectinate, carries an acute spine; the massive hand, of which the basal part is much longer than broad, and much longer than the process of the wrist, has its hind part prolonged into a broad, somewhat tapering, blunt-ended thumb; the triangular tapering finger applies closely against the irregular front or inner margin of the thumb, forming a complete chela; the blunt (perhaps worn) apex of the finger in our specimen does not quite reach the apex of the thumb; the front margin of the finger is rather concave than convex.

First Peræopods.—The first joint similar to that in the gnathopods, but more elongated, as long as the third and fourth joints together; the second joint longer than broad; the third much longer than the second, widening distally, the hind margin minutely pectinate, carrying three spines at intervals, the lowest the largest; the

fourth joint much longer than the third, carrying four spines along the hind margin, which with its rounded apex is minutely pectinate; the fifth joint slender, slightly curved, a little longer than the fourth, with cilia and spinules along the hind margin, which is produced into a tooth facing the base of the finger, this tooth being a little irregularly denticulate on the inner or front margin; the finger long and slender, curved, more than half the length of the fifth joint, the distal part except at the tip minutely furred.

Second Peræopods.—Branchial vesicles oval, smooth, not so long as the first joint (whether occurring with the first peræopods I am uncertain). The limb like that of the preceding pair, perhaps a little longer.

Third Peræopods longer than the second, and without strong marginal spines, the branchial vesicles of this and the following pair similar. The first joint of the limb elongate, distally a little widened, its front margin distally finely ciliated and produced at the apex into a thin spine-like tooth overlapping part of the second joint; the second joint with the hind margin ciliated and apically produced into a similar but shorter tooth; the third joint longer than in the preceding pairs, its hind margin ciliated and carrying two or three small spinules, apically produced into a short tooth; the fourth joint nearly as long as the first, nearly three times as long as the third, similarly armed, the apex not produced; the fifth joint shorter than the fourth, much longer than in the preceding pair, but similarly produced at the apex, the inner or hinder margin of the tooth having several denticles, besides which there is a little thin laminar process with finely pectinate edge; the finger is thin and curved, bulbous at the base, similar to that in the preceding peræopods but much shorter.

Fourth Peræopods similar to the preceding, but with the third joint a little longer, the fourth and fifth joints shorter, the fourth joint considerably shorter than the first, and the fifth than the fourth.

Fifth Peræopods similar to the fourth, except in the relative lengths of the joints, those of the fourth and fifth being here reversed, the fourth being much shorter than the fifth.

Pleopods.—The peduncles longer than the rami, as usual shorter in the third pair than in the two preceding pairs; the coupling spines have four retroverted teeth on one margin and two on the other, besides the apical teeth; the eleventh spine has the two arms almost of equal length, that with the expansion near the apex not the shorter; the joints of each ramus are six in number.

Uropods.—The peduncles and rami have the edges finely but closely ciliated; they are all rather narrow and elongate, those of the first pair the longest, the peduncles reaching beyond those of the second but not so far as those of the first; the narrowly lanceolate rami of the first pair are subequal, a little longer than the other pairs, and like them more than half the length of their peduncles, the adjacent edges faintly emarginate

and thickly ciliated near the base; in the second pair the outer ramus is slightly the shorter; in the third pair the peduncles are rather longer, the inner ramus not shorter but rather narrower, than in the second pair; the outer ramus is broken.

Telson very small, not longer than broad, apically narrowed, the apex rounded, with a thin edge.

Length about three-tenths of an inch, measuring from the front of the head to the back of the second pleon-segment and thence to the extremity of the uropods.

Locality.—The specimen was labelled "July 1875, lat. 35° N., Japan to Honolulu, surfacee." One specimen.

Remarks.—The specific name refers to the delicacy of the general texture and structure of the animal, which is in contrast with the strong chelæ of the second gnathopods and tenacious looking claws of the peræopods. From the Mediterranean species to which Claus gives the name of *Phronimopsis spinifer* at page 6 of *Der Organismus der Phronimiden*, but the name of "*Phronimopsis Zoa*" at page 82 in the explanation of the plates, the present species is distinguished by the absence of the spine-process on the peduncle of the upper antennæ which Claus finds in both sexes of his species; it is also very different from the type-species in the shape of the peræon and the relative size of the pleon, as well as in the absence of pigment-markings, while in many other respects it shows a remarkable resemblance to its European congener; from *Phronimopsis sarsi*, Bovallius, inhabiting "tropical parts of the Atlantic," it is distinguished, in having a peræon which can scarcely be described as "normal," in having the first segment of the peræon partially coalesced with the second, and in having the telson rather triangular than semicircular, a fourth of the length of the peduncles of the third uropods, instead of "shorter than a sixth."

For the original definition of the genus see Note on Desmarest, 1825 (p. 122). For the definition of *Hiella*, see Note on Straus-Durckheim, 1829 (p. 139); for that of *Lestrigonus*, see Note on Milne-Edwards, 1830 (p. 142). Bovallius in 1887 defines *Hyperia* as follows :-

" Head large, nearly globular, flattened anteriorly. Pereion smooth, in the females larger and more tumid than in the males. Carpus of first pair of pereiopoda [wrist of First Gnathopods] dilated, less produced than in second pair, the produced carpal process in both pairs spoon-shaped. Carpi of third and fourth pair [fourth joint of the First and Second Peræopods] not dilated. Last three pairs subequal, not or only a little longer than the two preceding pairs. Epimerals distinct. Uropoda short and broad. Telson very large."

Hyperia sibaginis, n. sp. (Pl. CLXV.).

First and seventh segments of the peræon dorsally the longest; the first three segments of the pleon much longer than any of the peræon-segments, the postero-lateral angles almost right angles, the produced points being minute in the first and second segments, and the third having none.

Upper Antennæ.—The peduncle short, the first joint tumid, not longer than broad, the two following joints very short; the first joint of the flagellum somewhat bent upwards, narrower than the peduncle, but longer, its lower margin longer than the upper, clothed with a brush of filaments, of which the longest are near the base; the remainder of the flagellum is linear, fringed with setules, of twenty-three joints, of which the first and second are the shortest, rather stouter than the rest.

Lower Antennæ.—The third (first free) joint of the peduncle not longer than broad, second rather shorter, third longer, bent a little upward, the proximal part wider than the distal; the flagellum linear, much longer than that of the upper antennæ, fringed in a similar manner, of about thirty joints, which are rather longer than those of the upper antennæ, the first not short, bulbous at its base.

Upper Lip unequally bilobed, the apieal cleft rather deep.

Mandibles almost rectangular, with the palp fixed at the upper front angle, the small cutting plate projecting at the angle below, while the lower angle to the rear is rounded; the cutting edge divided into nine denticles, the rather narrower secondary plate of the left mandible having an edge of ten or a dozen denticles; behind these plates is a group of spinules on the lower margin, immediately to the rear of which projects the

multidenticulate crown of the broad molar tubercle, with about five and twenty teeth in each row; on the left mandible there came into view a laminar edge which was finely peetinate rather than dentate; on the right mandible a row of fourteen projecting setules was observed; these minute details depend so much, as far as observation is concerned, on the position of the mandible when mounted, that they cannot easily be made of any service for specific characters; the first two joints of the palp together longer than the trunk, the first the thickest, about three-quarters the length of the second, the second a little shorter than the third, which is slightly curved, apically acute, smooth except for the adpressed cilia of the surface.

First Maxillæ.—Basal joint broad, length and breadth about equal, the following joint longer but less broad; the outer plate more or less triangular, furred with setules or spinules, and distally carrying a group of strong spines; the palp broader and much longer than the outer plate, with spinules along the inner border, two little spines at its apex, and the apical border having a sort of mixed peetination and denticleation.

Second Maxillæ.—The inner plate shorter than the outer, each apically narrowed and beset with spinules and setules.

Maxillipeds.—The first joint or chin short, the following joint long and narrow, longitudinally ridged on the inner surface, the ridge apparently ending in an apical tubercle surmounted by a spine which does not rise above the outer rounded distal margin of the joint; the two outer plates have their bases close together within the distal margin; they are narrow, with four little spine-teeth on the serrate inner margin, one such at the apex, and one just below it on the outer margin.

First Gnathopods.—Shape of side-plates not discerned. First joint narrowly flask-shaped, considerably longer than all the remainder of the limb; second joint with a spine at the hinder apex; third joint very little longer than the second, with a longer apical spine, the distal margin projecting a little behind the wrist; the wrist distally much wider than the hand, with a spine at the apex of the convex front margin, the straight hind margin having one spine near the apex and two at the apex, which is produced so as to clasp the base of the hand and is peetinate on its inner edge; the hand a little shorter than the produced wrist, having much of the nearly straight hind margin peetinate, the front margin carrying on the distal half two spines and an apical spinule; the finger curved, not half the length of the hand, finely peetinate on the inner edge.

Second Gnathopods.—The first joint rather longer than in the first gnathopods and its front straighter, the remaining joints very similar to those of the preceding pair, but all rather larger, the wrist more strongly produced and more decidedly longer than the hand.

First Peraopods.—The side-plates as in the other segments small and with the upper boundary very faintly marked. The branchial vesicles large. The first joint rather larger than in the second gnathopods, longer than the three following joints together,

widening almost at once from the narrow neck, carrying a spinule at the apex of the hind margin; the short second joint with its hind margin longer than the front; the third joint much shorter than the fourth, widening distally, the hind margin smooth except for a cilium at the centre and a small spine near the apex; the fourth joint not quite so long as the fifth, the front margin convex, smooth, the hind margin straight, fringed with little thin spinules, and having one spine near the apex; the fifth joint narrower, slightly curved, the little spinules fringing the hind margin being here more decurrent; the finger more than half the length of the fifth joint, slender, curved, a little bulbous at the base, both margins smooth, or with a little submarginal pectination near the base of the inner edge.

Second Peræopods very similar to the first, but with the first joint and the last three joints rather longer, the fourth and fifth equal in length, the armature as in the other pair.

Third Peræopods.—First joint a little expanded but not very widely, wider below than above, scarcely longer than the third and fourth joints together, the hind margin smooth, the front at first smooth, then serrate, more strongly and closely so as it approaches the apex; the second joint short, with a spinule at the front apex; the third joint longer than in the preceding peræopods, with a few spinules along the front margin; the fourth joint much longer than the third, the front margin fringed with little spinules, there being here as elsewhere a longer spinule or setule at intervals, planted within the margin; the fifth joint longer than the fourth, armed in like manner; the finger very slender, apically curved, not half the length of the fifth joint, the front margin below the bulb being pectinate for nearly a third of the finger's length.

Fourth Peræopods rather larger and longer than the third; the first joint having on one limb four, on the other limb five, spines at intervals along the middle of the front margin, which is serrate below; the other joints are armed as in the preceding pair; the fifth joint in particular has a greater length.

Fifth Peræopods shorter than the third, armed like the fourth. The first joint broader above than below, broader than in either of the preceding pairs; the fourth joint shorter than the third, very much shorter than in the preceding pairs; the finger half the length of the fifth joint, pectinate along nearly half of its inner margin.

Pleopods.—The peduncles stout; the coupling spines small, with acute apex and four teeth on each margin; the first joint of the inner ramus not very long, narrow at the base, and widened below, its inner margin ciliated, the cleft spine with slender not very unequal arms; the first joint of the outer ramus carrying four or five plumose setæ on the outer margin and having an interlocking process on its surface; the joints of each ramus eight in number, the joints not elongate, the accompanying pairs of setæ rather stout.

Uropods.—Peduncles of the first pair longer than the rami, the outer margin

apically acute, the distal margin being in this and the other pairs pectinate on the under surface ; the outer ramus a little shorter and broader than the inner, its outer margin having three pronounced teeth, the inner edge having a ciliated and pectinate emargination a little way below the base, the rest of the edge being microscopically pectinate almost down to the acute apex ; the inner ramus has its inner margin smooth, and the outer margin strongly pectinate, a ciliated emargination near the base facing that of the other ramus ; the peduncles of the second pair are scarcely longer than the rami, which are as large as in the first pair, the outer ramus with four teeth on its outer margin, the inner edge finely pectinate, with a slight unciliated emargination near the base, the inner ramus with the upper part of the outer edge faintly emarginate with a definite pectination, which becomes almost imperceptible on the lower part ; the peduncles of the third pair longer and broader than those of the first, the rami also similar to those of the first pair, but much shorter, with two teeth only on the outer margin of the outer ramus, and the inner ramus rather broader than the outer.

Telson.—The length scarcely equal to the breadth, forming three-quarters of a circle, about a third of the length of the peduncles of the last uropods.

Length, in the position figured, and in a straight line from the front of the head to the extremity of the uropods, less than a fifth of an inch.

Locality.—Station 200, October 23, 1874 ; off Sibago, Philippines ; lat. $6^{\circ} 47'$ N., long. $122^{\circ} 28'$ E. ; daytime, 80 fathoms ; surface temperature, $85^{\circ}.5$. The specimen described, a male.

Hyperia luzoni, n. sp. (Pl. CLXVI., A.).

Head deeper than long ; first two segments of the peraeon dorsally coalesced ; the first three segments of the pleon almost squared at the postero-lateral angles.

Upper Antennæ.—The first joint of the peduncle longer than broad, the second joint very short, and the third still shorter ; the first joint of the flagellum tapering, nearly as long as the peduncle, showing in the interior the preparation for the yet undeveloped brush, at the apex carrying a few filaments ; the remaining joints twenty-five in number, not linear.

Lower Antennæ rather shorter than the upper. The third (first free) joint of the peduncle longer than the fourth and shorter than the fifth ; the flagellum of twenty-four short joints, the first the longest, showing preparation within for subdivision into three joints.

Mandibles with rather elongate trunk, the teeth of the molar tubercle not very much crowded together, the first joint of the palp elongate, shorter than the second, which curves outwards forming an angle with the first, while the scarcely longer, acutely tipped third joint is directed inwards so as to form another angle with the second.

Lower Lip.—The principal lobes narrow, finely ciliated; the mandibular processes also narrow.

First Maxillæ.—The outer plate of the usual triangular form, strongly ciliated, and with the usual seven or eight strong spines at the distal end; the palp broad, only a little longer than broad, with four little unequal teeth at the apex of the inner margin, the distal margin finely pectinate.

Second Maxillæ.—The plates as usual strongly ciliated, and tipped with one or two spines.

Maxillipeds.—The second joint elongate; the outer plates short, broad at the base, the inner margin carrying four spinules, of which there are two at or near the rounded apex.

First Gnathopods.—Side-plates small. The first joint not so long as the remainder of the limb, broader above than below, the front margin being very sinuous; the second joint not longer than broad; the third very little longer than the second, the hind margin scarcely projecting beyond the wrist, with one spine at the apex; the wrist wider but not longer than the hand, the front margin smooth, the hinder carrying three spines, and the apex, which projects very little beyond the hand, having two more which are smaller; the hand distally narrowed, with one spine on the convex front margin, and three little spinules on the straight faintly pectinate hind margin; the finger slender, bulbous at the base, very slightly curved, more than half the length of the hand.

Second Gnathopods longer than the first. The first joint slender, bent, scarcely broader above than below; the third joint longer than the second, with two spines at the scarcely projecting hinder apex; the wrist a little longer than the hand, its straight and smooth hind margin being a little produced, the produced apex and distal margin carrying five spines; the slender hand has two spines on the convex front margin, the straight hind margin smooth; the finger more than half the length of the hand.

First Peraopods.—The first joint with the narrow neck bent, the rest of the joint long and straight, not broad, with smooth margins; the second joint a little longer than broad; the third not shorter than the fourth, with one spinule near the apex of the hind margin; the fourth joint with a spinule near the middle and a spine near the apex of the hind margin; the fifth joint a little curved, longer than the fourth, the hind margin very faintly pectinate; the finger a little bulbous and bent at the base, then straight, with a setule on the inner margin, lying along the apex.

Second Peraopods very similar to the first, but longer; the fourth joint longer than the third, each with two spines on the hind margin; the fifth joint considerably longer than the fourth, with two little setules besides the microscopic pectination of the hind margin; the finger about half the length of the fifth joint, with no apical setule as far as could be perceived. (On one side of the animal the first pereopod was almost exactly like the second.)

Third Peræopods.—The first joint oval, with smooth edges; the second joint short; the third rather longer than the fourth; the fifth longer than the third; each of these four with one or two minute spinules on the front margin; the finger slender, curved, acute, a little more than half the length of the fifth joint.

Fourth Peræopods.—The first joint narrower than in the preceding pair, with one spine not far from the apex of the front margin.

Fifth Peræopods like the two preceding pairs, but having the fourth and fifth joints shorter; the first joint is rather wider than in the preceding pair.

Pleopods more slender than in *Hyperia sibaginis*, the rami with seven joints, in other respects very similar.

Uropods.—The peduncles of the first pair longer than the rami, reaching almost equally far back with the peduncles of the third pair; the outer ramus a little shorter than the inner, pectinate on the inner margin, the inner ramus pectinate on the outer margin, both rami narrowly lanceolate; peduncles of the second pair shorter than the inner ramus, scarcely longer than the outer; peduncles of the third pair set wide apart, a little longer than the rami; the rami about equal, not reaching so far back as the rami of the first pair, which they in general resemble.

Telson forming an oval truncate at the base, about three-quarters of the length of the peduncles of the third uropods.

Length, three-twentieths of an inch, exclusive of the antennæ.

Localities.—January 9, 1875; China Sea, off Luzon; lat. $16^{\circ} 35' N.$, long. $117^{\circ} 47' E.$; surface; surface temperature, $76^{\circ}.5$. One specimen, young male.

January 1875; Zebu Harbour, Philippines; surface. Two specimens from this locality appear also to belong to this species.

Hyperia luzoni, young (?).

Head deeper than long; first two segments of the peræon dorsally coalesced; postero-lateral angles of the first, second, and third segments of the pleon squared or a little acute.

Upper Antennæ two-jointed, placed rather high up and reaching about down to the lowest point of the deep head, the first joint a little longer than broad, the second between two and three times as long as the first, tapering, with one or two long filaments at about the middle of the inner margin, and a row of elia near the outer margin at its lower half.

Lower Antennæ much shorter than the upper, with a short basal joint, and a longer slightly tapering one, on the blunt end of which there is a cilium.

Mandibles without palp.

Maxillipeds.—The shaft narrow, shaped like a dice-box, the inner plate small,

ciliated, the outer plates short and broad, their inner edges for more than half the length closely conjoined, scarcely or not at all overlapping, then diverging so as to form a wide shallow cup, with its cavity furred.

First Gnathopods.—First joint much bulged near the base on the outer margin; the hand with two spines on the hind margin of the wrist, none on the front margin of the hand.

Second Gnathopods.—There is a single spine on the front margin of the hand.

In the *Peræopods* and general details this form closely resembles the larger form from the other side of the Pacific.

Pleopods with six joints on the outer and five on the inner ramus.

Uropods.—Peduncles of the first pair equal in length to the inner ramus, reaching a point intermediate between the ends of the peduncles of the second and third pairs; the inner ramus reaching a little beyond the outer, not quite so far as the outer ramus of the third pair; peduncles of the second pair intermediate in length between the longer inner and shorter outer ramus; peduncles of the third pair longer than the outer ramus, the inner ramus broken, probably longer than the outer.

Telson somewhat triangular but with the apex rounded, on a level with the end of the peduncles of the first uropods.

Length, a little over one-tenth of an inch.

Locality.—Station 296, November 9, 1875; South Pacific; lat. $38^{\circ} 6' S.$, long. $88^{\circ} 2' W.$; surface; surface temperature, $59^{\circ} 8.$ One specimen.

Hyperia promontorii, n. sp. (Pl. CLXVI., B.).

The coalesced first and second and the seventh segments of the peræon the longest, each of the first three segments of the pleon much longer than any of the peræon-segments, their postero-lateral angles rounded; the body and limbs dotted with a few colour-spots.

Upper Antennæ.—First joint of peduncle longer than broad, the two following joints together more than half the length of the first joint; the first joint of the flagellum as long as the peduncle, with a thick brush of filaments on the breast, and two or three separate groups of filaments on the narrowed apical part, one group of two being on the tubercular projection of the apex; the second joint little longer than its distal breadth, its upper margin like that of the first joint straight, its lower margin oblique, produced, distally forming two or three tubercular projections each with one or two filaments; the remaining joints, which are more than twelve in number, are elongate, linear, with cilia or minute setules here and there; the slightly produced tubercular apices of the first two joints are the characteristic feature.

Lower Antennæ.—Opening of the gland-cone tolerably conspicuous; third (first free) (ZOOL. CHALL. EXP.—PART LXVII.—1888.)

joint of the peduncle broader and a little longer than the fourth, fifth joint longer than the third; flagellum linear, of more than thirteen elongate joints, of which the first is a little bulbous at the base.

Epistome domed, broader than deep, on one side projecting unsymmetrically.

Upper Lip deeper than the epistome, unsymmetrically bilobed by an oblique apical emargination.

Mandibles and *Maxillæ* nearly as in *Hyperia sibaginis*; the palp of the first maxillæ longer in proportion to its breadth.

Maxillipeds.—The outer plates rather large, with four little spinules along the inner margin and two at the apex.

First Gnathopods.—The upper boundary of the side-plates could not be clearly distinguished in any part of the pereon, though here and there faint indications of it seemed to exist. The first joint as long as the following four together, most dilated at the middle, the front margin being a little bowed out at that part, gland-cells visible in the first joint as well in both gnathopods as in the pereopods; the second joint not longer than broad; the third joint longer than the second, forming a kind of pentagon with three spines on the distal border which projects behind the wrist, the apex adjoining the wrist being finely peetinate; the wrist much broader but not longer than the hand, with a spine at the apex of the convex front margin, two spines on the straight hind margin, one at its produced apex, and four of less size within that apex; the hand with two spines on the convex front margin at the narrowed distal part, the hind margin nearly straight, peetinate except near the base, the narrow apical margin finely peetinate; the finger slender, curved, more than half the length of the hand, its inner margin microscopically peetinate.

Second Gnathopods longer than the first; the first joint a little widened distally instead of at the centre, the wrist produced to the middle of the hand and exceeding it in length, the hand with a small and a large spine on the hind margin, the spines here as in the first gnathopods being minutely plumose. The first and second gnathopods are, as usual in this and some other genera, situated very close together, and are so arranged that until they are separated it is not possible to obtain a lateral view of the lower joints of both.

First Peraopods.—Branchial vesicles of ample size, a description which applies to all the five pairs. The first joint narrow at the neck and slightly bent, then widened, exceeding in width as well as in length the first joint of the gnathopods; the second joint longer than broad; the third joint shorter than the fourth, with the hind margin straight, carrying a small apical spine, the front margin very convex; the fourth joint a good deal shorter and wider than the fifth, the hind margin peetinate but not closely, carrying a spine at the apex and one higher up, the front margin convex; the distal margin finely peetinate, projecting behind the fifth joint; the fifth joint slender, curved,

with the hind margin closely pectinate; the finger slender, curved, about half the length of the fifth joint, the bulb at the base squared, the inner margin faintly pectinate for a short distance below this.

Second Peræopods closely resembling the first, the fifth joint rather shorter.

Third Peræopods.—The first joint scarcely longer than that of the preceding pair, but broader, oval, narrowest above, the margins smooth, except for two minute spinules on the upper part of the front, and a setule at its apex; the four following joints longer than in the preceding pair, the second rather broader, the third, fourth, and fifth, rather narrower; the fourth and fifth pectinate along the front margin and having a small inward-curving spine at the apex; the finger about a third of the length of the fifth joint, its shape and armature as in the preceding pair.

Fourth Peræopods differing little from the third, except that all the joints are a little longer and, except the first, a little broader; the first is rather narrower and has three little spines disposed along the front margin.

Fifth Peræopods slightly shorter than the third; the first joint narrowed above, with two small spines on the lower half of the front margin; the four following joints rather stouter than in the third peræopods, the fourth and fifth rather shorter.

Pleopods not differing very materially from those described for *Hyperia sibaginis*.

Uropods.—Peduncles of the first pair the longest, reaching back to a point midway between the ends of the peduncles of the second and third pairs, longer than the rami, the distal margin pectinate; the outer ramus shorter than the inner, the outer margin of the outer and the inner margin of the inner not toothed, the other two edges having the ciliated emargination as described for *Hyperia sibaginis*, the remainder of the border being pectinate with little teeth almost to the acute tip; second pair like the first, but with the peduncle considerably, and the rami a little, shorter; third pair with the peduncles shorter than those of the first, and longer than those of the second pair, the rami similar to those of the other pairs but shorter.

Telson scarcely if at all longer than broad, forming an inverted arch, the apex nearly acute; the length less than one-half, more than a third, of that of the peduncles of the third uropods.

Length, without the antennæ, a fifth of an inch.

Locality.—Station 141, December 17, 1873; off the Cape of Good Hope; lat. $34^{\circ} 41' S.$, long. $18^{\circ} 36' E.$; surface; surface temperature, $66^{\circ}.5$. Several specimens, that described and figured being a male.

Remark.—The specific name refers to the capture of the species in the neighbourhood of the Cape of Good Hope.

Hyperia dysschistus, n. sp. (Pl. CLXVII.).

In this compact little species, the sixth and seventh segments of the peraeon are distinct, but the first five segments, though more or less faintly marked, do not appear to be separated except in the vicinity of the side-plates; the body is large as compared with the limbs; postero-lateral angles of the first three pleon-segments squared.

Upper Antennæ.—In the male (no doubt not adult) specimen, the peduncle consists of one joint broader than long, the flagellum of one thick joint, twice as long as the peduncle, at first tapering rapidly, and at the end of the tapering portion carrying six or eight filaments, the apical part of the joint not slender or tapering, with an indication at the rounded end of a minute second joint. In the female these antennæ were much more slender, tapering from the base to the acute apex, the distal part of the flagellum-joint carrying a series of four setules, and its tip being furnished with two which are longer than those on the side.

Lower Antennæ in the male not so thick as the upper, with only two joints distinguishable, the second much longer than the first, thick, with a blunt apex; in the female much smaller, tapering to an almost acute apex, with two minute setules side by side upon it.

Epistome deeper and broader than the *Upper Lip*; the latter with a rather deep oblique distal incision, making it as usual unequally bilobed.

Mandibles of the usual character, the molar tubercle very large, the palp not so long as the trunk, with its three joints but faintly separated, a character showing that the specimen was not fully adult. The mandibles in the female resembled those of the male, except in being without the palp.

First Maxillæ.—The outer plate appeared as usual triangular when seen in connection with the surface of the palp, but the distal margin with its row of unequal spines was seen to be far from acute, when the surface of the plate was seen and the palp turned edgewise. It is not easy to say whether there is any substantial difference either in the spines themselves or in their arrangement in the different species. There would seem to be some specific variation in the armature of the palp, but it is all of a minute order difficult to describe and not always easy to observe; in the present species the palp has a single comparatively large spine-tooth at the inner apex, the distal margin being cut into very slender sharp teeth, the series of which is continued some little way down the convex outer margin.

Second Maxillæ.—The outer plate longer than the inner, though not so much so as might be inferred from the figure *mx.2*, where the inner plate is foreshortened; in the lithographing all the spinules are given of equal thickness, but two or three of the apical spinules on each of the plates are in reality more spine-like than the rest.

Maxillipeds.—The inner plate as seen in profile almost triangular, beset with long

setules, and having a spinule on the apex attended by one or two smaller ones just below it; the outer plates narrow, more than half the length of the joint on which they stand, having three or four little spinules on the inner margin, one at the apex, and one just below it on the outer margin.

Triturating Organs.—As observed in the female, these are ovate with about thirteen spines round one side, the largest spines standing a little apart from the rest, which are graduated, diminishing in size as they retire from the largest.

First Gnathopods.—The upper boundary of the side-plates could not be distinguished, nor is it very clear in any of the segments. The first joint scarcely so long as the four following together, widening immediately below the neck with a considerable bulge of the front margin, below which it retains a breadth greater than that of the following joints; the second broader than long, with a spine at the hinder apex; the third a little longer but not broader than the second, its distal margin projecting behind the wrist and carrying two spines; the wrist broader but shorter than the hand, with a spine at the apex of the convex front margin, two on the straight hind margin, and one on and two within the slightly produced apex, which projects behind the hand; the hand has a spine some way above the apex, planted a little within the convex front margin, the hind margin straight, pectinate, and the distal margin minutely pectinate; the finger curved, more than half the length of the hand, at least half of the inner margin pectinate.

Second Gnathopods.—Branchial vesicles as long as the first joint and at the middle broader. The first joint with the front margin nearly straight, the hinder convex; the second joint with one spine at the hinder apex; the third joint with six spines set about its distal border; the wrist longer than the hand, being more produced than in the first gnathopods, with one spine at the apex of the front margin, one near the apex of the hind margin, and one on and several within it; the hand and finger as in the first gnathopods.

First Peræopods.—Branchial vesicles like the preceding pair. First joint widening from a narrow bent neck, the front margin then being straight and the hinder convex; the second joint longer than broad; the third joint shorter than the fourth, with a small spine at the apex of the hind margin; the fourth joint shorter than the fifth, the front margin convex, the hinder straight, loosely pectinate, with a spine at the apex; the fifth joint rather more closely pectinate; the finger slender, curved, more than half the length of the fifth joint, loosely pectinate along nearly half the inner margin.

Second Peræopods scarcely differing from the first, but with the fifth joint rather shorter.

Third Peræopods.—Branchial vesicles similar to the preceding pairs. First joint a little dilated, especially below, the hind margin nearly straight, the front convex, produced lower than the hinder, having two little spines, one above, the other below, the middle, and the distal part pectinate; the third joint shorter than the fourth, each with

a few little remote setules, and the fourth slightly pectinate; the fifth joint slender, considerably longer than the fourth, the front margin closely pectinate, with three or four setules at the distal end; the finger slender, curved, not half the length of the fifth joint, with two little spinules on the front margin just below the bulb of the base.

Fourth Peræopods.—The branchial vesicles less elongated than in the preceding pair, directed forwards. The limb similar to that of the third peræopods, but with the joints longer, four spinules on the front margin of the first joint, the third joint subequal in length to the fourth, and the finger without the two spinules.

Fifth Peræopods similar to the fourth but shorter; the first joint with three little spines on the front margin, the joint larger than in the third peræopods, a little shorter than in the fourth; the fifth joint shorter than in the third peræopods.

Pleopods.—The coupling spines small and slender, with a lateral pair of hooks below the apical pair; the arms of the eleventh spine subequal, the margin of the joint above this spine being finely ciliated; the inner ramus with six joints, the outer with seven or with six; the first joint of the inner ramus narrow at the base, longer than the first joint of the outer ramus.

Uropods.—The peduncles of the first pair the longest, longer than the rami; the rami narrowly lanceolate, minutely pectinate on their adjacent margins, the longer inner ramus reaching back as far as the apices of the rami of the third pair; the peduncles of the second pair shorter than those of the third, longer than the rami, which are smaller than those of the first pair, otherwise similar; peduncles of the third pair much longer than the rami; the rami nearly equal, the inner nearly as long as the inner of the second pair, and the outer a little longer than the outer of that pair.

Telson rather more than half as long as the peduncles of the third uropods, of nearly equal length and breadth, in outline an inverted arch with the apex nearly acute, reaching as far as the apex of the peduncles of the second uropods.

Length, in the position figured, from the front of the head to the back of the second pleon-segment, scarcely more than one-tenth of an inch. One of the females with the marsupial plates fully developed was smaller than this.

Locality.—April 3, 1874; off Cape Howe, Australia; lat. $37^{\circ} 33'$ S., long. $149^{\circ} 54'$ E.; surface, night; surface temperature at midnight, $66^{\circ}.5$. Three specimens, one male, two females.

Remarks.—The species which seems to come nearest to this is that described and figured by Dana under the name “*Lestrigonus Fabricii?* Edwards,” in the U.S. Explor. Exped., vol. xiii. pt. ii. p. 985, pl. lxvii. figs. 10a-d. Dana states that the last four segments of the peræon in his species are distinct and the first three coalesced along the back. The account he gives of the antennæ shows that he had an adult male specimen; of this he gives the length as “one and a half lines,” whereas Milne-

Edwards says of his "*Lestrigonus Fabreii*," "long d'environ cinq lignes," a very considerable difference, seeing that he also was describing an adult male, besides that in Milne-Edwards' species only the first two segments of the peræon are eoaaleseed. From Dana's species from the Sooloo Sea the Challenger one is distinguished by the fifth peræopods, which are decidedly shorter than the fourth, whereas in Dana's species they are both figured and specially described as being longer; in our species, moreover, the postero-lateral angles of the first three pleon-segments are squared, not rounded. The immature male and the female of "*Lestrigonus bengalensis*," Giles, 1887, show the peculiarity of having the first five segments of the peræon indistinctly divided or dorsally quite eoaaleseed, but in that species the peduncles of the second uropods extend beyond those of the other two pairs, and the telson is figured as much wider than long.

Hyperia schizogeneios, n. sp. (Pl. CLXVIII.).

The Head much deeper than long, with a widely emarginate proeess, forming a sort of divided chin below the insertion of the lower antennæ; the peræon narrowing distally, but deeper throughout than the pleon, also much wider than the pleon, especially at the centre, the preponderance of the front over the hinder part of the animal giving it a top-heavy appearance; the first three or sometimes four segments of the peræon dorsally eoaaleseed; the postero-lateral angles of the first three segments of the pleon squared, or the first almost rounded. The young while still in the egg, without indication of limbs, show the same preponderance of the front over the hinder part of the animal as the adult.

The Eyes occupying the whole surface of the sides of the head.

Upper Antennæ.—In the largest male specimen the peduncle has the usual three joints, and the flagellum has the usual large tapering first joint, which is followed by about twenty-three short joints, several of which are nearly as broad as long, the linear stage not having been reached. In the female the peduncle consists of a single joint, followed by a strongly tapering flagellum, also consisting of a single joint, very much longer than the peduncle, with four long filaments or pairs of filaments in a series on the inner side of the upper and thicker part.

Lower Antennæ.—In the male the last joint of the peduncle the longest, the flagellum similar to that of the upper antennæ, except that the first joint is not bulky, though nearly as long as the last joint of the peduncle, followed by twenty-one short joints, the last tapering to a point. In the female the peduncle consists of a short broad joint, and the flagellum of one scarcely longer, strongly tapering to an acute apex.

The Mouth-Organs of the female are shown *in situ* at the lower right-hand corner of

the Plate. The centre of the figure is occupied by the *Maxillipeds*, the outermost organs; these have a wide base supporting a narrow stem, on which stand the two outer plates, each of which has on its inner margin three small spines, one on the apex and one on the outer margin just below it; flanking the maxillipeds and partially concealed by them are the *Second Maxillæ*; these in turn partially overlie the *First Maxillæ*, the curving palps of which nearly meet within and underneath the outer plates of the maxillipeds; the apices of these palps being turned edgewise to the spectator appear narrower than they really are; they have in fact a small spine at the inner angle and a finely dentieulate margin; the *Lower Lip* is shut out of view; the trunks of the mandibles are seen on either side of the bases of the first maxillæ, the outer margins bending rather sharply round and meeting just where the outer plates of the maxillipeds begin to separate; the distal emargination of the *Upper Lip* is also seen within the triangle formed by the separation of these plates. In the male the *Mandibles* have the usual three-jointed palp.

First Gnathopods.—The first joint as long as the four following together, dilated a little at about the middle of the front margin; the second joint not longer than broad; the third longer than the second, five-sided, with two slightly plumose spines on the straight distal margin, which projects behind the wrist and has the corner adjoining the wrist finely peetinate; the produced wrist as long as the hand, much wider, with one spine on the apex of the convex front, one on the straight hind margin, a larger one on its apex, and two smaller ones within the apex; the hand with one spine on the convex front margin some way above the apex, the hind margin peetinate; the finger curved, more than half the length of the hand, with much of the inner margin finely peetinate.

Second Gnathopods.—Branchial vesicles large, the upper part wide, the apical narrowed. First joint a little longer than in the preceding pair, the base a little wider than the part which follows and which is a little ridged on the inner surface; the joint is slightly widened below; the remaining joints are similar to those of the first gnathopods, but the second and third and the wrist are rather longer, the process of the wrist being more elongate, beset with six spines.

First Peraopods.—Branchial vesicles large, as are also the following pairs. In the figure *br.* four successive branchial vesicles are shown in their relative position overlapping one another. First joint bent at the narrow neck, then widening, rather longer than in the second gnathopods; second joint longer than broad; third a little longer than the second, narrow at the neck, then much widened, with one spine near the apex of the almost straight hind margin; fourth joint longer than the third, much broader than the fifth, with a spine above the middle and a larger one near the apex of the straight loosely peetinate hind margin; fifth joint longer than the fourth, slightly curved, with the hind margin pectinate; the finger about half the length of the fifth joint, slightly curved, with the inner margin near the base a little peetinate.

Second Peræopods like the first, but the first and fifth joints a little shorter. In all the limbs gland-eells can be seen in the first joint, but in the first and second peræopods they are much more conspious in the fourth than in the first joint.

Third Peræopods.—First joint more or less oval, the lower end the wider; the second joint a little longer than broad; the third shorter than the fourth, with a couple of minute setules on the front margin; the fourth joint shorter than the fifth, with the front margin peetinate; the fifth joint slender, very slightly curved, the front margin peetinate, and having a little apieal inward curving spine; the finger slender, curved, about half the length of the fifth joint, with two little spinules on the front margin just below the dilated base.

Fourth Peræopods resembling the third, but with all the joints longer, and seemingly without the two little spinules on the finger.

Fifth Peræopods like the two preceding pairs, not longer than the third, the first joint narrower, the terminal joints scarcely peetinate.

Pleopods.—Coupling spines small, with two pairs of retroverted teeth; the elef spine with the arms nearly equal, the longer one having, as is probably the case in the kindred species, a small dilatation near the apex, this dilatation being so placed as to antagonise with the other arm just below the dilated part of that arm; joints of each ramus six in number.

Uropods.—Peduneles of the first pair longer than the rami; the rami narrowly lanceolate, with the adjaceant margins peetinate, the longer inner ramus more strongly than the outer; peduneles of the second pair a little longer than the outer ramus, shorter than the inner, the rami nearly as long as those of the first pair, which they nearly resemble; peduncles of the third pair nearly as long as those of the first, longer than the rami, which are subequal, the adjaceant margins finely peetinate; in all the rami there is a scarcely pereetible peetination also of the outer margin.

Telson triangular, longer than broad, a little more than half the length of the peduneles of the third uropods.

Length, in the position figured, from front of head to extremity of uropods, just over one-tenth of an inch. Some of the specimens were much smaller.

Locality.—April 26, 1876; off St. Vineent, Cape Verde Islands; lat. $16^{\circ} 49'$ N., long. $25^{\circ} 14'$ W.; surface temperature, $73^{\circ}\cdot2$.

Remarks.—The specific name—meaning divided chin, and derived from the Greek, $\sigma\chi\iota\zeta\omega$, I cleave, and $\gamma\acute{e}\nu\epsilon\iota\omega$, a chin—refers to the emarginate lower border of the head, which is a very conspious feature in this species. There are many points of resemblance between this species and *Hyperia dysschistus* found at the other side of the world, but the general shape and proportions are distinct, and the descriptions will have shown that in many minute details the two species differ. There is, however, a single specimen,

labelled "Zebu Harbour, Philippines, January 1875," which seems to be so close to *Hyperia schizogeneios* as scarcely to admit of being placed in a separate species.' The features of difference which this specimen presents are that the head is less deep; the wrist of the first gnathopods has on the straight hind margin two spines, one on and three within the apex, and the straight hind margin of the hand is pretty strongly pectinate on the lower part; the third joint of the second gnathopods has four spines about the apex, the wrist has the produced part beset with eight spines, the hand has two on its front margin; in the first pereopods the fourth joint is rather conspicuously broad; the hinder corners of the first three pleon-segments are squared, but perhaps the actual angles a little more rounded than in the Atlantic specimen; the first two pairs of pleopods have seven joints to each ramus, the third pair has six; the telson is a little more elongate. In case further comparison should make it necessary to distinguish this form from the other, I should propose for it the name *Hyperia zebui*. The length of the specimen is just over one-tenth of an inch.

Hyperia gaudichaudii, Milne-Edwards (Pl. CLXIX.).

1840. *Hyperia Gaudichaudii*, Milne-Edwards, Hist. Nat. des Crustacés, t. iii. p. 77.
 1849. " " Nicolet, in Hist. fis. y pol. de Chile por Claudio Gay, Zool., t. iii.
 1862. *Lestrigonus Gaudichaudii*, Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 289, pl. xlvi.
 fig. 3.
 1887. *Hyperia Gaudichaudi*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 16.

A large stout species, the back, especially at the front part of the pleon, having an imbricated appearance; head shorter than its depth; pereon tumid, broader than the pleon; the first three pleon-segments with the postero-lateral angles acute, but the produced points quite minute; the specimens in spirits retaining a light or dark brown colour, but with the uropods pale or almost white, the back in general covered with innumerable specks of colouring darker than the ground-colour; one specimen curiously mottled with wavy dark markings. The liver tubes with a crenate outline; the heart narrow, strong-walled. The following description refers to a male specimen:—

Eyes occupying the sides of the head, dorsally separate, the dividing tract forming a small triangle at the hind margin, a large one above the upper antennæ, and a more or less narrow line between these triangular spaces.

Upper Antennæ.—First joint of the peduncle broader than long, the second and third successively narrower, and so short as to be transversely almost linear; first joint of the flagellum longer than the peduncle, broad, tapering, the breast carrying the usual brush of filaments; the second joint broader than long, the third not longer than broad, the following joints increasing in length, though not in regular gradation, slender, lightly ciliated.

Lower Antennæ.—The third (first free) joint of the peduncle stout, not longer than

broad, the second joint shorter and narrower, longer on one side than on the other, the third joint nearly as long as the first two together, the apieal margin on one side deeply emarginate ; the first joint of the flagellum abruptly narrower than the last of the peduncle, widest near the base, longer than any of the five following joints, which are rather stouter than those of the upper antennæ, similiarly ciliated. In a complete antenna the joints of the flagellum are more than twenty in number.

Upper Lip deeper than broad, unequally bilobed by a rather deep incision of the distal margin.

Mandibles with the trunk broad, especially at the base, narrower distally, the upper front angle forming a small rounded lobe looking like the basal joint of the palp ; below and just in front of this is another rounded angle, from which the margin descends to the small cutting plate, the edge of which is divided into ten little teeth ; the secondary plate of the left mandible is similar to the principal, and of nearly equal size ; behind these there is a strongly ciliated or spinulose tract ; the molar tuberele is prominent, with broad crown carrying the usual long rows of denticles and cilia ; the first joint of the palp is shorter but broader than the second, with the hind margin convex till near the apex, the apieal margin oblique ; the second joint is shorter than the third ; the third is long, tapering to an extremely fine point, the almost straight front margin having the adpressed cilia projecting conspicuously beyond it. The lobe of the trunk which gives a four-jointed appearance to the palp is not separated at the base from the body of the trunk.

Lower Lip short, the front lobes wide apart, smooth ; the mandibular processes broadly rounded, as large as the front lobes.

First Maxillæ.—No distinct inner plate ; the outer plate broad, strongly ciliated or spinulose, and distally carrying five unequal spines, none of which are long, though two are very stout ; the palp longer but scarcely broader than the adjoining plate, with a noticeable spine at the apex of the inner margin, the apical and the distal half of the very convex outer margin being scabrous.

Second Maxillæ.—Both plates with the usual armature of slender cilia-like spines, the outer plate the longer, with two stronger spines on its narrow truncate apex, the inner plate having one such spine on, and one a little below, the apex.

Maxillipeds.—Second joint broad at the base, with a central ridge of the inner surface leading up to the strongly spinulose inner plate, which rises above the distal margin of the joint, and has one strong apieal spine ; the outer plates small compared with the joint on which they stand, the inner margin of one plate (in the specimen examined) not armed exactly like that of the other, in each a few little spines and spinules on and near the inner margin and the narrow but obliquely truncate apex, below which there is a little furring of the outer margin.

First Gnathopods.—Side-plates here as in the following pairs with the upper boundary

distinctly marked; this pair deeper behind than in front. First joint of the limb, as in all the limbs of the pereon, broadly dilated, with a large space left free from muscles, the lower part of the front of the joint in the first four pairs and the corresponding hinder part in the last three being channelled; in the first gnathopods this joint is most dilated at a little distance from the base; the apex of the hind margin has three or four spines; the second joint broader than long, with six or seven spines round the hinder apex; the third joint rather longer than the second, with a dozen spines round the distal margin where it projects behind the wrist; the wrist widening distally, longer than the hand and much broader, with three spines on the front apex, one on the margin a little higher up, three or four groups on the hind margin, and others on the surfaces adjoining it, the distal margin which projects behind the hand being set with about a dozen spines; the hand having spines singly or in pairs at nine points of the slightly convex serrate front margin, others on both surfaces, the hind margin straight, pectinate, carrying five small spines; the finger little curved, finely pectinate nearly to the tip, more than half the length of the hand.

Second Gnathopods similar to the first but longer. Branchial vesicles of great size, fully as long as the first joint and much broader. The front margin of the first joint nearly symmetrically convex, so that the greatest breadth of the joint is near the middle; there are eighteen or more spines round the distal margin of the third joint, which projects behind the wrist as in the first pair, but is longer than there; the wrist is longer than in the first pair, narrower at the base but distally wider, and a little produced downwards, similarly armed, the distal margin in both cases having some fine pectination; the hand is a little longer and narrower, with fewer spines than in the first pair, otherwise similar, as is also the finger. The spines which have been mentioned have in most or all cases a delicate feathering on parts of two edges; the pectination is not uniform throughout, but for the most part consisting of two or three little points alternating with one that is larger.

First Peraopods.—Front margin of the side-plates more flattened than in the preceding pairs. Branchial vesicles large like the preceding and following pairs. The first joint rather longer than in the second gnathopods, of the same breadth, but broadest below the centre, and with the muscles running up nearer to the base; there are six or seven little spines distributed along the hind margin, and three at its apex; the second joint is a little longer than broad; the third is shorter than the fourth, with a scarcely perceptible pectination of the hind margin; the fourth is much shorter than the fifth, but somewhat wider, with three little distant spines on the hind margin, and some slight pectination about its apex, which is in no way produced, but projects behind the fifth joint; the fifth joint narrow, curved, its concave hind margin minutely pectinate, the pectination becoming a little stronger round the apex; the finger very short, not a quarter the length of the fifth joint, apparently quite smooth.

Second Peræopods.—Side-plates rather broader than the preceding pair, of somewhat pentagonal shape, but with all the angles rounded. The limb nearly as in the preceding pair, but the first joint more regularly oval, the third joint rather longer and the fourth rather shorter.

Third Peræopods rather shorter than the two preceding pairs. Side-plates broader than deep, rather deeper in front than behind. The first joint with convex front margin, the hind margin of the front surface almost straight till near the rounded apex, which projects behind the other margin and the following joint; some of the muscles almost reach the base of the joint; the following joints similar to those of the second peræopods, but without spines or pectination, the fourth joint less wide, the fifth joint shorter but fully as broad; the finger similar.

Fourth Peræopods.—The side-plates broader than the preceding pair, very much broader than deep. The branchial vesicles longer and broader than the first joint. The limb scarcely differing from the preceding, but the first joint rather broader and more oval, the third and fourth joints subequal in length, the fifth joint a little longer than in the third peræopods.

Fifth Peræopods like the fourth, but the side-plates less deep, the first joint rather larger and more oblong, the fifth joint shorter than in the third pair. The third, fourth, and fifth peræopods are as nearly as possible equal to one another, but shorter than the first and second.

Pleopods.—The cleft spine has the serrate arm much stouter than the other, which is also shorter and has a very small subapical dilatation; the first joint of the inner ramus, besides being ciliated above the cleft spine, has some five or six plumose setæ below it; the first joint of the outer ramus is also bordered with five or six plumose setæ; each ramus has from eighteen to twenty joints.

Uropods.—Peduncles of the first pair longer but narrower than those of the third, longer than the rami, the distal margin minutely pectinate; the rami set a little apart at the base, elongate lanceolate, the adjacent edges pectinate, near the base slightly emarginate and furred, the other edges smooth, the apices acute; the outer ramus a little shorter than the inner; the peduncles of the second pair a little shorter and narrower than those of the third, longer than the rami; the outer ramus shorter and much narrower than the inner, its inner margin pectinate, the inner ramus a little shorter than the rami of the first pair but much broader, the outer margin and lower part of the inner margin pectinate; this ramus scarcely reaches the middle of the rami of the third pair; peduncles of the third pair much longer than the rami, very broad except near the base, the lower part of the inner margin pectinate, its apex sharply squared; the rami subequal in length, the outer much the narrower, with its outer margin smooth, the inner pectinate; the inner ramus broadly lanceolate, with both edges pectinate.

Telson longer than broad, not half the length of the peduncles of the third uropods,

its greatest breadth not equaling their greatest breadth; the apex narrow, but rounded.

Length.—Some of the specimens were an inch in length, others much smaller; some were almost fully extended, others doubled up so that the tips of the uropods were just under the antennæ.

Locality.—Station 312, January 13, 1876; off Port Famine, Patagonia; lat. $53^{\circ} 37' 30''$ S., long. $70^{\circ} 56' 0''$ W.; depth, 10 to 15 fathoms; surface temperature, $47^{\circ} 8'$. More than thirty specimens.

Remarks.—Milne-Edwards gives a very brief description of his species, which he says “Habite les mers du Chili.” Spence Bate described it afresh and figured it under the name “*Lestrigonus Gaudichaudii*.” He says “It closely resembles *L.* [*Lestrigonus*] *exulans*, but may be at once recognised by the distinct armature on the propoda of the gnathopoda.” It has many points of resemblance also to *Tauria maerocephala*, Dana, a mysterious species, of which Dana’s description does not wholly agree with his figures, see U.S. Explor. Exped., pl. lxviii. fig. 2d. According to Bovallius, Arctic and Antarctic Hyperids, Spence Bate’s *Lestrigonus exulans* is a synonym of Montagu’s *Hyperia galba*, while Krøyer’s *Lestrigonus exulans* is a synonym of Milne-Edwards’ “*Hyperia Latreillii*.” Milne-Edwards only distinguishes *Hyperia gaudichaudii* from *Hyperia latreillii* by the antennæ, using characters which are now known not to be of specific value, but the figures given by Bovallius of *Hyperia latreillii* show that it must come extremely near specifically to *Hyperia gaudichaudii*, although the one is a northern, the other a southern, form.

Specimens belonging to the genus *Hyperia*, or to one of the closely related genera, were obtained at many localities, but there has not been time to examine them all; many of very small size, little or not at all over a tenth of an inch in length, have the characters of adult males or females, while many are almost certainly the young of larger species; whatever their age or size they have not been neglected as uninteresting, but simply because certain conditions of time and space to which this Report is subject have made it desirable to pass them over.

 1887. " Hansen, Malacostraca marina Groenlandiae occidentalis, p. 58.

For the original definition of *Metoëcus*, see Note on Krøyer, 1838 (p. 179). The name being preoccupied must yield to *Hyperoche*, for the definition of which see Note on Bovallius, 1887 (p. 588). In his Arctic and Antarctic Hyperids Bovallius adds the observation that :—

" *Hyperoche* is easily distinguished from *Hyperia*, its nearest relative, by the form of the carpal processes of the first two pairs of pereiopoda [First and Second Gnathopods] being compressed, knife-shaped, sharply serrated. Also the carpi of the third and fourth pair [First and Second Peræopods] are different in form, with serrated hinder edges, or dilated as in the genera *Parathemisto* and *Euthemisto*. The general habitus is very similar to that of *Hyperia*." Hansen considers that both "*Hyperoche Kroeyeri*," Bovallius, and "*Hyperoche Luetkeni*," Bovallius, should be made synonyms of *Hyperoche medusarum* (Krøyer). Sars unites Boeck's *Tauria abyssorum* with Krøyer's species, and it is probable enough that *Hyperoche prehensilis* (Bate and Westwood) is only a young male of that species; its chief distinction, the dilated fifth joint in the peræopods, is shown by Fritz Müller to be a character of the young. Bovallius gives "*Hyperoche Martinezi*" as the name of Fritz Müller's "*Hyperia Martinezii*," and in view of the wording of Bovallius' generic definition it may be noticed that in that species the fourth joint or earpus of the first peræopod is figured by Müller¹ with serrated hinder edge and dilated. These two characteristics are also combined in the first peræopods of the Challenger species, though they are not very strikingly developed. In *Hyperoche medusarum* (Krøyer) Hansen found the fourth joint prolonged downwards in a serrate process only on the first peræopods, and not also on the second.

Hyperoche eryptodaetylus, n. sp. (Pl. CLXX.).

The Head short, not specially deep; all the segments of the peræon distinct, the pleon deeper than the peræon, the postero-lateral angles of the first three segments produced in short sharp points. Liver-tubes very large; heart large and with strong walls,

¹ Für Darwin, trans., p. 77.

extending with almost undiminished breadth to near the end of the sixth peraeon-segment.

The Eyes occupying the sides of the head almost completely.

Upper Antennæ.—Peduncle with the first joint as broad as long, the two following joints short; first joint of the flagellum stout, tapering, longer than the peduncle, with a thick brush of not very long filaments, the second joint narrower than the apex of the first, a little longer than broad, with a couple of filaments, the third, fourth, and fifth joints successively longer and narrower; there were six other linear joints remaining, each of them rather longer than the fifth joint.

Lower Antennæ.—Third (first free) joint of peduncle rather broader than long, the fourth shorter and narrower than the third, the fifth nearly as long as the third and fourth together; the first joint of the flagellum nearly as long as the peduncle, abruptly narrower, a little bulbous at the base, then linear; part of the second joint remaining, the rest of the flagellum missing.

Upper Lip unequally bilobed by a small triangular distal emargination.

Mandibles.—The trunk long and narrow, with the palp fixed at the upper front corner, and the small cutting plate projecting from the lower front angle; the edge of the cutting plate divided into ten or eleven little teeth; the secondary plate of the left mandible having its edge divided into ten teeth, which are smaller than those on the larger principal plate; between the cutting plate and the straight part of the lower margin there is a convex piece thickly set with long bristles, and above this there is a slightly projecting molar tubercle having its lower front angle armed with a tuft of bristles; the palp longer than the trunk, the first joint broader but shorter than the second; the second is in a line with the first, narrowest at the middle; the third is as long as the two preceding together, tapers to a fine point, is set at an angle to the second, and has its outer surface covered with adpressed cilia. It should be noticed that the molar tubercle in these organs differs strikingly from that in *Hyperia* and *Euthemisto*.

Lower Lip.—The distal and inner margin flattened, strongly ciliated; the mandibular processes short, with rounded apices.

First Maxillæ.—Inner plate wanting; the outer plate broad, partially folded, the distal part set all round with spines, of which many are like fine bristles, while others are proper spines; the palp reaching much beyond the outer plate, the inner margin fringed with closely set cilia, the rounded distal margin finely pectinate; there are also many groups of pectinate markings on the adjoining surface; there is a longitudinal fold of the inner surface starting from the base, and there are two or three scattered spinules on the outer surface.

Second Maxillæ.—The inner plate much shorter and apically more obtuse than the outer, both of them having the distal part beset with numerous bristle-like spines.

Maxillipeds.—The joint which carries the plates is at the base broader than the

extreme length, narrowing distally, but with the distal margin still broad, convex in the centre; the inner plate small, not projecting beyond the base of the outer plates, the latter not very much shorter than the joint to which they are attached; on the straight, sparingly serrate inner margin there are half a dozen spinules, there is one spinule at the apex, and one in a little notch of the outer margin just below it.

The Triturating Organs appear to have a feeble armature.

First Gnathopods.—The first joint as long as the third, fourth, and fifth together, expanded, the front margin convex, channelled along the lower half as in the following limbs, having the gland-cells conspicuous and numerous; the second joint about as long as broad; the third joint with a short front margin and a long straight smooth hind margin, having two spines upon and two within the produced apex; the trunk of the wrist nearly as long as the hand, the produced hinder part not quite so long as the hand, having the hinder margin and adjacent surfaces finely furred and carrying some minute spinules at intervals, the apex acute, the front or inner margin divided into about twenty-four teeth, near which there are four or five setules; the long narrow hand has two or three setules on the slightly convex front margin, the hinder margin being divided into about twenty-eight teeth, near to which there are a few setules; the narrow apical border is, like that of the trunk of the wrist, microscopically pectinate; the finger is small, curved, having the inner margin just below the base pectinate with half a dozen little teeth.

Second Gnathopods very similar to the first. Branchial vesicles of great size, much broader than the first joint. The first joint longer but scarcely broader than in the preceding pair, the third joint rather shorter, the hand rather longer; the inner margin of the process of the wrist has twenty-eight teeth, the margin of the hand facing it has thirty-four; there is a minute setule at the tip of the finger. In these gnathopods, and apparently in the first also, the finger can be retracted into the hand for almost its whole length, if not for the whole length (see the enlargement of fig. *gn.2*).

First Peraopods.—Branchial vesicles like the following pairs very large. The first joint longer than in the second gnathopods but less wide, the front margin convex, the hinder nearly straight; the second joint longer than broad, wider below than above; the third joint rather long and almost smooth-edged; the fourth joint longer than the third, with the hinder edge finely pectinate, produced into a little point, the distal margin also finely pectinate, and this on the inner surfaces not lying parallel with the outer but running obliquely up towards the hind margin; the fifth joint slender, set on to the front of the distal end of the preceding joint, which therefore projects behind it; the hind margin is finely pectinate. The apex of the fifth joint and the finger broken off.

Second Peraopods.—The first joints like those of the first pair, but the pectination of the fourth joint seemed to be slighter. The rest of the limb missing.

Third Peraopods.—First joint not so long as in the preceding peraeopods, a little

wider, especially just below the neck ; the second joint a little, and the third considerably, larger than in the preceding pairs. The rest of the limb missing.

Fourth Peræopods.—The first three joints as in the preceding pair, but the first a little larger ; the fourth joint curved as in the other peræopods, and longer than the third joint. The two other joints missing.

Fifth Peræopods.—The first joint rather larger than in the preceding pair, the third and fourth joints not so long, the fourth with the apical margin finely pectinate ; the fifth joint curved, slender, tapering, longer than the fourth joint ; its margin pectinate ; the finger missing.

Pleopods.—Coupling spines moderately strong ; the cleft spine stout, the longer arm denticulate within, and slightly widened apically beyond the dilatation of the other arm ; the inner ramus with twelve joints, the outer with thirteen.

Uropods.—Peduncles of the first pair much narrower, and only a little longer, than those of the third, reaching back very little beyond those of the second, longer than the narrow elongate rami ; the outer ramus rather shorter than the inner, pectinate on the inner margin, the inner ramus reaching back not quite to the apex of the outer ramus of the third uropods, pectinate along the outer margin and the lower part of the inner ; near the bases these rami have little confronting emarginations ; peduncles of the second pair intermediate in breadth, a little longer than the longer inner ramus ; the outer ramus much the shorter and narrower, strongly pectinate on the inner margin, the inner ramus pectinate on both margins, more closely on the outer somewhat sinuous margin ; the peduncles of the third pair very broad, much longer than the rami, their pectinate inner edges overlapping as soon as they meet just below the telson ; the broad distal border also partially pectinate ; the outer ramus the longer, with straight outer margin, the inner convex, pectinate ; the inner ramus broadly lanceolate, with both margins pectinate.

Telson scarcely so long as broad, rather more than a third of the length of the peduncles of the third uropods, a bluntly pointed arch in outline.

Length, from the front of the head to the back of the second pleon-segment, about one-fifth of an inch.

Locality.—Station 141, December 17, 1873 ; near the Cape of Good Hope ; lat. $34^{\circ} 41' S.$, long. $18^{\circ} 36' E.$; surface ; surface temperature, $66^{\circ}.5$. One specimen, male.

Remarks.—The specific name, derived from the Greek *κρύπτω*, I conceal, and *δάκτυλος*, a finger, refers to the retractile terminal joint in the gnathopods. It is of course likely enough that this character, though first observed in the present species, may be common to all the species of the genus, since in other respects they are separated only by small distinctions.

Genus *Hyperiella*, Bovallius, 1887.

1887. *Hyperiella*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk. Akad. Handl., Bd. 11, No. 16, p. 19.
 1887. " Bovallius, Arctic and Antarctic Hyperids, Vega-Exped., Bd. iv. p. 565.

For the definition of this genus, see Note on Bovallius, 1887 (p. 589). In his work on the Arctic and Antarctic Hyperids, Bovallius adds the observation that "this genus is a link between *Hyperia* and *Euthemisto*, the form of the body and of the first two pairs of pereiopoda [First and Second Gnathopods] resembles *Hyperia*, but the elongated fifth pair [Third Peræopods] and the long urus [afterpart of pleon] verge to *Euthemisto*."

Bovallius includes the little *Hyperia pupa* of Costa, from the Mediterranean, doubtfully in this genus, but the large telson and short small third uropods scarcely reaching beyond the telson make such an inclusion altogether improbable; for a different suggestion, see Note on Costa, 1857 (p. 297). Bovallius includes Dana's *Lestrigonus fuscus*, from the Mid-Atlantic, in this genus apparently without hesitation, but though Dana describes and figures the third peræopods as a little longer than the fourth and fifth pairs, he draws the fifth joint as of about the same length in all the three pairs, although in the ascertained species of this genus that joint is strikingly more elongate in the third peræopods than in the two following pairs.

Hyperiella dilatata, n. sp. (Pl. CLXXI.).

Head deep and broad, not long; all the peræon-segments distinct, the peræon in dorsal view broadly oval, the distal end the narrower; the pleon abruptly more compressed than the peræon, the postero-lateral angles of the first three segments produced in short sharp points. The liver tubes large, the heart narrow. The description is taken from the female.

The Eyes occupying all the surface of the head with the exception of a small triangular space in front above the upper antennæ, and a small postero-dorsal triangle.

Upper Antennæ inserted rather below the centre of the front of the head; the first joint of the peduncle longer than broad, twice as long as the second, which is about twice as long as the third; the flagellum consisting of one long tapering joint, curving a little outwards, two and a half times as long as the peduncle, the lower half of the inner margin fringed with setules not closely set.

Lower Antennæ more slender than the upper, the flagellum of which they about equal in length; the terminal (or third free) joint of the peduncle cylindrical, rather longer than either of the preceding joints; the flagellum of one straight tapering joint, more than once and a half as long as the peduncle, having a few small cilia or microscopic setules on various parts.

Upper Lip unsymmetrically bilobed, apparently with the surface very minutely furred near the small distal emargination.

Mandibles with a rather short trunk, the cutting edge small, divided into ten little teeth; the secondary plate of the left mandible (figured on the right hand of the Plate) much narrower than the principal, and apparently with fewer teeth; the molar tubercle broad and prominent, having on one edge of the crown a series of about twenty-one little spine-like teeth standing apart from one another, on the other edge a row of broad denticles, and several rows of minute denticles on the face of the crown; the palp is narrow, longer than the trunk, the first joint more than half the length of the second, which curves a little outwards, the third tapering, rather longer than the second.

Lower Lip.—The forward lobes not broad, wide apart, the rounded distal margins strongly ciliated; the mandibular processes rounded, divergent.

First Maxillæ.—Outer plate short and broad, distally folded, beset with strong bristles, and distally carrying five stout spines, two of which are of rather conspicuous size; the palp broad, reaching beyond the outer plate, having a longitudinal fold or ridge rising from the base, the inner margin closely fringed with spinules till within a little of the toothed apex, just within which the distal margin has a stout little double pointed spine-tooth, beyond this being cut into about a dozen little denticles; several little spines or prickles are set on the surface, a little below the distal margin.

Second Maxillæ.—The outer plate longer than the joint on which it stands, apically pointed but not acutely, thickly set with bristles and spines, the two of the latter at the apex being tolerably strong; the inner plate much shorter, not very dissimilar.

Maxillipeds short; the inner plate very inconspicuous when the maxillipeds are viewed from the outer surface; the principal joint has on this outer surface just within the distal margin a fan-like arrangement of five large spines, the distal half of each finely feathered, the central spine the longest; the outer plates are not much shorter than the joint on which they stand, the inner margin almost smooth for more than half its length from the base, then serrate and fringed with a number of little spinules of different sizes; the apex has a spinule and there are two or three minute ones on the outer margin just below the apex.

First Gnathopods.—Side-plates deeper than broad, the upper boundary pretty distinctly marked in this and the following pairs. The first joint about as long as the third, fourth, and fifth joints together, of nearly uniform breadth throughout, channelled along the lower three-fourths of the front margin; there are two spines at the apex of the hind margin; the second joint not longer than broad, with three spines at the hinder apex; the third joint widening distally and a little produced, projecting behind the wrist, the produced apical border beset with several strong spines, the hind margin smooth except for a little pectination at the apex; the wrist widening distally so as to be there much broader than the hand, the front margin smooth, with two apical spines, the

hind margin having a couple of spines at two successive points and a little pectination, the slightly produced and strongly projecting apex being beset with at least six spines; the hand slightly curved, about as long as the wrist, the convex and serrate front margin carrying a series of five spines, the surfacees having four apiece, the hind and distal margins being finely pectinate; the finger slender, curved, more than half the length of the hand, its inner margin for some distance from just below the base being pectinate.

Second Gnathopods.—Branchial vesicles not quite so long or so broad as the first joint, widening gradually to the distal end. The marsupial plates broader and rather longer than the branchial vesicles. The first joint longer and broader than in the preceding pair, not channelled in front, having three spines at the apex of the hind margin, and some prickles on the rounded front apex. The second joint as in the first pair, but the third joint considerably more elongated, with at least nine spines round the produced distal margin behind; the wrist with the hinder process reaching beyond the middle of the hand, the front or inner margin of the somewhat folded process having several spines, the apex of the front margin carrying three; the hand is more elongate than in the first pair, the front margin having a single spine near the base, then two pairs, and a single spine at the apex, this margin being as in the first pair furred rather than pectinate, while the hinder and apical margins and part of the inner margin of the finger are definitely pectinate; finger more than half the length of the hand.

First Peræopods.—Branchial vesicles and marsupial plates like those of the second gnathopods but larger. First joint longer but not broader than in the second gnathopods, narrow at the neck, the front margin nearly straight, the hinder carrying six small spines at irregular intervals; the second joint distally widened, longer than broad, with two small spines on the hind margin, and one on its slightly produced acute apex; the third joint much shorter than the fourth, distally widened, the hind margin straight, carrying three little spinules, and near the acute apex a strong spine. The fourth joint shorter but broader than the fifth, with a spinule or two on the convex front margin, the straight hind margin pectinate, carrying three spines and a stronger one at the apex, the distal margin a little pectinate, and on the inner surface curving upwards behind. The fifth joint elongate, slightly curved, the hind margin pectinate, the surfacee armed with four small spines, the distal margin pectinate; the finger slender, not half the length of the fifth joint, pectinate with seven little teeth on the inner margin near the base.

Second Peræopods.—Branchial vesicles distally much more widened than the preceding pair; marsupial plates like the preceding pair. The limb not materially differing from the preceding, but without the surface spines on the fifth joint.

Third Peræopods.—The branchial vesicles wider above than below. The marsupial plates smaller than in the preceding pair. The first joint widened a little below, the hind margin nearly straight, channelled, the front rather convex, apically acute; the second joint longer than broad, distally widened, apically acute, and slightly pro-

duced; the third joint much shorter than the fourth, having a small setule here and there; the fourth joint very much shorter but wider than the fifth, the front and apieal margins pectinate; the fifth joint like the fourth slightly curved, very long, the front margin pectinate; the finger little more than a quarter as long as the fifth joint, pectinate with seven or eight little teeth on the inner margin near the base. In a second specimen the fourth joint showed a tolerably conspicuous spine at the apex of the front margin.

Fourth Peraopods.—Branchial vesicles broader near the base than the preceding pair. The first joint shorter, scarcely dilated distally, with a spine at the acute apex of the front margin, and another a little higher up; the second and third joints resemble those of the preceding pair, with the front apex even more strongly produced; the fourth joint is shorter than in that pair, and the fifth joint only about half the length, so that it is only a little longer than the fourth joint of its own pair; the finger is short, curved, not pectinate.

Fifth Peraopods.—The side-plates very shallow. The limb like the preceding pair, but with the first joint rather shorter, having but one spine on the front margin at the apex; the fourth joint is also shorter, so that it is very little longer than the third.

Pleopods.—The coupling spines blunt-headed, with two pairs of retroverted teeth below the apieal pair; the cleft spine short and stout, the two arms nearly equal, the longer undilated arm showing two serrulate edges; each ramus having ten joints. In a second specimen the rami had only nine joints apiece.

Uropods.—The first and second pairs missing, the third pair with very long peduncles, of which the inner margin is apieally produced into a short sharp point; the inner ramus not half the length of the peduncle, rather narrowly lanceolate, serrate on both margins. In the dorsal view of the whole specimen, at the top of the Plate, the peduncles of the third uropods are foreshortened, and for that reason do not appear to be twice the length of the rami. A second specimen already referred to shows that the relative dimensions are variable; peduncles of the first pair narrower than those of the third, and not longer, the rami long and slender, the outer the shorter, denticulate and finely pectinate on the inner margin, the inner as long as the peduncle, pectinate on both margins, denticulate on the inner and on the lower part of the outer; peduncles of the second pair shorter than those of the first, the rami bearing the same proportion to the peduncle and being armed as in the first pair; the rami of the third pair subequal, more than half the length of the peduncle, ornamented as in the other two pairs. In a very small specimen the rami of the third pair are quite as long as the peduncles.

Telson triangular, longer than broad, less than half, but more than a third of the length of the peduncles of the third uropods.

Length.—The specimen of which the full figure is given measured a quarter of an inch from the front of the head to the extremity of the uropods.

Locality.—February 21, 1874; Antaretie Ocean; lat. $63^{\circ} 30'$ S., long. $88^{\circ} 57'$ E.; surface; surface temperature, $32^{\circ}\cdot 5$. Three specimens, one very small; and on the same date, surface to 100 fathoms, four specimens, of which three are very small.

Remarks.—The specific name refers to the greatly dilated peraeon. *Hyperiella antarctica*, Bovallius, 8 to 12 mm. in length, from “Antarctic Seas around Cape Horn,” differs from the present species in several small particulars, but very obviously in having the postero-lateral angles of the first three pleon-segments rounded instead of acutely produced.

 1887. „ Hansen, Malacostraca marina Groenlandiae occidentalis, p. 59.

For the original definition of the genus *Themisto*, see Note on Guérin, 1828 (p. 133). Bovallius in 1887, finding that the name *Themisto* was preoccupied, changed it into *Euthemisto*, for which he gives the following definition :¹—

"This genus differs from *Hyperia* by the narrow, gauge-shaped carpal process of the second pair of pereiopoda [*Second Gnathopods*] ; the carpus of the first pair being broad but not produced. From *Parathemisto* it differs by the strong development of the fifth pair [*Third Peræopods*] ; this latter characteristic however is not of any higher value, as there are transitions between the two genera."

It may be added that *Euthemisto* is distinguished from *Hyperia*, *Hyperoche*, and *Hyperiella* by the stronger development of the inner plate of the maxillipeds.

Euthemisto bispinosa (Boeck).

- 1887. *Euthemisto compressa* (*pars*), Hansen, Malacostraca marina Groenlandiæ occidentalis, p. 59.

In large specimens there is a bulge of the frontal margin on either side just below the rostral point ; the back is carinate along both the peræon and pleon, developing a dorsal tooth produced backwards from the centre of the hind margin in each of the last two or three segments of the peræon, and the first three or four of the pleon, in large specimens the tooth being very prominent in the last two segments of the peræon and the first two of the pleon ; the smaller the specimen the less important is the size of the teeth.

In Boeck's very brief account of the species it is stated that the last three pairs of peræopods have the first joint very narrow, not dilated, and of the third peræopods in particular it is said that the first joint is only slightly dilated, with a convex front and straight hind margin, and that the limb itself is little longer than in the following pairs. In the Challenger specimens, if they be rightly referred to this species, the third peræopods are very considerably longer than the fourth or fifth, in agreement with Boeck's figure ; the first joint is of the shape usual in the genus, being channelled behind.

Bovallius says of this species, "it is characterized by the carinated, serrated dorsal side, by the carpal process of the second pair of pereiopoda [*Second Gnathopods*] being shorter than the metacarpus, provided with a terminal spine, by the irregularly triangular carpi of the third and fourth pairs [*First and Second Peræopods*] being as long as the metacarpi [fifth joint], by the very short exterior rami of the uropoda, and by the small semicircular telson, not equalling a fifth of the length of the peduncles of the last pair of

¹ Arctic and Antarctic Hyperids, p. 568.

uropoda." He gives the length as 15 to 30 mm., and the habitat as Greenland, Spitzbergen. The telson, though very small, is as long as the breadth at the base, and is therefore nearer to half an oval than to half a circle, alike in Bovallius' figure and in the Challenger specimens.

Hansen considers that *Themisto compressa*, Goës, and *Themisto bispinosa*, Boeck, are the same species, the former grounded on the young, the latter on the adult. In specimens 7 mm. long, he has found, he says, the last three peræopods of equal length, and though in the third pair the fifth joint was longer than in the two following pairs, the fourth joint was somewhat shorter. In some specimens 8 to 9 mm. long he found the differences between these limbs extremely small, and in larger specimens he found all sorts of gradations in the differences of length. It must, however, be remarked that Goës clearly had the adult before him as well as the young, for he says, " *T. compressa* n., earinata, segmentum septimum sœpe etiam sextum et octavum margine postico in spinulam productum dorsalem in juvenibus exiguum, in adultis facile conspicuum; antennæ ♂ flagello multiarticulato, tenuissimo, valde elongato ut in Hyperis omnino." In Goës' figure the fifth peræopod is actually longer than the third or fourth. The Challenger specimens are numerous and of many different sizes, from one-quarter to three-quarters of an inch in length, and in the development of the dorsal teeth they vary greatly, but though many were examined especially with a view to this question, none of them in the least agreed with the figure given by Goës of the last three peræopods of his *Themisto compressa*; but the small specimens just as well as the large showed a very marked superiority of size in the third peræopods over the fourth and fifth. I do not, therefore, in the present state of the evidence, feel justified in accepting Professor Hansen's view that *Parathemisto compressa* (Goës) is the same species as *Euthemisto bispinosa* (Boeck).

Length, as above stated, varying from about one-quarter to three-quarters of an inch.

Localities.—Station 50, May 21, 1873; off Halifax, Nova Scotia; lat. $42^{\circ} 8'$ N., long. $63^{\circ} 39'$ W.; surface; surface temperature, 45° . Numerous specimens.

Station 46, May 6, 1873; off Nova Scotia; lat. $40^{\circ} 17'$ N., long. $66^{\circ} 48'$ W.; surface; surface temperature, 40° . Two specimens.

Remarks.—In one of the two specimens from the second locality, there is on one side of the animal a dwindled third peræopod, and the companion limb has perhaps not attained its full size, since the fourth joint is considerably larger than in the following pairs, while the fifth joint is very little larger.

 p. 568.

Back little compressed, and not dorsally dentate. Second segment of the peraeon the shortest; the first three segments of the pleon with the lower margin slightly serrate, the postero-lateral angles produced very slightly into acute points.

Upper Antennæ.—First joint of the peduncle longer than broad, the two following joints very short; the flagellum much longer than the peduncle, tapering, having a serrate inner margin and about a dozen pairs of filaments on the inner side, the end narrow, curved.

Lower Antennæ.—Third (first free) joint of the peduncle not longer than broad, the fourth longer than the third, and the fifth than the fourth; the flagellum slender, tapering, longer than the peduncle, either consisting of one long joint, or with a long first joint followed by a few or several short joints.

Upper Lip about as broad as its depth, unsymmetrically bilobed, one side of the distal emargination more oblique than the other.

Mandibles.—The cutting plate with fourteen little teeth, of which the lowest is the largest, standing a little apart from the rest; the secondary plate of the left mandible has an extremely narrow neck, with a front edge about two-thirds the width of that of the principal plate, against which it is so closely applied that the twelve little teeth are not easy to count; the right mandible is without a secondary plate, and on the principal plate the lowest tooth and the lowest but one are larger than the rest; behind the cutting plates there is a large bunch of spines, some of which are almost hair-like; the molar tubercle is large and prominent, with the usual rows of denticles, the row on the inner margin of the crown containing more than twenty teeth stouter than those on the surface of the crown, and attended each by a setule; the palp is placed on a little raised base which sometimes looks like an incipient joint; the palp itself is long and slender, the first joint shorter than the third, the two together about as long as the second, which is more or less bent, more in large specimens than in small; the third joint is apically acute.

Lower Lip.—The principal lobes distally squared and strongly ciliated; the mandibular processes apically narrowed.

First Maxillæ.—The outer plate has the somewhat narrowed distal half enveloped in spines, some of which are long and hair-like, others moderately slender, and some at the apex stout, of various lengths, three of them conspicuously strong; the one-jointed palp is considerably larger than the adjoining plate, its outer margin convex, smooth till near the apex, then a little serrate, a series of teeth and spines passing round the distal margin, the inner corner of which is raised and truncate, occupied by a short broad spine-tooth; the nearly straight inner margin is serrate with numerous sharp teeth and bordered with spines and spinules.

Second Maxillæ.—The inner plate shorter and rather broader than the outer, both distally beset with numerous spines of various lengths and thicknesses, and each having at the apex one longer and stronger than the rest; another strong one is planted a little below the apex, this and the apical spine being longer on the outer than on the inner plate.

Maxillipeds.—The inner plate is three-sided, long and narrow, the inner sides armed each with an oblique row of slender spines, the apex truncate and having a small spine-tooth on each of its slightly projecting corners; the outer plates longer than the inner one, not very broad, the outer margin convex, the inner a little concave, except near the base, a little serrate, armed with several long spines besides numerous spinules; the apex not quite acute.

First Gnathopods.—The first joint about as long as the third, fourth, and fifth together, with spines round the hinder apex, a little channelled distally in front; the short second joint similarly armed; the third joint a little longer than the second, with straight hind margin, distal spines, and a moderately acute front apex resting on the wrist; the wrist longer and broader than the hand, the front margin slightly convex, smooth, with submarginal spines, the hind margin serrate, fringed with spines, not apically produced downwards, but projecting a little beyond the hand, the surfaces also carrying some spines; the hand with convex front margin, the front nearly straight, at the middle finely pectinate, strongly so at and near the apex; there are several spines on the surfaces, and one in general conspicuously projecting from near the middle of the front margin; the finger curved, a little more than half the length of the hand, the inner margin strongly pectinate for the first half, more finely for much of the remainder. The spines, at least as a rule, are finely pectinate.

Second Gnathopods.—First joint not widened above as in the first pair, but longer than in that pair, equal to the third, fourth, and fifth joints together; the first and second joints with spines round the apex behind; the third joint much longer than the second; its distal margin, which is much higher up in front than behind, is almost encircled with spines; the front apex resting on the wrist is a little produced; of the wrist the proximal part is rather longer than the hand, the produced distal part rather

shorter; this is fringed with spines along the margin facing the hand and at the apex, which is not quite acute; the hand is longer and straighter than in the first gnathopods, with fewer surface spines and perhaps less pectination; the finger is as in the preceding pair, but not more than half the length of the hand.

First Peraopods.—The first joint narrow above and widened below, with sinuous slightly serrate front margin, the hinder convex, carrying a few little spines; the second joint with some small spines on the hind margin; the third joint not longer than the second, but distally wider, with spines along the faintly pectinate hind margin; the fourth joint (or wrist) large, ovate, the front margin convex, smooth, with spines at the apex, the inner surface carrying some spines, the hind margin finely pectinate and fringed with numerous spines, this margin in large specimens being sinuous, since in such specimens the apical part of the joint is narrowed almost abruptly; the fifth joint as long as, or longer than, the fourth and folding against it, narrow, curved, with convex front margin, the hind margin concave, pectinate; the finger slender, smooth, curved at the tip, not half the length of the fifth joint.

Second Peraopods similar in general shape and armature to the first, but with all the joints except the second larger, the first joint longer and of more uniform breadth, the fourth much longer and broader, the fifth only a little longer, so that in this pair it is shorter than the fourth joint.

Third Peraopods.—The side-plates broad and shallow. The first joint channelled behind, in front somewhat bowed out near the middle, with several spines along the front margin, of which the upper part is smooth; the second joint short, almost smooth; the third joint widening distally, as long as the distal breadth, with some spines along the front, and at the apex of the hind margin; the fourth joint considerably longer than the first, distally narrowed, with numerous spines along the serrate front margin, and some also along the hind margin; the fifth joint is much longer and narrower than the fourth, with a bulbous base; the front margin has a few spines, but is chiefly distinguished by the pectination, which near the base is faint, but grows stronger and stronger as it approaches the apex; the finger short and slender, a little curved.

Fourth Peraopods much shorter than the third, the inequality depending on the first, fourth, and fifth joints; the first joint channelled behind, with spines along the lower half of the sinuous front margin; the second joint short; the third as long as in the preceding pair, similarly armed, much narrower; fourth joint rather shorter than the first, with spines along both margins, numerous on the faintly pectinate front, and slender feathered spines along the inner surface; the fifth joint slightly curved, narrower than the fourth, rather longer than the first, with spines along the slightly convex and serrate hind margin, others along the pectinate front margin, with slender spines on the adjacent surfaces; the finger slender, smooth, almost straight, not a quarter the length of the fifth joint.

Fifth Peræopods similar to the fourth, the first joint perhaps a little longer, with some spines on the lower part of the inner hind margin; the third joint narrower, with some spines on its inner surface; the fourth joint shorter and narrower than in the preceding pair; the fifth joint slightly shorter than in the preceding pair, with the hind margin smooth, and the front having a very faint pectination, which, instead of becoming stronger towards the apex, is entirely absent from the lower part of the joint.

Pleopods.—The cleft spine placed at the middle of the long first joint, with the serrate arm a little longer than that which bears the narrow subapical dilatation; the first joint of the outer ramus having a tongue-like interlocking process, and carrying three or four setæ on a bulge of the outer margin near the centre; the joints of the inner ramus numbering from thirteen to fourteen, of the outer from fourteen to fifteen.

Uropods.—Peduncles of the first pair longer than the rami, which are rather long and narrow, the outer shorter and narrower than the inner; the adjacent margins of the two rami in all three pairs finely pectinate; the peduncles of the second pair rather shorter but broader than those of the first, the inner apex acute; the outer ramus shorter and much narrower than the inner, shorter than the outer ramus of the first pair, the inner ramus a little shorter than the peduncle, with which it appears to be almost coalesced, a little shorter but broader than the inner ramus of the first pair; peduncles of the third pair the broadest and longest, the rami respectively broader than those of the first pair, and nearly as long.

Telson small, triangular, the breadth at the base equalling the length.

Length of the two largest specimens, three-fifths of an inch.

Localities.—January 23, 1874; off the north-east coast of Kerguelen Island; surface; surface temperature, 40°·5. A large number of specimens, most of them not full grown.

Station 302, December 28, 1875; off Patagonia; lat. 42° 43' S., long. 82° 11' W.; surface; surface temperature, 55°. Six specimens, not adult.

Station 314, January 21, 1876, Cape Virgins to Falkland Islands; lat. 51° 35' S., long. 65° 39' W.; surface; surface temperature, 48°. Numerous specimens, not adult.

Remarks.—In the first instance I regarded the Kerguelen specimens, one of which is figured on Pl. CLXXII., as distinct from the South American, one of which from Station 302 is figured on Pl. CLXXIII.; but the differences appear to depend upon the age of the specimens, in the young ones the process of the wrist of the second gnathopods being less outdrawn than in the adults, and similarly the fourth joint in the first and second peræopods being much less widened, the fifth joint of the third pcræopods less elongate, and the back of the animal less compressed. The type-specimen described and figured by Guérin was taken by M. Gaudichaud at the Falkland Isles. Bovallius, Arctic and Antarctic Hyperids, p. 568, says of this species, that "it is characterized by the carpal process of the second pair of pereiopoda [Second Gnathopods] being provided with long

hairs, without terminal spine, by the exterior and interior rami of the uropoda being equal in length, and by the minute, triangular telson." He gives the length as "26 mm.," as though he had seen and examined a specimen, since Guérin's measurement is "long de neuf lignes." The hairy wrists of the second gnathopods and the equal rami of the uropods agree with Guérin's figures, but Guérin makes no mention of these characters in his text, and the figures by themselves certainly cannot be trusted. If all the particulars of Guérin's account were to be accepted, his species would be unique, since he gives four joints to the mandibular palp, only five joints apiece to the gnathopods and peræopods, and can find no joints at all in the maxillipeds. Whether the southern specimens here described belong to Guérin's species or not, they certainly bear a very striking resemblance to the northern species, *Euthemisto libellula* (Mandt), in some of its stages of growth.

Euthemisto thomsoni, n. n. (Pls. CLXXIV., CLXXV.).

1879. *Themisto antarctica*, Thomson, Trans. New Zealand Inst., vol. xi. p. 243, pl. xii. figs. 2, 3
(*non* Dana).

1886. " " " Thomson and Chilton, Trans. New Zealand Inst., vol. xviii. p. 151.

Peræon and *Pleon* carinate, the last three segments of the peræon and the first three of the pleon having the hind margin produced into a strong dorsal tooth; the peræon broad at the centre, especially in the female; the first three segments of the pleon laterally ridged, with the postero-lateral angles produced into small acute points.

Upper Antennæ.—First joint of the peduncle longer than broad, the two following very short; the flagellum in the female consisting of a single joint, long, tapering, sharply curved at the tip, with small spines and setules round the convex margin, the concave margin rather deeply serrate till near the apex, a fringe of slender filaments projecting from a parallel inner margin; in the male the flagellum terminates in several slender joints.

Lower Antennæ.—Third (first free) joint of the peduncle little longer than broad, fourth considerably longer than the third, fifth longer than the two together; flagellum in the female consisting of one slender, tapering joint, considerably longer than the peduncle; in the male the flagellum has a long first joint followed by several short ones.

The Mouth-Organs agree so closely in all their main features with those described for *Euthemisto gaudichaudii* that it is unnecessary to do more than refer to the figures on Plate CLXXV.

First Gnathopods closely agreeing with those of *Euthemisto gaudichaudii*.

Second Gnathopods differing little from those of *Euthemisto gaudichaudii*, unless in having the process of the wrist longer, reaching nearly to the extremity of the hand.

First Peræopods.—The armature and general structure of both the first and second peræopods are similar to those in *Euthemisto gaudichaudii*, but in the particular specimen

figured the fourth joint is a long oval, more than twice as long as broad, thus in the adult making an approach to the shape which the joint has in the young; the fifth joint as long as the fourth, with pectinate hind margin; the finger smooth, gently curved, not half the length of the fifth joint.

Second Peræopods similar to the first; the first, third, and fourth joints rather longer, the fourth also a little broader; the fifth joint scarcely so long as the fourth.

Third Peræopods.—The first joint about equal in length to the first in the following pair, with spines along the front margin of the somewhat widened lower part; the second joint short, with minute spinules in front; the third joint nearly twice as long as the distal width, with spines along the front margin, at the apex of the hind margin, and one as in the other species higher up that margin; the fourth joint longer than the first, more than twice the length of the third, narrowing a little distally, with spines along both margins, but most along the front; the fifth joint in the specimen figured as long as the third and fourth together, much narrower than the fourth, a little bulbous at the base, gently curved, with a few spines on the upper half of the convex hind margin, the concave front margin fringed with spines and finely pectinate, not more strongly near the apex than higher up, though with three or four strong teeth at the apex; the finger short, curved, smooth. The fifth joint in other specimens is straight, longer than the third and fourth joints together, with pectination increasing towards the apex, agreeing in shape with this joint in the other species, yet apparently not attaining the same proportionate length (see fig. prp.3.A).

Fourth Peræopods differing little from the third; the third joint narrower, but if anything rather longer; the fourth joint about four-fifths of the length of that in the preceding pair, not dilated at the upper part, with spines along each of the serrate margins and on the inner surface; the fifth joint not a great deal shorter than in the preceding pair, rather broader, with spines on the edges and the inner surface, the front margin finely pectinate; the finger as in the third peræopods.

Fifth Peræopods similar to the fourth, but with the first joint rather longer, the inner of the two hind margins having spines on the lower part; the fifth joint rather longer than in the fourth pair, with spines on the surface, but the hind margin not serrate or spined and the front not pectinate.

Pleopods.—The cleft spine as in *Euthemisto gaudichaudii* both in form and position, and as in that species the first joint of the inner ramus has two plumose setæ at the distal end of the inner margin; in the pleopod examined the joints of the inner ramus were sixteen in number, of the outer seventeen.

Uropods.—The peduncles of the first pair narrower than those of the second and scarcely so long, rather longer than the long and narrow inner ramus; the outer ramus also narrow, rather more than half the length of the inner; in all the pairs the adjacent edges of the two rami are finely pectinate; peduncles of the second pair as broad as

those of the third, distally a little broader, with the inner apex acutely produced; the inner ramus broadly lanceolate, almost as long as the peduncle, longer than any of the other rami; the outer ramus much narrower and shorter, longer than the outer ramus of either of the other pairs; peduncles of the third pair longer than those of the second; the rami respectively a little smaller than those of the second pair.

Telson triangular, a little longer than the breadth at the base, not a quarter the length of the peduncles of the third uropods, the apex slightly rounded.

Length of the specimen figured, more than nine-tenths of an inch.

Localities.—Station 146, December 29, 1873; between Marion Island and the Crozet Islands; lat. $46^{\circ} 46'$ S., long. $45^{\circ} 31'$ E.; surface, daytime; surface temperature, 43° . Two specimens about nine-tenths of an inch long, three about six-tenths of an inch, seven or eight a quarter of an inch or less.

Station 147A, January 1, 1874; off Crozet Islands; lat. $46^{\circ} 45'$ S., long. $50^{\circ} 42'$ E.; surface; surface temperature, 42° . One specimen.

Station 158, March 7, 1874; in the Southern Ocean; lat. $50^{\circ} 1'$ S., long. $123^{\circ} 4'$ E.; surface; surface temperature, 45° . Three specimens.

March 9 and 10, 1874; south of Australia; lat. $48^{\circ} 18'$ S., long. $130^{\circ} 4'$ E.; surface; surface temperature, 50° . Six specimens.

Remarks.—The species appears to stand extremely near to the northern *Euthemisto bispinosa* (Boeck). The peculiarities of the fourth joint in the first and second peraeopods and of the fifth joint of the third peraeopods in the specimen figured from Station 146 are, I think, only individual peculiarities. They led me to suppose that the species belonged to the genus *Parathemisto* (see Note on G. M. Thomson, 1879, p. 500). In Dana's *Themisto antarctica*, to which Mr. Thomson assigns the species, the back is not dentate, and the third peraeopods are, as in other species of this genus, very strikingly longer than the fourth and fifth. The present species therefore seems to me to be distinct, and as the name *antarctica* is preoccupied, I have renamed it in compliment to Mr. G. M. Thomson.

Numerous small specimens, labelled "February 2, 1874, Antarctic Ocean, surface," and "February 3, 1874, between Kerguelen and Heard Island, surface," appear to belong to this species, the third peraeopods not being elongate, but the specimens are young,¹ with the backs rounded not dentate, the wrist process of the second gnathopods not very elongate.

One specimen, from Station 149B, January 17, 1874, lat. $49^{\circ} 28'$ S., long. $70^{\circ} 30'$ E., 25 fathoms, measuring seven-tenths of an inch, is distinguished from the rest by having the third peraeopods very long, the dorsal teeth proportionately to the length of the animal very small, and the head and body seaceous with a fine down. Should it be necessary to separate this specimen from the other, I would propose for it the name *Euthemisto scabra*.

¹ Compare Hansen's remarks on the young of *Themisto bispinosa*, quoted p. 1409.

Euthemisto australis, n. sp.

Back very slightly or not compressed; first three segments of the pleon large, with the postero-lateral angles produced into acute points and the lower margins serrulate.

Upper Antennæ.—First joint of the peduncle nearly as broad as long, the two following joints short; first joint of the flagellum broad and long, fringed with a brush of filaments, the second and third joints very short, followed by eight slender joints.

Lower Antennæ.—Gland-cone conspicuous, the three free joints of the peduncle as in the other species; the flagellum (in the male) of many long and slender joints, together sometimes nearly as long as the animal.

*Mouth-Organ*s so far as observed similar to those in the other species, but in the mandibular palp the second joint is about twice as long as the first and a very little longer than the third.

The Gnathopods agree closely with those of small specimens of *Euthemisto gaudichaudii* (see Pl. CLXXIII.).

First Peræopods.—The first joint narrow at the neck, which is a little bent, widened below, with two little spines on the lower part of the hind margin; the front margin channelled below; the second joint with two spines on the hind margin; the third joint widening distally, longer than the second joint, the hind margin nearly straight, very hairy, carrying three little spines; the fourth joint longer than the third, widening distally, the hind margin continuous with that of the preceding joint, and hairy like that, carrying four spines, not so long as the front margin which is smooth and a little convex, the inner surface having a row of five unequal spines, the distal margin sinuous, projecting behind the fifth joint, on the inner surface minutely pectinate; the fifth joint longer but much narrower than the fourth, the front margin convex, smooth except for a few little spinules, the hind margin straight, pectinate, and carrying six or seven spinules, the inner surface armed with eight unequal spines; the finger curved, smooth, scarcely half the length of the fifth joint.

Second Peræopods similar to the first, except in the first joint which is longer, and the fourth which is longer and scarcely so broad, forming a narrow oval, without the characteristic distal widening found in the preceding pair, so that below the lowest spine of the hind margin there is here a further tract of that margin, which in the preceding pair is bent so as to form part of the distal margin; the fifth joint not longer than the fourth, and not longer than the corresponding joint in the first peræopods.

Third Peræopods.—First joint narrow above, widened below, channelled behind, with the outer margin triflingly serrate, the sinuous front margin having some small spines; the second joint short; the third more than twice as long as the second, the straight front margin hairy, carrying some spinules, and at the apex a spine, and a smaller one within the apex, the hind margin produced into a subacute apex carrying a

spine; the fourth joint not wider than the third, about twice as long, nearly as long as the first joint, the front margin hairy, fringed with eight spines, the hinder margin having spines at the apex and two or three higher up; the fifth joint slender, longer than the fourth or the first, with a very slight curve, the front margin carrying five spines, and at first hairy, the hairiness passing into strong pectination towards the apex; the finger slender, smooth, distally a little curved, about a fourth the length of the fifth joint; in the specimen specially examined, the fifth joint in one of these limbs was not so long as in the other, so that the finger was more than a quarter of the length.

Fourth Peræopods not differing much from the third, the first joint about as long but rather less widened below, with four spines on the lower part of the front margin, the third joint as long but less widened distally, the fourth joint much shorter, scarcely once and a half the length of the third, with five unequal spines along the hairy front margin, the fifth joint nearly as long as the third and fourth together but shorter than in the preceding pair, with spines along the front margin, others more slender on the inner surface, and two or three on the hind margin, the front hairy near the base, but pectinate for almost the whole length; the finger nearly a third of the length of the fifth joint.

Fifth Peræopods similar to the fourth, the first joint a little longer, with three spines on the lower part of the front margin, the straight outer hind margin with only a single indent, the inner hind margin having as usual some spines near the apex; the third joint rather longer and narrower, the fourth rather shorter and narrower, than in the preceding pair; these two with little spinules at intervals along the otherwise smooth front margin, the fourth joint not one and a half as long as the third, with six unequal spines projecting from the inner surface; the fifth joint as long as or a little longer than the third and fourth together, the hind margin smooth, the front armed only with little spinules, but with five unequal spines projecting from the inner surface; the finger between a third and a fourth of the length of the fifth joint.

Pleopods.—Coupling spines with three pairs of retroverted teeth below the half-moon-shaped apex; cleft spine placed below the middle of the first joint of the inner ramus, the serrate arm the longer, the subapical dilatation of the other arm small; a single plumose seta on the outer margin of this joint in the third pair; two such setæ in the first and second pairs; the first joint of the outer ramus has three or four setæ on the bulging part of the outer margin; each ramus has eleven or twelve joints.

Uropods.—Peduncles of the first pair scarcely longer than the inner ramus, the outer ramus much shorter than the inner, the adjacent margins strongly pectinate, bulging near the base so as to overlap one another, but contracting a little below the base, the other margins smooth; the peduncles of the second pair broader but shorter than those of the first, not so long as the inner ramus, the apex of the inner margin acutely produced; the outer ramus little more than half the length and less than half the breadth of the broadly lanceolate inner ramus, the adjacent margins of the two rami strongly pectinate; peduncles

of the third pair broad except at the base, rather longer than those of the first pair, the apex of the inner margin acutely produced; the outer ramus about half the breadth of the inner, more than half its length, reaching back as far as the inner ramus of the first pair, its inner margin strongly pectinate; the inner ramus shorter than the inner ramus of the first or the second pair, both margins strongly pectinate except near the base.

Telson less than a third of the length of the peduncles of the third uropods, about as long as the breadth at the base, somewhat triangular, but the sides and apex much curved.

Length about a quarter of an inch.

Locality.—March 15, 1874; south-west of Melbourne; lat. $39^{\circ} 45' S.$, long. $140^{\circ} 40' E.$; surface; surface temperature, $60^{\circ} 2$. Several specimens.

Remarks.—The specific name refers to the southern locality at which the species was found. The shape of the fourth joint in the first peraeopods, the hairy margins in this and the three following pairs, and the pectination on both edges of the inner ramus of the third uropods are the distinguishing features of the species.

A specimen, not in very good order, from Station 162, April 2, 1874, off East Moneœur Island, Bass Strait, surface, appears to belong to this species. The first joint of the flagellum of the upper antennæ has a narrow apical prolongation, within which can be seen several small joints in preparation, and this is followed by six short joints.

Genus *Parathemisto*, Boeck, 1870.

For the original definition of the genus, see Note on Boeck, 1870 (p. 397). *Hyperia obliqua*, Krøyer, 1838, appears to be the earliest described species belonging to this genus, but according to Hansen, Malacostraca marina Groenlandiae occidentalis, p. 57, that species is itself involved in great obscurity, since Krøyer states that he had but a single specimen, and the single specimen in the Copenhagen Museum referred by Krøyer to this species is only, Hansen says, a small *Hyperia latreillei*. On the other hand, he thinks

that this is probably not Krøyer's original specimen, but that Krøyer was really describing a specimen of *Parathemisto*, as his figures indicate; in that case, however, he considers that there is little or nothing to separate *Parathemisto oblivia* (Krøyer) from the later *Parathemisto abyssorum*, Boeck, of which he has found several specimens from Greenland in Krøyer's collection. Under these circumstances it is reasonable that the specific name *oblivia* should be dropped on the ground of uncertainty and insufficient description. The next species claiming admission into the genus is *Hyperia trigona*, Dana, 1852, "length six to eight lines," coming "probably from the Lagulhas Bank, near Cape Horn." The Brit. Mus. Catal. Amph. Crust., p. 297, gives the measurement of this species as "Length $\frac{6}{20}$ ths of an inch = '6-8 lincs' (Dana)." Bovallius, Arctic and Antarctic Hyperids, p. 568, renames the species *Parathemisto trigona*, but gives the measurement as "Length 25-30 mm.," adding "Hab. Off Cape Horn (Dana)." For *Hyperia oblivia*, Spence Bate, 1857, Bovallius gives the name *Parathemisto longipes*. The species is rather obscure, but such as it is, it must bear the specific name *graeilipes*, proposed by Norman in 1869. The remaining species included in the genus are *Parathemisto compressa* (Goës), 1865, and *Parathemisto japonica*, Bovallius, 1887.

Parathemisto pacifica, n. sp.

The lower margins of the first three pleon-segments a little serrate and produced into small acute points; the hind margin bulging out beyond the postero-lateral angles.

Upper Antennæ.—First joint of the flagellum (in the male) as long as all three joints of the peduncle, with fourteen pairs of filaments along the convex margin, the apex narrowed; fourteen joints follow, of which the first is the shortest, a little longer than broad.

Lower Antennæ.—Last joint of the peduncle considerably longer than the preceding joint; first joint of the flagellum the longest, nearly as long as the last of the peduncle, but much more slender, a little bulbous at the base; sixteen slender joints follow in the specimen examined.

Upper Lip.—The distal emargination making one lobe half an oval, the other nearly square, yet with the end a little convex.

Mandibles.—The trunk compact, much shorter than the palp; the cutting edge with fourteen denticles, of which the lowest is the largest, a little apart from the rest; the secondary plate of the left mandible widens from a narrow neck, its broad distal edge having thirteen denticles which lie very near to those of the principal plate; behind the cutting plates there is the usual tuft of spines and the broad dentieulate molar tubercle; the first joint of the palp is straight, elongate, yet shorter than the third; the second joint is slightly bent, longer than the third.

Lower Lip.—The distal margin of the principal lobes flattened, strongly ciliated.

Maxillæ similar to those in the genus *Hyperia*.

Maxillipeds.—The inner plate tolerably clongate.

First Gnathopods.—First joint a little widened at the upper part; the second joint with slender spines about the hinder apex; the third joint not much longer than the second, with front apex acute, resting on the wrist, the hinder apex having three or four pectinate spines; the wrist longer than the hand, having pectinate spines at two points of the convex front margin, the hind margin fringed with several spines, some being at the apex, which projects a little squarely behind the hand; the hand much wider at the base than the apex, with spines at five points of the very convex front, the hind margin nearly straight, strongly pectinate with about twenty teeth; the finger curved, more than half the length of the hand, its eoneave inner margin pectinate with slender teeth for more than half its length.

Second Gnathopods.—Branchial vesicles shorter but broader than the first joint. The first joint widening a little distally, its front margin not bulging; the third joint much longer than in the preceding pair, having no acute apex, most of it surrounded with spines; the proximal part of the wrist rather longer than the hand, the apical process behind three-quarters of the hand's length, fringed within with fine pectination and with spines, of which a strong one at the apex reaches beyond the apex of the hand; the hand rather longer and narrower than in the first pair, similarly armed; the finger pectinate.

First Peræopods.—The first joint with narrow neck, then widened, having spines at three points of each margin, those of the more convex hind margin all rather near the apex; the second joint with two spines on the slightly furred hind margin; the third joint with spines at four points of the hind margin, which is strongly furred; the apex of the front is produced downwards and armed with spines; the fourth joint is considerably longer than the third, with spines at three points of the slightly convex front margin; the hind margin nearly straight, strongly furred, having several spines on or near it, distally projecting beyond the fifth joint, and the distal margin minutely pectinate; the fifth joint rather longer than the fourth, the hind margin pectinate, the front convex; the finger curved at the tip, more than half as long as the preceding joint, having a little pectination of the inner margin.

Second Peræopods longer than the first, the fifth joint not longer than the fourth, the finger about half the length of the fifth joint.

Third Peræopods.—The first joint channelled and straight behind, the front margin with spines at eight points of the widened lower part of the joint; the second joint with a spinule and small spine on the front margin; the third joint elongate, with two spines and a spinule on the faintly pectinate front margin, and two or three spines at the slightly downdrawn hinder apex; the fourth joint much longer than the third, scarcely narrowed distally, with four spines spaced along the pectinate front margin, two

or three spinules along the hind margin, and a spine at its apex; the fifth joint much longer and more slender than the fourth, with a little spine high up on the convex hind margin, and one a little lower down on the pectinate front margin; the finger slender, curved at the tip.

Fourth Peraopods rather longer than the third; the first joint with eight spines along the front margin, which is almost straight like the hind margins; the second joint as in the preceding pair, the third joint more elongated than in that pair, the fourth joint with one or two additional spines, and the fifth joint more elongate, with four spines on each margin; the finger about a quarter of the length of the preceding joint. The branchial vesicles to this pair are much broader at the upper part than is the case with the preceding pairs.

Fifth Peraopods shorter than the third pair; the first joint rather longer than in the fourth pair, but the third, fourth, and fifth joints shorter, with the front margin not pectinate as in the other two pairs.

Pleopods.—The peduncles with some slender marginal spines; the eleventh spine with the arms nearly equal, that with the subapical dilatation slightly the longer, the other conspicuously roughened on the inner side; the rami slender, with ten joints apiece.

Uropods.—Peduncles of the first pair a little longer than the inner ramus; the rami elongate, the outer considerably shorter than the inner, the adjacent margins strongly pectinate, with a slight emargination near the base, in which the teeth are very closely set; peduncles of the second pair shorter than the inner ramus, which is longer and much broader than the outer; the outer just reaching beyond the peduncle of the third pair; the adjacent margins of the rami strongly pectinate, the teeth being themselves to some extent pectinate; the peduncles of the third pair as long as those of the first and broader, considerably longer than the rami, the inner apex produced, acute; the rami reaching a little beyond those of the first pair, the apices very narrow and acute, the outer ramus narrower and a little shorter than the inner, pectinate only on the inner margin, the inner pectinate on both margins with pectinate teeth, but at the upper part of the inner margin not toothed, only very finely pectinate.

The Telson scarcely longer than the breadth at the base, scarcely a third of the length of the peduncles of the third uropods, the sides converging with a gentle curve to a narrowly rounded apex, which does not reach the meeting point of the inner margins of the peduncles just mentioned.

Length, three-tenths of an inch.

Locality.—Station 240, June 21, 1875; Pacific, between Japan and the Sandwich Islands; lat. $35^{\circ} 20' N.$, long. $153^{\circ} 39' E.$; surface; surface temperature, $64^{\circ} 8$. Seven specimens; the specimen described, a male.

Remarks.—The specific name refers to the ocean in which the species was captured.

From *Parathemisto japonica*, Bovallius, the present species is distinguished by having the fifth joint of the first peræopods longer, instead of shorter, than the fourth, and pectinate, instead of smooth; and also by having the third peræopods longer than the second, and the rami of the third uropods unequal. In having the fourth peræopods longer than the third or fifth, the two species are in agreement.

Family PHROSINIDÆ.

In 1852 Dana placed the genera *Phronima* and *Primno* in the subfamily Phronimidæ, and the genera *Anchylomera*, *Phrosina*, *Themisto*, in the subfamily Phrosinidæ. In 1862 Spence Bate placed the genera *Phrosina*, *Primno*, and *Anchylomera* in the subfamily Phrosinides. For the same three genera, as first subfamily or first group of the Phronimidæ, Claus in 1879, Carus in 1885, and Gerstaecker in 1886, resumed the name Phrosininae. In 1887 Bovallius, without change as to the genera, instituted the family Anchylomeridæ, for which, I think, the name Phrosinidæ should be preferred by right of inheritance from the terms Phrosininae and Phrosinides, as well as in deference to its derivation from the eldest of the genera. The definition which Bovallius gives for the family is as follows :—

"Head mediocre, a little tumid, not deeper than the body. Eyes large, occupying the sides of the head. First pair of antennæ fixed at the anterior side of the head, with multiarticulate flagellum (in the male). Second pair fixed at the inferior side of the head, multiarticulate (in the male), or wanting (in the female). Mandibles with palp. Epimerals [side-plates] distinct. Seventh pair of pereiopoda [*Fifth Peræopods*] reduced or transformed. Peduncles of uropoda laminiform, without rami."

It cannot, however, be stated without reserve that the mandibles have a palp, since in the genus *Phrosina* that appendage has not yet been detected¹ in either sex, and, though present in the male, it is wanting in the female, as well in *Anchylomera* as in *Primno*. In regard to *Phrosina* and *Anchylomera*, it is scarcely accurate to say that the head is not deeper than the body, although there is none of that extreme prolongation noticeable in *Phronima* and *Phronimella*. The eyes in this family are divided each into two groups of ocelli, though the groups are contiguous on the surface. The side-plates are not invariably distinct, but distinct in some segments of the peræon and not in others. It would be better to describe the uropods as laminiform, undivided, without mention of peduncles or rami.

¹ Risso's statement on the subject, quoted on the next page, can scarcely be accepted without corroboration.

For the original definition of the genus, see Note on Risso, 1822 (p. 117), and for a fuller definition, see Note on Risso, 1826 (p. 128). For the brief account of *Pisitoe*, see Note on Rafinesque-Schmaltz, 1814 (p. 87), and for the confused account of *Dactylocera*, see Note on Latreille, 1829 (p. 137). Risso includes in his definition of the genus "mandibules palpigères," but after an interval of sixty-six years the statement is still in need of confirmation. Milne-Edwards denies it, saying, Hist. Nat. des Crust., t. iii.

¹ Milne-Edwards, Costa, and Boeck consider that *Pisitoe bispinosa*, Rafinesque-Schmaltz, 1814, is probably a synonym of Risso's later *Phrosina semilunata*, but they have not felt justified by Rafinesque's brief description in accepting his names for the genus and species.

² Latreille in this work gives *Phrosina*, Risso, but transfers the type species, *Phrosina semilunata*, to his own genus *Dactylocera*, assigning to Risso's genus Risso's second species *Phrosina macrophthalma*, which is a doubtful one, and *Cancer galba*, Montagu, which certainly does not belong to *Phrosina*.

³ In this work Latreille confuses *Vibiliæ* and *Phrosina* together under the name *Dactylocera*.

⁴ In the Note on Lucas, 1840, at p. 184 the name is wrongly given as *Dactylocerus*, the original form as quoted by Desmarest from Latreille MS.

⁵ As the plate containing *Dactylocera nicaensis* is referred to in the Hist. Nat. des Crust., t. iii. p. 91, the date is perhaps earlier than 1840.

p. 90, note, "Dans l'espèce que j'ai examinée, il n'existe aucun vestige d'appendice palpiforme inséré aux mandibules; mais dans la figure que M. Costa a donnée de ce genre, on voit de chaque côté de la bouche un petit appendice sétaé qui paraît être un palpe mandibulaire, et qui est considéré par ce naturaliste comme une seconde paire d'antennes; il serait possible que ces appendices ne fussent autre chose que les pièces terminales des pates-mâchoires devenues plus saillantes que d'ordinaire." The small appendages here referred to are placed too high up in Costa's figure to admit of the explanation offered by Milne-Edwards, but they are also too low down to admit of Costa's own explanation; they are perhaps the projecting tips of the first pair of gnathopods. Spence Bate agrees with Milne-Edwards in giving "Mandibles without an appendage," but he probably bases the statement only on the examination of a female specimen.

1887. " *Nicetensis*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 28.

The large head deeper than long, produced at the top of the front into two little acute horns; the first two segments of the peraeon equalised; the first segment of the

pleon having the postero-lateral angles somewhat squared, the second having them more acute, the third having a very convex lower margin curving up to an acute apex, between which and a less produced dorso-lateral tooth on either side there is a sharp re-entering angle; the fourth segment is longer than the coaleseed fifth and sixth, and its hind margin forms an obtuse angle at the centre. Viewed from the front the detached head has a balloon-like appearance, the mouth organs representing the narrow lower end.

The Eyes cover most of the head, leaving free a small space near the horns, and a narrow lateral tract dividing the upper from the lower group of ocelli, except along the back of the head; the ocelli of the upper group are the larger.

Upper Antennæ.—Under pressure the horns of the specimen have assumed a jointed appearance, from accidental folding of the skin; some such appearance as this may have led Milne-Edwards to suggest that these horns represented the upper antennæ. There can, however, be no doubt that Mr. Spence Bate is right in regarding as the upper antennæ the organs placed just behind and below the horns; these, in our specimen, have two free joints, the first not longer than broad, the second conical, a little bent, twice as long as its greatest breadth, with ten or twelve cylinders spreading out from the inner side and the apex. In a male specimen, taken off Malta by Dr. Bruee, the horns are not acute; the first joint of the peduncle of the upper antennæ is tumid, the two following joints much narrower than the first and not so long as broad; the first joint of the flagellum is fringed with filaments on the lower margin and apex, being produced beyond the short second joint; the third joint is longer than the second, and as long as the upper margin of the first; there are eighteen other joints, several of the upper ones being distally widened, while the lower are filiform; the ends of the antennæ being broken, the full number of joints was not ascertained.

Lower Antennæ.—These are wanting in the female. In the male specimen from Malta the lower antennæ are present, projecting from the lower part of the front of the head, therefore at some distance below the upper pair; the peduncle is not very stout; of the three free joints the third is nearly as long as the two preceding together; the filiform flagellum has thirty-three joints, of which the first is the stoutest, though itself abruptly narrower than the peduncle; the joints at the middle of the flagellum are the longest.

Upper Lip very small, distally narrowed, with a rather wide emargination, one of the lobes thus formed appearing to be minutely (perhaps accidentally) bifid.

Mandibles rather long and narrow, the cutting-edge nearly straight, striated, and very finely dentieulate, with a prominent tooth at each corner; there is a spine-row of several very small spines and a long molar tubercle the crown of which is covered with a brush of numerous small spines. Neither in the specimen here described nor in the male specimen from Malta was there a mandibular palp.

Under Lip.—The principal lobes ciliated, the mandibular processes smooth, connected with the other lobes by a very convex outer margin.

First Maxillæ.—Inner plate seemingly wanting; the outer plate narrows distally, carrying its three strongest spines on the apex, with six or seven slighter ones along the inner margin, the series being continued by hair-like spines in pairs or singly at four or five points; the one-jointed palp reaches over the apex of the plate, its distal margin carrying five little teeth, and the inner margin being also to some extent denticulate.

Second Maxillæ.—The inner plate is much shorter than the outer; it has a small spine at the apex with a spinule beside it on the outer side, and some cilia along the inner margin; the outer plate has a spine at the apex, one on the inner margin a little below the apex, and cilia or setules along both margins.

Maxillipeds.—The outer plates are very narrow, slightly curved in a lateral view, closely adjoining one another from base to apex; tapering, though not to a sharp point; the apex has a group of three spinules, and there are a few spinules at distant intervals on the margins; there are also some setules longer than the spinules; the short inner plate projects inwards a little beyond the base of the outer plates, and has a group of spinules on its rounded apex, the inner margin in a lateral view being very concave.

First Gnathopods.—Side-plates not distinct from the segment, the lower front angle directed a little forward, more or less acute. The limb short, just half the length of the second peræopods, less than a third of the third peræopods; the first joint almost clear of the side-plate, rather longer than the remaining joints united, widening a little distally, ornamented with stellate or dendritic markings; the second joint short, as broad as long; the third scarcely longer than the second, apically acute, lying almost entirely upon the wrist, with some hair-like setules projecting upon the hind margin; the wrist cylindrical, widening distally, the hand also cylindrical, having its margins continuous with those of the wrist, longer than the wrist, very much narrowed distally, forming with its short slender finger a pencil-point ending. Gland-cells were not observed in the first joint, but as the muscles of that joint are relegated, as in the second gnathopods, to a narrow space in the hinder distal half, it may be assumed that the large vacuum thus left is intended for gland-cells.

Second Gnathopods.—Branchial vesicle nearly as long as and rather broader than the first joint, with accessory inflations, one longitudinal starting from the base, the others transverse. The limb very similar to that of the first gnathopods, but with all the joints longer; the first joint widest at the centre, with gland-cells along the whole course; the second joint twice as long as broad, and as long as the third joint; the wrist and hand longer, but more slender, than those of the preceding pair; the finger more elongate, with some extremely minute hairs visible on one edge.

First Peræopods.—The side-plates small, produced at the lower part of the front into a rounded lobe. The branchial vesicles of these and the three following pairs of peræopods of very irregular and complex form, supplying a very large aerating surface.

The first joint free from the side-plate, widening a little distally, but with the proximal part very narrow, producing a sort of flask-shape with the neck a little bent; the second joint longer than the third, the front apex, where the joint is widest, being at some distance from the following joint, except when that is bent upwards; the third joint as broad as long, the base much narrower than the somewhat squared distal end; the wrist attaining a much greater breadth than any of the other joints, the distal breadth about equalling the length, the front margin convex, the hinder strongly sinuous, the distal dentieulate, with six little teeth and a large hind one with a small one at its base; the hand and finger are in shape and function like the finger and nail of the gnathopods in many Amphipoda Gammarina; the hand matches the length of the distal margin of the wrist, upon which it closes; its front margin is convex, the hinder nearly straight; the finger is slender, slightly curved, about a fourth of the length of the hand, and when the hand is closed, the finger crosses the projecting apical tooth of the wrist.

Second Peræopods.—The side-plates more squared than the preceding pair, the rounded lobe being at the top of the front and directed more upwards than outwards. The limb is similar in shape to that of the first peræopods, but larger; the hinder apex of the third joint is much more sharply outdrawn, so that the distal breadth of this joint is greater than its length; the distal teeth of the wrist are much more pronounced, varying greatly in size; the length of the finger does not seem to be increased in proportion to that of the hand, and, though socketed, it is perhaps not movably jointed.

Third Peræopods.—Side-plates not large, broader than deep. The first joint expanded but not greatly, about twice as long as broad, the front margin rather more convex than the hind one, with shallow sparse serration and a small acute apex; the hind margin not reaching so far down as the front one, some serration faintly perceptible on the distal half; the second joint short, triangular, the front and the two hind margins straight, with acute apices, the two lower margins sinuous; the third joint widening distally, the hind margin longer than the front, the front apex and the hinder one acute, decurrent; the fourth joint large, the convex hind margin with an acute decurrent apex, besides which the broad distal margin has six pronounced teeth, the front one very large followed by a smaller, two very large, two smaller, connected with the apex by a rounded angle, within which the fifth joint hinges; the fifth joint, which here acts as finger, is much longer than any of the other joints, and is sabre-like, acute, apparently with the sixth joint entirely absorbed or absent.

Fourth Peræopods.—Side-plates small. Branchial vesicles very complex. Limb very like that of the third peræopods, but much smaller; the first joint as long, but much narrower, with the front margin less convex than the hinder; the third joint has the front process more produced than the hinder one, the joint being altogether as long as the

following joint though not so broad; the fourth joint also differs from that of the preceding pair as well by its much smaller size as by having four teeth instead of six, graduated in size, the outermost being the longest; the finger-formed hand is not so long as the first joint, and has a peetination on the surface near and parallel with its concave front margin; the finger is here distinct, though very small, its concave front margin not continuous with that of the fifth joint. The produced front apex of the third joint in this limb seems to have suggested the name *longispina*, which Mr. Spence Bate has given to a species of *Phrosina*, but the character is shown in Milne-Edwards' figure of *Phrosina nicaensis*, and is found in all the Challenger specimens of the genus, although the process does not quite attain to the length shown in the figure of *Phrosina longispina*; as the process not uncommonly lies against the fourth joint, it easily may be, and no doubt often has been, overlooked.

Fifth Peræopods.—The side-plates with sinuous front and lower margins at right angles, connected by a very convex hind margin; the limb reduced to a simple membranous plate, the front margin slightly convex, with a minutely pointed apex, the hind margin almost semicircular but widening out at the two ends. I can perceive no trace of a second joint, other than a little semicircular mark which scarcely reaches the small cavity between the apex of the front margin and the bend of the hind margin to meet it.

Pleopods.—The two coupling-spines very small with the usual inverted saucer-like head, and having a lateral saw of four teeth, certainly on one, probably on either edge; the cleft spine with stout shaft, the two arms slender, short, equal in length; the joints of the rami ten to eleven, the first joint in each narrow at the base, then widening; the first joint of the outer ramus having the not uncommon twisted connecting process descending from the peduncle and directing its narrow apex towards the inner ramus.

Uropods.—The two long distally rounded plates of the first pair are slightly longer than, and not so broad as, those of the third pair, with minutely peetinate edges; the two plates of the second pair are shorter than either those of the first or third. All the six plates more or less overlap, their broadly rounded ends being of great tenuity, and often showing prismatic colours; they are diversified by irregular markings, the third pair having stellate markings on the lower part.

The Telson, a little longer than broad, about two-sevenths of the length of the third uropods, a half-oval, difficult to distinguish, owing to its thinness, divided by a very fine line from the preceding segment of the pleon.

Length.—The specimen, in the position figured, measured in a straight line rather more than one-fifth of an inch.

Locality.—The specimen here described was obtained in the North Atlantic, from the surface, at night, April 29, 1876; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface temperature, $73^{\circ} 7$. Another was taken in the North Atlantic, June 18–19, 1873; lat. $35^{\circ} 18'$ N., long. $51^{\circ} 42'$ W., also at the surface; surface temperature, 71° .

Remarks.—There can, I think, be no reasonable doubt that *Phrosina semilunata*, Risso, and *Phrosina nicaensis*, Milne-Edwards, are the same species; as specimens are reorded an inch in length, the species evidently attains a much greater size than shown by the Challenger specimens, but unless it be in the greater or less development of the dorsal and lateral angles of some of the pleon segments, there seems to be very little variation between very small and very large examples.

Phrosina pacifica, n. sp.

This species has so great a resemblance to that which I have already described as *Phrosina semilunata*, Risso, that it is unnecessary to do more than note the points of difference.

The skin appears to be studded with numerous minute hairs. The *Antennæ* end acutely, having a small linear terminal joint, the preceding large joint being apically produced a little way alongside of it.

The first joint of the *First Gnathopod* exhibits no dendritic markings.

In the *Second Peræopods*, the finger-formed fifth joint ends acutely, without the least trace of a separate finger.

The first joint of the *Third Peræopods* is much expanded, so that the joint is not nearly twice as long as broad, with the greatest breadth a little above the centre; the fourth joint, between the apical tooth of the hind margin and the other six acute distal teeth, has a blunt tooth adjoining the hinge of the following joint.

In the *Fourth Peræopods* the fourth joint has five distal teeth instead of only four, besides the apical tooth of the hind margin; the terminal finger is extremely minute, scarcely distinct, except that its front margin is not quite continuous, and its somewhat longer hind margin by no means continuous, with that of the fifth joint.

The Fifth Peræopods have a tiny triangular second joint, with blunted tip.

The rami of the *Pleopods* have fifteen joints.

The Uropods appear in all the pairs to have microscopically pectinate edges, but this may be the case also in the other species; there are no stellate markings to break the glassy clearness of the terminal portions; the third pair are rather broader, and end more squarely, though with rounded corners; the second pair are a little broader and not very much shorter than the first.

The Telson is a little broader than long.

Localities.—April 3, 1875, North Pacific, south of Japan; lat. $24^{\circ} 49' N.$, long. $138^{\circ} 34' E.$; surface; surface temperature, $71^{\circ}.5$. One specimen.

Station 230, April 5, 1875; North Pacific, south of Japan; lat. $26^{\circ} 29' N.$, long. $137^{\circ} 57' E.$; surface; surface temperature, $68^{\circ}.5$. One specimen.

Phrosina australis, n. sp.

The only differences of importance that I can discover between this species and *Phrosina semilunata*, Risso, refer to the uropods, of which the first and second pairs, instead of having broadly rounded terminations, are distinctly narrowed and acute or nearly so; the telson also is less rounded apically than in the other species; the rami of the pleopods have seven or eight joints. The fourth segment of the pleon has the hind margin straight across the back. In the first and second pereiopods, the denticulation of the distal margin is less marked than in the other species, and in the fourth pereiopods this margin has three teeth in the front part, that nearest the fifth joint being the broadest of the three.

Length, rather under a quarter of an inch.

Locality.—Station 164D, June 14, 1874; east of Australia; lat. $34^{\circ} 3'$ S., long. $152^{\circ} 20'$ E.; surface; surface temperature, $67^{\circ}\cdot 5$. One specimen.

Remarks.—The specific name refers to the capture of the species far in the south. The difference in the uropods is rather striking as combined with the very close resemblance in other parts between this and the type species.

The following list will show the distribution of the genus *Phrosina* as illustrated by the Challenger specimens:—

1. June 18–19, 1873, east of Bermuda; lat. $35^{\circ} 18'$ N., long. $51^{\circ} 42'$ W.; surface. One specimen.
2. April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface, night. One specimen.
3. Station 346, April 6, 1876; Tropical Atlantic; lat. $2^{\circ} 42'$ S., long. $14^{\circ} 41'$ W.; surface. One specimen.
4. Station 164D, June 14, 1874; east of Australia; lat. $34^{\circ} 3'$ S., long. $152^{\circ} 20'$ E.; surface. One specimen.
5. Station 201, October 26, 1874; off Samboangan; lat. $7^{\circ} 3'$ N., long. $121^{\circ} 48'$ E. One specimen, a fifth of an inch long, mounted in Canada balsam.
6. April 3, 1875, North Pacific, south of Japan; lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E. One specimen.
7. Station 230, April 5, 1875; North Pacific, south of Japan; lat. $26^{\circ} 29'$ N., long. $137^{\circ} 57'$ E.; surface. Four specimens.

This range is extended by specimens which have been reported from the Mediterranean and the Cape of Good Hope, and by *Phrosina longispina*, Spence Bate, "found in the stomach of a shark, lat. $26^{\circ} 27'$ S., long. 90° W." It is probably under some misapprehension that Bovallius assigns the last-named species to the "South Atlantic."

For the original definition of the genus, see Note on Milne-Edwards, 1830 (p. 143). For the definition of *Hieraconyx*, see Note on Guérin, 1836 (p. 164). For the account of *Cheiropristis*, see Note on de Natale, 1850 (pp. 236-239). At page 239 I have accepted Spence Bate's suggestion that de Natale's "*Cheiropristis Messanensis*" belongs to the genus *Anehylomera*, but it should be noticed that the figure given in the Brit. Mus. Catal. Amph. Crust., pl. lii. fig. 4, with the name *Anchylomera sedentaria*, and a reference to "*Phronima sedentaria*, Costa, Pochi Crust. del Messina," has nothing to do with *Cheiropristis messanensis*; it is in fact a reproduction of the "*Phronima Coceoi*" figured in de Natale's Lettera¹ al Sig. Achille Costa, Su pochi Crostacei del porto di Messina, and represents a true *Phronima* of the male sex.

To the definition of the family Bovallius in 1887 adds only a few words for the definition of the genus, as follows:—

"The first two pairs of pereiopoda [First and Second Gnathopods] simple, the third, fourth, and fifth pairs [First, Second, and Third Peræopods] subcheliform. The uropoda are rounded behind."

To these characters it may be added that the female is distinguished from the male

¹ See Appendix, Note on de Natale, 1850 (pp. 1621-1624).

by the absence of the mandibular palp, by the reduction of the upper antennæ to a minute rudiment, by the absence of the lower antennæ, and by the loss of the terminal joints of the fifth pereopods.

The head wider and deeper than long, the front having its lower margin at the centre produced downwards in a narrow triangle over the small triangular group of the mouth organs; first and second segments of the pereon dorsally coalesced, the composite segment being longer than the third or fourth, the first at the sides descending below and entirely clear of the second; the fifth segment longer below than any of the other pereon-segments; the first three segments of the pleon large, with the postero-lateral angles rounded; the fourth segment with a transverse dorsal depression; the fifth and sixth segments coalesced, the composite segment short. The heart strongly walled, with three pairs of venous ostia.

The Eyes occupying all the surface of the large head except a small triangular space on the top at the centre of the hind margin and the slightly depressed tract down the front which in the male is occupied by the antennæ.

Upper Antennæ of the male planted in the frontal cavity, which does not reach the top of the head. The three joints of the peduncle very short and closely combined, the first the longest and a little inflated; the first joint of the flagellum directed upwards so as to form an angle with the peduncle,¹ which it exceeds in length, on the lower side produced into a pointed process under the first two or three or four short succeeding joints, the whole under side of the joint and both sides of the process furnished with a close brush of filaments set in transverse rows; the joints after the first abruptly narrower, the second to the fifth short, the rest rather elongate; these delicate flagella were broken in almost all the specimens; in one specimen twenty-one joints were counted; each joint, the first three excepted, has on the under side two little prominences, from which depend small groups of filaments. In the female the upper antennæ are represented only by a pair of minute tubercles.

Lower Antennæ of the male inserted immediately below the upper. The peduncle with three free joints, the first having a very convex upper margin, the second shorter, scarcely longer than broad, the third longer than the first, slightly bent upwards and having its lower margin much more convex than the upper; the flagellum abruptly narrower than the peduncle, the first joint a little knobbed at the base as if to form a ball and socket joint with the end of the peduncle; the general structure of the flagellum as in the upper antennæ, but with no very short joints at the base, the joints in general longer, with three instead of two groups of filaments on the under side; in one specimen there were twelve joints remaining, but many may have been missing. Milne-Edwards assigns forty joints to the flagellum of the upper antennæ, and more than fifty to that of the lower in his description of "*Anehylomera Blossevilleii*." The figures *a.s.A.*, and *a.i.A.*, were not drawn from the same specimen as the full figure and the other separate parts.

Mandibles.—The cutting edge very slightly convex, striated, having a tooth at the upper end curving downwards and another at the lower end curving a little upwards; the secondary plate on the left mandible has its edge more or less dentate, and approaches much nearer the edge of the primary below than above; on the lower margin of the mandible, behind the lower tooth of the cutting plate, there is a bush of spine-like bristles; the molar tubercle, much broader than deep, has its crown set round with spinules, the outer margin, which is next the trunk of the mandible and nearly parallel with the cutting edge, being crenulate; the palp placed behind the molar tubercle, at about the centre of the mandible, has the first joint large, much broader than either of the following,

¹ Milne-Edwards says of the antennæ "les inférieures coudées," but the "elbow" is more pronounced between the peduncle and flagellum of the upper antennæ, than between the joints of the peduncle of the lower.

and not very much shorter than the two together; the third joint is thinner than the second, very little shorter, with a narrow curved tip; the hind margin of each joint is convex; the second forms an angle with the first by bending backwards, the third with the second by bending forwards.

Lower Lip.—The principal lobes broad, well ciliated, dehiscent, the connecting band having a scarious ridge at the centre on the inner surface; the mandibular processes rather broad.

First Maxillæ.—The outer plate has a row of setules or very thin spines on the inner margin, which are followed by seven spines along the obliquely sinuous apical margin, the three on the actual apex being much stouter than the rest; a second row of setules is planted on the surface at a little distance from the spines; the one-jointed palp is narrower than the plate but reaches a little beyond it; it has five little apical spines, one or two on the lateral margin, and setules on the outer margin.

Second Maxillæ.—Both plates tapering, tipped with small spines and fringed with setules; the outer plate the longer.

Maxillipeds.—A narrow stem rising from a broad base carries a pair of slender outer plates, set close together, tapering, fringed on or near the outer margin with hair-like spinules, and having a little tooth on the inner margin near the apex; the inner plate is rather more than half as long as the outer, set with hair-like spinules; its apex rounded, the plate itself springing unjointed from the strongly curved central ridge of the stem. The figure *mp.B.*, representing the outer surface, is taken from a female specimen.

First Gnathopods.—Side-plates not distinct from the segment. The first joint of these diminutive limbs is as long as the remaining joints united, adapted for gland-cells, the front margin convex, carrying some minute setules, the hind margin sinuous; the second joint quite short; the third joint not much longer, apically acute, most of it lying on the inner side of the wrist; the wrist shorter than the hand, widening distally, fringed on and about one margin with short spinules, the other slightly furry; the hand near the base about as wide as the wrist, with convex margins, the distal half tapering, the margins fringed with spinules or setules, of which there is a third row on a ridge of the hand's inner surface; the finger not half the length of the hand, socketed in the apex of the hand and bending over in the specimen figured, so as to be scarcely visible. Milne-Edwards was only able to distinguish four joints in these and the following gnathopods, "the first long and cylindrical, the two following very short, and the last large, flattened, lanceolate, ending in a very sharp point."

Second Gnathopods.—The branchial vesicles longer and much broader than the first joint of the limb, having like the following pairs several subsidiary folds or pockets down the centre. The side-plates not distinct from the segment, covered with scale-like markings; the segment above each side-plate sending out a strong interlocking process

from the hind margin. The first joint is longer and broader than that of the first gnathopods, by which it is overlapped above; the front margin convex, the hinder sinuous, the interior of the joint containing a long oval pocket of gland-cells; the second, third, and fourth joints similar to those of the preceding pair, but thinner; the hand much longer, thinner at the base, from which it tapers to nearly the middle, in a somewhat oval form, fringed with spinules or setules, the remainder being drawn out into a long, slender, nearly straight process, with parallel sides, the minute finger being socketed in the apex as in the preceding pair, minutely scabrous on its inner surface.

First Peraeopods.—Side-plates distinct, much broader than deep, shallow, axe-like, but with the ends rounded. The brachial vesicles sack-like, much longer than the first joint, with some nine subsidiary pockets. The limb much longer than the gnathopods; the first joint with a bent neck, the distal half wider than the proximal; the second joint considerably longer than broad, channelled in front; the third not quite so long as the second, widening at once from the narrow neck, so that without the neck the width is fully as great as the length, the hind margin finely pectinate; the fourth joint not so long as the first joint, but broader, with scabrous surface; the front margin smooth, gently convex; the hind margin forming with the emarginate distal border (where the joint is widest) a triangular process, both these margins being pectinate, and the hind margin having also a small tooth or projection at two or three points, attended by spinules, of which there are several submarginal on the lower part of the joint; the fifth joint a little shorter than the fourth, much thinner, folding across the distal margin of the fourth joint as though it were a finger to it, and in this position extending much beyond it; the hinder margin pectinate, the front gently convex, furrowed, the fur extending over much of the surface; the finger slender, slightly curved, more than half the length of the fifth joint, pectinate for two-thirds of the hind margin.

Second Peraeopods differing very slightly from the first, except that the fourth joint is rather narrower at the base, has a more regular hind margin, and distally forms a triangular process which is considerably longer than that in the preceding pair, so that the fifth joint, although rather longer than in the first peraeopods, does not extend so much beyond the fourth joint as in that pair. In both pairs the expanded fourth joint contains gland-cells.

Third Peraeopods massive. The side-plates larger than in the preceding pairs, if not in proportion to the increased size of the joint; the process on the inner surface is broad, with sinuous lower margin. The first joint of great breadth; the front margin formed by an oblique line descending to the point of greatest breadth, and below this by a strongly sinuous line, at first concave and then convex; the hind margin has an upper rounded lobe and is then gently sinuous; there is a ridge down the centre of the inner surface, with a small lobe at each extremity; the second joint a little longer than broad,

channelled behind, with the nearly straight front margin ending in a pointed apex, the hind margins strongly convex, that of the inner surfacee the more extensive ; the third joint much broader than long, short, cup-like to receive the fourth joint, the hinder apex produced ; the fourth joint having its convex hind margin smoothly continuous with that of the preceding joint, the front margin shorter, nearly straight, the distal margin of great breadth, cut into six or seven graduated teeth, the foremost the largest, the two next the hinge minute ; the narrow, slightly curved, fifth joint tapers a little, and closes down upon the teeth just mentioned, reaching a very little beyond them (or in some specimens not beyond them), and in combination with these forming a powerful elasper ; the finger is slender, tapering, nearly straight, not half the length of the hand. There are some minute spinules on the limb, chiefly on the front margin of the fifth and on the teeth of the fourth joint.

Fourth Peræopods much slighter in structure though not much shorter than the third. Side-plates small and shallow. First joint nearly as long as that of the preceding pair, which it resembles, widest just below the neck, much narrowed lower down, the front margin very sinuous, pectinate below, a narrow lobe at the apex partly overlapping the next joint, the hinder margin below the upper expansion nearly straight ; the second joint short, channelled before and behind ; the third joint not longer than the second, a little broader than long, pectinate in front, the hind margin convex, the inner surfacee seaborous ; the fourth joint oval, longer than the second and third together, narrower at the distal end, the front margin a little unevenly convex, finely pectinate, the inner surfacee strongly seaborous down the centre ; the fifth joint narrow, scarcely shorter than the fourth, pectinate in front, furred behind, the hind margin with a little more convexity than the front ; the finger slender, slightly curved, more than half the length of the fifth joint, two-thirds of the inner margin pectinate.

Fifth Peræopods.—The side-plates not distinct from the segment, which, it may be mentioned, displays on either side when flattened out a singularly sinuous margin both behind and before. The first joint attains its greatest width immediately below the point of attachment, and thence narrows gradually to the distal end, with a straight hind margin and slightly concave front one, the length being a little less than that of the first joint in the preceding pair ; there are numerous conspicuous gland-cells along the centre ; the remaining joints are feeble, together not nearly as long as the first, against which, along the protecting ridge of its inner surface, they are commonly folded back ; the second joint short, lying across and within the rounded and three-lobed apex of the first joint ; the third longer, oval ; the fourth narrower than the third, but much longer ; the fifth narrower than the fourth, shorter than the third, bent ; the finger little more than half the length of the fifth joint, not pointed, but a narrow oval, the distal end serrated with some minute retroverted teeth. In the female the first joint is similar to that in the male, or with the hinder lobe of the apex a little more produced down-

wards; to the central piece of the apex there is attached a stump of the second joint, which completes the limb in this sex.

Pleopods.—Peduncles stout, squared or oblong, with the lower margin lobed on either side, and sending out a small hammer-headed process over the outer ramus; the two coupling spines are small, but elaborately spined, the heads being smooth domes with zigzag edges, and a set of three retroverted teeth projecting from each margin of the shaft; the single cleft spine is not very elongate, with a rather broad, strongly ciliated stem, the arms rather short and thin, the longer roughened on two margins, the shorter having the subapical dilatation; the outer ramus has eleven, the inner ten joints; the first joint in each ramus being broad, but not very long, the rami themselves broad, not tapering rapidly.

Uropods all extremely transparent, except in the upper part, where they show hexagonal cell markings, visible also in other parts of the animal; the ends of all are rounded, sometimes more flatly in the first and third pairs than in the second, and all have a marginal ciliation of extreme fineness, most easily observed at the distal ends, and perhaps absent from the upper parts; there do not appear to be any peduncles¹ distinct from the supporting segments; all the pairs have a shape in general oval, but with a constriction on the inner side near the base; the first pair reach as far as the third, and are therefore longer than the third, but a little less broad; the second pair attached at the top of the double-segment, are less broad than the first and shorter than the third; the third pair attached at the lower end of the double-segment, bend inwards, so that one plate lies upon the other for most of its length.

Telson rather broader than long, about half the length of the third uropods, in shape an inverted arch, with the apex broadly rounded.

Length.—The specimen, in the position figured, measured a quarter of an inch, in a straight line from the front of the head to the end of the third segment of the pleon.

Locality.—April 4, 1875; North Pacific, south of Japan; lat. $25^{\circ} 33' N.$, long. $137^{\circ} 57' E.$; surface; surface temperature, 69° .

Remarks.—In the young taken out of the mother, and less than a twentieth of an inch long, the general shape and proportions of the adult are already seen, the fourth joint is distally widened in the first four pairs of pereiopods, but the fifth joint is comparatively broader; the pleopods have as usual in the young two-jointed rami, the second joint much shorter than the first.

The name "*Anchylomera Blossevillii*," Milne-Edwards, afterwards written "*Anchylomera Blossevilleii*," will probably cover all the species named in the synonymy, since

¹ Milne-Edwards, Hist. Nat. des Crust., t. iii. p. 87, says that these uropods "sont réduites en un petit article basilaire à peine perceptible, auquel est attachée une grande lame ovalaire de consistance membraneuse." Bovallius regards the membranous plates as themselves the peduncles. Whether they are in fact the peduncles without rami, or the rami without peduncles, or the rami and peduncles combined, cannot at present be decided, but there is perhaps as much to be said for the third view as for either the first or the second.

none of the distinctions given, which can be depended upon, seem to be of specific value. For example, in "*Anchylomera Hunterii*," Milne-Edwards, the flagellum of the upper antennæ has "only about fifteen joints," but in *Anchylomera*, as in some other genera of the Hyperina, the flagella of the male antennæ go through many changes of length and thickness, being shorter and thicker in an intermediate stage than they are in their final development. In regard to *Anchylomera antipodes*, Spence Bate, we read in the description of the female, "fifth pair of pereiopoda consisting of the basos only, which is longer than broad," while in the description of the male it is said that all the pereiopods are practically the same as in the female; but this general observation rather implies that the pereiopods of the male had not been specially examined. In *Anchylomera purpurea*, Dana,¹ which is figured with the antennæ of an adult male, the fifth pereiopods are like those here described, except that Dana has probably overlooked the small and obscure second joint; in *Anchylomera thyropoda*, on the other hand, of which the antennæ are "very short without a flagellum," Dana says that the fifth pereiopods are "obsolete excepting coxa." The Challenger specimens, alike from the Atlantic and the Pacific, show that in the male the fifth pereiopods have the full number of joints, but that in the female the number is curtailed. The ciliation of the uropods varies in different specimens, being liable, I am inclined to think, to removal by various accidents. So far, then, as all the characters are concerned, which have been hitherto used for specific distinctions within this genus, it may be said that, where they are not beyond doubt merely sexual, they are probably either due to the particular age of the individual specimen or to accident.

The following list of Stations shows the distribution of the genus *Anchylomera* as illustrated by the specimens in the Challenger collection:—

1. North Atlantic, between Tenerife and St. Thomas, West Indies. Five specimens, three male, two female.
2. Station 348, April 9, 1876; Equatorial Atlantic; lat. $3^{\circ} 10'$ N., long. $14^{\circ} 51'$ W.; surface to 200 fathoms; surface temperature, 84° . One specimen, male.
3. Station 347, April 7, 1876; Equatorial Atlantic; lat. $0^{\circ} 15'$ S., long. $14^{\circ} 25'$ W.; surface; surface temperature, 82° . One specimen, male. The antennæ were complete in this specimen, the flagellum in each pair consisting of thirty-four joints.
4. June 8, 1874, off Port Jackson; surface, night; surface temperature, 67° . One specimen.
5. South Pacific, between Sydney and Wellington; surface. One specimen, male.
6. June 15, 1874, between Sydney and Wellington; lat. $34^{\circ} 6'$ S., long. $155^{\circ} 12'$ E.; surface; surface temperature, $62^{\circ} 7$. Three specimens.

¹ In the Brit. Mus. Catal. Amph. Crust., pl. lii., the gnathopods and second pereiopod of *Anchylomera purpurea* have been accidentally numbered as though they belonged to *Platyscelus rissoinæ*.

7. Station 165, June 17, 1874; between Sydney and Wellington; lat. $34^{\circ} 50'$ S., long. $155^{\circ} 28'$ E.; surface; surface temperature, $64^{\circ}.5$. Four specimens.
8. South Pacific, between Api and Cape York; surface. One specimen, female.
9. April 3, 1875, North Pacific, south of Japan; lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E.; surface; surface temperature, $71^{\circ}.5$. Specimens numerous; also one specimen, female.
10. April 4, 1875, North Pacific, south of Japan; lat. $25^{\circ} 33'$ N., long. $137^{\circ} 57'$ E.; surface; surface temperature, 69° . Specimens numerous.
11. Station 230, April 5, 1875; North Pacific, south of Japan; lat. $26^{\circ} 29'$ N., long. $137^{\circ} 57'$ E.; surface; surface temperature, $68^{\circ}.5$. Four specimens.
12. Between Papua and Japan, surface. One specimen.
13. July 1875, between Japan and Honolulu. Two specimens.
14. July 1875, between Japan and Honolulu; lat. 35° N.; surface. Three specimens.

To complete the known range of the genus we must add to the above-mentioned localities Milne-Edwards' specimens from the Indian Ocean and the Isle of Bourbon, Guérin's from between the Falkland Isles and Port Jackson, Spence Bate's *Anchylomera antipodes*, lat. 58° S., long. 172° W., Dana's species respectively from lat. 27° S., long. $45^{\circ} 10'$ W., and lat. 39° S., long. 54° W., and the Mediterranean species "*Cheiropristes Messanensis*." All the localities together show that the genus is distributed round the world, and since it reaches lat. 58° in the south, it is possible that it may eventually be found to extend beyond lat. 40° N., which is about as far as our present information carries it.

Head irregularly globose, when detached together with the mouth organs having in a front view a sort of balloon-shape, the rostral angle above the upper antennæ rounded, folded inwards; the first segment of the peræon very narrow below, but dorsally the longest of the peræon-segments except the seventh; the seventh peræon-segment and the two first of the pleon produced backwards into sharp processes in the middle of the back; the peræon not carinate, but tending to be so, especially at the last segment; the first three segments of the pleon not very strongly carinate, the postero-lateral angles of the first two squared, of the third very acute, the fourth segment longer than the coalesced fifth and sixth.

Eyes covering most of the surface of the head, the upper and lower eye on each side of the head contiguous, but the upper having much larger ocelli than the lower.

Upper Antennæ.—The peduncle consisting of one joint, which is short and stout, cylindrical, widening distally; the flagellum also consisting of one joint, which is long, prismatic in section, tapering at first rapidly, with five short filaments on either side, beyond these becoming very narrow, and drawn out to a fine point.

Lower Antennæ wanting in the female, or only represented by a small protuberance.

Mandibles.—The cutting edge narrow, minutely striated, with a little tooth at either end; a small group of spinules adjoins the tooth of the lower end; the secondary plate of the left mandible is very small; the molar tubercle broad, its crown fringed with comparatively long teeth and set with numerous hair-like spines; behind the molar tubercle the lower edge forms a very convex lobe; there is no palp (in the female).

Lower Lip short and compact.

First Maxillæ.—The plate narrows to the distal margin, on which it carries three comparatively large spines and a smaller one at the outer corner; six small ones fringe the inner margin, having below them four or five that are almost thread-like; the one-jointed palp reaches beyond the plate, is very slightly curved, of almost even breadth

throughout, with six little spine-teeth spaced along the inner margin, perhaps as many close-set on the distal border, and five slender spines along the outer margin.

Second Maxillæ.—The outer plate narrow and tapering, beset with hairs, and having a spinule or two at the apex ; the inner plate much shorter, triangular, its outer margin standing out nearly at right angles to the outer plate, the apex tipped with a spinule, the inner margin carrying some hairs.

Maxillipeds.—The inner plate inconspicuous, almost obsolete, with rounded apex ; the outer plates narrow, tapering, hairy on the outer, slightly convex surface, carrying two minute spinules on the nearly acute apex, and two or three at irregular intervals along each margin.

First Gnathopods small, without any distinct side-plates. The first joint about as long as the next four joints together, with sinuous margins, the joint being narrower in the middle than above and below ; the muscles do not reach to the middle of the joint, the upper space being required for gland-cells ; the second joint longer than broad, bent, so that the remainder of the limb is directed forwards and a little upwards to the mouth ; third joint about as long as the second, the apical point lying upon the wrist ; wrist cylindrical, as long as the preceding two joints together ; hand also cylindrical, narrowing distally, longer than the wrist, having some minute spines and hairs on the margin ; finger when outstretched about a third the length of the hand, the margin fringed with short stiff hairs ; the nail short, pointed.

Second Gnathopods larger than the first, which they tend to overlap. The side-plates triangular, sharply pointed forwards, of a shape more commonly found attached to the first than to the second gnathopods. Branchial vesicles longer than the first joint, not broader, narrow at the neck. Marsupial plates very thin and transparent, smooth-edged, rather longer than the first joint, shorter than the branchial vesicles. The first joint oval, much wider than that of the first gnathopods, the muscles occupying only a small space low down at the back, the remainder being nearly filled with the gland-cells ; the remaining joints closely resemble those of the preceding pair, but are larger, the wrist both broader and longer, and a little dilated at the proximal end ; the hand longer than the wrist, tapering, with a slight curve, without hairs but with a few minute spinules ; the finger not a fifth the length of the hand, without any nail.

First Peraopods.—The side-plates produced in front, broader than deep, deeper behind than in front. Branchial vesicles rather longer than the first joint. The marsupial plates rather longer and broader than the branchial vesicles. The first joint narrow, widening slightly from the narrow base ; the second joint longer than broad, with one spinule at the middle of the hind margin ; the third longer than the second, with two spinules wide apart on the hind margin ; the fourth joint almost as long as the second and third together, with four spinules on the hind margin, two of them at strong indents, a fifth spinule within the little produced apex ; the fifth joint

a little longer than the fourth, the hind margin finely and obliquely pectinate, and with five hair-like spinules standing out at right angles to the margin; the finger more than one-third the length of the first joint, strongly bent at the tip.

Second Peræopods very similar to the first, but with the side-plates a little less shallow in front, the first joint less slender, the third joint larger, with the two indents of the hind margin more marked, the fourth joint also larger, equalling the length of the fifth, which is itself rather longer than in the first peræopods.

Third Peræopods.—The side-plates produced in advance of the main framework of the segment, from which they are in this and the two next pairs very indistinctly separated. Branchial vesicles broad, irregular in shape, not quite so long as the first joint. Marsupial plates narrow, longer than the first joint. The first joint entirely free from the side-plate, muscular, widening downwards, channelled behind, the hind margins nearly straight, the front slightly convex below, sparingly serrate; the second joint not longer than broad, channelled behind, with one apex squared, the front margin a little serrate; the third joint little longer than the second but much wider, the front margin oblique with a sharp apex, the lower margin sinuous; the fourth joint very large and muscular, longer than the first joint, widest near the base, not twice as long as broad, the hind margin slightly convex, with a small apical tooth, the front margin cut into fifteen oblique teeth, the first a long one with a little denticle high up on its front; this is followed by three short, a long, four short, a long, and five short teeth, of these five the middle one being the longest; between the last of these and the apical tooth of the hind margin is the curved hinge of the narrow fifth joint, which is of almost even breadth throughout, and when closing upon the hand-like fourth joint just crosses beyond the tip of its second long tooth; almost continuous with the margins of the fifth joint are those of the finger, which is long, tapering, and in its distal half much curved; it is over half the length of the fifth joint, the two together being longer than the fourth.

Fourth Peræopods.—Branchial vesicles distally very broad. The first joint not so massive but as broad and nearly as long as in the preceding pair, the greatest breadth near the middle, the hind margin forming an angle (very slightly rounded) at the top, then running in a straight course to the distal end, the front margin convex, the lower part with five indents and a little apical point; the second joint angled behind, and having one indent in front; the third joint much longer than the second, the front margin with two indents and an apical tooth, the hind margin with one or two minute indents, and a long deurrent apical tooth; the fourth joint a little longer than the third including the apical tooth, its hind margin having two minute indents and a small apical tooth, its front margin cut into six teeth, of which the first, third, and fifth are scarcely more than serration; the fifth joint as long as, or a little longer than, the fourth, slender, slightly curved, the front margin pectinate; the finger slender, about one-third the length of the fifth joint, the end much curved.

Fifth Peraopods.—The first joint as long as that of the fourth peræopods but narrower, about equal in length to the remaining joints together or a little longer, curved, narrowing a little distally, the hind margin convex and very shallowly serrate; the second joint short, bent back at right angles, not as long as the distal end of the first joint, below which it partially appears; the third joint turned upwards, rather longer than the second; the fourth straight, considerably longer but rather narrower than the second; the fifth longer and narrower than the fourth, though in one of the limbs of this pair the difference in length between these two joints was very slight; the finger considerably more than half the length of the fifth joint, with convex hind margin, the front concave to the point of greatest breadth, then straight and pectinate, the fine teeth of the comb standing at right angles to the margin, and increasing successively almost to the apex.

Pleopods.—The two coupling spines very short and small; it appears as if the teeth of the apical caps were prolonged, so that one or other looks like a lateral tooth according to the position in which the spine happens to be seen; the cleft spine is short, with stout shaft and very short arms, the arm with the subapical dilatation longer than the roughened one; the joints of the rami number from eleven to twelve; the first of the inner ramus is attached a little above the first of the outer, and is a good deal narrower at its base than distally; as usual the peduncles of the first pair are considerably longer than those of the third.

Uropods.—The first pair are longer than the second or third, reaching beyond the second, but not so far back as the third; the plate is lanceolate, attaining its greatest breadth not far from the base, being obliquely pectinate along most of the outer margin as far as the apex, and much more slightly on the lower half of the inner margin; the second pair are fully as broad as the first, and nearly as long as the third; the outer margin is much more convex than the inner, with half a dozen distant indentations, and fine pectination along the lower half, the inner margin being likewise pectinate in the lower part; the third pair are much broader than the first or second, with a length more than twice the breadth; the breadth varies little except at the two extremities; the outer margin, which is slightly pectinate, and has one or two indentations, ends in an acute apex, from which the pectinate distal margin runs obliquely back to the principal apex, which the pectinate inner margin reaches by a sinuous curve.

Telson small, triangular, rather broader than long, much narrower than the third uropods and little more than one-fifth of their length, the apex slightly rounded.

Length.—The specimen, in the position figured, measured three-tenths of an inch.

Locality.—Station 287, October 19, 1875; South Pacific; lat. $36^{\circ} 32'$ S., long. $132^{\circ} 52'$ W.; surface; surface temperature, $57^{\circ}\cdot8$. One specimen, a female with the young far developed.

Remarks.—Guérin's account differs in making the wrist and hand of the second

gnathopods equal in length, and the postero-lateral angles of the first three pleon-segments rounded; he neither mentions nor figures the dorsal tooth of the seventh peraeon-segment and the first two pleon-segments, and the telson, as he figures it, can scarcely be considered triangular; but the more striking peculiarities of his new species probably diverted his attention from features less notable, which in this genus happen to be very difficult to make out; that he divides the sixth joint of the fifth peraeopods into two in the figure is obviously due to some accident.

In the young, less than one-twentieth of an inch long, the shape is not more slender than in the parent, none of the segments are dorsally produced; the upper antennæ appear to consist of one thick joint, longer than thick, and a terminal short joint; in the gnathopods the fingers have a greater proportionate length than in the adult; the first and second peraeopods have the fourth joint distally dilated, the front margin being produced into a pointed apex, within which lies a somewhat curved spine as long as the apical process, and having the side pectinate which faces the fifth joint; the long third peraeopod has a broad fourth joint with the front margin smooth, ending in a small apical tooth, within which is planted a spine that projects beyond it; the much narrower fourth joint of the fourth peraeopods is similarly armed; the fifth peraeopods are feeble as in the adult; the rami of the pleopods, as usual at this stage of development, have only two joints, a long and a short one, the long one having a cleft spine at the upper part.

Primno latreillei, n. sp. (Pl. CLXXIX., A.).

The general outline not differing materially from that of *Primno macropa*; the last segment of the peraeon is dorsally pointed behind but not strongly produced.

The Upper Antennæ (in the male) have the first joint of the peduncle as broad as long, the second very short, the third inconspicuous or absent, the flagellum of the specimen figured, consisting of one joint, slightly bent, proximally tumid, the tumid part having a small group of five short filaments at the distal end; the remainder of the joint tapering, crossed by numerous lines indicating the future joints. In fig. a.s.C., from another specimen, the second joint of the peduncle is more distinct, the flagellum with the tumid part forming the first joint, the remainder tapering, indistinctly divided into about eighteen small joints. In the female these antennæ are nearly as in *Primno guerini*.

The Lower Antennæ are shorter and thinner than the upper, the three free joints of the peduncle short, not longer than broad; the flagellum in the specimen figured consisting of one joint, long, curved, narrowing in the distal half, but not to a sharp point; the internal appearance in these as in the upper antennæ indicated a future resolution into numerous joints, and perhaps the surface is marked with rings as in the upper pair, but on the glassy skin this could not be made out with certainty.

In fig. *a.i.C.*, from another specimen, the flagellum is longer and contains twenty distinct joints, of which the first is the longest.

The Mouth Organs show no special characters of distinction from those of *Primno guerini*; in the specimen figured the mandibles have a small one-jointed palp; in the second specimen the mandibular palp was two-jointed, the second joint shorter than the first. The condition of the antennæ, as well as the fact that the mandibular palp had not attained its full number of three joints, indicates that each of the specimens is a male not fully adult.

The Gnathopods show no difference from those of the preceding species, except slight variations in proportion of parts, such as might belong to the individual rather than the species; it may, however, be noticed that the side-plate of the second gnathopod is produced into an extremely sharp point, and the first joint less conspicuously dilated than in the species compared.

First Peraopods.—The side-plate is less produced in front; the indents of the third and fourth joints are more pronounced, and the fourth joint is as long as the fifth.

Second Peraopods.—The fourth joint is longer than the fifth.

Third Peraopods.—The teeth on the front margin of the wrist are as follows, a moderately long one with a denticle on its upper margin, two short, a long, four short, a very long one, two short, a long, and three short, close to the hinge of the fifth joint; the fifth and sixth joints together are not as long as the fourth, and the sixth joint or finger is not half the length of the fifth joint. The teeth of the margin of the fourth joint seem much inclined to vary, depriving them of their value as specific characters; thus in the second specimen in one limb these teeth were as follows—one long, two short, one long, four short, one long, three short, one long, three short, the last of these three being double-tipped; in the other limb they were one long, two short, one long, three short, one broken (probably long), three short, one long, four short, the last double-tipped. In the female specimen the teeth on one limb were—one moderately long, two short, one long, four short, one long, four short, one long, four short, the last double-tipped; on the other limb they were—one long, three short, one long, four short, one long, three short, one long, five short, the last double-tipped.

Fifth Peraopods.—These seem to show the most characteristic differences; the first joint is a good deal narrower distally, having a very convex, slightly serrate, hind margin, and a sinuous front margin which is concave above; the five following joints together considerably shorter than the first joint, the first four with shape and proportions nearly as in *Primno macropa*; the finger half the length of the preceding joint or less, with the front margin nearly straight to the apex, then oblique for a very short distance, that portion pectinate with some microscopic hairs or spinules, the terminal one being the strongest, projecting from the tip of the hind margin which as in the other species is bent sharply round at its apex.

Uropods.—The first and second pairs are in near agreement with those of *Primno guerini*; the third pair differ by the smoothness of the margins, the outer having four indents, distant, the intervals not pectinate; in all three specimens examined the distal ends of this pair were broken, an accident which might easily happen to structures of so slight a texture.

Length.—The specimen, in the position figured, measured, in a straight line from the front of the head to the end of the uropods, a fifth of an inch.

Locality.—Station 164D, June 14, 1874; east of Australia; lat. $34^{\circ} 3'$ S., long. $152^{\circ} 20'$ E.; surface; surface temperature, $67^{\circ}.5$. Three specimens, two males, one female.

Remark.—The specific name is given in honour of the celebrated French naturalist, Latreille.

Primno menevillei, n. sp. (Pl. CLXXIX., B.).

This species closely resembles *Primno macropa* in general form and appearance; the first two segments only of the pleon carinate.

Upper Antennæ.—The peduncle of one joint longer than wide, slightly widened distally; the long joint of the flagellum nearly as in the female of *Primno macropa*, with a short row of four pairs of filaments, below which a transverse wrinkle gives the appearance of a division of the joint into two.

The left mandible, lower lip, first maxilla, and second maxilla of the left side, are figured in position in the Plate, both from the outside and the inside. In the figure of the outer side (on the right hand in the Plate), it will be noticed how the convexity of the lower lip, between the front lobe and the mandibular process, fits the concavity of the lower margin of the mandible; in the left hand figure, the mandibular process of the lower lip and its hairy front lobe will be seen peeping out on either side of the molar tubercle of the mandible which hides the central part of the lower lip.

The finger, nail, and distal part of the hand of the first gnathopod are more highly magnified in one of the figures of the species, to show the character of the pectinate hairs on the margin, but this character belongs also to the other species. It is not always easily observed, because its prominence depends on the particular position in which the joints are seen. The true length of the finger is often obscured by its not being outstretched.

Second Gnathopods.—The first joint greatly dilated.

First Peræopods.—The front end of the side-plate is rounded.

Third Peræopods.—The first joint is not very much wider below than above; the teeth of the front margin of the wrist are as follows, the first short, slightly indented on

the upper side, the second long, then two short, a long, three short, a long, two short, a long, and a strongly cleft one adjoining the hinge of the fifth joint; of the cleft tooth the hinder division is the broader and has part of its hind margin finely serrate; the fifth and sixth joints together are scarcely as long as the fourth, the fifth is slender, the finger not quite half its length.

Fourth Peræopods.—The decurrent apical tooth of the hind margin in the third joint is not very long; the front margin of the fourth joint has five teeth, two very small and three larger; it exceeds the length of the third joint.

Fifth Peræopods.—The upper part of the first joint considerably wider than the distal end, the remaining joints together shorter than the first, proportions between them as in *Primno guerini*, except that in the present species the finger is only half the length of the fifth joint; the pectinate distal border of the finger forms a decided angle with the front margin.

The First Uropods differ from those of *Primno macropa* by having the inner margin produced into a small tooth at a little distance from the apex of the plate; the third pair differ by having the inner as well as the outer margin produced into a tooth, the serrate distal margin being produced into an apex between and beyond them.

Telson triangular, not broader than long.

Length.—The length of the specimen was a little over a fifth of an inch.

Locality.—March 9–10, 1874, south of Australia; lat. $48^{\circ} 18' S.$, long. $130^{\circ} 4' E.$; surface; surface temperature, $52^{\circ} 3$. One specimen, female.

Remarks.—The specific name is taken from the addition to his name which Guérin assumed, thereby becoming Guérin-Méneville; an undescribed species was named "*Primno Guerinii*" by White in 1847.

Primno antarctica, n. sp.

Postero-lateral angles of the third pleon-segment not produced.

Upper Antennæ.—The peduncle cylindrical, a single joint longer than broad; the flagellum a single joint little longer than the peduncle, strongly tapering, carrying three filaments above the centre, and one or two setules near the apex.

Gnathopods as in *Primno latreillei*.

First Peræopods.—Second joint as long as the third; third with a minute sub-apical tooth to the hind margin; fourth joint longer than the fifth, with a tooth at the middle of the hind margin, and a larger apical tooth, within which there is a spine not quite so long as the tooth; fifth joint smooth, a little bent at the base; the finger strongly curved at the tip, more than half the length of the fifth joint.

Third Peræopods.—First joint channelled behind, expanded a little below the base,

the lower part of the front margin being slightly convex and very shallowly serrate, the hind margins straight; the second joint channelled behind, the front margin with an acute apex, very little produced; the third joint distally rather broader than the length, the front apex and one of the hinder apices acute, scarcely produced; the fourth joint with the apex of the hind margin acute, not produced; the teeth of the front margin reckoning from the base are, two small, a large one, two small, a very large one, a small one, a very large one, two small ones, the last being double-tipped; the fifth joint is narrow, much shorter than the fourth, its extremity when folded back touching the tip of the third tooth (reckoning from the base); the finger more than half the length of the fifth joint, strongly curved apically.

Fourth Peræopods.—First joint with convex front margin, having some faint distal serration; the third joint widening distally, the front apex acute, not produced, the hinder apex not acute; the fourth joint with three teeth along the front margin; the fifth joint much narrower than the fourth and a little shorter, its front margin spinulose, the apical pectinate; the finger much more than half the length of the preceding joint, apically curved.

Fifth Peræopods.—The first joint not so long as the remaining joints together, as broad as the first of the preceding pair but not so long, the front margin bulging out near the base, then straight, the hind margin convex, slightly crenulate; the second and third joints short, equal in length; the fourth longer than the two preceding together; the fifth longer than the fourth; the sixth shorter than the fourth, rather more than half the front margin smooth and straight or a little convex, the remainder set obliquely, with a row of straight outstanding hairs or spinules and an apical bent nail-like spine.

Pleopods.—Coupling spines with two pairs of lateral teeth below the apical; arms of the cleft spine very slender, that with the subapical dilatation the longer; joints of the rami six or seven in number.

Uropods.—The first pair long and narrow, with a single minute tooth to the inner margin, some way above the very narrow apex; the rest of the ornamentation is extremely minute, but there is some shallow serration of the lower part of the outer margin; the second pair shorter than the first, with the inner margin smooth except for fine furring, the outer convex, with three little teeth, the apex acute; the third pair shorter than the first, longer than the second, broader than either, yet not very broad, having on the outer margin two small teeth and near the apex one very long one; on the inner margin there is one tooth, higher up than the long one of the outer margin; the finely pectinate apex is produced considerably beyond both.

Telson small, not longer than the breadth at the base, rounded, but with a slight apical narrowing.

Length, three-twentieths of an inch.

(Zool. Chall. Exp.—Part LXVII.—1888.)

Xxx 182

Locality.—February 21, 1874, Antarctic Ocean; lat. $63^{\circ} 30'$ S., long. $88^{\circ} 57'$ E.; surface; surface temperature, $32^{\circ}\cdot 5$. Two specimens.

Remarks.—The specific name refers to the place of capture. The narrow and apically outdrawn third uropods are a very distinctive feature of this species.

The following table shows the distribution of the genus *Primno* as illustrated by the Challenger specimens:—

1. Station 354, May 6, 1876; North Atlantic; lat. $32^{\circ} 41'$ N., long. $36^{\circ} 6'$ W.; tow-net. One specimen, female, a third of an inch long, mounted in Canada balsam (probably *Primno macropus*).
2. Station 319, February 12, 1876; South Atlantic; lat. $41^{\circ} 54'$ S., long. $54^{\circ} 48'$ W.; surface. One specimen, a little over a tenth of an inch long.
3. Station 318, February 11, 1876; South Atlantic; lat. $42^{\circ} 32'$ S., long. $56^{\circ} 29'$ W.; 2040 fathoms, tow-net at trawl. One specimen, young male, less than a fifth of an inch long, mounted in Canada balsam along with other species, including a small *Podocerus falcatus*, Montagu. A second specimen, differently mounted, two-fifths of an inch long.
4. January, 1874, Kerguelen Island. One specimen mounted in Canada balsam, a third of an inch long, marked "Phronima sp."
5. Station 154, February 19, 1874; Antarctic Ocean; lat. $64^{\circ} 37'$ S., long. $85^{\circ} 49'$ E. Three specimens, mounted in Canada balsam, the largest one-tenth of an inch long (probably *Primno antarctica*).
6. February 20, 1874, Antarctic Ocean; lat. $63^{\circ} 49'$ S., long. $87^{\circ} 24'$ E. Two specimens, mounted in Canada balsam, the larger three-twentieths, the smaller one-tenth, of an inch long (probably *Primno antarctica*).
7. February 21, 1874, Antarctic Ocean; lat. $63^{\circ} 30'$ S., long. $88^{\circ} 57'$ E.; surface. Two specimens (*Primno antarctica*).
8. March 9–10, 1874, south of Australia; lat. $48^{\circ} 18'$ S., long. $130^{\circ} 4'$ E.; surface; One specimen (*Primno menevillei*).
9. Station 159, March 10, 1874; south of Australia; lat. $47^{\circ} 25'$ S., long. $130^{\circ} 22'$ E. One specimen, mounted in Canada balsam (probably *Primno menevillei*).
10. Station 164D, June 14, 1874; east of Australia; lat. $34^{\circ} 3'$ S., long. $152^{\circ} 20'$ E.; surface. Three specimens (*Primno latreillei*).
11. Station 165, June 17, 1874; between Sydney and Wellington; lat. $34^{\circ} 50'$ S., long. $155^{\circ} 28'$ E. Three specimens (*Primno latreillei*).
12. Station 287, October 19, 1875; South Pacific; lat. $36^{\circ} 32'$ S., long. $132^{\circ} 52'$ W.; surface. One specimen (*Primno macropus*).

The range of the Challenger specimens is therefore from lat. $32^{\circ} 41'$ N. to lat.

64° 37' S. To the range which they show from east to west there are only two localities to be added from earlier sources, namely, the waters of the Pacific off Chili, in which Guérin's type specimen was obtained, and the Atlantic, lat. 8° S., long. 46° E., which White gives for his *Primno guerinii*.

Family PHOREIDÆ, Spence Bate, 1862.

Spence Bate in 1862 established the Phoreidæ as the fourth family of the division Hyperina, placing it between the family Platyscelidæ and the family Oxycephalidæ; in the definition of the family he includes the character "third pair of pereiopoda imperfectly developed," but as all the joints of the third pereiopods are present, and some of them of unusual length, the mere fact of their tenuity can scarcely be described as imperfect development. Bovallius in 1887 gives the following diagnosis:—

"Head nearly globular, a little tumid, deeper than the body. Eyes occupying the lower parts of the sides or the whole sides of the head. First pair of antennæ fixed at the anterior side of the head; first joint of flagellum tumid, the rest subterminal. Second pair few-jointed, short, not angularly folded, fixed at the inferior side of the head. Mandibles with palp (in the males), or wanting palp (in the females). Seventh pair of pereiopoda [*Fifth Peraopods*] reduced. Peduncles [?uropods] normal."

As far as I know, no description distinctly referring to the mandibles of the female in any species of this family has yet been published.

Genus *Phorcorrhaphis*, n. n. (*Phorcus*, Milne-Edwards, 1830).¹

For the original definition of the genus, see Note on Milne-Edwards, 1830 (p. 142). The following descriptions of new species will show that the size of the second pereon-segment does not at any rate afford a generic character, and that the fourth pereiopods

¹ *Phorcus* being preoccupied by Risso in 1826 for a genus of Mollusca, the name is altered to *Phorcorrhaphis*, from *Phorcus* and *ῥάφις*, a needle, in reference to the needle-like third pereiopod.

are by no means always longer than the third, the reverse being more probably always the case; the length of the fifth pereopods, together with their possession of a full complement of joints, makes it inappropriate to speak of them as "presque rudimentaires."

Phorecorrhis zamboangæ, n. sp. (Pl. CLXXX.).

First segment of the peræon longer than the next two united.

Eyes obscure, probably covering the sides of the head.

Upper Antennæ.—The first joint of the peduncle scarcely longer than broad, perhaps representing the first two joints coaleseed; a short second (or third) joint seems on the under side to be coalesced with the flagellum, of which the first joint is longer than the peduncle, tumid, tapering, the breast seemingly prepared for about fifteen transverse rows of filaments; on the upper side there is a small slender second joint affixed, which does not reach the apex of the first. The remainder missing.

Lower Antennæ attached below near the back of the head, much smaller than the upper; third (first free) joint once and a half as long as the fourth; fourth not broader than long; fifth about as long as the first, a setule at the lower apex; these three joints in a continuous line; the first joint of the flagellum equal in length to the last of the peduncle, half its breadth, bent down at right angles to it; the second joint minute, blunt, narrower than the first and not half its length.

Mouth Organs very small and feeble; the *Epistome* appears to be shallow and flat-topped; of the *Mandibles* four figures are given, one of part of a mandible in connection with the epistome, two of a mandible in connection with the maxillipeds, and one of part of a mandible flattened out and showing the dentate cutting edge, but owing to the minuteness of the objects these figures are all more or less speculative; if the appearances can be trusted the *First Maxillæ* consist each of a single long plate apically armed with a few straight spines, and the *Second Maxillæ* each of a narrow triangular unarmed plate; the *Maxillipeds* are broad, the inner plate broad, distally rounded, and smooth-edged, the outer plates folding partially round its sides and projecting not far beyond it.

First Gnathopods small and smooth. The first joint with convex margins, narrowest at each extremity, not so long as the four following joints together, the muscles occupying a very small space; the second joint a little curved, longer than broad, longer than the third joint; the fourth longer than the second; the fifth longer than the fourth, with both margins convex, but the front the more so; the finger more than half the length of the fifth joint.

Second Gnathopods longer than the first, not inserted close to them, the structure very similar but the first joint narrower; the third joint as long as the second, the finger as

long as the fifth joint, slightly curved, of nearly uniform breadth till close to the apex, which is prolonged by an almost setiform nail, with a setule on the inner side.

First Peræopods stouter than the gnathopods, and longer, with smooth margins, the first joint widening distally, the second rather longer than broad; the third longer and broader than the fourth; the fifth joint slightly curved, a little longer than the third, with an exceedingly minute pectination of the distal margin; the finger small, with the base much wider than the rest.

Second Peræopods like the first, but longer, the third joint as long as the fifth.

Third Peræopods.—Branchial vesicles oval, very small. First joint twice as long as the branchial vesicles, rather narrowly oval, longer and considerably broader than the first joint of the preceding pair, having minute submarginal setules along the front; second joint a little longer than broad; third joint straight, narrow, longer than the first, fringed with between twenty and thirty little submarginal setules along the front; fourth joint shorter and more slender than the third, similarly furnished, its length on one side of the specimen longer than that of the first joint, on the other side shorter; fifth joint linear; armed along the front with distant microscopic spinules or setules; the tip of the narrowly tapering joint broken off, but the part remaining exceeding the length of the long third joint.

Fourth Peræopods.—Branchial vesicles a little longer than in the preceding pair, the limb shorter. The first joint longer than in the third peræopods and twice as broad, with a few little setules along the front, which has an occasional mark of serration, the most pronounced being at the apex; the second joint not longer than broad; the third joint nearly as broad as the first and not very much shorter, the hind margin extremely convex, the apex broadly produced downwards, with some microscopic pectination or furring of its margin, the front border with a slight serrature of six teeth and the apex acute; like the two following joints it has some tiny submarginal spinules or setules; the fourth joint much shorter than the third and little more than half the breadth, the hind margin convex, the front cut into eight or more decurrent teeth; the fifth joint a little longer than the fourth, much narrower, the front margin cut into fourteen decurrent teeth, the narrower apical border finely pectinate and having at the back two produced teeth; the finger small, tapering; the tip broken.

Fifth Peræopods slender, longer than the gnathopods. The first joint narrowest distally, as long as the three following joints together, the muscles occupying a very small part of the joint; the second joint longer than broad; the third slender, curved, smooth like the rest of the limb; the fourth rather longer than the third; the fifth shorter than the third; the finger very small and crooked.

Pleopods.—Peduncles stout, those of the first and second pairs longer than the rami; coupling spines minute, round-headed, with only the apical pair of retroverted hooks; the cleft spine slender, rather sinuous, the two arms nearly equal; the first joint of the

inner ramus having two plumose setæ on the inner margin below the eleft spine; the first joint of the outer ramus having on the outer margin two short setæ and one long one; the inner ramus has five joints, the outer six.

Uropods.—Peduncles of the first pair not longer than the rami, the distal margin minutely pectinate; outer ramus shorter and narrower than the inner, the lower part of each margin cut into decurrent teeth, the upper part of the margins very finely pectinate, the inner ramus with the teeth occupying more of the margins than in the outer ramus; peduncles of the second pair scarcely as long as the outer ramus, which is much shorter and narrower than the inner, with the outer margin smooth almost to the apex, the inner margin as in the preceding pair; the outer ramus is similar to that of the first pair, a little broader; the peduncles of the third pair not longer than broad; the outer ramus the shorter, with the outer margin almost straight and smooth, the inner convex, minutely pectinate for some distance, and with five decurrent teeth not far from the acute apex; the inner ramus with rather sinuous inner margin, at first smoothly convex, then cut into three or four little decurrent teeth, below which the ramus forms two lobes, the outer little more than a third the length of the inner, with smoothly rounded apex, the inner being a little sinuous, of nearly uniform breadth to the narrowly rounded tip, at which there is a little fold of the inner margin.

Telson of rather peculiar form, nearly twice as long as broad, reaching to the end of the outer ramus of the third uropods and equalling in length the inner ramus, the lateral margins sinuous, so that the apical half of the telson is much narrowed, distally tapering to a narrowly rounded apex.

Length of the specimen, in the slightly bent position figured, a little less than one-fifth of an inch.

Locality.—Station 202, October 27, 1874; off Samboangan,¹ Philippine Islands; lat. $8^{\circ} 32'$ N. long. $121^{\circ} 55'$ E.; surface temperature, 83° . One specimen, male.

Remarks.—The specific name is taken from the place of capture named on the label. The rami of the third uropods are the most distinctive feature of the species. A second specimen, which must, I think, belong to this species, was taken at Station 81, July 13, 1873; North Atlantic; lat. $34^{\circ} 11'$ N., long. $19^{\circ} 52'$ W.; north-west of Madeira. This specimen shows the eyes occupying the sides of the head, the first flagellum joint of the upper antennæ with a large brush of filaments, the second with three broad ones on the inner margin, the third with two and a setule, the fourth about as long as the second, shorter and much thinner than the third, with two setules at the tip; this last joint reaches a little beyond the apex of the first but not beyond its filaments; the postero-lateral angles of the first three pleon-segments are rounded; the limbs are rather stouter than in the eastern specimen, and the fourth peracopods have the third joint more

¹ Also spelt "Zamboanga," whence the specific name.

elongate, with the apiees more acute, as is also the case with the fourth joint, the marginal armature of the whole limb being stronger; also in the fifth peræopods the first joint is more dilated; the inner ramus of the pleopods has six, the outer seven, joints; the length of the specimen in a slightly curved position was one-fifth of an inch.

Phorocorrhaphis edwardsi, n. sp. (Pl. CLXXXI.).

First segment of the peræon as long as the two following together; postero-lateral angles of the first pleon-segment squared, of the two following segments obtuse.

Eyes occupying the sides of the head.

Upper Antennæ similar to those of *Phorocorrhaphis zamboangæ*, but of the three subterminal joints of the flagellum the first is the longest; the large first joint of the flagellum has a great brush of filaments.

Lower Antennæ minute as in the species just mentioned, the terminal joint of the peduncle longer than the two preceding together, and also longer than the two-jointed flagellum.

Mouth Organs very minute, not made out with sufficient distinctness for description; the general character, as might be expected, the same as in the preceding species.

First Gnathopods.—First joint elongate, oval, as long as the four following together, gland-cells large; the second joint a little longer than broad; the third a little longer than the second, with oblique distal margin; the wrist longer than the third joint, a little shorter than the hand, which is straight, with the margins very slightly convex; the finger curved, half the length of the hand, or rather more.

Second Gnathopods.—All the joints longer than in the first gnathopods, the first joint more slender, longer than the four following joints together; the wrist and hand each a little longer than the third joint; the finger almost straight, very slender, tipped with a slender nail, and with this as long as the hand.

First Peræopods longer and much stouter than the gnathopods, the margins almost entirely smooth. The first joint not much longer than that of the second gnathopods, the second longer than broad, the third longer than the fourth, subequal in length to the slightly curved fifth; the finger about half the length of the fifth joint, bent.

Second Peræopods like the first, but with most of the joints longer; the bent finger not half the length of the fifth joint.

Third Peræopods.—Branchial vesicles shorter than the first joint, narrow at the neck, widened below, with an indent in the lower margin. The limb similar to that of *Phorocorrhaphis zamboangæ*, the first joint rather more widened near the base, with four or five little indents along the front margin, the third joint considerably longer than the first, the fifth longer than the third and much longer than the fourth. In one specimen, mounted in Canada balsam during the voyage, one of the extremely fragile

third peræopods is complete; in this, the needle-like fifth joint is more than twice the length of the fourth, fringed along the front margin with thirty or more tolerably distant setules; the finger is almost straight, about half the breadth of the apical part of the fifth joint, and perhaps not more than a tenth of the length of that joint, and yet from its tenuity having an elongate appearance; the nail is small, setule-like.

Fourth Peræopods shorter than the third. Branchial vesicles more widened below than in the preceding pair, but not on the whole larger. First joint longer than in the preceding pair and more than twice as broad, the convex hind margin sometimes, but not always, having a little indent; the front with five or six small serration-teeth, the gland-cells large; the second joint scarcely longer than the proximal breadth, with two or three submarginal setules; the third joint expanded for gland-cells, broad except at the point of attachment, much longer than broad, but not so long as the first joint, the front margin with five or six serration-teeth, the hinder apex more produced than the front one, neither of them acute, each with a little pectination of the adjacent distal margin, stronger behind than in front; the fourth joint subequal in length to the third, only half the breadth, the front margin cut into twenty-three decurrent teeth, the hinder distal margin finely pectinate; the fifth joint as long as the first, more slender than the fourth, tapering, its front margin cut into numerous decurrent teeth; the finger minute, curved.

Fifth Peræopods slender, longer than the gnathopods, about as long as the first peræopods; the first joint slender, longer than the third and fourth together; the second short, but longer than broad; the third curved, shorter and not broader than the fourth; the fourth rather less curved; the fifth shorter and more curved than the third; the finger minute, curved, much wider at the base than distally.

Pleopods.—Coupling spines not observed; the cleft spine with the dilated arm the longer, its dilatation unsymmetrical and followed by a much produced point; the first joint of the inner ramus has a sinuous apically pointed interlocking process, the pleopods in this and other respects being probably in close agreement with those of *Phoreorrhaphis zamboangæ*; the inner ramus has six joints, the outer seven.

Uropods.—The peduncles of the first pair shorter than the rami; the outer ramus narrower but only a little shorter than the inner, finely pectinate near the base, and cut into decurrent teeth for the greater part of each margin; the inner ramus reaching as far as the apex of the outer of the third pair, with most of the outer margin and the distal part of the inner denticulate; the peduncles of the second pair shorter than those of the first, and shorter than the rami; the outer ramus shorter and narrower than the inner, with its outer margin almost smooth, the inner denticulate, the inner ramus nearly as long as the outer of the first pair and ornamented like the inner ramus of that pair; the peduncles of the third pair widening distally, so that the distal margin equals the length, the rami longer than the peduncles, the outer shorter and much narrower than the inner, its outer margin almost smooth, the inner pectinate and denticulate, the broadly lanceolate

inner ramus having the upper part of the margins smooth, the lower part strongly denticulate.

Telson triangular, as broad as long, a little longer and broader than the peduncles of the third uropods.

Length, in the slightly bent position figured, one-fifth of an inch.

Locality.—April 3, 1875; North Pacific; lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E.; surface; surface temperature, $71^{\circ}.5$. Two specimens, male.

Remarks.—The specific name is given in honour of Milne-Edwards, who instituted the genus *Phorcus*. Two specimens, mounted in Canada balsam during the voyage, one of which has been referred to above, are labelled "Amphipod, surface, Australia." They are both males and evidently belong to this species. A specimen taken March 15, 1874; south of Australia; lat. $39^{\circ} 45'$ S., long. $140^{\circ} 40'$ E.; surface temperature, $60^{\circ}.2$, has the inner ramus of the third uropods reaching as far back as the inner ramus of the third pair, and the telson decidedly longer than broad.

Dana's *Phorcus hyalocephalus*, from the Atlantic, is distinguished from both the Challenger species by having the first two segments of the pereon nearly concealed. "*Phorcus Reynaudii*" or "*Raynaudii*," as described by Milne-Edwards, has the second segment of the thorax or pereon "notablement plus développé qu'aucun des six autres segmens," and, as described by Spence Bate, it has the fourth joint of the third pereopods longer than the third joint, the fifth of the same length and thickness as the fourth, and the finger longer than the fifth joint and of the same diameter. In "*Phorcus Loréni*," Bovallius, from the Caribbean Sea, the first gnathopods are said to be as long as the second, and the first segment of the pleon is said to be shorter than the last two segments of the pereon.

The following table shows the distribution of the genus *Phorcorrhaphis* as illustrated by the Challenger specimens:—

1. Station 81, July 13, 1873; Atlantic, north-west of Madeira; lat. $34^{\circ} 11'$ N., long. $19^{\circ} 52'$ W. One specimen (*Phorcorrhaphis zamboangae*).
2. Off Australia; surface. Two specimens (*Phorcorrhaphis edwardsi*).
3. March 16, 1874; south of Australia; lat. $39^{\circ} 22'$ S., long. $142^{\circ} 27'$ E.; surface. One specimen.
4. March 15, 1874; south of Australia; lat. $39^{\circ} 45'$ S., long. $140^{\circ} 40'$ E.; surface. One specimen.
5. Station 288, October 21, 1875; South Pacific; lat. $40^{\circ} 3'$ S., long. $132^{\circ} 58'$ W.; surface. One specimen, nearly a quarter of an inch long (probably *Phorcorrhaphis zamboangae*).
6. Station 181, August 25, 1874; Pacific, between Api and Cape York; lat. $13^{\circ} 50'$ S., long. $151^{\circ} 49'$ E.; surface. Three specimens.

7. Station 202, October 27, 1874; off Samboangan; lat. $8^{\circ} 32'$ N., long. $121^{\circ} 55'$ E. One specimen (*Phorecorrhaphis zamboanga*).

8. April 3, 1875, North Pacific; lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E.; surfacee. Two specimens (*Phorecorrhaphis edwardsi*).

Only three other localities have been hitherto recorded for this genus, a different species coming from each locality,—*Phorcus reynaudii*, Milne-Edwards, from the Indian Ocean; *Phorcus hyalocephalus*, Dana, from the “Atlantie, latitude 1° south, longitude $18^{\circ} 20'$ west”; and *Phorcus loréni*, Bovallius, from the Caribbean Sea. Bovallius alone makes any reference to the females of this genus, and he only incidentally in giving the characters of the family; all the Challenger specimens appear to be of the male sex.

• Genus *Lycaopsis*, Claus, 1879.

1879. *Lycaopsis*, Claus, Die Gattungen und Arten der Platysceliden, pp. 32, 41.

1887. „ Bovallius, Systematical List of the Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 29.

1887. „ Claus, Die Platysceliden, p. 66.

For the shorter of the original definitions of this genus, see Note on Claus, 1879 (p. 493). In 1887 Claus places the genus next to *Phorcus*, and describes it to the following effect:—

“ Form *Lycaea*-like, with thick deep head, elongate peraeon and pleon. Segments of the peraeon comparatively long, strongly imbricated, especially the two segments carrying the Gnathopods. Front Antennae of the female five-jointed, with long stiliform terminal joint, those of the male with three-jointed flagellum. Hind antennae short, with hook-like bend, five-jointed, without counting the extensive basal-plate which has a joint-like distinctness. The eyes extended over almost the whole surface of the head with large pigment mass. Mandibles outdrawn, stiletto-like. Maxillipeds with large split inner plate, and broad outer plates with shell-like curvature (schalenförmig gebogenen). Gnathopods weak, simple; the first pair with large gland-cells in the dilated first joint, those of the second pair thinner and more elongate. Laminar first joint in the third and fourth pereopods comparatively elongate, that of the latter much the more extensive. Fourth pereopods very strong, much longer than the preceding pair, almost twice as long. The fourth and fifth joints of this pair considerably elongated and with pectinate front margin. Fifth pereopods feeble, but elongate, with the full number of joints. Branchial vesicles limited to the fifth and sixth segments. Peduncles of the first pair of uropods as long as the leaf-shaped rami.”

Bovallius in the same year, 1887, places the genus in the family Phoreidæ, to which it clearly belongs.

Lycæopsis pauli, n. sp.

Head much deeper than long, deeper than the peræon; postero-lateral angles of the first three pleon-segments squared, or with scarcely perceptible outdrawn points; the fourth pleon-segment shorter than the following composite segment.

Upper Antennæ lying directed downwards within the frontal groove of the head; first joint longer than the second; the third longer than the preceding two together, tapering, with filaments on the inner margin; the following joint short and almost linear.

Lower Antennæ placed just behind and above the mouth organs; the joint containing the gland-cone partially free, the next or third joint of the peduncle longer than the fourth, but slightly shorter than the fifth; the flagellum at right angles to the peduncle, the first joint shorter and much narrower than the last of the peduncle, the second or terminal joint not half the length of the first.

First Gnathopods.—First joint with the front margin almost straight and the hind margin nearly parallel to it, the joint being very slightly dilated above; the larger part of it occupied by the gland-cells; the second joint longer than broad, bent; the third scarcely so long as the second, the fourth rather longer than the second, with convex front margin; the fifth longer than the fourth, narrowed distally; the finger curved, strong, much more than half the length of the fifth joint, the limb seemingly smooth throughout.

Second Gnathopods.—The first joint narrower than in the first pair, with parallel margins, the front convex, the hinder concave; the second joint considerably longer than broad, the third longer than the second, the fourth not longer than the third; the fifth longer than the fourth; the finger rather longer than the hand, almost straight, with a narrow, slightly curved, acute nail.

First Peræopods much longer and stouter than the gnathopods; the first joint straight, a very little widened below; the second joint with the hinder margin longer than the breadth of the joint; the third joint longer and broader than the fourth, with convex front margin; the fifth joint longer than the fourth, scarcely so long as the third, tapering, a little curved; the finger not half the length of the fifth joint, bulbous at the base, then suddenly narrowed and bent, the terminal part straight, tapering to a sharp point, the distal division being longer than the proximal; the limb like the gnathopods almost entirely smooth.

Second Peræopods scarcely differing from the first, except that the joints are rather longer.

Third Peræopods.—Side-plates bilobed, broader than deep. Branchial vesicles small scarcely half the length of the first joint, irregularly oval, narrower at the neck than distally. The first joint expanded but not widely, neither margin being strongly convex,

the front serrate with six distant teeth, of which the apical is the longest ; the second joint a little longer than broad ; the third joint narrower than in the second peræopods, straight, with three distant teeth on the front margin. The rest of the limb missing.

Fourth Peræopods much larger than the third, but not as disproportionate as in *Lycæopsis themistoides*, Claus. Branchial vesicles little larger than the preceding pair, scarcely half the length of the first joint, narrow at the neck, the remainder an oval, broad at both ends. The first joint not much longer but much more widely expanded than in the preceding pair, the front margin serrate in the same manner ; the second joint a little longer than broad ; the third joint straight, three-quarters of the length of the first joint, much longer than the fourth, the front margin serrate with eight or nine teeth ; the hind margin smooth, except for a little apical setule ; the fourth joint with the front margin divided into ten decurrent teeth, closely set ; the fifth joint slightly curved, longer than the third, nearly as long as the first, the front margin slightly concave, serrate with sixteen adpressed teeth, which near the apex become longer and more distant than higher up ; the finger small, the hind margin forming a tooth, beyond which the remaining quarter of the joint projects like a nail.

Fifth Peræopods.—Side-plates broader than deep, narrowly outdrawn behind. The first joint not nearly so long as the third, fourth, and fifth joints together, a little widened for gland-cells at the upper part, the front margin straight, the hinder convex till near the apex ; the second joint longer than broad, the third twice the length of the second, the fourth longer than the third, the fifth longer than the fourth in one of the limbs, not longer in the other ; the finger very small, with bulbous base and strongly curved termination ; the total length of the limb exceeding that of the first joint of the preceding pair.

Pleopods.—Coupling spines minute ; the cleft spine with unsymmetrical subapical dilatation of the longer arm ; the inner ramus with four joints, the outer with five.

Uropods.—Peduncles of the first pair reaching the end of the coalesced segment, about as long as the rami ; the rami reaching nearly as far back as those of the third pair, the inner margin and lower part of the outer cut into decurrent teeth ; the peduncles of the second pair reaching nearly as far as those of the first, longer than the outer, shorter than the inner, ramus ; the outer ramus much shorter and narrower than the inner, seemingly with both margins smooth, the inner ramus ornamented like those of the first pair ; the peduncles of the third pair little longer than broad ; the outer ramus rather shorter and much narrower than the inner, smooth ; the inner with teeth on less than half the outer, and more than half the inner, margin.

Telson extremely transparent, so that its boundaries are difficult to observe, very little longer than broad, the sides at first convex, then flattened, converging to a broadly rounded apex, about a third of the length being beyond the peduncles of the third uropods.

Length, at full stretch, one-tenth of an ineh.

Locality.—Station 108, August 27, 1873; off St. Paul's Rocks; lat. $1^{\circ} 10' N.$, long. $28^{\circ} 23' W.$; surface; surface temperature, 78° . One specimen, female, with eggs.

Remarks.—The specific name is taken from the place of capture. Bovallius describes a species of this genus, *Lycaopsis lindbergi*, from “tropical parts of Atlantic,” but it differs from the present in having the joints of the fourth pereopods very dilated, the third joint of that pair longer than the fifth; the first joint of the fifth pereopods dilated, ovate; the peduncles of the second uropods shorter than the outer ramus, the coalesced fifth and sixth segments of the pleon longer than the third uropods, and the telson nearly twice as long as the peduncles of those uropods. From *Lycaopsis themistoides*, Claus, a specimen of which has been sent me by Dr. Bruce from the neighbourhood of Malta, the present species differs as well by its more diminutive size, as in having the fourth joint of the fourth pereopods shorter instead of longer than the third; the first joint of the fifth pereopods not quite linear, and shorter than the third, fourth, and fifth joints together; the composite segment of the pleon not shorter than the third uropods, and in some other particulars.

Family T Y P H I D A E, Dana, 1852.

Milne-Edwards in 1840 established the “Tribu des Hypérines anomales” for the genera *Typhis*, *Pronoe*, and *Oxycephalus* (see Note on Milne-Edwards, 1840, p. 190). In 1852 Dana established the equivalent family Typhidae, with additional genera distributed among three subfamilies, Typhinæ, Pronoinæ and Oxycephalinæ (see Note on Dana, 1852, p. 259). In 1862 Spence Bate united the first two of these subfamilies to form the family Platyscelidæ (see Note on Spence Bate, 1862, p. 337). Claus in 1879 adopted the title Platyscelidæ as the equivalent of Milne-Edwards’ *Hyperina anomala*, including under it the five families, Typhidae, Seelidæ, Pronoidæ, Lycæidæ, Oxycephalidæ (see Note on Claus, 1879, p. 490). Bovallius in 1887 drops the divisional or tribal title Platyscelidæ, but retains the five families, naming them respectively Eutyphidae, Paraseelidæ, Pronoidæ, Tryphaenidæ, Oxycephalidæ (see Note on Bovallius, 1887, p. 590).

The earliest description of any species belonging to this group appears to be that given of *Oniscus gibbosus* by J. C. Fabricius in 1775 (see Notes on Fabricius, 1775, p. 40, and 1793, p. 59). This species, which was afterwards called *Gammarus gibbosus*, and which probably belongs to the Pronoidæ, is figured in the Banksian Museum among the zoological drawings by Sydney Parkinson in Captain Cook’s First Voyage, with the name “*Onidium gibbosum*, T. 16. P. Sept. 7. 1768.”

For the Eutyphidae Bovallius gives the following diagnosis:—

"Body very broad. Head large, deeper than the body, a little produced anteriorly. Eyes large, occupying the whole sides of the head. First pair of antennæ fixed at the under-side of the head; first joint of flagellum tumid, the rest of flagellum subterminal. Second pair fixed at the under-side of the head, angularly folded (♂) or wanting (♀). Mandibles with palp. Femora of fifth, sixth and seventh pairs of pereiopoda [first joint of *Third, Fourth, and Fifth Peraopods*] transformed into perfect opereula. Seventh pair [*Fifth Peraopods*] reduced."

For the original definition of the genus *Typhis*, see Note on Risso, 1816 (p. 97). For the brief original definition of *Platyscelus*, see Note on Spence Bate, 1861 (p. 327).

¹ " *Platyscelus Batei*," Streets, 1877, with the wrists of the gnathopods not produced and neither wrists nor hands serrated, cannot belong to this genus, unless based on an incompletely developed specimen.

For the short definition of *Eutyphis*, see Note on Claus, 1879 (p. 490). Since *Thyropus*, Dana, clearly coincides, as indicated by Bovallius, with *Tanyseelus*, Claus, while *Dithyrus*, Dana, is involved in much doubt (being considered by Bovallius to be the same as *Hemityphis*, Claus, and by Claus himself to be the same as *Eutyphis*), the name *Platyscelus* remains as the earliest synonym of the preoccupied *Typhis*. It is unfortunate that *Platyscelus* should come so near to two earlier names, *Platyscelis* and *Platyscelum*, but it is not for all that the same as either. It has also the advantage of being explanatory of the title *Platyseelidae*, which Claus has adopted for the group, at the head of which this genus in right of priority may be considered to stand.

Platyscelus ovoides (Risso?).

1879. *Eutyphis ovoides*, Claus, Die Gattungen und Arten der Platysceliden, p. 9.

1887. " " Claus, Die Platysceliden, p. 35, Taf. i. figs. 1-11, Taf. ii. figs. 1, 2, Taf. iii. figs. 1-3.

The depression in the front of the head between the eyes and the rostral triangle not transverse as in *Platyscelus armatus*, but triangular.

Eyes.—The lower division approaching the rostrum more closely than in the species just mentioned.

The Second Gnathopods, the Third, Fourth, and Fifth Peraopods, the Uropods and Telson, as well as the general appearance of the specimen, agree so completely with Claus' figures and description of *Eutyphis ovoides*, that, though its place of capture is so distant from the localities hitherto recorded for the species, there seems no reason to doubt the identification. The First Gnathopods were not examined. The third joint in the first, second and third peraeopods is here relatively much shorter than in the species next described. In the Fourth Peraopods the middle part of the hind margin is setiferous, but this part is not straight, as it is in *Thyropus ovoides*, Spence Bate.

Uropods.—Peduncles of the first pair with the outer margin and outer part of the distal margin pectinate, the outer ramus a little shorter and narrower than the inner, having its outer margin pectinate, and the distal margin on the inner side of the minute apex also pectinate, but much more finely; the inner ramus has the margins pectinate distally, more finely on the outer than on the inner side; peduncles of the second pair very short, the outer ramus almost smooth, decidedly shorter and much narrower than the inner, the inner having its broad distal margin finely pectinate on either side of the minute apex; the third pair with the outer ramus much shorter and narrower than the inner, not apically widened, pectinate near the apex, more on the inner than on the outer margin; the inner ramus coalesced with the peduncle, pectinate along almost all the outer margin and on the lower part of the inner, apically acute though widened a little above the apex, not reaching quite to the narrowly rounded apex of the telson.

Length.—From the front of the head to the end of the third pleon-segment the specimen measured almost half an inch.

Locality.—Station 243, June 26, 1875; North Pacific; lat. $35^{\circ} 24'$ N., long. $166^{\circ} 35'$ E.; deep tow-net. One specimen, female with numerous eggs.

Remarks.—On various parts the specimen has slightly swollen blotches, probably caused by some parasite.

In *Dithyrus faba*, Dana, the first joint of the fourth peræopods is represented with the terminal part outdrawn as in this species, but it would be rash to identify the two on the existing evidence. Whether Risso's *Typhis ovoides* and Spence Bate's *Thyropus ovoides* are really the same species as Claus' *Eutyphis ovoides* is still perhaps open to question. *Platyscelus intermedius*, G. M. Thomson, from New Zealand, seems scarcely if at all distinguishable from *Platyscelus ovoides*.

Platyscelus armatus (Claus) (Pl. CLXXXII.).

1879. *Eutyphis armatus*, Claus, Die Gattungen und Arten der Platysceliden, p. 19.

1887. *Eutyphes armatus*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 45.

1887. *Eutyphis armatus*, Claus, Die Platysceliden, p. 36, Taf. ii. figs. 3-15.

Head broad, with downward bent, triangular rostrum, the apex of which is wedge-like; a depression crosses the front of the head just below the eyes and above the rostral triangle; the peræon is of great breadth, its first two segments extremely short, especially at the centre; the first three segments of the pleon with oblique lateral depressions; the fifth and sixth segments and the telson coalesced, forming an equilateral triangle, the sides of which neatly fit the straight section of the hind margin in the first joint of the fourth peræopods; the apex of the first joint of the third pereopods reaches the rostral point of the head, the animal being thus able to assume a compact egg-shape, but having the side-plates of the fourth, fifth, and sixth peræon-segments projecting, those of the fifth segment most prominently and sharply.

Eyes large, divided by a narrow central line, occupying all the surface of the head except the front portion already indicated; in each eye a lower division is indistinctly marked off from the much larger dorsal, the lower division not reaching as far as the rostrum.

Upper Antennæ (of the male).—The first joint of the peduncle longer than broad, the second short; the first joint of the flagellum much longer than the peduncle, strongly bent, the convex margin thickly beset with long hair-like filaments, not itself projecting beyond the base of the next joint, which is about twice as broad as long, carrying a few pairs of filaments; the next joint shorter, and not half as wide, with a pair of filaments below the centre, then narrowing; the fourth joint not present in the specimen examined.

Lower Antennæ (of the male).—Third (first free) joint of the peduncle forming a narrow neck, then widening till near the apex, which, however, is wider than the neck, the edges smooth; the fourth joint less than twice as long as the third, widened at the distal end; the fifth joint rather shorter than the fourth; the first joint of the flagellum less than a third of the length of the last of the peduncle, the second joint a very little shorter than the first.

Mandibles.—The trunk sinuous, the palp attached behind the centre; the cutting edge with a rounded strongly projecting tooth at the upper corner, in the left mandible the lower corner also projecting a very little flatly with denticulate edge, the intermediate space striated and very minutely denticulate; each mandible has a secondary plate, triangular, with the front edge closely adjoining that of the principal plate and very similar to it but of smaller extent; on the left mandible there is an additional plate overlapping the lower part of the secondary one, to which it is similar but smaller and with undenticulate edge; the first joint of the palp is considerably the longest, the second a little longer than the third.

First Maxillæ.—The single plate has four teeth at the distal end of the inner margin.

Maxillipeds.—The outer plates broad, with sinuous inner margin and the apex rounded, distally carrying a few setules.

First Gnathopods.—Side-plates with the lower front angle acute, to which there runs a ridge of the inner surface. First joint narrow near the base, then widening a little abruptly with convex front margin carrying distant setules or slender spines; second joint with such spines on the lower part of the hind margin; third joint wrist-like, with slender spines along the hind margin, a few on the surfaces and on the lower part of the front margin; the wrist longer and much broader than the hand, with slender spines distributed as on the preceding joint, but not on the lower part of the denticulate hind margin; the produced hinder apex forms a broad triangle, not as long as the hand, having a dozen little teeth on the inner or front margin; the hand has about fifteen little teeth on the hind margin, and two or three on the apex; the finger is minute, little curved.

Second Gnathopods.—Side-plates with the lower hinder angle rounded and produced a little backwards. The first joint longer than in the preceding pair, with the front margin concave; the third joint longer than in the first gnathopods, and the wrist considerably longer though but little broader, with numerous spines on the inner surface, the produced apex nearly as long as the hand, with about twenty teeth on the inner edge; the hand a little longer than in the preceding pair, with about twenty denticles on the hind margin, and two or three on the apex; the finger as in the first pair.

First Peræopods.—Branchial vesicles very large. First joint longer than that of the second gnathopods, with a narrow neck, then widened, with convex hind margin; second joint longer than broad; third joint curved, elongate but shorter than the first joint, the

front margin eonvex, the hinder eoneave, the joint much narrower and more elongate and with the gland-cells less conspicuous than in *Platyscelus ovoides*; the fourth joint shorter and narrower than the third, less curved; the fifth joint straight, much shorter than the fourth; the finger small, narrow, curved, folding closely against the apical part of the fifth joint, which at first bulges a little and is then narrowed, carrying one or two quite minute spines or spine-like processes.

Second Peræopods very similar to the first.

Third Peræopods.—Side-plates forming a strong acutely projecting process; within them there is a small triangular process pointing backwards. First joint two and a half times as long as broad, with the hind margin forming a long bow, the front a little sinuous, faintly serrate, considerably longer than all the remaining joints together, much of the surface showing scale-like sculpture; the third joint stouter and a little longer than the fourth; the fourth with a little pectination at the distal part of the front margin; the fifth rather longer than the fourth, with the front margin finely pectinate; the finger minute.

Fourth Peræopods.—First joint longer and very much broader than in the preceding pair, with the front margin much excavate to receive the convex hind margin of the first joint of the third peræopods, the hind margin very convex at the upper part; then nearly straight, channelled, with a short longitudinal groove of the sculptured surface near and in front of the top of the channelled part, of which the inner margin is fringed with setules; second joint short and bent, considerably above the broad distal margin of the first, and not reaching its hind margin; the third joint longer and broader than the fourth, having the front margin pectinate with teeth which as they approach the apex are retroverted, the apex very slightly produced; the fourth joint armed like the third, the apex not produced; the fifth joint little more than a third as long and less than a third as wide as the fourth, straight, nearly smooth but with some extremely minute pectination of the front margin; finger not observed. This limb and the preceding are figured from the inner surface. In fig. *prp.4*, the fifth joint is missing only from a defect in the specimen; the groove of the first joint shows through from the outer surface.

Fifth Peræopods.—The first joint as long as that of the second gnathopods, of tolerably uniform breadth, curved so that the front margin is somewhat eoncave, the hinder convex; at the extremity of the front margin there are two or three quite minute terminal joints.

Pleopods.—The peduncles stout, strongly produced into a rounded lobe on the inner side, the very small coupling spines being placed above this lobe; the eleft spine not very strong, with subequal arms, one of them having a slight subapical dilatation; the inner ramus with thirteen or fourteen joints, the outer with fourteen or fifteen.

Uropods.—Peduncles of the first pair shorter than the rami, widening distally, set as far apart as possible, the outer margin and outer corner of the distal margin pectinate;

the rami nearly equal, the inner a little the longer, the outer with the outer margin and lower part of the inner pectinate and a small pointed apex, the inner similar, except that of the outer margin only the lower part is pectinate; the peduncles of the second pair little longer than broad; the outer ramus about as large as one of the preceding, the inner considerably larger; peduncles of the third pair not longer than broad; outer ramus shorter than the inner, with smooth outer and pectinate inner margin, the inner ramus apparently coalesced with the peduncle, both margins pectinate for most of their length, the pointed apex not quite reaching the end of the telson.

Telson, reckoning from the bases of the third uropods, broader than long, triangular, with rounded apex, the margins continuous with those of the coalesced segment.

Length of the figured specimen, in its folded position, two-fifths of an inch.

Localities.—April 3, 1875, North Pacific, between New Guinea and Japan; lat. $24^{\circ} 49' N.$, long. $138^{\circ} 34' E.$; surface; surface temperature, $71^{\circ}.5$. Two specimens.

April 28, 1876, North Atlantic; lat. $17^{\circ} 47' N.$, long. $28^{\circ} 28' W.$; surface, night; surface temperature, 73° . One specimen, half an inch long with the pleon flexed. (Figs. *ep.A.* and *mx.²A.*) With this were taken two smaller specimens, not having the acutely projecting side-plates, yet probably belonging to this species, and either presenting one of the stages of growth, or being, as Claus suggests in his description of *Eutyphis inermis*, a smaller unarmed variety.

April 29, 1876, North Atlantic; lat. $18^{\circ} 8' N.$, long. $30^{\circ} 5' W.$; surface, night; surface temperature, $73^{\circ}.7$. One specimen, with the acute side-plates, and one specimen unarmed.

Platyscelus rissoinæ, Spence Bate.

1862. *Platyscelus Rissoinæ*, Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 329, pl. lii. figs. 9, 8*b*, 8*c*, 8*d*, 8*i*.¹

The species, at least as represented by the Challenger specimen, has a strong resemblance to *Platyscelus ovoides* (Risso ?) and also to *Platyscelus armatus* (Claus), with which latter species Claus supposed Spence Bate's species might be identical, but our specimen is a large one and yet is without the acutely projecting side-plates, which seem to be a distinguishing character of the adult *Platyscelus armatus*; the following particulars may be noticed:—

Lower Antennæ not as in the type specimen with "the first three joints subequal," but with the first free joint longer than all the following joints together, the second and third subequal to one another, the fourth much more slender than the third and only half its length; there is also a minute fifth joint tipped with a little setule.

¹ Though from the numbering the figures 8*b* to 8*i* appear to refer to "*Thyropus ferus*" (Milne-Edwards), it is clear from the descriptions that they refer to *Platyscelus rissoinæ*; the figures which Milne-Edwards gives of the gnathopods of his *Typhis ferus* are quite different and are not copied in the British Museum Catalogue, which gives only the full figure and the upper antennæ of that species.

First Gnathopods.—The wrist apically squared rather than produced.

Second Gnathopods.—The wrist broader as well as much longer than that of the first pair, the hand, when bent against it, not reaching at all beyond the apex of the wrist's process.

First and Second Peræopods.—The first joint with elongate neck.

Third Peræopods.—Front margin of the first joint not at all serrulate, the fifth joint much shorter than the fourth.

Fifth Peræopods.—The first joint a little narrowed apically.

Uropods.—The rami of the first pair are broad, abruptly narrowed distally, the outer ramus rather shorter than the inner (not, as in Spence Bate's description, equal); of the second pair the proportions were not ascertained (Spence Bate gives the rami equal). In the third pair the apex of the longer inner ramus reaches beyond the telson as in Claus' figure of *Platyscelus armatus*.

Length, sixth-tenths of an ineh.

Locality.—Station 172A, July 22, 1874; off Tongatabu; lat. $20^{\circ} 56' S.$, long. $175^{\circ} 11' W.$; 240 fathoms; surface temperature, 75° . One specimen, female, containing numerous young ones.

Remarks.—The species is separated from the Mediterranean *Platyscelus ovoides* by details of the third and fourth peræopods, in the third pair the first joint having its front margin almost completely smooth instead of finely serrate, and in the fourth pair the first joint having the slit on the outer surface extremely small instead of tolerably long, its position corresponding with that in *Platyscelus armatus*.

The young show some curious differences from the young of Risso's species as figured by Claus. The head corresponds with that described by Spence Bate for the young of his *Platyseelus serratus*, being long and narrow, tapering anteriorly. The mouth organs bulge conspicuously on the under side of the head.

The Upper or Anterior Antennæ are situated on the under surface of the head very near the rounded apex, which is folded under; the first joint thick, longer than broad, the second narrower, not longer than broad, the third much smaller than the second, carrying an apical setule; the first joint of the flagellum nearly as long as the first of the peduncle, with a subapical group of four short filaments, the second joint shorter with four long filaments at the truncate apex, one longer than the other three.

The Lower Antennæ are attached far back, a little above and in front of the base of the mouth organs; the first joint is rather long, the second and third shorter, these three presumably constituting the peduncle; the two following joints are much shorter and slenderer, about equal in length, the terminal one tipped with four filaments, the penultimate having a single subapical filament.

The Gnathopods are peculiar; the first joint is, as in the adult, the longest, it is

distally much widened; the second is longer than the third; the third has a long slender spine at the hinder apex; the fourth or wrist is distally narrowed, with a spine at the apex of the hind margin, and a concave distal margin projecting behind the hand; the hand is much narrower than the wrist, with a short, convex hind margin, while the front is prolonged tongue-like in front of the slender curved finger, the acute apex of which projects a little beyond it, and has an adjacent cilium.

The Peræopods are very like those figured by Claus for the young of *Platyscelus ovoides*.

The First and Second Peræopods have the first joint rather dilated, the second joint about as long as the fourth, the third a little longer than either, with a seta or slender spine at the hinder apex; the fifth joint is longer than the third, which, like the fourth, has the slender spine of the hind margin above the apex; the finger is slender, curved, more than half the length of the fifth joint.

The Third Peræopods have the first joint more dilated than in the following pairs; the second joint is longer than the fourth, about equal to the fifth, the third is longer than the second, these four having each a subapical spine or seta on the front margin, the fifth also one at the apex behind; the finger is curved, with a little acute nail; much more than half as long as the fifth joint.

Fourth Peræopods shorter than the third or fifth; the first joint as long as the other joints together, with the hind margin convex, the front nearly straight; the second joint a little longer than broad, shorter than the fourth joint; the third joint longer than the fourth; the fifth joint shorter than the fourth, and abruptly very much narrower, quite unlike the fifth joint in any of the other limbs; the finger is minute, appearing to form a sharp but very short point in front, behind which there is a fold of the finger scarcely longer than the front, with a cilium in the bend. The second, third, and fourth joints have each a subapical seta, but much smaller than in the preceding limbs.

Fifth Peræopods elongate; the first joint narrower than in the preceding pair, the second joint longer than broad; the third longer than the second, the fourth than the third, the fifth than the fourth; the fifth is slightly narrowed at the neck and apex; the finger is very small, horseshoe-shaped, retractile, capable of lying completely within the narrow truncate apex of the fifth joint.

Pleopods.—Peduncles not longer than the rami. The two coupling spines well-developed; each ramus consisting of two joints, the first broad and long, with a plumose seta at each apex, the second short, as broad as its length, with the usual two apical setæ; there is a small cleft spine near the top of the inner margin of the first joint of the inner ramus.

Uropods.—Peduncles of the first pair as long as the inner ramus; the outer ramus shorter than the inner, both almost smooth, narrowing to rounded apices; peduncles of the second pair shorter than the inner ramus; the outer ramus rather shorter than in the first pair; peduncles of the third pair as long as the short outer ramus; the inner ramus

is longer and broader than the outer, and broader than any of the other rami; in this pair each ramus has a cilium or setule at the rounded apex. None of the rami are here long and acute as represented by Claus and Spence Bate for the young of the species which they describe.

Telson almost circular, reaching a little beyond the peduncles of the third uropods.

Length.—About a fifteenth of an inch.

Platyseelus serratulus, n. n.

1879. *Eutyphis serratus*, Claus, Die Gattungen und Arten der Platysceliden, p. 11.

1887. " " Claus, Die Platysceliden, p. 37, Taf. iii. figs. 5–14.

The rostral angle produced, the segments imbricated.

Lower Antennæ, of the male, with the second joint of the flagellum rather longer than the first.

Epistome, as in the other species, forming a shallow dome, much broader than deep.

Maxillipeds.—The outer plates very broad, the inner plate having two little embedded spinules below the centre of the distal margin.

First and Second Peraopods.—Third joint not very elongate, not much longer than the fourth, the gland-cells not conspicuous; fourth joint not much longer than the fifth.

Third Peraopods.—The third joint slightly longer than the fourth.

Fourth Peraopods.—The first joint has a much longer slit on the outer surface than is found in *Platyseelus armatus* or *Platyseelus rissoinæ*.

Localities.—April 28, 1876; North Atlantic; lat. $17^{\circ} 47'$ N., long. $28^{\circ} 28'$ W.; surface, night; surface temperature, 73° . One specimen.

Station 348, April 9, 1876; North Atlantic; lat. $3^{\circ} 10'$ N., long. $14^{\circ} 51'$ W.; surface to 200 fathoms; surface temperature, 84° . Four specimens, the largest, a male, under one-fifth of an inch long; in this specimen the fifth peraeopods have a minute tubercular second joint, and no third joint; as in the specimen last mentioned the telson is distally more narrowed than in Claus' figure.

Station 106, August 25, 1873; between St. Vincent and St. Paul's Rocks; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; surface to 40 fathoms; surface temperature, $78^{\circ} 8$. One specimen, female, a fifth of an inch long. In the fifth peraeopods there are two small terminal joints, the end one longer and thinner than the penultimate.

Station 108, August 27, 1873; off St. Paul's Rocks; lat. $1^{\circ} 10'$ N., long. $28^{\circ} 23'$ W.; surface; surface temperature, 78° . One specimen.

Remarks.—Claus, who identifies *Platyseelus serratulus*, Spence Bate, with *Typhis ovoides*, Risso, himself establishes a new species with the name *Eutyphis serratus*; as the generic name *Platyseelus* is here allowed its right of priority, an alteration is at the

same time required of the preoccupied specific name. Bovallius, in his Systematical List of the Hyperina, does not mention Claus' *Eutypphis serratus*, perhaps considering it to be the same with *Typhis ferus*, Milne-Edwards, 1830, figured in the Annales des Sciences naturelles, t. xx. pl. xi. figs. 8-18. If those figures, however, may be trusted, the present species, though agreeing in respect of the lower antennæ of the male and in various other points, differs in several particulars; in the first gnathopods the process of the wrist, which is pectinately toothed along both margins, at its base is closely adjacent to the hand, not separated from it by a space; in the second gnathopods the third joint is more out-bowed in front, and the wrist has the distal process as long as the proximal part; the third joint of the first pereiopods is of less proportional length; and whereas in Milne-Edwards' figure the rami of the third uropods are subequal, the inner if anything the shorter, in Claus' species the outer ramus is much shorter and narrower than the inner, which is only feebly jointed to the peduncle, if not coalesced with it; the telson is also broader at the base than the length in Claus' species, but the reverse in Milne-Edwards'. In the Challenger specimen the apex of the telson is a little narrowed, not broadly rounded as in Claus' figure.

Genus *Hemityphis*, Claus, 1879.

- 1879. *Hemityphis*, Claus, Die Gattungen und Arten der Platysceliden, pp. 4, 12.
- 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 482.
- 1887. *Dithyrus*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 46.
- 1887. *Hemityphis*, Claus, Die Platysceliden, pp. 31, 38.

For Claus' definition of *Hemityphis*, see Note on Claus, 1879 (p. 491). The points by which Claus distinguishes *Eutypphis* from *Hemityphis* are simply, that in *Eutypphis* (*Platyscelus*) the two terminal joints of the hinder male antennæ are very short, and the outer plates of the maxillipeds are slightly concave on the inner margin, while in *Hemityphis* the two terminal joints of the hinder male antennæ are long (though notably shorter than the two preceding joints), and the inner margins in the maxillipeds are deeply concave.

Bovallius in 1887 identifies *Hemityphis* with *Dithyrus*, Dana, but without giving his reasons. Claus has pointed out that Dana established his genus *Dithyrus* on a damaged specimen of the female sex, and suggests that the type species, *Dithyrus faba*, may be the same as his own *Eutypphis inermis*. Dana's figures and descriptions do not in fact supply the means of deciding whether he was dealing with a species of *Platyscelus* or *Hemityphis*. The figure, which he gives as representing either the first or the second pereiopod, by the straight downward-pointed finger is rather in agreement with *Hemityphis* than with *Platyscelus*, but on so minute a detail it is impossible to lay much stress, where it has not been observed for a special purpose. According to Dana

the first peræopod in his species is a little longer than the second, whereas both in *Platyscelus* and *Hemityphis* the reverse is the case; this would tend to show either that Dana's genus is different from both those mentioned, or that no extreme weight is to be given to his accuracy in minutiae. The long peræon shown in the full figure of *Dithyrus faba* is more like that of a species of *Platyscelus* than it is to those hitherto figured of *Hemityphis*, and, in the absence of other evidence, it seems just that *Hemityphis*, Claus, which can be perfectly well recognised, should hold its place, and that the name, *Dithyrus*, Dana, should stand aside until some species has been found to correspond with Dana's definition.

Hemityphis tenuimanus, Claus (Pl. CLXXXIII.).

- 1879. *Hemityphis tenuimanus*, Claus, Die Gattungen und Arten der Platysceliden, p. 12.
- 1887. *Dithyrus tenuimanus*, Bovallius, Systematical List of Amph. Hyper., Bihang. till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 46.
- 1887. *Hemityphis tenuimanus*, Claus, Die Platysceliden, p. 38, Taf. iv. figs. 1-13.

The Head broad, sloping a little downwards and forwards, the rostral angle not projecting but folded underneath; the peræon with evenly convex sides as viewed from above, all the seven segments very short, so that all of them together at the centre of the back do not equal the length of the head or one-third the length of the pleon; on the other hand the greatest width of the animal is at the centre of the peræon; the first three segments of the pleon are long, the first about as broad as the head, the two following successively narrower; the sides are earinate, the hind borders below the earina being emarginate; the fourth segment is much shorter but not much narrower than the third; the fifth and sixth segments and the telson are coalesced, forming a triangular piece, of which the sides are a little convex near the base, slightly interrupted at the insertion of the third uropods, but otherwise converging in a nearly straight course to the narrowly rounded apex.

Eyes large, leaving the front of the head and a small triangular space behind free, the lower division of the eye much smaller than the upper, not projecting so far forward, and with smaller ocelli.

Upper Antennæ placed very close together on either side of the rostral point, and projecting very slightly beyond the head; first joint of the peduncle cylindrical, rather longer than broad, second and third joints obscure or obsolete; first joint of the flagellum much longer than the peduncle, bent abruptly at right angles to it, fringed on the inner side with a great number of rows of filaments, set so closely as to make a thick brush which streams out beyond the succeeding joints; the distal end of the joint is itself a little produced on the inner side, with a rounded apex; the next joint is very small, about twice as long as broad, carrying several filaments, and reaching a little

beyond the apex of the preceding joint; the succeeding joint is about half as long and broad, with two or three apical filaments, and followed by a minute terminal joint.

Lower Antennæ (in the male).—The third (first free) joint of the peduncle moderately thick and long, slightly curved, narrowing distally; the fourth joint very slender, very much longer than the preceding, thickening distally; the fifth joint similar to the fourth, subequal in length, less thickened distally; the first joint of the flagellum is longer than the third joint of the peduncle, thinner than the fifth, and about two-thirds of its length; the second joint of the flagellum is almost as thick and long as the first.

Mandibles.—The small cutting edge has an oblique finely dentate margin, that of the one mandible more oblique than that of the other; the secondary plates similar to the primary, but not quite so large; the palp is set far back, with the first joint longer than the second or third, but not equal to both together, the third is about equal in length to the second, but narrower.

First Maxillæ with three little teeth close-set on the inner margin near the apex.

Second Maxillæ broader than the first, with narrow apex.

Maxillipeds.—The inner plate is very short, rather broad; the outer plates are broad, the outer margins very convex, the inner sinuous; the apices narrowly rounded.

First Gnathopods.—Side-plates small, the lower front corner forming a somewhat acute angle, nearly bisected by a ridge on the under side. The first joint reaching much beyond the side-plate, widening till near the distal end, then narrowing, the front margin convex, carrying a few setules, the hind margin more convex than the front, with a setule a little above the apex; the second joint short, with one or two setules on the hind margin; the third joint longer than the second, distally widened, with three setules on the lower half of the front margin, and one at the apex of the hinder; the wrist not wider than the third joint, but longer even without the triangular process at the end of the slightly sinuous, finely denticulate, hind margin; the narrow, curved, somewhat tapering hand is longer than the front, but shorter than the hind, margin of the wrist, less than twice the length of the process, its front margin convex, its hinder slightly concave, and like the margin of the process which faces it scarcely denticulate; the finger is very short and slender, less than a third of the length of the hand.

Second Gnathopods.—The side-plates with the lower front corner rounded. The branchial vesicles large, of very thin texture. The first joint rather longer than in the preceding pair, with the front margin concave except at the two ends, the hind margin very convex; the other joints are nearly as in the first gnathopods, but the third joint is a little longer and narrower, with several setules along the hind margin, the wrist has the front margin shorter, the hind margin longer and straighter, with two or three setules on the proximal half, and forming a longer process, serrate on both edges. In the first joint there are gland-cells, in both pairs of gnathopods.

First Peraopods.—The side-plates similar to the preceding pair. The branchial

vesicles of great size. The first joint very similar in shape to that in the second gnathopods, but with the muscles more strongly developed, the greatest breadth some distance above the distal end, the sides smooth; the second joint longer than broad; the third joint longer than the fourth or fifth, widest not far from the base, the front margin convex, the hinder slightly eoneave; the fourth joint a little curved, wider than the fifth, but scarcely so long; the fifth having some fine denticulation at the hinder apex; the finger curved, very short and thin, at the base narrower than the fifth joint, and almost immediately abruptly narrowing.

Second Peraopods very similar to the first, but with the second, third, fourth, and fifth joints considerably longer.

Third Peraopods.—Side-plates deeper behind than in front, with a strong triangular tooth on the inner side at about the middle of the lower part, directed backwards. Branchial vesicles not so large as the first joint. The first joint more than twice as long as broad, the hind margin evenly convex, the front sinuous, the chief coneavity being below the centre, the distal part curling round below the second joint; the plate is narrowest at the two extremities, having its greatest width near the centre; the remaining joints folded back against its inner surface do not reach the top; the second is short, the third longer than the fourth, the fifth longer than either, having its convex hind margin produced into a minute spike; the front margin is minutely pectinate in the third, fourth, and fifth joints; the finger is rather longer than in the preceding feet, with the hind margin a little jagged.

Fourth Peraopods.—The side-plates with the hind margin longer than the front, the two nearly parallel. The branchial vesicles broad, not nearly so long as the first joint. The first joint larger than in the preceding pair, the lower part a little narrower than the upper, the upper part of the hind margin strongly convex, the lower half where the margin is double nearly straight; near the lower end of the convex part there is a very small slit on the outer surface; the front margin is for the most part eoneave, the lower margin slightly oblique, rounded in front; a strip along the front and lower margins has a striated appearance, observable also round much of the border of the first joint in the third peraeopods; the remaining joints together equal about one-third the length of the first; the second joint short, attached some way up and within the hind margin of the first; the third joint very long, the front margin a little longer than the hinder, forming a small apical triangle, and strongly pectinate almost from the base to the tip; the fourth joint narrower than the third and little more than half its length, similarly peetinate, narrowing distally; the fifth joint, which is the last, slender, acute, more than half the length of the fourth, finger-like.

Fifth Peraopods.—Side-plates small, triangular, deeper than broad, the apex not reaching nearly as far as the lower border of the preceding pair. The limb consisting of a single joint, laminar, almost ereseent-like, bending across the top of the preceding limb

on the inner side; there is a small incision just above the apex of the convex hind margin, followed by a little rounded lobe, as if a second joint had been thought of, and the intention abandoned; the front margin is concave except where it curves round to this lobe.

Pleopods.—The peduncles strong, with a deep lobe at the inner end of the lower margin; the two coupling spines small, with circular heads, the rims of which are denticulate; the cleft spine short and strong, the arms subequal; the joints of the rami numbering ten or eleven on the inner, eleven or twelve on the outer.

Uropods.—The peduncles of the first pair widening distally, very slightly longer than the rami, pectinate on the outer margin and outer half of the lower margin; the outer ramus long oval, but with apex somewhat angular, the outer margin and lower part of the inner pectinate; the inner slightly shorter and narrower, being flattened on its outer side, almost smooth; the peduncles of the second pair starting almost from the same point as the preceding but scarcely half their length; the outer ramus elongate oval, narrow, and almost pointed at each end; the inner ramus longer than the outer or than any of the other rami, widening distally, and ending in an obtuse angle; the peduncles of the third pair very small, attached below the middle of the composite segment, at the point where the part of it belonging to the telson may be supposed to begin; the rami nearly like those of the second pair, but considerably smaller, and the inner having its outer side the straighter; this ramus reaches just beyond the telson, while the outer ramus just reaches beyond the inner ramus of the first pair, but not so far as the outer ramus of that pair.

The Telson has been already described.

Length of the specimen figured in lateral view three-tenths of an inch; length of specimen A. a quarter of an inch. Both males.

Locality.—March 15, 1874, 100 miles South of Australia; lat. $39^{\circ} 45'$ S., long. $140^{\circ} 40'$ E.; surface; surface temperature, $60^{\circ} 2$. Nine specimens. In these specimens the shortness of the peræon, especially dorsally, and a somewhat more depressed habit of body, with greater obliquity of the head, induced me for a long time to place them under a separate specific name.

March 16, 1874, 50 miles south of Australia; lat. $39^{\circ} 22'$ S., long. $142^{\circ} 27'$ E.; surface; surface temperature, 61° . Six specimens.

April 28, 1876, North Atlantic; lat. $17^{\circ} 47'$ N., long. $28^{\circ} 28'$ W.; surface, night; surface temperature, 73° . Seven specimens, shorter and stouter than those from the waters south of Australia.

From this same locality there were also obtained thirteen specimens probably belonging to this species, but in a damaged condition, twelve of them having entirely lost the third and fourth peræopods.

Genus *Paratyphis*, Claus, 1879.

1879. *Paratyphis*, Claus, Die Gattungen und Arten der Platysceliden, pp. 4, 13.
 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 483.
 1887. *Paratyphes*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 47.
 1887. *Paratyphis*, Claus, Die Platysceliden, pp. 31, 39.

For the original definition of the genus, see Note on Claus, 1879 (p. 491). Some modification will be required for the inclusion of the species "*Paratyphes Thécli*" added to the genus by Bovallius, for in that species "the short and weak chela-process of the wrist," mentioned by Claus, is wanting to the second gnathopods, and the side-plates of the third pereopods are without inner tooth-process. The new species, *Paratyphis promontorii*, is also without any process of the wrist in the second gnathopods.

For distinguishing the genus from the other genera of the family Typhidae, Claus gives the characters :—

"The *First Gnathopods* without, the *Second* with quite rudimentary, chela. The two terminal joints of the hinder male antennæ of moderate length."

Paratyphis promontorii, n. sp.

In general form agreeing with *Paratyphis maculatus*, Claus.

Upper Antennæ.—The peduncle and first two joints of the flagellum as in the species just mentioned, the two terminal joints missing.

Lower Antennæ.—Third (first free) joint of the peduncle curved at the base, about half as long as the following joint, which is rather longer than the fifth; the first joint of the flagellum is more than half as long as the last of the peduncle, and the following joint about as long as the third joint of the peduncle.

Upper Lip forming an arched dome.

Mandibles.—The trunk tolerably broad behind the palp, in front of it long and narrow, with nearly straight upper and sinuous under margin; the upper margin is continuous with the projecting tooth of the cutting edge, which is divided into about twenty minute denticles; on the left mandible there is a secondary plate, similar to the principal but rather smaller; the first joint of the palp is the longest and broadest, but not so long as the two following together; the third joint is longer than the second, slightly curved, not acute.

First Maxillæ.—The four teeth near the top of the inner margin are very small; the apex of the plate is narrowly rounded.

Second Maxillæ.—In these the apex appears to be acute.

Maxillipeds.—The inner plate broader at the base than the length, with two little embedded spinules at the centre of the slightly convex broad distal margin; the outer

plates broad, their inner margins almost meeting; there are a few little setules on the surfacee.

First Gnathopods.—The side-plates with the lower front angle acute. The first joint long and straight, longer than the remaining joints together, with gland-eells; the second joint a little longer than broad, with a slender spine on the hind margin; the third joint shorter but rather broader than the fourth, with a slender spine above the apex of the convex front margin, and three such spines on the hind margin; the wrist similarly armed and having also two or three surface-spinules; the hind margin is straight, seemingly a little pectinate, the front margin scarcely convex, so that the joint is of nearly uniform breadth throughout, and projects a little on either side of the hand, which is much narrower and shorter, tapering, armed with a few hairs; the finger straight, acute, about a quarter of the length of the hand.

Second Gnathopods very similar to the first, but the first joint is longer and somewhat curved; the third joint is rather longer than the wrist, which is a little broader but not longer than that of the first pair, with more spines along the hind margin; the apex is not in the least produced; the hand is a little larger than in the first gnathopods but of the same shape.

First Peræopods much longer than the gnathopods; the first and second joints very like those of the second gnathopods but rather stronger; the third joint rather elongate, slightly curved, longer than the fourth, having two spinules at the upper and one at the lower part of the concave hinder margin; the fourth joint longer than the fifth, slightly curved; the fifth joint distally narrowed, having a few setules and some very minute pectination along the almost straight hind margin; finger slender, about a third or a fourth the length of the fifth joint, a little bent.

Second Peræopods similar to the first, but with the joints more elongate except the finger.

Third Peræopods.—Side-plates not broader than deep, the lower hinder angle much rounded, the inner process not very large, a little bent, directed more downwards than backwards. The first joint elongate, much more than twice as long as the greatest breadth, longer than all the other joints together, the hind margin not very strongly convex, the front sinuous, produced in a rounded point a little below the hind margin; the short second joint lying across the narrow hinder part of the distal margin of the first joint; the third joint long, narrow, straight; the fourth equal to the third in length; the fifth rather shorter than the fourth, a little curved, and like the two preceding joints with insignificant armature; the finger small, acute, not a fifth the length of the preceding joint.

Fourth Peræopods.—The first joint longer and broader than that of the preceding pair, the front margin concave, the upper part of the hind margin very convex, below this the joint narrows, with straight hind margin nearly parallel to the front but not

reaching so low; the longitudinal groove as described in the account of the genus; the second joint is short and bent, not reaching the hind margin, below the middle of the straight part of which it is placed; the remaining joints are just long enough to reach the top of the straight part; the third joint longer than the following joints together, pectinate, with backward turned teeth along the front margin, the apex of which is acutely triangular, produced to about a third of the length of the following joint; fourth joint much narrower than the third, with smaller teeth along the front and no produced apex; the fifth joint finger-like, about half the length and breadth of the fourth, the front margin straight, having a decurrent setule which does not reach quite to the acute apex, the hind margin convex.

Fifth Peraopods.—Side-plates triangular. The limb very thin in texture and transparent; the first joint curved, narrow at the base and still more narrow at the apex, the hind margin strongly convex till close to the apex, the front margin less strongly concave; the minute second joint not longer than broad; the third joint long and narrow, almost straight, a little clubbed at the end, this filiform appendage being bent back against the first joint, and equalling nearly a quarter of its length.

Pleopods.—Joints of the rami eight to nine in number.

Uropods.—Peduncles of the first pair curving inwards, strongly pectinate on the outer margin and outer apex, about as long as the rami, which are nearly equal, the inner slightly the longer, in each the outer margin closely pectinate, the inner margin except near the base slightly serrate; peduncles of the second pair about half the length of those of the first, the outer ramus shorter than the inner, with the margins nearly smooth; peduncles of the third pair very little longer than broad, the outer ramus much narrower than the inner, more than three-quarters of its length, smooth; the inner ramus coalesced with the peduncle, reaching beyond that of the first pair and to the end of the telson, almost smooth.

The Telson triangular, broader at the base than the length, with well-rounded apex, its sides almost continuous with the strongly converging sides of the preceding segment.

Length, about one-fifth of an inch.

Locality.—Station 142, December 18, 1873; off the Cape of Good Hope; lat. $35^{\circ} 4'$ S., long. $18^{\circ} 37'$ E.; surface; surface temperature, $65^{\circ}.5.$. One specimen, male.

Remarks.—The specific name alludes to the taking of the species near the Cape of Good Hope. I should have been inclined to identify it with *Paratyphis théeli*, Bovallius, but that, in his brief description of that species, Bovallius expressly says—“Epimeral of fifth pair [third pereopods] without spinous process.” From Claus’ species, *Paratyphis maculatus* and *Paratyphis parvus*, it is distinguished by the wrist of the second gnathopods, the fifth pereopods and the third uropods. A specimen, however, which in most respects bears a close resemblance to that above described, has only a

minute rudiment of a second joint on the fifth peræopods. The specimen in question was labelled "October 5, 1873. South Atlantic, surface, night"; that is, in lat. $29^{\circ} 1' S.$, long. $28^{\circ} 59' W.$; surface temperature, $65^{\circ} 2$. In the lower antennæ it has the first joint of the flagellum scarcely half as long as the last of the peduncle, and the second joint almost as long as the first. It may perhaps represent a distinct species, or it may indicate that parts of the animal are very variable, and that some of the species already established should be united.

Paratyphis pacificus, n. sp.

Head with triangular point below; peræon-segments very short.

Lower Antennæ.—First joint of the flagellum more than half as long as the last of the peduncle, second joint five-sixths of the length of the first.

Maxillipeds short and broad.

First Gnathopods nearly as in *Paratyphis promontorii*, but the lower front angle of the side-plates more acute, the hand nearly as long as the wrist, and the finger more than a third the length of the hand.

Second Gnathopods.—The wrist rather longer than the third joint, with few spines, the hind margin outdrawn into a little pectinate apex; the hand rather longer than the wrist.

First Peræopods.—The first joint sinuous, the third not longer than the fourth.

Second Peræopods like the first, but considerably longer.

Third Peræopods.—The side-plates with a very short, blunt, striated process on the inner side. The fourth joint finely pectinate on the front margin, a little shorter than the third; the fifth joint longer than the third, with a small spinule or tooth at the apex of the slightly convex hind margin; the finger slender, slightly bent, not a quarter the length of the fifth joint.

Fourth Peræopods.—The slit on the outer surface of the first joint is shorter than in *Paratyphis promontorii*, and the third joint has the produced apex blunter, this and the two following joints being shorter than in the species just named.

Fifth Peræopods.—First joint very thin in texture and transparent, very narrow at both extremities, curved; the second and third joints quite minute, the second almost coalesced with the first.

Pleopods.—Peduncles produced on the inner side; coupling spines minute; the cleft spine with a very slight subapical dilatation of the longer arm; the joints of the rami from seven to nine in number.

Uropods.—Peduncles of the first pair pectinate along the outer margin and its apex, about equal in length to the rami, which are equal, reaching nearly to the end of the telson, the outer with strongly pectinate outer margin, the inner with the lower

part only of that margin peetinate and not strongly, the inner margin only slightly serrate; the seeond pair as in *Paratyphis promontorii*; the third pair with the outer ramus less than half the breadth, but a little more than half the length of the inner, the margins of each being very minutely peetinate; the inner ramus reaches a little beyond the telson.

The Telson as in the species just mentioned, but with much narrower apex, the sides straighter and converging more rapidly.

Length, less than a fifth of an inch.

Locality.—August 24, 1875; 400 miles south of Hawaii; lat. $13^{\circ} 1'$ N., long. $151^{\circ} 50'$ W.; surface at night; surface temperature, $78^{\circ} 2$.

Remark.—The specific name refers to the capture of the species in the Mid Pacific Ocean. From *Paratyphis parvus*, Claus, it is distinguished by the produced apex of the third joint in the fourth pereiopods, the two- to three-jointed fifth pereiopods, and the longer outer ramus of the third uropods, but the species bear a close resemblance to one another.

Genus *Tetrathyurus*, Claus, 1879.

- 1879. *Tetrathyurus*, Claus, Die Gattungen und Arten der Platysceliden, pp. 4, 14.
- 1886. „ Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 483.
- 1887. „ Bovallius, Systematical List of Amph. Hyper., Bihang. till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 47.
- 1887. „ Claus, Die Platysceliden, pp. 31, 40.

For the definition in the original language, see Note on Claus, 1879 (p. 491).

In the preliminary table of the family Typhidae, Claus gives as the character common to *Tetrathyurus* and *Amphithyurus*:—

“ Both pairs of gnathopods subchelate. The two terminal joints of the hinder antennae in the male as long or nearly as long as the preceding.”

To distinguish *Tetrathyurus* from the companion genus he gives the characters:—

“ Gnathopods simply subchelate. Laminar first joint of the fourth pereiopods without pocket-shaped groove.”

Tetrathyurus moncauri, n. sp. (Pl. CLXXXIV.).

Dorsal surface of the head with a downward slope, the rostral triangle bent in and tip-tilted; the back broadly rounded; first two segments of the pereon very short dorsally, especially the second; the first three segments of the pleon conspicuously larger than any of the pereon-segments.

Eyes divided as in *Tetrathyridius forcipatus*, leaving free a narrow strip at the base of the head, another along its centre, and a space over the rostrum.

Upper Antennæ.—The first joint of the peduncle cylindrical, the following joint almost evanescent; the first joint of the flagellum large, the upper margin short, with a tuft of filaments at the apex, the lower margin very long and convex, this part being lined with the thick brush of long filaments and produced into a rounded apex along half the second joint; the third joint is much thinner than the second, but scarcely shorter, armed like it with a tuft of filaments; the fourth joint linear, a little longer than the third, with setules at the apex.

Lower Antennæ.—Gland-cone conspicuous; third joint of the peduncle thick, scarcely curved, about a third as long as the much thinner fourth joint, which is straight, distally widened; the fifth joint slightly longer than the fourth; the first joint of the flagellum thinner than the last of the peduncle and a little shorter, the terminal joint very slender, more than three-quarters of the length of the preceding joint.

Mandibles.—The trunk tolerably straight, very narrow, the striate cutting edge forming an acute angle with the upper margin, the secondary plate of the left mandible similar to the principal plate but smaller; the first joint of the palp broader and longer than the second, the second curved, making an angle with the first, the third a little sinuous, tapering, longer than the first, making an angle with the second.

First Maxillæ slender, apically pointed.

Second Maxillæ seemingly represented by a pair of broad smooth plates, which are apically narrowed.

Maxillipeds.—The broad outer plates have the outer margins somewhat folded in, and the inner margins overlapping, the distal portion of each plate carrying a couple of setules.

First Gnathopods.—The first joint distally widened, the second not longer than broad, the third distally widened, longer than the wrist, the margins carrying some small spinules; the wrist broader and rather longer than the hand, with spinules on the hind margin; the hand oblong, a little curved, the slightly concave hind margin a little apically produced; the finger small, with dilated base, the curved tip when the finger is closed down reaching beyond the narrow concave two-rimmed palmar margin, which has three or four little setules on it or adjacent to it.

Second Gnathopods.—The branchial vesicles large and oval as in the following pairs, much broader than the first joint. The first joint longer than in the first pair, proximally narrow and bent, with spinules along much of the sinuous front margin; the remaining joints nearly as in the first gnathopods, but the hand having the hinder apex a little more produced.

First Peræopods much longer than the gnathopods; the first joint similar in shape to that of the second gnathopods, the second joint longer than broad, the third broader and

a little longer than the fourth, both rather slender and curved, the fifth shorter than the fourth ; the finger minute.

Second Peræopods similar to the first, but with the third and fourth joints decidedly longer.

Third Peræopods.—The side-plates with a small process on the inner side, forming a blunt triangle. The first joint larger than the branchial vesicles, about as long as the third, fourth and fifth joints together, an oval narrower at the basal than the distal end, and with the front margin flattened, this being a little serrate at the lower end, the whole border fringed with more or less distant setules ; the second joint not reaching the lower margin of the first, the third like the two following, carrying some spinules along the front margin, broader than the fourth, but scarcely so long ; the fourth joint curved, longer than the fifth ; the finger minute.

Fourth Peræopods.—Side-plates having on the inner side a process which is a little produced over the first joint in a thin lamina rounded in front, while behind a small hook-like piece connects the process with the side-plate. The first joint large, continuously broad, the front margin concave to fit the convex hind margin of the much smaller first joint of the preceding pair, the hind margin convex from the base for nearly half the length, the remainder straight, the parallel inner edge beginning above the end of the convex part, the lower part fringed with a few setules ; the remaining joints together about half the length of the first, the second not reaching either its hinder or its lower margin ; the third joint longer than the three following together, a little produced at the front apex, its front margin pectinate ; the fourth joint longer and much broader than the fifth, its front margin pectinate ; the fifth joint narrowly oval, with decurrently pectinate front margin, the pectination minute ; the finger curved, minute.

Fifth Peræopods very small and feeble ; the first joint scarcely longer than that of the first gnathopods but broader, the front margin almost straight, the hinder convex ; the remaining joints minute, together not nearly half the length of the first, their length united scarcely exceeding its breadth, the third joint longer and broader than the fourth, the fourth than the fifth.

Pleopods.—Peduncles stout, produced downwards at the rounded inner angle ; the coupling spines short, the rounded apices forming three or four retroverted teeth ; the cleft spine with a very narrow subapical dilatation of the shorter arm ; the joints of the rami nine or ten in number.

Uropods.—Peduncles of the first pair about as long as the outer ramus, with some submarginal setules and the lower part of the outer margin pectinate ; the outer ramus shorter and narrower than the inner, both with the margins finely pectinate and the apex very acute ; peduncles of the second pair shorter than the outer ramus ; the rami as in the preceding pair, but respectively shorter, and the outer margin of the outer ramus

smooth except for one or two indents; peduncles of the third pair longer than the outer ramus, a little shorter than the inner, which is distinguished from the peduncle by an indent on the inner margin and a suture of the under surface; the rami ornamented like the preceding pair, but respectively much smaller.

Telson coalesced with the preceding segment, though the lateral margins of the two are not continuous; the breadth of the telson at what seems to be its proper base being less than the length; the apex narrow, somewhat rounded, not reaching so far as the apex of the inner rami of the third or of the first uropods; there are a few little setules about the apex and two or three on each lateral margin.

Length.—One-fifth of an inch.

Localities.—Station 162, April 2, 1874; off East Moncœur Island, Bass Strait; lat. $39^{\circ} 10' 30''$ S., long. $146^{\circ} 37' 0''$ E.; surface; surface temperature, $63^{\circ} 2$. Several specimens.

Station 164A, June 13, 1874; east of Australia; lat. $34^{\circ} 9'$ S., long. $151^{\circ} 55'$ E.; surface to 50 fathoms; surface temperature, $70^{\circ} 2$. One specimen.

Remarks.—The specific name refers to the place of capture. In *Tetrathyurus rectangularis*, Bovallius, from the Indian Ocean, the last joint of the lower antennæ is less than half as long as the preceding joint, the finger in the gnathopods is more than a third of the length of the hand, and the fourth peræopods are said to be without finger.

Tetrathyurus arafuræ, n. sp.

In general appearance and in respect to the antennæ and mouth organs so far as examined this species agrees substantially with *Tetrathyurus moncœuri*.

First Gnathopods.—The third joint much wider than the wrist, so as to project beyond it both before and behind, having one spinule at the flattened apex of the front margin and four spinules on the hind margin; the wrist oval, the front margin smooth, the hinder with four spinules.

Second Gnathopods.—The third joint much longer as well as broader than the wrist, with two spinules on the front apex and seven along the hinder margin and its apex; the wrist also with seven spinules along its convex hind margin.

First and Second Peræopods very long and slender, more conspicuously so than in the other two species here described.

Third Peræopods.—First joint a long oval, nearly equal in length to all the remaining joints together, the front margin sinuous with some minute spinules, the smoothly convex hind margin interrupted just before the broad apex of the joint is reached, the short second joint partially overlapping the small emargination thus formed; the third joint about as long as the fifth, much shorter than the fourth.

Fourth Peraopods.—The large first joint more than twice as long as the remaining joints together; the third joint much longer than the three following joints together pectinate along the front margin with retroverted teeth, the apex produced half way along the fourth joint; the somewhat crooked finger is nearly half the length of the fifth joint.

Fifth Peraopods.—The first joint transparent, two or three times as long as broad, a little curved, the apex divided, the hinder division produced a little below the front. There is no trace of any other joints.

Uropods.—Peduncles of the third pair much shorter than the rami; the outer ramus nearly equal in length to the inner, its outer margin nearly smooth, the inner finely pectinate; the inner ramus quite distinct from the peduncle, much of each margin finely pectinate.

Telson coalesced with the preceding segment, longer than broad, triangular, the narrowly rounded apex extending just beyond the apices of the third uropods, the sides slightly concave above and below.

Length about one-fifth of an inch when fully extended.

Locality.—September 13, 1874, Arafura Sea; lat. $8^{\circ} 18' S.$, long. $135^{\circ} 7' E.$; surface; surface temperature, 79° . Three specimens, two of them, perhaps all three, males.

Remark.—The specific name is taken from the place of capture.

Tetrathyridius forcipatus, Claus.

- | | |
|-------|--|
| 1879. | <i>Tetrathyridius forcipatus</i> , Claus, Die Gattungen und Arten der Platysceliden, p. 14 |
| 1887. | " " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 47. |
| 1887. | " " Claus, Die Platysceliden, p. 40, Taf. v. figs. 10-18, Taf. vi. figs. 1-3. |

The rostral triangle conspicuously produced, the lower margin of the head forming an acute angle on either side of it.

Eyes.—One division large, with large pigment, this pair occupying almost all the sides and top of the head; the other division very small, with small radiating ocelli, not set closely together, this pair placed in the front of the head on either side of the rostral triangle.

Fourth Peraopods.—The third joint with its front apex more produced, and produced more sharply than in *Tetrathyridius monoceruri*, this and the two following joints being relatively narrower and shorter than in that species, but similarly pectinate, the finger small.

Fifth Peraopods.—The first joint drawn out to a very narrow apex, perhaps tipped with a minute second joint.

Telson reaching as far as or a little beyond the apex of the inner ramus of the third uropods, the apex without setules.

Localities.—April 28, 1876, North Atlantic; lat. $17^{\circ} 47'$ N., long. $28^{\circ} 28'$ W.; surface, night; surface temperature, 73° . One specimen, male.

April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface; surface temperature, 74° . Four specimens.

Remark.—A specimen of this species has been sent me by Dr. Bruce from Malta.

Genus *Amphithyrus*, Claus, 1879.

- 1879. *Amphithyrus*, Claus, Die Gattungen und Arten der Platysceliden, p. 15.
- 1886. „ Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 483.
- 1887. „ Bovallius, Systematical List of Amph. Hyper., Bilang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 48.
- 1887. „ Claus, Die Platysceliden, pp. 31, 41.

For the original definition of the genus, see Note on Claus, 1879 (p. 491). In the preliminary table of the family Typhidae, Claus gives as the character common to *Tetrathydrus* and *Amphithyrus* :—

“Both pairs of gnathopods subchelate. The two terminal joints of the hinder antennæ in the male as long or nearly as long as the preceding.”

To distinguish *Amphithyrus* from the companion genus he gives the characters :—

“Gnathopods doubly and complexly subchelate. The laminar first joint of the sixth pair of legs [Fourth Peræopods] with large pocket-shaped groove.”

Amphithyrus orientalis, n. sp.

For the appearance of this species both in general form, and with certain exceptions also in detail, I may refer to the figures given by Claus in Die Platysceliden, Taf. vii., of his species *Amphithyrus sculpturatus* from the Atlantic Ocean. It is also in general shape like *Parascelus zebu* of this Report. The head is a little produced below; the postero-lateral angles of the first three pleon-segments are not acute, and the fourth pleon-segment has a well-marked dorsal depression.

Upper Antennæ.—First joint of the peduncle widening distally, second and third joints very short, scarcely distinct in parts of the circumference; first joint of flagellum large, strongly bent, with a large brush of long filaments fringing the long convex margin and passing right round the produced rounded apex; the second joint not reaching beyond the apex of the first, tapering distally, its outer margin convex, carrying five groups of broad filaments; the third joint not longer than the second, much more slender, with two groups of long filaments on the outer margin; the fourth joint slender, spiniform.

Lower Antennæ.—Third (first free) joint of the peduncle short, pyriform, greatly dilated near the base, smooth-edged; the following joints elongate, ciliated, the fourth joint being scarcely as long as the fifth; the first joint of the flagellum is narrower than the last of the peduncle, but only a little shorter, and the second joint is more than three-quarters the length of the first, the terminal filaments being longer than those on the margin.

The Mouth Organs appear to a great extent to coincide with those which Claus figures for *Amphithyrus bispinosus*. The palp of the *Mandibles* is long, the first joint the broadest, long, but a little exceeded in length by the second, the third joint being narrower than the second but as long, with a rounded not an acute tip. The trunk of the *First Maxillæ* is of uniform breadth for some distance, but narrows towards the apex by the inner margin turning obliquely outwards, this inner margin being armed near the apex by two somewhat curved retroverted teeth; the *Maxillipeds* have the inner plate broadly rounded, the distal border smooth, with two embedded spinules at the centre, the outer plate broad, partly folding round the inner and reaching not very far beyond it.

First Gnathopods.—The side-plates a little produced forwards at the rounded lower angle; as in many other species of the group the upper boundary of the side-plates is present, but very difficult to perceive, which may account for its omission in the figure of *Amphithyrus sculpturatus*. First joint about as long as the following four joints together, widened nearer to the apex than the base, the muscles running to about the middle of the joint; second joint a little longer than broad, with a setiform spine near the hinder apex; the third joint broad, rather longer than broad, the hinder apex acute, scarcely produced; the wrist as broad as the third joint, and with its acutely produced hinder apex equalling it in length, not as in *Amphithyrus sculpturatus* exceeding it; just within the acute tip of the triangular apex there is a little spinule; the hand is about as long as the wrist, but much narrower, the hind margin having a produced apex like that of the wrist but smaller, the front of the hand, however, being produced quite as far as the apex, so that there is a triangular cavity between them over which the small curved finger bends; the finger has a cilium on or near the inner margin. There are gland-cells observable in the first four joints, and in the second, third and fourth a series of minute ducts appear to connect these with the hind margin.

Second Gnathopods.—Side-plates deeper than wide, with convex front and concave hind margin. The branchial vesicles large, but not so large as those of the following limb. The first joint a little bent, longer than in the first gnathopods, longer than the rest of the limb; the second joint longer than broad, with four setiform spines on the hind margin; the third joint considerably broader and perhaps a little longer than the wrist, with four setiform spines along the hind margin, two or three others probably having been lost; the wrist, hand, and finger nearly as in the first gnathopods, but the process of the hand does not reach quite so far as the apex of the front; near the hind

margin of the wrist there are four little spinules on the surfacee. The gland-cells as in the first pair.

First Peræopods.—Side-plates, branchial vesicles, and first joint of the limb similar to those of the second gnathopods, but larger. Gland-cells conspicuous in the first and third joints; the second joint longer than broad; the third joint broader and longer than the fourth, its front margin very convex, the hinder smooth and almost straight; the fourth joint similar in shape; the fifth joint longer than the fourth, shorter than the third, slender, tapering, slightly curved, like the other joints quite smooth; the finger very small, curved, acute.

Second Peræopods similar to the first, but with the third, fourth, and fifth joints decidedly longer, and the hind margin of the fifth joint finely pectinate.

Third Peræopods.—The side-plates much narrower below than near the base, having a round-ended backwardly directed lobe projecting from the inner surface just above the attachment of the limb. The first joint large, elongate oval with flattened sides, sub-equal in length to the four following joints together, the front margin descending below the hinder one, the hexagonal markings very conspicuous over the whole surface both of this and the following joints; the second joint rather longer than broad, partly embedded in the distal end of the first joint; the third joint slightly shorter and stouter than the fourth; the fourth finely pectinate along the front margin and more conspicuously round the front part of the apical margin; the fifth joint straight, tapering, not longer than the third, with the front margin finely pectinate; finger missing.

Fourth Peræopods.—The side-plates deeper behind than in front, the front margin nearly straight, the hinder convex. The first joint larger than in the preceding pair, two or three times as long as the rest of the limb, the front margin convex near the base and at the lower corner, the long intermediate part nearly straight, the hind margin irregularly convex; facing the hind margin in its upper half is a longitudinal curved slit, the half of an oval in shape, with a transverse or oblique slit at either end; below this there is a hind margin of the inner surface running parallel to that of the outer, and below this an oblique sinuous fold of the inner surface a little above the rounded hinder apex; just above this fold is the short second joint, which with part of the next is covered by the first joint; the third is much longer than the three following joints together, the front margin to the end of the almost acute produced apex being pectinate with slightly retroverted teeth; the fourth joint which is narrower is similarly armed, and has the front margin rather longer than the hinder; the fifth joint is dwindled, attached at about the middle of the oblique apex of the preceding joint, not being a third either of the length or breadth of that joint; there is a minute curved blunt finger to correspond.

Fifth Peræopods.—No upper boundary of the side-plates could be perceived. The first joint long, slender, curved, narrowest at either extremity, four or five times as long as all the feeble remaining joints together, the front margin concave, the hinder convex,

both smooth; third joint a little longer and broader than the second; fourth longer and narrower than the third; fifth oval, about as long as the third; finger apparently triangular, very sharp at the tip; all the joints of this limb but the first may be regarded as rudimentary.

Pleopods.—Peduncles stout, produced downwards at the inner angle; eleft spine with the arms subequal; inner ramus with six joints; outer with seven.

Uropods.—Peduncles of the first pair longer and broader than those of the second, but not reaching much beyond them, longer than the rami, the lower half of the outer margin pectinate; outer ramus longer than the inner, both acute, strongly pectinate on both margins; peduncles of the second pair scarcely as long as the outer ramus; the outer is the longer, very slightly toothed on the outer margin, strongly pectinate on the inner, as the inner ramus is on both margins; peduncles of the third pair short, the outer ramus much the shorter, with one or two teeth on the outer margin, the inner margin at first smooth and convex, then concave and strongly pectinate, the much broader inner ramus reaching beyond the telson, pectinate on both margins except near the base.

Telson narrower than the segment with which it is coalesced, about as long as broad, forming in outline an inverted arch, the apex acute. The hexagonal markings conspicuous all over it except just at the tip, where there are some very small submarginal setules; there is also some extremely minute marginal pectination.

Length, from front of the head to back of the second pleon-segment, one-fifth of an inch.

Locality.—July 1875, between Japan and Honolulu; lat. 35° N.; surface. One specimen, male.

Remarks.—The specific name explains itself. The differences are not very great between this eastern species and the western *Amphithyrus sculpturatus*. The sculpture is the same in both. In Claus' species, however, the first joint of the flagellum of the lower antennae does not so nearly equal the last joint of the peduncle as in the Challenger species; in the second gnathopods Claus figures (though without describing)¹ on the front of the wrist a strong spine of which I here find no trace, while he does not indicate any armature of the thin margin of this and the two preceding joints; judging by his figures also the fifth and sixth joints in the fourth and in the fifth pereiopods differ from the corresponding parts in the present species; in the third uropods he gives a more normal outline to the inner margin of the outer ramus, and the telson he figures as having the end broadly rounded, not as in the Challenger species pointed, his description of it being “telson broad and short, rounded off at the end.”

¹ It may therefore be an accidental error in the engraving of the plate.

Amphithyrus sp.

Length.—One-tenth of an ineh.

Locality.—September 13, 1874, Arafura Sea; lat. $8^{\circ} 18' S.$, long. $135^{\circ} 7' E.$; surface; surface temperature, 79° . One specimen, male.

Remark.—I forbear to give a name to this interesting little species, as there is not time at my disposal to give an adequate deserption of it.

Amphithyrus bispinosus, Claus.

1879. *Amphithyrus bispinosus*, Claus, Die Gattungen und Arten der Platyseeliden, p. 15.
 1887. " " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 48.
 1887. " " Claus, Die Platyseeliden, p. 41, Taf. vi. figs. 4–16.

The Challenger specimen clearly and closely agrees with the deserption and figures of the species given by Claus. The species is well marked by the large laterally projecting spine-like proeess of the side-plates of the third peræopods. The side-plates, with the exception of those of the fifth peræopods, have their upper boundary distinct; the lower front angle in the first pair is directed a little forwards, and is almost acute; the postero-lateral angles of the first three pleon-segments are rounded. The sculpture of the integument, though in many parts showing hexagonal markings, in others takes the form of more or less parallel wavy lines.

The Eyes are separated by a central spaee which is broad over the aeute point separating the upper antennæ.

The Lower Antennæ in this specimen are not tightly folded as in the fully adult male; the third (first free) joint of the peduncle is more or less pear-shaped; the next or fourth joint is more than twice as long, sinuous; the fifth is straighter and rather longer than the fourth, each having a subapieal spinule, but being otherwise smooth-edged; the flagellum consists of one serpentine joint, longer than the last joint of the peduncle.

The Mouth Organs so far as observed were in agreement with Claus' figures; seen from below they exhibit a small *Epistome* occupying the space between the bases of the two mandibular palps; the upper margin is flat, the lateral margins convex, while the lower border shows a curved emargination, overarched by a much larger triangular depression of the surface. The mandibular palps in our specimen are sinuous, the joints undeveloped.

First Gnathopods.—First joint straight, widening a little distally, rather longer than the remainder of the limb; second joint with a spinule at the hinder apex; the three following joints subequal in length to one another, the wrist rather the longest by reason

of its sharply produced hinder apex, which has a notch with a cilium on the front or inner side; the hand has a similar but smaller process, the tip of which does not reach so far as the distal end of the front of the hand; the finger is small, strongly curved, with a cilium on the inner margin.

Second Gnathopods with all the joints larger than those of the first pair; the first joint considerably longer, bent; the second joint with a spinule or bristle a little above the hinder apex; the third joint distally widened, the hind margin very finely pectinate, with a bristle some way above the rounded apex; the wrist with three or four little setules on the surface near the somewhat sinuous finely pectinate hind margin, which is drawn out into an acute process reaching beyond the very small process of the hand, almost to its extremity; the hand about as long as the third joint, and about half its breadth.

First Peræopods.—First joint closely resembling that of the second gnathopods; second joint longer than broad; third about as long as the fourth, fifth longer than either, slender; finger slender, curved, about a quarter as long as the preceding joint.

Second Peræopods like the first, but with the fourth and fifth joints decidedly longer, the fourth longer than the third; the armature in both pairs of the slightest description.

Third Peræopods.—First joint an elongate oval, with flattened sides, not so long as the remaining joints together; the third joint scarcely longer than the fourth, but shorter than the fifth, these three having the front margin minutely pectinate; in the fourth joint the pectination is continued round the apical margin; the fifth joint is shorter than that of the second peræopods.

Fourth Peræopods.—The first joint very much larger than in the preceding pair, of irregular outline, broadest distally, with a large ear-shaped groove on the surface; the remaining joints by comparison insignificant, the second attached low down within the hind margin, the third about twice as long as the fourth, widening a little towards the slightly produced apex, pectinate along the front margin with nearly forty slightly retroverted teeth; the fourth joint similarly produced and pectinate with about a dozen strong teeth, besides some minute ones near the base; attached behind the obtuse front apex of the fourth joint is a rudimentary fifth joint with a little blunt rudimentary finger, the two together not reaching the end of the process of the fourth joint.

Fifth Peræopods feeble; the first joint slender, curved, having at the tip a little diminutive wrinkled representative of the following joints, which perhaps disappears at a later stage, as it is not indicated in Claus' figure.

Pleopods.—Peduncles produced downwards at the inner angle; the coupling spines minute, with an apical pair of hooks; cleft spine apparently with both arms to some extent dilated; inner ramus with five, outer with six, joints.

Uropods and acutely pointed *Telson* in close agreement with Claus' figures. The

inner ramus of the third pair of uropods is coalesced with the peduncle, as Claus figures it, though he does not mention the circumstance in his description. In *Amphithyrus sculpturatus* this ramus is free, and so also is it in *Amphithyrus orientalis*, though it is not perhaps in either species very freely movable, its position under the telson making such freedom not especially necessary.

Length.—At full stretch the specimen would not have measured one-tenth of an inch, and it was much less than this with the pleon flexed.

Locality.—Atlantic, surface. One specimen, male.

Family SC E L I D A E, Claus, 1879.

The account which Claus gives of this family both in 1879 and 1887 is as follows :—

" Shape of the body and the antennæ as in the Typhidæ, the ventral surface however generally strongly flattened; the pleon relatively larger and more produced, flexing. Lower antennæ of the female well developed. Mouth organs outdrawn, beak-like, mandibles narrow and elongate. The branchial vesicles are simple laminæ. Laminar first joint of the third peræopods ovoid, that of the fourth peræopods considerably longer and more extended. Fifth peræopods feeble, but in general with the full number of joints."

Bovallius in 1887 changes the name of the family to Parascelidæ, without, I think, sufficient cause for the alteration. He gives the following diagnosis :—

" Head large, a little deeper than the body, anteriorly produced downwards. The eyes large, occupying the whole sides of the head. First pair of antennæ fixed at the under side of the head; first joint of flagellum tumid, the rest of flagellum subterminal. The second pair fixed at the under side of the head, angularly folded (δ) or reduced (φ). Mandibles with palp. Femora of fifth and sixth pairs of pereiopoda [first joint of *Third* and *Fourth Peræopods*] transformed into imperfect opereula. Seventh pair [*Fifth Peræopods*] not transformed."

As regards the flagellum of the upper antennæ, it may be observed that the expression "subterminal" is not suitable to all the genera of the family, since in some the second joint of the flagellum is attached at the apex of the first. The statement that the mandibles have a palp is no doubt intended to apply only to the male.

Genus *Thyropus*, Dana, 1852.

1852. *Thyropus*, Dana, Amer. Journ. Sci. and Arts, ser. 2, vol. xiv. No. 41.
 1852. " Dana, U.S. Explor. Exped., vol. xiii. pt. ii. pp. 1008, 1012, 1443.
 1879. *Tanyscelus*, Claus, Die Gattungen und Arten der Platysceliden, p. 17.
 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 483.
 1887. *Thyropus*, Bovallius, Systematical List of Amph. Hyper., Bilang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 43.
 1887. *Tanyscelus*, Claus, Die Platysceliden, pp. 43, 45.

For the original definition of *Thyropus*, see Notes on Dana, 1852 (pp. 259, 269). For Claus' shorter definition of *Tanyscelus*, see Note on Claus, 1879 (p. 492). His longer definition is to the following effect:—

" Body broad and produced, ventrally flattened. Point of the head outdrawn. Maxillipeds broad. Terminal joint of the lower male antennæ scarcely half as long as the preceding joint. Mouth-organs projecting beak-like. Mandibles strongly elongated, with narrow cutting-edge. Maxillæ with four comb-like dental-processes at the distal end of the plate. The two pairs of gnathopods simple, only distinguished from the following limbs by a shorter and more compact form. Laminar first joint of the fourth peræopods strikingly elongated and distally narrowed, *with short pocket-shaped groove at a distance from the ridge of the hind margin*. Fifth peræopods¹ almost completely developed, with the laminar first joint long."

Claus himself suggests that his *Tanyscelus sphæroma* may be the same as Dana's *Thyropus diaphanus*, and Bovallius without uniting the two species assigns them both to the genus *Thyropus*. Judging by the figures and description which Dana gives of his type-species, *Thyropus diaphanus*, and especially by what he says of the eyes and antennæ, there seems good reason for accepting his genus, though the type species has not yet been identified, and perhaps from defects or deficiencies in the account never will be. Dana considered that *Typhis ferus*, Milne-Edwards, belonged to this genus, and Spence Bate, as Claus has pointed out, wrongly made *Thyropus diaphanus*, Dana, a synonym of Milne-Edwards' species under the name *Thyropus ferus*.

Thyropus danæ, n. sp.

For the general appearance of the species Claus' figure of "*Tanyscelus sphæroma*" may be consulted. The head is much deeper than long, with flattened front, a little produced downwards; the first two segments of the peræon very short, the fifth, sixth, and seventh long, with conspicuously overlapping margins.

Eyes not quite reaching to the front of the head, but leaving free the produced lower point of it, and a long triangular space above this; the upper and lower groups

¹ In regard to the fourth and fifth peræopods, see remarks on the definition of the next genus, *Parascelus*.

of ocelli conterminous, of nearly equal extent, the upper groups triangular, the lower almost circular.

Upper Antennæ.—Peduncle moderately stout; first joint of flagellum longer than the peduncle, set at right angles to it, carrying a large brush of filaments; second joint attached at the apex of the first, a little longer than broad, having some long apical filaments; the third joint considerably longer and more slender, with filaments some way from the apex; the fourth joint much shorter and thinner than the third, with some apical setules.

Lower Antennæ.—Third (first free) joint of the peduncle rather more than a quarter as long as the following joint, distally narrowed; fourth joint long and slender, distally widened; fifth joint equal in length to the fourth; first joint of flagellum slender, three-quarters of the length of the preceding joint; second joint rather more than half the length of the first.

First Gnathopods.—Side-plates with convex front margin. The first joint a little widened below; the second longer than broad; the third about three times as long as wide, longer and broader than the fourth joint, with a hair-like setule at each apex and one above the centre of the hind margin; the fourth joint similar, but a little narrowed distally, with a setule at each apex; the fifth joint shorter and narrower than the fourth, a little curved, distally narrowed; the finger little curved, acute, less than half the length of the fifth joint; the whole limb peraeopod-like.

Second Gnathopods similar to the first, but scarcely so long, having the first and second joints a little longer, but the third and fourth decidedly shorter, each of the two latter joints having the apical setules and a setule near the middle of the hind margin; there is also a setule near the apex of the second joint.

First Peræopods like the gnathopods, but rather longer, the difference in length depending chiefly on the fourth and fifth joints which are about equal in length; there is a spinule near the hinder apex of the second joint and one high up on the hind margin of each of the three following joints, besides subapical setules.

Second Peræopods a little longer than the first.

Third Peræopods.—The side-plates nearly as deep as the breadth, the margins convex; within the side-plates there is a long straight spine-like process pointing backwards. The first joint broadly oval, almost smooth-edged, a little shorter than the third, fourth, and fifth joints together; the second joint scarcely longer than broad, with a setule above the front apex; the third joint very much shorter than the fourth, with three setules on the front margin; fourth joint longer than the fifth, with a setule at the apex behind, and three setules on the front margin, which is sparsely and finely pectinate; the fifth joint slender, tapering, longer than the third, having three setules on the hind margin and one on the front, which has a little scarcely perceptible pectination; the finger not a quarter the length of the preceding joint.

Fourth Peræopods.—The first joint much longer than in the preceding pair, having in the broad upper part a small semicircular slit on the outer surface, followed by a longitudinal groove on the inner surface reaching far down into the narrowed lower part; the front margin presents a considerable concavity to fit the hind margin of the first joint of the preceding pair, and its rounded apex is produced below that of the hind margin; the upper part of the hind margin is strongly convex, the lower nearly straight; the small second joint is fixed so high up within the hind margin of the first joint, that the finger cannot reach the apex of that joint; the third joint considerably longer than the fourth, the hinder apex rounded, very slightly produced, the front margin not produced, pectinate with teeth directed a little backwards, increasing in strength as they approach the apex; the fourth joint stouter and a little longer than the fifth, its front margin armed much like that of the third; the fifth joint straight, narrowing distally, with very fine pectination of the front margin; the finger small, acute, about a third the length of the fifth joint.

Fifth Peræopods.—Side-plates triangular, with straight hind margin, and slightly rounded apex; they are coalesced with the segment, except for a small space behind. The first joint much longer than broad, with the hind margin convex till very near the narrow apex, the front margin concave for most of its length; the second joint not longer than broad, with very convex front margin; the third two or three times as long as the second, not broader, strongly bent upwards, with convex front margin and smoothly rounded apex. In the absence of any other joints beyond the third on this limb, the present species differs strongly from "*Tanyseelus sphæroma*," Claus.

Pleopods.—Coupling spines minute; cleft spine with a narrow subapical dilatation to the longer arm; joints of the rami seven to eight in number.

Uropods.—Peduncles of the first pair bending inwards, shorter than the rami, the convex outer margin finely pectinate; the outer ramus shorter and narrower than the inner, with finely pectinate outer margin; the broad inner ramus does not quite reach the end of the telson, narrowing rather suddenly to its sharp apex, with the inner margin divided into about eight little teeth and like the outer finely pectinate; the peduncles and rami of the second pair much shorter than those of the first, the rami narrow, the outer much smaller than the inner, the inner margin finely pectinate, and the outer also at the lower part; the peduncles of the third pair widening distally, a little longer than the distal breadth, rather longer than the outer, a little shorter than the inner, ramus; the little outer ramus not half the length nor nearly half the breadth of the inner ramus, the inner margin in each finely pectinate, the inner ramus reaching a little beyond the telson.

Telson distally broadly rounded, not so long as the breadth at the base of the third uropods, where it is completely coalesced with the broad preceding composite segment, its position marked by the gently converging sides of the segment being here

abruptly contracted for a little space, beyond which the gentle convergence is continued.

Length, in the rolled position, less than a fifth of an inch, and scarcely longer than a fifth if unrolled.

Locality.—Station 106, August 25, 1873; between St. Vincent and St. Paul's Rocks; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; surface to 40 fathoms; surface temperature, $78^{\circ}\cdot 8$. Three specimens, that described a male.

Remarks.—The specific name is given out of respect to the founder of the genus. Dana's *Thyropus diaphanus* was taken in the "Atlantic, latitude $4^{\circ} 25'$ south, longitude $21^{\circ} 30'$ west;" its "length, when extended, one-fourth of an inch; when folded up, one-eighth of an inch." It agrees in many respects with the species just described, but, if Dana's figures and descriptions may be trusted, it has the apex of the first joint of the flagellum in the upper antennæ produced over the base of the second joint, the second joint of the flagellum of the lower antennæ much less than half the first, the telson subacute, and the rami of the third uropods subequal. The last two characters cannot possibly be reconciled with the Challenger species, or with *Thyropus sphæroma* (Claus).

Thyropus sphæroma (Claus).

- 1879. *Tanyscelus sphæroma*, Claus, Die Gattungen und Arten der Platysceliden, p. 17.
- 1887. *Thyropus sphæroma*, Bovallius, Systematical List of the Amph. Hyper., Bihang. till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 43.
- 1887. *Tanyscelus sphæroma*, Claus, Die Platysceliden, p. 45, Taf. viii. figs. 1-11.

The Challenger specimen corresponds closely with Claus' figures and description. There is the distinguishing line of little spots of colour partly on the side-plates and partly on the adjacent margins of the segments; it is distinguished by these from *Thyropus danae*, above described, as well as by the fifth peræopods, which have a slender fourth joint much longer than the third, and a short fifth joint. The distal end of the first joint of the fourth peræopods also appears to be less narrow than in the preceding species.

Length, at full stretch, scarcely a fifth of an inch.

Locality.—April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface, night; surface temperature, $73^{\circ}\cdot 7$. One specimen, male.

Remark.—The back of the peræon in our specimen, though tumid and rounded, shows a tendency to be irregularly arched.

Genus *Parascelus*, Claus, 1879.

1879. *Parascelus*,¹ Claus, Die Gattungen und Arten der Platyseeliden, pp. 17, 18.
 1885. " Carus, Prodromus Faunæ Mediterraneæ, pars ii. p. 425.
 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 483.
 1887. " Bovallius, Systematical List of Amph. Hyper., Bilang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 43.
 1887. " Claus, Die Parasceliden, pp. 43, 45.

For the shorter definition of this genus by Claus in 1879, see Note on Claus, 1879 (p. 492). In the fuller account he says :—

"Body moderately broad and rounded, yet with flattened ventral surfaces, as in *Tanyseelus*. Upper lip and maxillipeds projecting beak-like. The former with tongue-shaped projecting epipharynx. Mandibles narrow, outdrawn almost stiletto-like. Upper antennæ as in *Tanyseelus*. Limbs of the peræon very slender, with very long first joint. *The gnathopods simple* (enden klauenförmig). The wrist in the gnathopods with small tubercular prominence a suggestion as it were of a chela-forming process. Laminar first joint of the third peræopods compactly ovoid. *Laminar first joint of the fourth peræopods elongate, distally narrowed, without pocket-like groove*. Fifth peræopods completely developed. The rami of the uropods are narrow fin-laminæ (Flossenblätter), the inner of the second pair being the largest."

Gerstaecker in the definition of this genus includes two other characters, namely, that the head has summit-eyes and lateral-eyes combined, and that there are two gland-cells in the fourth joint of the first and second peræopods.

Dana's account of *Thyropus* does not include any mention of the pocket-like groove of the fourth peræopods as either present or absent, but the very elongated termination of the first joint in those limbs, with the remaining joints not reaching to its apex, confirms the view that *Thyropus* coincides rather with Claus' *Tanyseelus* than with his *Parascelus*. In Dana's *Thyropus* the fifth peræopods have only two or three joints, but it is evident that these limbs vary in the number of joints within the genus, if not within the species or in the individual.

Parascelus zebu, n. sp. (Pl. CLXXXV.).

Head deeper than long, the flattened front a little produced at the lower end over the insertion of the upper antennæ; the second segment of the peræon the shortest; first three segments of the pleon postero-laterally almost squared.

Eyes as in *Thyropus*.

Upper Antennæ.—In the male, first joint of the peduncle widening distally, the two following joints short, incompletely developed; the first joint of the flagellum

¹ Given as *Parascelus* in the *Zool. Jahresb.* (see Scudder's *Nomenclator Zool.*, p. 248).

tumid, bent so that the convex lower margin with the brush of slender filaments is much longer than the upper, which has at its apex two broad filaments ; the second joint not broader than long, not so broad as the narrowed apex of the first joint, carrying three filaments ; the third joint narrower but much longer than the second, with two filaments near and one at the apex ; the fourth joint missing.

In the female, first joint cylindrical, bent, much longer than broad, second joint about half as long as the first, third half as long as the second and narrower, not longer than broad, with some apical setules ; first joint of the flagellum longer than the last of the peduncle, carrying some filaments, second joint longer and more slender than the first, third more slender than the second.

Lower Antennæ inserted at the lower part of the back of the head. In the male, the second joint of the peduncle (perhaps including the first in coalescence) is distinct, broader than long ; the next or third joint is much longer, but tolerably stout, narrowing distally, smooth-edged, more than a quarter but less than a third the length of the following joint, which is slender, ciliated, distally bulging ; the fifth joint is similar to the fourth, but more slender and a little longer ; the first joint of the flagellum is not quite two-thirds the length of the last of the peduncle, much more slender ; the second joint is not quite two-thirds of the first in length.

In the female, the third (first free) joint of the peduncle slender, scarcely longer than the fourth, the fourth with a subapical setule, the fifth a little longer than the third, with a setule remote from the apex ; the first joint of the flagellum in line with the peduncle, rather narrower and shorter than the preceding joint, with three setules near the apex ; second joint much narrower and shorter than the first, with a group of very small apical setules.

Mouth Organs very small, and from the delicacy of their texture difficult to manipulate in dissection. The *Epistome* forms a shallow dome over the cutting edges of the mandibles ; the *Mandibles* are long and narrow, the trunk rather deeper near the base than further on, the cutting edge and secondary plate of the left mandible apparently represented by two bent teeth, the palp attached near the base of the trunk, which it exceeds in length, the first joint longer than the second, the third longer than the first, narrow, tapering to a fine point ; the *First Maxillæ* are long, narrow, extremely transparent plates, the outdrawn triangular termination having on the inner margin close to the apex four minute teeth ; the shape of the *Second Maxillæ* was not discovered ; the outer plates of the *Maxillipeds* are broad, overlapping, with convex outer margin.

First Gnathopods.—The side-plates deeper than broad, the front margin convex, the lower margin with two setules near the rounded front angle. The first joint attached near the middle of the hind margin of the side-plate, slightly bent, nowhere broad, but broader below than above ; the second joint scarcely longer than broad, having like the

first joint a bristle near the apex of the hind margin ; the third joint longer than the wrist, with four bristles on the front and two on the straighter hind margin ; the wrist with five bristles on the convex front margin and four, of which the lowest is the longest, on the almost straight hind margin, of this the apex being narrowly and smoothly rounded, standing off from the hind margin of the hand and a little produced ; the hand scarcely so long as the wrist, much narrower, tapering, having one bristle near the apex ; the finger very small, curved, carrying one short bristle, and perhaps a denticle on the inner margin near the apex. Gland-cells can be traced in the first four joints of this and the following pair.

Second Gnathopods similar to the first pair but longer, especially in respect of the first and third joints. The branchial vesicles of comparatively enormous size. The first joint sinuous, only slightly widened below, carrying one bristle near the apex of the hind margin and another rather higher up ; the hinder apex of the wrist a little more narrowly produced than in the preceding pair ; the hand not longer.

First Peræopods.—Side-plates longer than the preceding pair. Branchial vesicles like the preceding and following pairs of great size. First joint similar to that of the second gnathopods, but longer and more slender, smooth ; the second joint longer than broad ; the third subequal in length to the fourth but rather shorter, with a bristle at the apex in front, one at the apex behind, and two widely apart higher up ; the fourth joint rather more bent than the third, with four or five bristles along the hind margin ; the fifth joint shorter than the fourth, straight except at the base, tapering, with three small bristles on the hind margin ; the finger as in the gnathopods, very small.

Second Peræopods similar to the first, but with the joints rather longer, and larger side-plates.

Third Peræopods.—Side-plates broader behind than in front, larger than the preceding pair, having a strongly bent tooth on the inner surface. First joint large (yet not so large as the branchial vesicles), broadly and almost regularly oval, with five little setules at the lower end of the front margin, length of the joint almost equal to that of all the following slender joints together ; just below the tooth of the side-plate there is as usual a fold on the inner surface of this joint ; second joint longer than broad, rather deeply socketed in the distal end of the first joint ; the third joint shorter than the fourth, the fourth a little longer than the fifth, these and the finger being similar to those of the preceding pereopods, but the fourth and fifth of greater length. In all the limbs it is possible that the finger may have some peetination and some other armature than a spinule of the inner margin near the tip, but the characters were too minute to be more than guessed at.

Fourth Peræopods.—The side-plates much larger than any of the other pairs, much deeper behind than in front. The branchial vesicles much larger than the side-plates but much smaller than the first joint of the limb. The first joint two or three times as long

as the remaining joints together, the front margin forming a little protuberance near the base, thence running with a long and a short concavity to the rounded slightly produced apical angle; the hind margin forms a great bend at the upper part, becoming almost straight lower down at the narrowed part of the joint, at this part a second hind margin of the inner surface, commencing and running a nearly parallel course, fringed with thirteen or fourteen bristles, takes the place of the other margin for a space not quite reaching to the apical angle; the short second joint is embedded in the first about one-third of the length from the sinuous distal margin; the third joint is longer than the remaining three together, strongly pectinate with retroverted teeth along the front margin down to the slightly produced and rounded apex; the fourth joint is much narrower than the third, much broader and rather longer than the fifth, the front margin pectinate; the fifth joint is a little bent at the base, tapering, with the front margin a little furred; the finger less than half the length of the fifth joint. The five terminal joints have a length sufficient to enable the finger to reach the apex of the first joint.

Fifth Peropods.—Side-plates deeper than broad, the upper boundary incomplete. The first joint enormously larger than the remainder of the limb, strongly bent so that there is a deep concavity above the centre of the front margin, the lower part of which is straight, while the hind margin makes a great bow from the base to the apex, the distal part of the joint being strongly narrowed, so that the apex is not broader than the short bent second joint; the third joint is rather narrower than the second, a little sinuous, shorter than the fourth; the fourth is much longer than the fifth, which is equal in length to the third; the finger seems to be represented by a curved spinule, with a small setule on the apical margin behind it. There was no sign of damage to either limb, and the character of the termination was the same in both.

Pleopods.—Peduncles produced below on the inner side; the two coupling spines very short, the rounded apex having its border cut into three or four retroverted teeth; the cleft spine attached at the top of the first joint of the inner ramus, its arms short, that with the dilated end rather the shorter, the joint having three or four setæ below the cleft spine; the joints of the broad tapering rami are seven in number on the inner and eight on the outer ramus; the inner ramus is broader than the outer.

Uropods.—The peduncles of the first pair shorter than the rami, widening distally, having the lower part of the outer margin pectinate; the outer ramus much narrower but very little shorter than the inner, its outer margin finely pectinate, the inner almost smooth, the inner ramus with the lower half of its inner margin denticulate, most of the outer margin finely pectinate; the peduncles of the second pair scarcely half the length of the first, the inner ramus narrower and rather shorter than that of the first pair, the outer ramus narrower but longer than that of the first pair, much longer than its own outer ramus, the pectination minute; the peduncles of the third pair about as long as broad, the outer ramus much narrower and shorter than the inner, the margins

minutely peetinate, the inner ramus broad, with fine marginal peetination, the tips reaehing baek beyond all the other rami and a little beyond the apex of the telson.

Telson broader than long, triangular, with rounded apex, not quite so broad at the base as the segment with which it is coalesced; the triangle formed by the sides of the telson and those of the two preceding coalesced segments is of about equal breadth and length.

Length, three-twentieths of an inch from the front of the head to the back of the second pleon-segment, so that the total length may be regarded as one-fifth of an inch.

Locality.—January 1875, Zebu Harbour, Philippines, surface. Three specimens, one male, one female, the third not speacially examined.

Remarks.—The speiefie name refers to the place of eapture. This species closely approaches *Parascelus edwardsii*, Claus, taken in the Atlantie Ocean, and is distinguished from it chiefly by the fifth pereopods, the first joint of which is much more bent than in the Atlantie species, while the following joints bear a very much smaller proportion to the first joint, and the relative sizes of the fourth and fifth joints are different. The proportions differ also to some extent in the uropods, in the present species the inner ramus of the second pair being the longest of all the rami, but in the Atlantie species shorter than the inner ramus of the first pair.

Parascelus parvus, Claus.

- 1879. *Parascelus parvus*, Claus, Die Gattungen und Arten der Platysceliden, p. 20.
- 1887. „ „ Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 44.
- 1887. „ „ Claus, Die Platysceliden, p. 47, Taf. viii. figs. 12–17.

For the general appearance of this little species, I may refer to the figure of *Parascelus parvus* given by Claus in Die Platysceliden, Taf. viii. All the segments of the pereon are distinct, the back is broadly rounded, the postero-lateral angles of the first three pleon-segments are not acute. The liver-tubes are very large, the heart very narrow.

Eyes as in the preceeding species.

Upper Antennæ.—First joint much the longest, curved, with a bristle or very slender spine at the outer apex, the second joint not twice as long as broad, the third not longer than broad, armed with two bristles, the first joint of the flagellum as long as the second of the peduncle, but more slender, the second joint longer than the first, having like it two apical bristles, the third joint linear, slightly longer than the second, having on the tip two or three bristles about as long as the joint.

Lower Antennæ.—The third (first free) joint of the peduncle slightly curved, much

shorter and more slender than the first of the upper antennæ, second joint longer than the first, third rather longer than the second, carrying one long marginal bristle; the first joint of the flagellum much shorter and narrower than the last joint of the peduncle, carrying one marginal and one or two apical bristles, the second joint almost linear, much shorter and narrower than the first, having some short bristles at its tip.

Mouth Organs small and feeble; the *Epistome* forming a dome broader than deep over the mandibles; the *Mandibles* narrow, narrowing towards the bent apex, which on the left mandible has a bidentate appearance, the two teeth representing the cutting edge and the secondary plate; whether there is any secondary plate on the right mandible is doubtful; the palp, being a character of the male, was not present.

First Gnathopods.—Side-plates squared, the front angle rounded, carrying a bristle. The first joint about as long as the third, fourth, and fifth together, widening a little near the distal end, having three minute setules on the front margin; second joint scarcely longer than broad, with a bristle near its hinder apex; the third joint subequal in length to the wrist and rather wider, the front margin convex, the hinder straight, with bristles at two points; the wrist similar to the third joint, with bristles near the front apex and at three points of the hind margin, of which the smoothly rounded apex projects a little behind the hand; the hand scarcely if at all longer than the wrist, much narrower, tapering, the front margin convex, with a short bristle near the apex, the front margin almost straight, smooth; the finger short, curved, armed with a setule, the tip bent, acute.

Second Gnathopods.—Branchial vesicles longer than the first joint and wider, narrow near the base, widening distally. Marsupial plates incompletely developed, represented by a very small oval lamina. First joint longer than in the first pair, not conspicuously widened at any part, quite as long as all the remaining joints together, with a bristle at the hinder apex; the second joint longer than broad, with two bristles on the bent hinder margin; the remaining joints as in the first pair but rather longer, not wider, the third with bristles at four points of the hind margin, the wrist with bristles at five points.

First Peræopods.—Branchial vesicles and marsupial plates as in the second gnathopods but rather larger. The first joint a little longer than in the preceding limbs, very slightly widened towards the distal end; the second joint longer than broad; the third narrower but rather longer than in the second gnathopods, similarly armed; the fourth joint much longer than the third, narrow, with a bristle at the apex of the slightly convex front margin, and four along the straight hind margin; the fifth joint slender, as long as the fourth, bent at the neck, then a little widened, straight, tapering to a narrow apex, with three bristles near the front, and four along the faintly furred or pectinate hind margin; the finger very small, about a fifth as long as the fifth joint.

Second Peraopods in close agreement with the first, the fifth joint perhaps a little longer than the fourth. The brachial vesicles are more bowed out at the centre behind.

Third Peraopods.—Side-plates broader than in the preceding pairs, without bristles, the hind part deeper than the front. The branchial vesicles similar to the preceding pair. The first joint very little longer but much broader than in the preceding limbs, the neck narrow, the remainder of the joint oval, with about eight bristles round the front margin and two or three near the top of the hinder; the remaining joints as in the preceding pair, but more elongate, bent back upon the first joint, and the two terminal joints folding against the front of the fourth joint; the third joint appears to be without spines on the front margin.

Fourth Peraopods.—Side-plates scarcely so large as the preceding; the brachial vesicles more dilated behind near the centre. First joint of long irregular pear-shape, much longer than all the remaining joints together, or than the first joint of the other pairs, broadest near the base, the hinder and rounded distal margin fringed with bristles not closely set, the hind margin on the inner surface but not on the outer emarginate for the reception of the short second joint; the third joint longer than the fourth, its front margin pectinate and carrying two bristles, apically a very little produced; the fourth joint similarly armed, but with three bristles; in each of these joints the pectination near the apex is retroverted; fifth joint scarcely so long as the fourth and much narrower, the front margin finely pectinate; the finger small but more than half the length of the fifth joint, slightly curved, tapering, pectinate on the inner margin. The third joint is capable of reaching beyond the apex of the first.

Fifth Peraopods.—Side-plates very distinct, broader than deep, the upper and lower margins parallel, the rounded hinder angle having one bristle. The first joint a little bent, rather wider above than below; the second joint nearly as broad as the extremity of the first, not longer than broad, the third joint broader than the fourth but not so long; the fourth joint with one bristle standing out stiffly near the apex of the straight front margin; the fifth joint scarcely so long as the third, bent at an angle to the fifth, but otherwise straight; on the inner side near the apex there is a stout little spine; the finger quite minute, the narrowed apical part bent up so as to convert the finger into a little sturdy hook.

Pleopods.—Coupling spines minute, with apical teeth; the cleft spine having the serrate arm shorter than that with the subapical dilatation, the first joint of the inner ramus having only one seta below the cleft spine; the rami with six joints apiece.

Uropods.—Peduncles of the first pair longer than those of the second, in both pairs shorter than the rami; the rami have pectinate edges, those of the second pair being apparently rather larger than those of the first; in each case the inner ramus is the longer; this applies also to the third pair, in which the peduncles are very short, the outer ramus reaching a little and the inner considerably beyond the telson.

Telson coaleseed with the preeeding segment, about as broad as long, narrowing to the rounded apex.

Length.—In the slightly bent position, which is probably natural to the animal, the specimen measured scarcely more than one-tenth of an inch.

Locality.—June 13, 1874, east of Australia; lat. $34^{\circ} 13'$ S., long. $151^{\circ} 38'$ E.; surface to 50 fathoms; surface temperature, $61^{\circ} 8$. One specimen, female.

Remarks.—From the specimen of *Parascelus parvus* which Claus describes from the Atlantie Oceean, the Challenger specimen differs by having the hinder apex of the wrist in the gnathopods smooth, instead of weakly crenulate, as well as by rather different relative lengths of the joints in the lower antennæ and the fourth and fifth peræopods.

Genus *Schizoscelus*, Claus, 1879.

- 1879. *Schizoscelus*, Claus, Die Gattungen und Arten der Platysceliden, pp. 17, 20.
- 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Ed. v. Abth. ii. p. 484.
- 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 44.
- 1887. " Claus, Die Platysceliden, pp. 42, 43.

For the shorter definition given by Claus, see Note on Claus, 1879 (p. 491). The fuller definition is to the following effect:—

" Peræon broad and round, with comparatively thin produced pleon. Mouth-organs outdrawn beak-like. The two terminal joints of the lower male antennæ nearly as long as the preeeding. A packet of gland-cells with cuticular longitudinal ducts in the first joint of the first and second peræopods. *The first gnathopods simple, the second complexly chelate.* *The laminar first joint of the fourth peræopods with long, half-sickle-shaped slit.* The other joints of the limb (Beinanhang), attached almost at the distal end of the laminar joint. Fifth peræopods completely developed. The rami of the uropods widened fin-like. The inner ramus of the second pair especially enlarged."

Bovallius includes in this genus the *Typhis rapax* of Milne-Edwards, 1830, but many of the expressions used by Milne-Edwards in describing that species in his later work are opposed to such an identification. He says that it is of a more elongate form than *Typhis ferus*, that the first gnathopods have a large hand, that the second gnathopods have a very large claw, and that the laminar first joint of the fourth peræopods is not so developed as that of the third. By these characters, which are ill-suited to *Schizoscelus*, he is probably pointing to one of the Pronoidæ.

Schizosecelus ornatus, Claus.

1879. *Schizosecelus ornatus*, Claus, Die Gattungen und Arten der Platysceliden, p. 21.
 1887. " " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 44.
 1887. " " Claus, Die Platysceliden, p. 44, Taf. x. figs. 1-11.

A small compact species, not easily distinguishable at first sight from *Parasecelus zebu*, from the same locality. Head short, broad, flattened in front, the rostrum having the tip slightly upturned; the second segment of the peraeon not shorter than the first.

Eyes not covering the whole sides of the head, the ocelli of each eye apparently forming a single continuous group, which is long and rather narrow.

Upper Antennæ.—First joint of the peduncle not longer than broad, the two following joints very short, incompletely developed; the first joint of the flagellum very thick at the base so as to be nearly as broad as the length, one margin very convex, the other almost straight, the narrowed apex having on one side a series of filaments, on the other side the slender second joint which carries a filament and one or two setules; the third joint is thinner and rather longer than the second, and has a minute setule at the apex. To judge by Claus' account, when these antennæ are fully developed the filament-bearing apex of the first joint of the flagellum forms a separate second joint.

Lower Antennæ.—Gland-cone distinct; third joint of peduncle curved, two-thirds the length of the next, which is slightly sinuous, widest distally; the fifth joint about as long as the fourth; the first joint of the flagellum half the length of the last of the peduncle, sinuous; the second joint straight, longer than the first, sharply bent upon it but scarcely jointed. In the fully developed antennæ the proportions of the joints are different.

First Gnathopods.—The first joint about as long as the remainder of the limb, the hind margin sinuous; the second joint scarcely longer than broad, having a spinule on the hind margin above the apex; the third joint scarcely longer than the second, having a subapical spinule on the hind margin; the wrist a little longer and stouter than the third joint, with two spinules on the hind margin, and one at the apex of the front; the hand a little longer than the wrist, and at the base rather narrower, thence tapering, slightly curved, like the three preceding joints having a straight distal margin; the finger small, thick at the base, then rather abruptly narrowed, the terminal part bent, acute, the inner margin having a small tooth-process not far from the base.

Second Gnathopods.—The branchial vesicles oval, as long as the first joint and considerably broader. The first joint longer than in the preceding pair; the second and third joints rather larger than in that pair, the third joint having three spinules on the hind margin; the wrist with two spinules on the upper part of the hind margin, its process laminar, as long as the hand and nearly as wide, the apical part triangular, having on

the border facing the hand four slender spaced teeth, the apex forming a fifth, near which the hinder margin has three little teeth and some slight serrations; the hand and finger as in the first pair.

First Peræopods.—Branchial vesicles larger than the preceding pair, longer than the first joint. The first joint widening distally, the second not longer than broad, with a subapical spinule on the hind margin; the third joint distally widened, carrying two spinules near the apex of the very convex front margin, and a longer one at the apex of the hind margin; the fourth joint rather longer than the third, with a spinule at the front apex, a short and a long one on the hind margin; the fifth joint longer and narrower than the fourth, slightly curved and tapering; the finger scarcely half the length of the fifth joint, gently curved, tapering.

Second Peræopods like the first, with the third, fourth, and fifth joints a very little longer.

Third Peræopods.—Side-plates with a small blunt process on the inner side. Branchial vesicles not so large as the first joint. The first joint a broad oval, about as long as the remainder of the limb, the front margin flattened, descending slightly below the hind margin, having some spinules at the lower end; the second joint with one spinule on the front margin; the third joint a little shorter than the fourth, distally widened, with a spinule at the hinder apex and three spinules on the front margin; the fourth joint having a spinule at the hinder apex, two spinules on the front margin, all the front of the joint minutely sebrous, the distal margin variously pectinate; the fifth joint much narrower than the fourth, rather longer, the hind margin convex, the front nearly straight, with scarcely perceptible pectination; the finger slender, tapering, curved, not nearly half as long as the fifth joint.

Fourth Peræopods.—Branchial vesicles smaller than the preceding pair. The first joint longer than in the third peræopods, widest proximally, most of the front margin straight, descending below the hind margin, a row of eight spinules fringing the curve which unites it to the distal margin; the hind margin has some spinules or setules along the convex upper part; along a groove of the outer surface extending from the apex of the front margin towards, but not reaching, the apex of the great longitudinal slit, a row of little circular marks was observed, five in number, and a row near the upper margin of the joint; the small second joint attached near the apex of the slit; the third joint as long as the two following together, distally a little widened and produced in front for nearly half the length of the following joint, the front margin pectinate; the fourth joint abruptly narrower than the third, its front margin pectinate; the fifth joint finger-like, tapering, much narrower than the fourth, but nearly as long, finely sebrous in front; the finger obsolete, perhaps represented by the acute apex of the fifth joint.

Fifth Peræopods slender and feeble; the first joint not quite so long as the remainder of the limb, not very broad, the front margin nearly straight, the hinder convex, the apex

narrow; the second joint much longer than broad; the third longer than the second, distally widened, with slightly convex hind margin; the fourth slightly longer but narrower than the third, a little widened distally; the fifth shorter than the third, with a minute hooked finger embedded in the rounded apex.

Pleopods.—The two coupling spines very small, with apical hooks; the cleft spine slender, the longer arm having an elongate subapical dilatation; the inner ramus with six joints, the outer with seven.

Uropods.—Peduncles of the first pair not so long as the rami, the outer margin pectinate; the rami long, lanceolate, reaching beyond the telson, the inner rather the longer, each with the outer margin strongly pectinate, the inner margin more slightly pectinate and serrate; peduncles of the second pair short; the outer ramus much shorter and narrower than the inner, its outer margin with one or two teeth and a subapical spinule, the inner margin pectinate, the inner ramus subequal to those of the first pair, both margins pectinate; peduncles of the third pair very short, the rami similar to those of the second pair but smaller, and the inner ramus less strongly pectinate, the outer not reaching to the end of the telson, the inner reaching beyond it.

Telson broadly triangular, with rounded apex, the margin very minutely pectinate.

Length, one-tenth of an inch, if fully extended.

Locality.—January 1875, Zebu Harbour, Philippines; surface. One specimen, male.

Remarks.—It is clear from the antennæ it is not fully adult, although of the same size as Claus' specimens from the Atlantic. The shape of the fifth peræopods is intermediate between that which Claus figures for the male and that which he figures for the female. The tooth on the finger of the gnathopods is not figured by Claus, the process of the wrist of the second gnathopods as he represents it does not entirely agree with that in the Challenger specimen, and he gives a wider apex to the telson, but the differences do not seem to justify the establishment of a new species. The little circular marks on the front rim of the segments and on the outer surface of the first joints of the third and fourth peræopods are very difficult of observation, nor was I able to discover whether Claus' expression "Integument mit Grubenreihen" was properly applicable to them, since I could not make out any depression of the surface in connection with them.

Family PRONOIDÆ.

In 1852 Dana made the Pronoinæ the second subfamily of the Typhidæ, with the two genera *Pronoe* and *Lycæa*. Claus in 1879 made the Pronoidæ the third family of the Platyscelidæ, with the genera *Pronoë*, *Eupronoë*, and *Parapronoë*. He defines it as follows:—

"Body only moderately broad, laterally compressed, Gammarid-like, with powerfully developed, semi-flexing pleon. Rostral point very short and scarcely noticeable. Hinder pair of antennæ present in the female. Plates of the maxillæ powerfully developed. Branchial vesicles with lateral accessory compartments. The laminar first joint in the third and fourth peræopods only moderately extensive and not completely covering the breast."

Bovallius includes in the family, together with the three other genera, the genus *Amphipronoë*, Spence Bate, about the validity of which Claus is doubtful. He gives in 1887 the following definition:—

"Head large, not deeper than the body, a little produced anteriorly. Eyes large, occupying the whole sides of the head. First pair of antennæ fixed at the under-side of the head; first joint of flagellum tumid, the rest of flagellum subterminal. The second pair fixed at the under-side of the head, angulated (*Pronoë*) or angularly folded. Mandibles with palp. Femora of the fifth and sixth pairs of perciopoda [first joint of *Third* and *Fourth Peræopods*] broad but not transformed. Seventh pair [*Fifth Peræopods*] reduced."

It is a question of terminology whether the first joint of the third and fourth peræopods should be said to be "transformed" in the Typhidæ and "not transformed" in the Pronoidæ; the general character is the same in both, though there are differences of proportion.

Genus *Pronoe*, Guérin, 1836.

- 1836. *Pronoe*, Guérin, Magasin de Zoologie, Ann. 6, Classe vii. p. 6.

- 1862. *Pronoë*, Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 336.
- 1879. " Claus, Die Gattungen und Arten der Platysceliden, p. 23.
- 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 484.
- 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 40.
- 1887. " Claus, Die Platysceliden, p. 48.

For the original definition of the genus, see Note on Guérin, 1836 (p. 165). To distinguish it from *Eupronoë* and *Parapronoë*, Claus gives the characters, "Both pairs of gnathopods simple. Front antennæ of the male with two-jointed flagellum, hinder antennæ short, only once or twice folded" (see p. 492).

Claus' fuller definition of this genus is to the following effect:—

¹ It should be observed that *Pronoe brunnea*, the only species referred by Dana to this genus, is now transferred to *Eupronoë*, Claus.

"Body produced, strongly compressed laterally, with large triangular head, strongly narrowed in front. Front antennæ of the male with tumidly produced peduncle (mit kolbig gestrecktem Sehaft) and two-jointed flagellum. Hinder antennæ of the male five-jointed, with short middle joint, not laid together in zigzag folding. Both pairs of gnathopods have a monodaetyle termination (neither chelate nor subchelate). Third pereopods very strong and long, with produced laminar first joint. Fourth pereopods very thin and feeble, with the laminar first joint broad and irregularly extended. Fifth pereopods rudimentary, reduced to the extensive first joint with wart-like appendage. The peduncles of the uropods elongate, those of the second and third pairs about as long as their fin-like widened rami. Telson quite reduced."

The two-jointed flagellum of the upper antennæ in the above definition refers only to the slender terminal joints, not including the large joint regarded in this Report as the first of the flagellum.

Pronoe capito, Guérin (Pl. CLXXXVI.).

The synonymy of the species will be found in the places cited for that of the genus, with the exception of the references to Dana and Gerstaecker.

Upper Antennæ.—Peduncle not very tumid, first joint not longer than broad, second and third joints much shorter; first joint of the flagellum nearly twice as long as the peduncle, almost straight, but with somewhat sinuous margins, the upper with some fine hairs at intervals, the under with a thick brush of filaments; the minute second joint attached at the apex of the first, carrying some filaments below the centre of its lower margin; the third joint linear, longer than the second.

Lower Antennæ.—Opening of the gland-cone in a laminar joint, at some distance from the point at which the third joint of the peduncle is socketed; the third joint narrow, straight, in the same line with the fourth, which is only half as long; the fifth joint forming an angle with the fourth, not half as long; the flagellum bent back at right angles to the fifth joint of the peduncle, the first joint longer than the second, the two together shorter than the third joint of the peduncle; the last three joints of the peduncle and the two of the flagellum fringed with short filaments, which are closest together on the terminal joint of the flagellum, but infrequent on the fifth joint of the peduncle.

Mandibles.—The cutting edge straight, striated, and finely dentieulate, with a blunt tooth or projection at the upper end and a small sharp upturned tooth at the lower; the secondary plate of the left mandible similar to the principal, but without projections at the extremities; the palp with very large first joint, much broader and longer than the two following together; the second broader and a little longer than the third; the third curved, blunt-ended, having adpressed hairs on its surface.

Lower Lip.—The front lobes narrow, not quite acute, the lip widened below, not produced into mandibular processes.

First Maxillæ.—The distal margin forming two processes, of which the inner is the longer; the inner margin indented and carrying a spinule a little below the apical process.

Second Maxillæ.—These appear to reach somewhat beyond the first maxillæ and to have the outer margin produced into a small process, while the inner margin apically bulges inwards.

Maxillipeds.—The second joint broad, the distal margin and adjacent parts of the outer surface scabrous with spinules of various sizes; the inner plate small, longer than broad, the two embedded spinules planted near together some way below the distal margin; the broad outer plates covering most of the inner plate and arching over it, the corrugated inner margin minutely pectinate; little spinules are spread about on the lower part of the outer surface, and a row is submarginal to the distal part of the outer border.

Length, in the position figured, nine-twentieths of an inch.

Localities.—October 1875, South Pacific; surface. One specimen, male.

April 28, 1876, North Atlantic; lat. $17^{\circ} 47'$ N., long. $28^{\circ} 28'$ W.; surface; surface temperature, $72^{\circ}\cdot8$. Five specimens, males.

April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface, night; surface temperature, 72° . One specimen, male.

Remarks.—The figures, with the exception of fig. *l.i. A.*, are taken from the Pacific specimen; it differs from the Atlantic specimens in being without pigment spots, in having longer hands to the gnathopods, and in not having a minute marginal groove in the upper part of the first joint of the fifth peræopods. For these reasons I at first proposed to make of this a new species under the name *Pronoe immaculata*, but I abstain from doing so for want of opportunity to determine whether these slight differences are constant, and for the further reason that, as Guérin says nothing of his species being spotted, but describes it as "jaunâtre," it is possible that the flecked specimens may have the better claim to be treated as new.

Genus *Eupronoë*, Claus, 1879.

- 1879. *Eupronoë*, Claus, Die Gattungen und Arten der Platysceliden, pp. 23, 26.
- 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 484.
- 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 40.
- 1887. " Claus, Die Platysceliden, pp. 48, 50.

For the original definition of this genus, see Note on Claus, 1879 (p. 492), and for the suggestion that *Orio*, Cocco, 1832, as limited by de Natale in 1850, may be the

same as *Eupronoë*, see Note on de Natale, 1850 (pp. 240, 241). Dana's *Pronoe brunnea* is considered by Claus and Bovallius to belong to this genus.

Claus' fuller definition of the genus is to the following effect:—

“Body *Pronoë*-like, still only little compressed, with short arched head. The front antennæ of the male seven-jointed, with three-jointed flagellum, those of the female six-jointed. The hinder antennæ of the male packed in with zigzag folds, the basal joint very long, the terminal joint short, almost finger-like; the hinder antennæ of the female weak, four-jointed. Mandibles compact, with deep cutting edge, bounded by two teeth. The maxillary plates well developed. Maxillipeds with weak short inner plate, the outer plates with deeply convex inner margin fringed with hairs. The first gnathopods complexly subchelate, the second complexly chelate. Third peræopods long and strong, with the laminar first joint forming a large elongate oval. The laminar first joint of the fourth peræopods broad and extensive, distally triangularly narrowed, with the distal margin sinuous (mit ausgeschweiftem Vorderrand). Fifth peræopods reduced to a three-sided pointed laminar first joint and a pimple-like appendage. Peduncles of the uropods moderately shortened, those of the last pair very short. The rami of the last two pairs are long fin-like leaves of great tenuity, reaching much beyond the medium-sized telson.”

In this Report four of the seven joints of the upper antennæ are regarded as belonging to the flagellum.

Eupronoë inscripta, n. sp. (Pl. CLXXXVII.).

This species has many points of resemblance with *Eupronoë maculata*, Claus, but instead of being very strongly flecked like that species, it has but few flecks, and on the other hand the first three pleon-segments are very strongly printed with numerous transverse lines; they have their postero-lateral angles not rounded but more or less acute; the first joint of the mandibular palp is broader, straighter, and less elongate, than that represented in Claus' figure; the third joint in the fourth peræopods has a more produced front apex, and the first joint of the fifth peræopods has a breadth more than half the length instead of considerably less than half.

Head longer than deep, narrowed in front; first two segments of the pleon together as long as the whole of the peræon; the after part of the pleon broad and flat.

Eyes.—The upper and lower groups of ocelli closely combined.

Upper Antennæ.—The first joint of the peduncle much broader than long, the two following joints incompletely developed, the third overlapped by the second; first joint of the flagellum very large, but not broader at the base than the first joint of the peduncle, the lower margin very long and convex with a great brush of long filaments, the rounded apex produced as far as the end of the second joint, the upper margin

smooth and nearly straight; the second joint quite small, longer than broad, with a narrow neck; the third joint slender, broken.

Lower Antennæ.—Gland-cone conspicuous; the third (first free) joint of the peduncle elongate, about four-fifths of the length of the following joint, bent near the base, the concave margin ciliated like the rest of the antenna, the fourth joint narrow, dilated a little near the apex; the fifth joint a little or not at all shorter than the fourth; the first joint of the flagellum curved, about three-quarters as long as the third joint of the peduncle; the second joint straight, very short and narrow.

Epistome with the distal border furred.

Mandibles.—Cutting edge broad and straight, striated, and microscopically denticulate, with a projecting tooth at each extremity; the secondary plate of the left mandible denticulate like the principal plate, but with no projecting teeth; close to the base of the secondary plate, at some distance from the top of it, there is situated a little tooth-like process; on the right mandible a ridge corresponding with the base-line of the secondary plate on the left mandible is not produced into a plate, but adjoining it there is a tooth-like process larger than that on the left mandible. First joint of the palp a little shorter than the second and third together, much broader than either; the third longer than the second, curved, almost acute.

Lower Lip with the apical part strongly furred or ciliated.

First Maxillæ.—Immediately below the little apical tooth there are on the inner margin three small erenate or three-pointed teeth.

Maxillipeds.—The inner plate short, as broad as the length, with two embedded teeth below the centre of the strongly furred apical margin; outer plates broad and long, strongly furred on and near the inner margin; these plates when *in situ* bent at an angle to the basal joints extend in front of the cutting edge of the mandibles to the upper lip.

First Gnathopods.—The side-plates with the lower front angle acute. The first joint strongly twisted, very narrow at the middle, above this forming a great rounded elbow behind, the lower part of the joint dilated, with the hind margin nearly straight, the front very convex; the second joint not longer than broad; the third wrist-like, distally dilated so as to be broader than long, scarcely perceptibly pectinate at the rounded apex behind; the wrist dilated, as broad as long, as long as the hand, with smoothly convex front margin, the hind margin finely pectinate except near the base, the teeth of the pectination slender and sharp, the upper part of the margin very convex, the lower part a little concave, the muscles occupying only the front part of the joint; the hand without palm, apically not half as broad as in the upper part, the hind margin pectinate, but near the apex very slightly; the finger half the length of the hand, slightly curved.

Second Gnathopods.—Side-plates transversely oval. The first joint with a narrow straight piece above and a broadly dilated piece below; the second and third joints nearly as in the first pair, but larger; the wrist with the proximal part broader than long, the

front margin a little produced, with rounded apex, the hind margin pectinate except near the base, the triangular distal process rather broad, not quite so long as the hand, with the inner margin pectinate as well as the outer; the hand similar to that of the first pair, but a little larger, and with the whole of the hind margin distinctly pectinate; the finger rather less than half the length of the hand, slightly curved; there are numerous gland-cells in the first four joints of these and the preceding gnathopods.

First Peraopods with scarcely any perceptible armature; the first joint narrowest near the base and a little narrowed distally; the second joint short; the third shorter than the fourth, widening from a narrow neck, the front apex rounded, not produced; the fourth widest near the base, narrowing distally; the fifth narrower than the fourth, scarcely longer, apically narrowed; the finger slender, curved, about a third the length of the fifth joint.

Second Peraopods very similar to the first, but with a much longer third joint, this being longer than the fourth; the fourth joint is rather narrower than in the preceding pair, shorter than the fifth.

Third Peraopods.—Side-plates narrowed in front. First joint oblong, about twice as long as broad, not nearly so long as the following joints together, the front margin descending a little below the hinder, and with some shallow serration of the lower part; the angles are not very strongly rounded; the second joint short, yet long enough to reach below the front margin of the first joint; the third joint longer than the fourth, finely pectinate along the front and apical margins; the fourth joint more strongly pectinate than the third, except close to the apex, where the pectination becomes very fine on one surface and ceases on the other; the fifth joint slightly curved, longer than the third, more strongly pectinate than the fourth, the hind margin having an apical spine; the finger slender, about a third of the length of the fifth joint, a little bulbous at the base.

Fourth Peraopods.—First joint very large, broadly pear-shaped, longer than all the following joints together, the front margin a little sinuous, the hind margin extremely convex above, reaching nearly as far down as the front, the short distal margin straight, with rounded corners, the front one serrate with four or five indents; the second joint very short; the third as long as the fourth and fifth together, strongly pectinate along the front margin, and produced for three-quarters of the length of the fourth joint; the fourth joint more than half the length of the fifth, the front margin pectinate, not produced; the fifth joint slightly curved, with pectinate front margin, and a spine at the apex of the convex hind margin; the finger about a third of the length of the fifth joint.

Fifth Peraopods.—The first joint smooth, pear-shaped, not twice as long as the breadth at the upper part; the second (terminal) joint about a quarter as long as the first, oval, the neck narrow.

Pleopods.—Peduncles stout; coupling spines small; left spine apparently with the dilated arm longer than the other, the dilatation narrow; the first joint of the inner

ramus not very elongate, but having several setæ below the cleft spine; joints of the rami twelve or thirteen in number.

Uropods.—Peduncles of the first pair much shorter than the rami; the rami long, three-sided, strongly pectinate on two edges, the outer narrower than the inner but about equal to it in length, the apex of each acute, free from teeth; peduncles of the second pair a very little shorter than those of the first, much shorter than the rami; the rami thinly laminar, smooth, with rounded apices, reaching beyond those of the first pair; the peduncles of the third pair not longer than broad; the rami like those of the second pair, but the outer rather shorter than the inner, and the apices more broadly rounded.

Telson broad at the base, arched in outline, longer than broad, about two-thirds the length of the inner ramus of the third uropods, the acute apex not quite reaching the apices of the first uropods.

Length, about nine-twentieths of an inch.

Localities.—October 5, 1873, South Atlantic; lat. $29^{\circ} 1'$ S., long. $28^{\circ} 59'$ W.; surface, night; surface temperature, $65^{\circ} 2$.

Station 230, April 5, 1875; North Pacific, south of Japan; lat. $26^{\circ} 29'$ N., long. $137^{\circ} 57'$ E.; surface; surface temperature, $68^{\circ} 5$. Two specimens, the one examined a male.

Remarks.—The specific name refers to the markings of the pleon-segments. The specimen from the Pacific was nearly two-fifths of an inch in length, and differs from the Atlantic specimen very slightly, as in having the elbow more exaggerated in the first joint of the first gnathopods, and in having a still broader first joint to the fifth peræopods. Claus' *Eupronoë maculata* is from Zanzibar.

Eupronoë pacifica, n. sp.

The species bears a general resemblance to *Eupronoë minuta*, Claus. The first two segments of the peræon are dorsally coalesced, the side-plates of all the seven segments distinct. The postero-lateral angles of the first three pleon-segments are all more or less blunt, those of the third segment well rounded; the fourth segment about as long as the composite segment which follows it. On many parts of the animal hexagonal markings are conspicuous.

Upper Antennæ.—The three joints of the peduncle successively shorter; the first joint of the flagellum equal in length to the second and third of the peduncle, broad at the base, rapidly tapering, carrying two transverse bands of four filaments apiece, the second joint cylindrical, shorter than the first, with two filaments, the third joint filiform, much longer than the second.

Lower Antennæ.—First free joint a little bent at the base, a little longer than the second; the second scarcely longer than the third; the third and fourth subequal, all of them smooth, not much angled in position; there is a minute apieal joint. The antennæ in the specimen are no doubt those of a young male, the first three joints belonging to the peduncle, and the last two to the flagellum.

Mandibles.—The cutting edge finely dentieulate between the two more prominent teeth, of which one stands at each corner; the tooth-like process representing the secondary process on the right mandible very small; the palp (in the specimen) short and curved, with only an indication of division into three joints.

First Maxillæ.—There are four strong teeth projecting from the distal part of the plate's inner margin, the appearance being suggestive of a little spine-tooth embedded in a process rather wider than the tooth.

Second Maxillæ much shorter than the first, smooth.

Maxillipeds.—The inner plate nearly as broad as long, the distal margin furred, having at the centre two little embedded spines, the outer corners rounded, the outer plates broad, much longer than the inner, submarginally furred on the inner surface near the inner edge.

First Gnathopods.—First joint not twisted, dilated at and below the middle, the margins smooth, the front sinuous; the second joint not longer than broad; the third longer and broader than the wrist, with narrow neck, distally widened, with a rounded apex in front very slightly produced, the hind margin very minutely pectinate, distally produced into a broad rounded lobe; the wrist scarcely so long as broad, the front margin convex and apically a little acute, the hind margin sinuous at the narrow neck, then convex and pectinate, projecting far behind the much narrower hand; the hand longer than the wrist, narrow at the neck and still more at the apex, the hind margin pectinate at the centre; the finger slender, curved, half the length of the hand or a little more.

Second Gnathopods.—First joint a little longer and less dilated than in the preceding pair; second joint short; third joint as in the first pair, but the front and hind apical lobes more equal; the wrist broader than the third joint, its proximal part shorter than the hand, the broad triangular apical process also shorter than the hand, pectinate on both margins, at the base standing a little apart from the hand, which resembles that of the first gnathopods, but has the hind margin more strongly pectinate; finger as in the first pair.

First Peraopods with smooth margins or scarcely perceptible armature. First joint a little bent at the base, and below this the front margin sinuous, the hinder gently convex; the second joint a little longer than broad; the third shorter than the fourth, but broader, with narrow neck, the apices rounded; the fourth narrowing distally, with straight distal margin; the fifth joint longer than the fourth, slightly bent, narrow,

especially at the apex ; the finger slender, curved, between half and a third of the length of the fifth joint.

Second Peraopods similar to the first, but with the first joint rather more slender and sinuous, and the third, fourth, and fifth joints longer.

Third Peraopods.—The first joint not so long as the remaining joints together, oblong, a little widened in the upper half, the front margin descending a little below the hinder, the produced portion being narrow, with no flat distal margin ; the third joint broader than the fourth but shorter, the hind margin descending a little below the finely pectinate front margin, so that the distal border is oblique ; the fourth joint broader than the fifth but a little shorter, the front margin pectinate ; the fifth joint almost straight, the pectination of the front margin more oblique than in the other two joints ; the finger slender, smooth, apieally a little curved, half the length of the fifth joint.

Fourth Peraopods.—The first joint much longer than all the remaining joints together, the front margin nearly straight but with a little lobe at the base, the hind margin convex, the distal margin oblique, between half and a third of the greatest breadth of the joint, the front corner with some minute serration and the margin itself with some microscopic pectination or striation ; the narrowly rounded apieal lobe of the hind margin fully reaches the flattened distal end of the front of the joint ; the short second joint placed at the top of the distal division of the first, not long enough to reach the lower end of the slit ; the third joint with the front margin strongly pectinate, the teeth directed a little backwards, the apical prolongation of the front broad, completely overlapping the fourth joint and reaching beyond it ; the fourth joint very finely pectinate on the front margin, about as long as the proximal portion of the third joint ; the fifth joint a little longer than the fourth, finely pectinate on the front margin ; the finger little more than a third the length of the fifth joint, very finely pectinate.

Fifth Peraopods.—Side-plates with the slightly convex hind margin much deeper than the straight front, so that the lower margin is very oblique. The first joint about as long as the greatest breadth of the first joint in the preceding pair, the greatest breadth about a third of the length, the front margin concave, the hinder convex, the apex narrow ; the second or terminal joint narrowly oval, between a third and a fourth of the length of the first joint, about three times as long as broad.

Pleopods.—The peduncles showing hexagonal markings; coupling-spines small, without lateral teeth ; eleft spine with a very narrow dilatation ; eight or nine joints to each ramus.

Uropods.—Peduncles of the first pair pectinate at the apex of the outer margin, not longer than the outer ramus, which is narrower and a little shorter than the inner, and reaches a little beyond the telson ; both rami strongly pectinate on two edges, with the apex acute, free from teeth ; peduncles of the second pair shorter than those of the first pair, the rami thinly laminar, apieally rounded, the outer shorter than the inner, both

reaching beyond the inner ramus of the first pair; peduncles of the third pair short, the rami similar to those of the second pair, reaching considerably beyond them, the outer very little shorter than the inner.

Telson about as long as the breadth at the base, with slightly curved sides and well-rounded apex, about half the length of the rami of the third uropods, much shorter than the preceding composite segment.

Length, about one-fifth of an inch.

Locality.—Station 251, July 10, 1875; North Pacific; lat. $37^{\circ} 37'$ N., long. $163^{\circ} 26'$ W.; surface temperature, 65° . One specimen, male, not adult.

Remarks.—The specific name refers to the ocean in which the species was found. From *Eupronoë minuta*, Claus, it is distinguished especially by the more produced third joint of the fourth pereiopods, but also by the simple, not twisted, first joint of the first gnathopods, and the more slender first joint of the fifth pereiopods.

Eupronoë minuta, Claus.

- 1879. *Eupronoë minuta*, Claus, Die Gattungen und Arten der Platysceliden, p. 28.
- 1887. ,, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 41.
- 1887. ,, Claus, Die Platysceliden, p. 53, Taf. xiv. figs. 7–12.

The fourth segment of the pleon shorter than the following composite segment.

Eyes light-coloured in the specimens preserved in spirits.

Upper Antennæ.—The first joint of the peduncle broader than long, as broad as the first joint of the flagellum.

Lower Antennæ.—Third (first free) joint of the peduncle swollen at the base, then narrow, and the distal half again widened, the eoneave margin elevated; the fourth joint longer than the third, and the fifth than the fourth; the first joint of the flagellum a little curved, about half as long as the last joint of the peduncle, the second joint very slender, about a seventh of the length of the preceding joint.

First Gnathopods.—The first joint more strongly twisted than in Claus' figure, the portion below the twist much longer than broad; the remainder of the limb nearly as in *Eupronoë pacifica*.

The Second Gnathopods and First and Second Peraopods nearly as in *Eupronoë pacifica*.

Third Peraopods with the first joint more elongate than in the species just named, and the front margin concave at the centre instead of convex.

Fourth Peraopods.—The first joint with slightly sinuous front margin, but without a lobe at the base, the distal margin of the front part not oblique, reaching below the

apex of the hind margin; the hind margin not uniformly eonvex, but almost straight for a large spaee on either side of the eentre; the apical part of the third joint not quite reaching the apex of the fourth; the fourth joint about as long as the fifth.

Fifth Peraopods nearly as in *Eupronoë pacifica*, but the first joint rather broader at the upper part, and the narrowly oval terminal joint smaller in proportion to the first.

The Pleopods, Uropods, and Telson differ little from those of *Eupronoë pacifica*, but the telson has a narrower apex.

Length, about one-fifth of an ineh.

Locality.—Station 288, October 21, 1875; South Pacific; lat. $40^{\circ} 3'$ S., long. $132^{\circ} 58'$ W.; surfacee; surfacee temperature, $54^{\circ}.5$. Five specimens.

Eupronoë intermedia, n. sp. (Pl. CLXXXVIII.).

Viewed from above the head has a triangular outline, with an almost aente apex; the fourth segment of the pleon a little shorter than the following composite segment.

Antennæ nearly as in *Eupronoë inscripta*; in the upper antennæ the first joint of the flagellum, besides the great brush of filaments on the eonvex margin, has two broad filaments on the apex of the upper margin; the second has four near the middle, the third has two; the fourth joint is linear, nearly as long as the two preeeding together.

Upper Lip a broad shallow dome.

Mandibles.—The trunk sinuous, forming an upward bent angle behind the palp and one downward bent in front of it; the cutting edge broad, with a prominent tooth at each extremity, the lower one the more acute, the intermediate margin straight, very minutely dentieulate; the left mandible shows a similarly dentieulate seeondary plate, without prominent teeth at the extremities, and besides this near the middle of the straight hind margin of the seeondary plate there is a small proeess like a short blunt tooth or spine; there is a similar and not larger proeess on the right mandible; the palp is placed on a short joint-like elevation, the first joint broader and longer than either of the others, not equal in length to the two together.

First Maxillæ.—There are four teeth on the inner margin near the apex of the plate.

Second Maxillæ and *Maxillipeds* as in *Eupronoë pacifica*.

First Gnathopods.—Side-plates with the advaneed front corner rounded, not aeute. The first joint strongly twisted, the neek very narrow, but the elbow as broad as the lower part of the joint; the third joint broader than the wrist, not more produced behind than in front, the hinder margin peetinate chiefly at the lower part; the wrist not longer than broad, distally narrower than near the base, the hind margin sharply

peetinate except at the upper part; the hand a little longer than the wrist, but much narrower, the hind margin finely peetinate; the finger more than half the length of the hand.

Second Gnathopods as in *Eupronoë inscripta*, but the wrist somewhat less bulky, and the finger half the length of the hand.

First Peraopods.—First joint a little bent, proximally narrow, then somewhat widened; the third joint a little shorter than the fourth, the rounded front apex slightly produced; the fourth joint scarcely narrowed distally, the straight hind margin lightly peetinate; the fifth joint longer than the fourth, the slightly concave hind margin pretty strongly peetinate; the finger slender, with a bulbous hinge, nearly half as long as the fifth joint.

Second Peraopods similar to the first, but the third, fourth, and fifth joints longer, the third as long as the fourth or rather longer, the fifth more slender than in the preceding pair.

Third Peraopods.—The first joint with the front margin concave at the centre, with six sharp serration teeth below, the front apex rounded, not very broad, produced a little below the hind margin; the third joint longer than the fourth, peetinate along the front margin, the hind margin having a slightly produced pointed apex; the fourth joint more strongly peetinate along the front, the peetination near the apex being finer than above; the fifth joint longer than the third, peetinate like the fourth, but still more strongly, the hind margin ending in a slender tooth or spine; the finger as in the preceding pairs.

Fourth Peraopods.—The front margin of the first joint slightly concave, the hinder gently convex so as to give the joint a uniform breadth for more than half its length; the distal margin in front, instead of sloping up to the hind margin as in *Eupronoë pacifica*, slopes downwards away from it, forming a narrow distal piece of the front below the hinder part of the joint; the second joint very small, not nearly reaching the extremity of the first; the third joint longer than the fourth and fifth together, the front margin strongly peetinate, produced nearly to the end of the trunk of the fourth joint, the hind margin with the apex acute, a little produced; the fourth joint much shorter than the fifth, peetinate more finely than the third, and apically a little produced; the peetination of the fifth joint intermediate in strength between that of the third and that of the fourth; the finger a little peetinate, about half the length of the fifth joint. It will be seen, by a comparison of the two figures of *ppp⁴*, that the produced portions of the third and fourth joints only come into view when the inner surface of the limb is under observation.

Fifth Peraopods.—The first joint narrowly pear-shaped, the front margin nearly straight, the hinder not at all apically produced; the terminal joint narrowly oval, not quite a third as long as the first.

Pleopods.—Joints of the rami from nine to ten in number.

Uropods scarcely differing from those of *Eupronoë inscripta*, except that the peduncles of the first and second pairs appear to be shorter in proportion to the rami.

Telson rather more than half the length of the third uropods, a little longer than broad, triangular, with a tolerably acute apex, gradually reached without any abrupt narrowing.

Length, between a fifth and a quarter of an inch.

Locality.—Station 106, August 25, 1873; Tropical Atlantic; lat. $1^{\circ} 47' N.$, long. $24^{\circ} 26' W.$; surface to 40 fathoms; surface temperature, $78^{\circ} 8$. One specimen, male.

Remark.—The specific name refers to the similarity which the species presents in different points to various others, such as *Eupronoë armata*, Claus, and those which have been mentioned in the description.

Eupronoë atlantica, n. sp.

Head deep and laterally somewhat compressed; the frontal space which is not occupied by the eyes having little dark colour-spots.

Eyes very dark in the specimens preserved in spirits.

Lower Antennæ.—Third (first free) joint of the peduncle slightly longer than the fourth, the fifth a little longer than the third; the first joint of the flagellum only a third as long as the last of the peduncle, the small and slender second joint not a quarter the length of the first.

First Gnathopods.—Side-plates produced to an almost acute apex in front. First joint not twisted, broadest below the middle, both margins somewhat sinuous, the front one the more so, this having five cilium-bearing indents; near the hind margin at the upper part of the inner surface there are short lines or grooves corresponding with those which in some species form the great projecting elbow in this joint; second joint very small; third joint much larger than the wrist, narrow at the neck, the distal breadth equalling the length of the joint, most of the very convex hind margin finely pectinate; the wrist not longer than broad, at its widest much narrower than the preceding joint, the irregularly convex hind margin pectinate where free from the lobe of the front joint; the hand rather longer than the wrist; the finger curved, fully half the length of the hand.

Second Gnathopods.—First joint with the sinuous front margin almost smooth, the hind margin smooth, slightly convex; the third joint smaller than the wrist, the hind margin slightly furred, its rounded apex a little produced; the proximal part of the wrist not so long as the hand, the pectinate process rather broad, not so long as the hand, on

the inner or front margin having three little teeth, then with a smooth piece bending slightly away from the hand, the rest of the margin pectinate; the hand with three little teeth at the base of the hind margin, followed by a short smooth portion, the remainder being pectinate. The three little teeth of the wrist-process above mentioned appear to be present in all the species of the genus, though they are often very inconspicuous; the teeth at the base of the hand do not appear to be so constant.

Peræopods in close agreement with those of *Eupronoë minuta*. The third pair have a backward-directed blunt lobe on the inner side of the side-plates, and the branchial vesicles of the fourth pair besides the lateral pockets have a second division behind the larger front one, the front division being strongly narrowed near the apex; but these characters are, I believe, common to all the species of the genus.

Telson longer than the breadth at the base, the apex narrowly rounded, the length more than half the total length of the third uropods, the relative size exceeding that of the telson of *Eupronoë minuta*.

Length of the extended specimen, about a fifth of an inch.

Localities.—April 28, 1876, North Atlantic; lat. $17^{\circ} 47'$ N., long. $28^{\circ} 28'$ W.; surface, night; surface temperature, 73° . Several specimens.

April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface, night; surface temperature, $73^{\circ} 7$. Several specimens.

Remarks.—The characters here given of the lower antennæ, gnathopods, and telson, appear to separate this species from that which I have supposed to be Claus' *Eupronoë minuta*, to which otherwise it shows many points of resemblance in detail. If preserved specimens may be trusted, the two forms can, moreover, be easily distinguished by the colour of the eyes.

The following table will show the distribution of the genus *Eupronoë* as illustrated by the Challenger specimens:—

1. Station 353, May 3, 1876; North Atlantic; lat. $26^{\circ} 21'$ N., long. $33^{\circ} 37'$ W.; surface. Three small specimens.
 2. April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface, night.
 3. April 28, 1876, North Atlantic; lat. $17^{\circ} 47'$ N., long. $28^{\circ} 28'$ W.; surface, night.
- Fourteen specimens; the length of a specimen, fully extended, about one-fifth of an inch, rather under than over.
4. Station 106, August 25, 1873; Tropical Atlantic; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; surface to 40 fathoms. One specimen. (*Eupronoë intermedia*, see p. 1517.)
 5. October 5, 1873, South Atlantic; lat. $29^{\circ} 1'$ S., long. $28^{\circ} 59'$ W.; surface, night. (*Eupronoë inscripta*, see p. 1510.)
 6. March 15, 1874, south of Australia; lat. $39^{\circ} 45'$ S., long. $140^{\circ} 40'$ E.; surface.

Several specimens. (Apparently a species near to, but not identical with, *Eupronoë atlantica*; the specimen examined measured three-tenths of an inch in length.)

7. March 16, 1874, south of Australia; lat. $39^{\circ} 22'$ S., long. $142^{\circ} 27'$ E.; surface. Ten specimens, males, agreeing with those last mentioned.

8. Station 164B, June 13, 1874; east of Australia; lat. $34^{\circ} 13'$ S., long. $151^{\circ} 38'$ E.; surface to 50 fathoms. One specimen.

9. April 4, 1875, North Pacific, south of Japan; lat. $25^{\circ} 33'$ N., long. $137^{\circ} 57'$ E.; surface. One specimen.

10. July 1875, North Pacific, between Japan and Honolulu; surface. Several specimens.

11. Station 251, July 10, 1875; North Pacific; lat. $37^{\circ} 37'$ N., long. $163^{\circ} 26'$ W. (*Eupronoë pacifica*, see p. 1513.)

12. August 24, 1875, Mid Pacific; lat. $13^{\circ} 1'$ N., long. $151^{\circ} 50'$ W.; surface, at night. Four small specimens.

13. Station 287, October 19, 1875; South Pacific; lat. $36^{\circ} 32'$ S., long. $132^{\circ} 52'$ W.; surface. Five small specimens.

14. Station 288, October 21, 1875; South Pacific; lat. $40^{\circ} 3'$ S., long. $132^{\circ} 58'$ W.; surface. Four specimens.

Genus *Parapronoë*, Claus, 1879.

- 1879. *Parapronoë*, Claus, Die Gattungen und Arten der Platysceliden, pp. 23, 29.
- 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 485.
- 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Haudl., Bd. 11, No. 16, p. 42.
- 1887. " Claus, Die Platysceliden, pp. 48, 53.

For the shorter definition of this genus, see Note on Claus, 1879 (p. 492). The fuller definition which Claus gives of it is to the following effect:—

“ Body *Pronoe*-like, but less strongly compressed, with more rounded head, the pleon bent and having its hinder section generally flexed. Antennæ and mouth-organs like those of *Eupronoë*, the latter, however, far longer and more produced. The first gnathopods simple, the second complexly chelate. Laminar first joint of the third peræopods broad and of oval form, that of the fourth peræopods of greater extent, triangular, distally narrowed and truncate, with short longitudinal ridge. First joint of the fifth peræopods of smaller extent, the appendage rudimentary, one- or two-jointed. Hinder section of the pleon distinguished by the elongation of the coalesced fifth and sixth segments. Last pair of uropods with very short peduncle and short, more or less fin-like, rami.”

In further observations on the genus Claus says, “ Both antennæ have the same (ZOOL. CHALL. EXP.—PART LXVII.—1888.)

jointing as those of *Eupronoë*, yet the peduncle of the front pair is more slender and produced, the penultimate joint of the hinder antenna relatively shorter, since it scarcely equals a third of the preceding joint." In the shaft or peduncle of the front pair he includes, it must be remembered, what in this Report is regarded as the first joint of the flagellum. In regard to the jointing of the hinder antenna, it may be noticed that the third (first free) joint of the peduncle is shorter than the next joint in *Eupronoë armata*, Claus, and other species of *Eupronoë*, in the new species *Parapronoë campbelli*, and in the new genus *Sympronoë*, which includes *Parapronoë parva*, Claus, but in *Parapronoë crustulum*, Claus, and *Parapronoë clausi*, n. sp., this joint is longer than the next following.

Parapronoë campbelli, n. sp. (Pl. CLXXXIX.).

Head and peræon much compressed, head much shorter than peræon, pleon longer than head and peræon together; the first two segments of the pleon with the postero-lateral angles acutely produced, the third segment with the angles not rounded but not produced; the fourth segment not very much shorter than the composite segment which follows; the body flecked with numerous spots of colour, which are orange in the preserved specimens, the first three segments of the pleon inscribed with numerous little longitudinal marks.

Upper Antennæ.—First joint of the peduncle broader than long, the two following joints short, all three strongly marked with hexagonal scale-markings; the first joint of the flagellum rather sharply bent, the upper margin having distally three pairs of filaments, the lower margin very convex, covered with a dense brush of filaments, the rounded apex not produced to the end of the small second joint, which from a narrow neck is a little dilated, and carries on the upper margin two pairs of filaments; the third joint is longer and more slender than the second, and has very near the apex a pair of short filaments.

Lower Antennæ.—The third (first free) joint of the peduncle long, a little curved, more than two-thirds the length of the next joint, the distal part wider than the proximal, the concave margin fringed with little filaments like the corresponding margin of the following joints; the long and narrow fourth joint a little widened at the distal end; the fifth joint a very little shorter than the fourth; the first joint of the flagellum slender, a little curved, scarcely more than half the length of the third joint of the peduncle, the filaments at and near the apex longer than elsewhere; the second joint minute, about a quarter of the breadth of the preceding joint, and scarcely twice as long as broad; to this succeeds a much smaller third joint tipped with three little setules.

Mandibles.—The trunk rather long and narrow, the cutting edge downward bent, with a prominent tooth at the top and another much smaller and sharper at the

other extremity, the intermediate edge strongly striated and minutely dentieulate; the left mandible has a secondary plate apparently broad and shallow; each mandible has to the rear of the cutting edge and near the top of it a little blunt spine-like process; the palp is long and slender, all three joints slightly curved, the first not very broad, but broader than the other two, especially at the bend; the third is scarcely longer than the second, these two together being much shorter than the first. The breadth of the cutting edge is considerably less than the length of the third joint of the palp.

Lower Lip.—The plates narrow, tapering, apically acute; the mandibular processes rounded.

First Maxillæ.—Near the base the narrow plate has a projection on the inner side; at some little distance from the narrow smoothly rounded apex, there are four short triangular and equilateral teeth on or a little within the inner margin.

Second Maxillæ.—The distal part of the plate is much narrowed, forming an acute apex, below which there is an emargination longer than deep, and bounded by a little sharp point above facing a rounded angle below.

Maxillipeds.—The inner plate large, of nearly equal breadth and length, the distal margin sinuous; the two central embedded spines not reaching the distal margin, and having below them two much smaller spines; the outer plates distally overlapping one another and overarching the inner plate, showing within the sinuous inner margin five or six small spines.

First Gnathopods.—Side-plates deeper than broad, with front margin a little concave, the lower angle rounded. The first joint having the neck rather narrow and bent, the upper part of the front margin having three little indents; the second joint not longer than broad; the third joint wrist-like, from a narrow neck widening distally to a breadth greater than the length, the front apex almost acute, a little produced, slightly pectinate, the hinder apex widened and more strongly pectinate; the wrist longer and much broader than the hand, widest a little below the wide neck, the hind margin pectinate with sharp not quite regular teeth, three or four of the strongest being on the distal margin; the hand smooth, narrower at the apex than at the neck, attached much nearer to the front than to the hind margin of the wrist, the front margin convex, the hinder a little sinuous; the finger smooth, curved, about half the length of the hand.

Second Gnathopods.—The interlocking process of the segment on the front margin a little way above the side-plate has little grooves leading to a serrate edge; the same form occurs in the following segments. The branchial vesicles of this pair and of the four following pairs of limbs are large, with numerous lateral accessory pockets. The first joint is distally widened, with smooth margins, the front a little sinuous, the hinder convex; the second joint short, the third nearly as in the first pair, but with the apices on a level with one another, neither produced; the wrist with the proximal part about as wide as the third joint but not quite so long and like the third joint having an

extremely minute furring of the hind margin, the apical process large, longer than the base, almost as long as the hand, almost acute, finely pectinate at the upper part of the hind margin, the lower part having nearly twenty teeth, the front or inner margin smooth at the base, then armed with fourteen teeth, which are larger than those on the opposite side; the hand shaped and placed as in the first gnathopods, but with the hind margin near the base finely pectinate, and below more strongly with about twenty small unequal teeth; the finger not half the length of the hand.

First Peraopods.—First joint similar to that of the second gnathopods, but narrower above and more widened below; the second joint rather longer than broad; the third with narrow neck, then much widened and distally scarcely narrowed, the front margin convex, with the apex rounded; the fourth joint narrower than the third and very slightly longer, smooth, a little curved, the distal margin finely pectinate; the fifth joint narrower than the fourth, of about the same length, finely pectinate along the hind margin, within which there are also five minute spinules; the finger curved, scarcely a third the length of the fifth joint.

Second Peraopods.—The first and second joints narrower than in the preceding pair, the three following joints longer and narrower; the third joint strongly bent, the front margin convex, the hinder concave, both smooth; the fourth joint a little longer and narrower, also smooth, slightly curved; the fifth joint slender, almost as long as the fourth, with six microscopic spinules along the slightly furred hind margin and some very fine pectination at the distal extremity; the finger less than a quarter of the length of the first joint.

Third Peræopods.—The side-plates with a curved tongue-like backward directed process on the inner side. The first joint a sort of oblong or long oval, about two and a half times as long as the greatest breadth, which is rather below the middle, not quite equal in length to the following joints together, the front margin nearly straight, with a little shallow serration of the lower part, the surface adjoining the front margin marked with seven or eight more or less parallel longitudinal lines, the distal margin somewhat flattened, the surface above this marked with some little oblique curved lines; the second joint longer than broad, so placed as not to be able to reach either the distal or the hinder margin of the large first joint; the third joint more than twice as long as the second, the hinder apex a little produced, almost acute, pectinate, the front margin at first smooth, then feebly and by degrees more strongly pectinate; the fourth joint about once and a half as long as the third, a little narrowed distally, all the front margin pectinate; the fifth joint much narrower than the fourth, almost as long, a little bulb forming the hinge, the hind margin smooth, produced into a small apical tooth, the whole front margin pectinate, the teeth become smaller towards the narrow apex, of which the margin is also finely fringed; the finger about a fifth of the length of the fifth joint.

Fourth Peræopods.—Branchial vesicles with a second lobe to the rear of the larger front portion. The first joint scarcely longer than in the preceding pair, and distally narrower, but above much broader, the hind margin smooth, convex, the long tongue-like distal part not reaching quite so low as the distal part of the front; the front margin almost straight, very slightly concave below, with an almost pointed apex, behind which the short distal margin slopes downwards to the more rounded apex of the long slit, a little in front of which the inner surface is grooved; the joint nearly twice as long as all the remaining joints together; the short second joint is placed at the top of the slit which divides the apical part of the first; the third joint is as long as the fourth and fifth together, the proximal part broader and rather longer than the fourth joint, the front apical process more than half the length of that joint, the hind margin smooth, with a short produced apex, the front margin strongly pectinate from one end to the other, and having small teeth between the large ones; the fourth joint broader and longer than the fifth, pectinate like the third but less strongly; the fifth joint finely pectinate with decurrent teeth along the front margin and round the apex, the hind margin produced into a little tooth; the finger minute, not curved, but a little crooked.

Fifth Peræopods.—Side-plates with a very long hind margin, forming an acute apex. The first joint at the upper part more than half the breadth of the first joint of the preceding pair, and more than half as long as that joint, the apex behind rather broadly rounded; the very minute second joint longer than broad; the third joint shorter than the second and a little narrower, a little longer than broad, smoothly rounded distally.

Pleopods.—Peduncles stout; the coupling spines small, with only the apical retroverted teeth; the cleft spine having a subapical unsymmetrical dilatation of the longer arm, the backward serrature of the shorter arm being strongly marked; as in the genus *Eupronoë*, the first joint of the inner ramus has several plumose setæ below the cleft spine, in the present specimen as many as six; the first joint of the outer ramus has also several plumose setæ; the joints of the rami from twelve to thirteen in number.

Uropods.—Peduncles of the first pair shorter than the rami, three-edged, the inner margin with a produced acute apex; the outer ramus three-edged, shorter than the inner, both with the margins strongly pectinate, except near the bases and the acute apices, the teeth larger and less numerous on the inner than on the outer margin; the peduncles of the second pair nearly as long as those of the first, the rami broader and rather longer, the outer ramus nearly as long as the inner, its outer margin forming only a few little distant teeth, the pectination otherwise as in the first pair; peduncles of the third pair very short, broader than long, the inner margin with a produced acute apex; the rami rather shorter than in the two preceding pairs, the outer a little shorter than the inner, with the outer margin smooth, the inner strongly pectinate except at the two extremities; the inner ramus with almost smooth margins, distally pectinate very minutely, the apex acute.

Telson long and tongue-like, more than twice as long as broad, nearly as long as the preceding composite segment and not much shorter than the third uropods, the sides gently convex, the apex acute; there are many little curved lines across this and various other parts of the animal.

Length.—From the front of the head to the end of the first segment of the pleon about a quarter of an inch, the total length about two-fifths of an inch.

Locality.—July 1875, between Japan and Honolulu; lat. 35° N.; surface. Six specimens; the specimen described, a male.

Remark.—The specific name is given in compliment to Lord George Campbell, the author of the very entertaining work, Log Letters from the Challenger.

Parapronoë clausi, n. sp. (Pl. CXC.).

Head large, rounded; the postero-lateral angles of the first three pleon-segments not rounded but scarcely or not produced, the lower margin in the first interrupted, the hinder part starting from the inner surface a little above the termination of the front part; the fourth segment considerably shorter than the following composite segment; the body spotted with numerous small orange spots.

Upper Antennæ nearly as in *Parapronoë campbelli*, but the rounded apex of the first joint of the flagellum not at all produced, the small second almost as long as the much narrower third joint, and carrying filaments at three points of the upper margin.

Lower Antennæ differing much from those of *Parapronoë campbelli*, and agreeing with those of *Parapronoë crustulum*, Claus; the gland-one projecting from the wall of the head (see fig. g.c.); the third (first free) joint of the peduncle much longer than the fourth, the fourth a little longer than the fifth; the first joint of the flagellum not more than a third of the length of the last joint of the peduncle, narrow at each end; the second joint very short and slender, the third still more minute; all the joints fringed with short filaments, except the third joint of the flagellum which is tipped with little hairs or setules.

Upper Lip semicircular.

Mandibles.—The trunk long, nearly straight, but upward bent at the base and with very sinuous lower margin; the cutting edge forming part of the lower margin, very broad, convex, strongly striated, and finely dentieulate, with a blunt tooth at the upper or front corner, in the rear of which there is a groove on the surface ending in a small tubercle; to the left mandible there is a long shallow secondary plate, similar to the principal but without the upper tooth; the palp has a large strongly bent first joint, very much longer than the two following joints together; the second rather longer than the third. The breadth of the cutting edge much exceeds the length of the third joint of the palp.

Lower Lip of very thin texture, the plates curved, rather narrow, tapering to an acute apex, very minutely furred; the mandibular processes produced, apically rounded.

First Maxillæ nearly as in *Parapronoë campbelli*, but the apex more acute, the four marginal teeth more blunt.

Second Maxillæ shorter than the first, divergent at the base, then closely united as far as the small projecting tooth or angle of the inner surface, then again diverging to the nearly acute apex, the inner margin of each plate at this part having a little fold and a setule near it.

Maxillipeds nearly as in the species above named, but the inner plate less broad, with a rather deep central indent on the distal margin, from which the sides slope away; the outer plates broad at the base, the spines within the inner margin less numerous or less conspicuous than in the other species. The boat-shaped appearance of these organs is not indicated by the outline figures.

First Gnathopods.—Side-plates deeper in front than behind, with a diagonal ridge directed to the lower front corner. The limb differing in many points from that of *Parapronoë campbelli*; the first joint with the upper part of the front margin pectinate; the wrist widens immediately from the broad neck, then narrows so that the distal end is narrower than the neck, and projects scarcely more behind the hand than in front of it, the hind margin very sinuous, pectinate, the short distal margin behind the hand being also pectinate with fine teeth; the hand is longer than the wrist; the finger half the length of the hand, bulbous at the base, the inner margin rather sinuous.

Second Gnathopods differing from those of *Parapronoë campbelli* in having the first joint not bent, the hind margin of the wrist pectinate for a greater distance, its apex acute and a little incurved, the irregularly pectinate inner or front margin of the distal process very sinuous, at the base standing away from the hand, then bending towards it and again away from it; the hand is rather shorter than in the first pair but broader, bent at the neck, then having both margins convex, the hinder pectinate, the apex rather abruptly narrowed; the finger more than half the length of the hand, with concave inner margin.

First and Second Peræopods scarcely differing in pattern from those of *Parapronoë campbelli*, except that in the first joint the lower part of the front margin is a little concave; the fourth and fifth joints in both are finely pectinate.

Third Peræopods.—Side-plates almost semicircular, but bilobed, the circumference being interrupted where the smaller front lobe meets the hinder; on the inner surface as usual a bent tongue-like process is directed backwards. The first joint very large, as it were five-sided, the front margin being obtusely angled, the lower part not so long as the upper, with a slight serration, the hind margin nearly straight, with the corners strongly rounded, the lower margin between them straight; a tract in front marked

with parallel lines longitudinally, the lines at the broadest part being about twenty in number; the remaining joints nearly as in *Parapronoë campbelli*; the fifth joint rather longer than the fourth.

Fourth Peraopods.—The first joint not much longer or even much broader than in the preceding pair, not nearly twice as long as broad, the front margin bulging a little near the base, slightly channelled, for the most part straight, serrate near the short sinuous apical margin; the very convex hind margin much longer than the front, rising much above it, and the tongue-like apex (in one of the specimens examined) descending a little below it; the groove of the inner surface in front of the straight slit has a sinuous margin; the remaining joints are nearly as in *Parapronoë campbelli*, but the fifth joint more curved; the finger extremely minute, retraetile within the pectinate apex of the preceding joint.

Fifth Peraopods.—The first joint pear-shaped, not as long as the breadth of the first joint in the fourth pair, sometimes as in the other species with an indent low down on the front margin, the rounded apex behind produced a little; the minute second joint very little longer than broad; the third joint longer than the second, nearly twice as long as broad, the apex rounded.

Pleopods.—Coupling spines very short; cleft spine with very short arms, the longer arm with a small subapical dilatation; there are several plumose setæ on the first joint of the inner ramus below the eleft spine, and eight on the outer margin of the outer ramus; the joints of the rami fourteen or fifteen in number.

Uropods.—Peduncles of the first pair shorter than the rami; the outer ramus a little shorter than the inner, its outer margin closely pectinate except close to the base and the acute apex, the inner margin with the pectination looser, beginning below the centre, and not approaching so closely to the apex; the inner ramus with the upper half of the outer margin smooth, the lower half as in the outer ramus, the inner margin with the pectination carried rather higher up than in the outer ramus; the peduncles of the second pair decidedly shorter than those of the first, the rami of nearly the same length as in that pair but broader and narrowing much more abruptly at the apex; the outer ramus rather shorter than the outer of the first pair, its outer margin almost smooth, with five little indents at the lower part, the inner margin pectinate at the lower part; the inner ramus about as long as the inner of the first pair, with both margins pectinate on the lower part; the peduncles of the third pair very short, broader than long; the outer ramus considerably shorter than the inner, with the outer margin smooth except for a single indent, the inner margin for the most part pectinate; the inner ramus longer than the telson, very loosely pectinate on both margins, more strongly on the inner than on the outer, and on the lower than on the upper part, the apex (in the specimen, not acute.

Telson triangular, elongate, reaching beyond the outer ramus of the third

uropods, but not nearly to the apex of the inner ramus, the length nearly twice the breadth at the base, the apex not quite acute.

Length, about half an inch, when fully extended.

Localities.—March 15, 1874, south of Australia; lat. $39^{\circ} 45'$ S., long. $140^{\circ} 40'$ E.; surface; surface temperature, $60^{\circ}\cdot 2$. Ten specimens.

October 1875, South Pacific, surface. Five specimens. The specimen examined was a male, and differed from the specimen above described in having the third joint of the fifth peræopods distally narrowed, almost acute.

Remarks.—The specific name is given in compliment to the distinguished zoologist, to whose highly important work, *Die Platysceliden*, reference has been so frequently made. The present species has many points of resemblance to *Parapronoë crustulum*, Claus, from "the Atlantic Ocean, Lagos, Zanzibar"; it differs from that species in the shape of the wrist of the first gnathopods, in the more irregular inner margin to the wrist process of the second gnathopods, in the more produced third joint of the fourth peræopods, and in the widened rami of the second uropods.

Parapronoë clausoides, n. sp. (Pl. CXCI.).

This species seems to unite some of the characters of *Parapronoë clausi*, just described, with some of those of *Parapronoë crustulum*, to be described presently. The head is large and rounded; the first three pleon-segments have the postero-lateral angles acutely produced, that of the first segment most strongly, the lower margin being excavate in front of the tooth; the fourth segment is much shorter than the composite following segment; the body quite free from spots of colour, and in this respect differing from both the species above mentioned.

The Upper Antennæ are those characteristic of the female; the first joint of the peduncle longer than broad, with sinuous margins, the second short, broader than long; the long first joint of the flagellum somewhat curved and tapering, carrying on the concave margin nine pairs of filaments; the second joint of the flagellum is much more slender than the first and less than half as long; the third much more slender than the second, more than half as long.

Lower Antennæ.—The gland-cone prominent; of the four free joints, which are slender and not folded, the first is longer than the two following together, the third a very little longer than the second, and the fourth than the third.

The Mandibles are of the usual character, but in the female without palp. The figure *m.m.* represents them drawn apart at the bases but with the distal ends and the outermost teeth of the cutting plates overlapping, close to the small almost semicircular upper lip.

The Maxillæ and *Maxillipeds* presented no specially distinctive features.

The Gnathopods are like those of *Parapronoë crustulum*, differing therefore from those of *Parapronoë clausi*.

The First, Second, and Third Peraopods as in the two compared species.

Fourth Peræopods.—The front and hinder apices of the first joint on a level; the third joint as in *Parapronoë clausi*, with the process more than half the length of the fourth joint, not less than half that of *Parapronoë crustulum*; the finger minute.

Fifth Peræopods with the second joint much shorter than the third, which is longer than that in *Parapronoë clausi*, the end of the first joint being also more broadly rounded in this species than in that.

Uropods.—The first two pairs very nearly as in the two other species, but the peduncles of the second pair less differing in length from those of the first pair; the rami of the third pair subequal in length, both of them broad, the chief narrowing not beginning till near the apex, the outer armed as in *Parapronoë crustulum*, the inner with smooth outer margin, the inner margin smooth along the upper half, then faintly pectinate and more strongly near the apex.

Telson nearly as long as the third uropods, nearly twice as long as the breadth at the base, not regularly triangular, since the sides converge near the apex much more rapidly than in the upper part; the apex is blunt.

Length, fully extended, over half an inch.

Locality.—June, 1874; between Sydney and Wellington; surface.

Remarks.—The specific name points to the likeness between this species and that named *Parapronoë clausi*. From *Parapronoë crustulum*, Claus, it is distinguished by the more prolonged third joint in the fourth peræopods, the two terminal joints of the fifth peræopods, and by characters of the uropods and telson.

Parapronoë crustulum, Claus (Pl. CXIII., A.).

1879. *Parapronoë crustulum*, Claus, Die Gattungen und Arten der Platysceliden, p. 31.

1887. " " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 42.

1887. " " Claus, Die Platysceliden, p. 55, Taf. xv. fig. 1-15.

Head rounded; the postero-lateral angles of the first two pleon-segments acutely outdrawn, of the third segment squared, the lower margin of the first segment deeply emarginate, so as to form a second angle below and in front of the postero-lateral angle; the fourth segment much shorter than the following composite segment; the whole body except the head dotted with little dark spots.

Eyes extremely dark.

Lower Antennæ.—Gland-cone very prominent; third (first free) joint of the peduncle curved, a very little longer than the fourth joint, which is distally a little curved in the opposite direction; the fifth joint about four-fifths the length of the fourth; the slender first joint of the flagellum considerably less than half the length of the last joint of the peduncle, the second and third joints quite minute.

Mandibles.—The left mandible with a very prominent tooth at the top or front of the long straight cutting edge, the secondary plate not much shorter than the principal, a minute tubercle on the surface adjoining its hind margin; the cutting edge on the right mandible more convex; the first joint of the palp very long, curved, not very broad, the second and third joints subequal in length, together much shorter than the first, the third more slender than the second.

Maxillæ of the usual pattern, the second pair much smaller than the first.

Maxillipeds.—The distal margin of the inner plate very sinuous, the outer plates broad and long.

First Gnathopods.—The side-plates with the lower front angle acute, with a diagonal ridge of the under surface directed to it. The first joint pretty evenly broad except at the neck, the front margin indented at the top and microscopically pectinate; the third joint widening greatly from the narrow neck, so that the distal breadth is much greater than the length of the joint, the convex hind margin pectinate on the lower half, the front forming a rounded apex, the distal margin extremely sinuous; the wrist widening immediately from the broad neck to a breadth a little less than that of the third joint, then narrowing greatly, so as to project but little behind the hand and scarcely at all in front, the sinuous hind margin longer than the front, pectinate, the hinder part of the distal margin pectinate with three or four little teeth; the hand smooth, shorter than the wrist, its length equalling or little exceeding the wrist's greatest breadth; the finger about a third of the length of the hand.

Second Gnathopods.—The first joint with the front margin nearly straight; the third joint a little longer than in the first gnathopods; the wrist pectinate with six little teeth on the round front apex, the triangular process behind shorter than the trunk, broad at the base, shorter than the hand, pectinate on both margins, the pectination of the hind margin continued some way up the trunk of the joint; the hand rather widened at the centre, pectinate along the hind margin; the finger scarcely more than a third of the length of the hand.

First and Second Peraopods as in *Parapronoë clausi*.

Third Peraopods like those of *Parapronoë clausi*, but the bent process within the side-plates is more narrowly produced, and the fifth joint is more decidedly longer than the fourth.

Fourth Peraopods very near to those of the species just mentioned; the two limbs of the specimen differ slightly in regard to the first joint, since in one the apex of the

hind margin does not reach quite so low as that of the front, while in the other the two apices are on a level; the produced apex of the third joint is rather less instead of rather more than half the length of the fourth joint; the finger is minute.

Fifth Peræopods differing chiefly from those of the species just mentioned by having only two joints, the second or terminal joint minute, a little longer than broad, directed backwards, the front margin convex, the hinder nearly straight, with a small incision high up, probably indicating an original division of the joint into two. The shape of the male organs on the ventral surface of the seventh peræon-segment is shown in the figure *ppr⁵*.

Pleopods.—The spines as in the other species; the joints of the rami about fifteen in number, the first joint not very long.

Uropods.—The first two pairs as in *Parapronoë clausi*, the pectination here seen to be continued, though not strongly, up the inner margin of both rami of the second pair; the outer ramus of the third pair almost as long as the inner, with two or three little indents on the outer margin, the inner margin pectinate except near the base and at the apex; the inner ramus with smooth outer margin, the lower half of the inner pectinate with little close-set teeth, not as in *Parapronoë clausi* with comparatively large teeth wide apart.

Telson twice as long as the breadth at the base, almost as long as the third uropods.

Length, to the end of the second pleon-segment, a little over two-fifths of an inch.

Localities.—Pacific, between Papua and Japan, surface. One specimen, male, to which the above description applies.

North Atlantic, between Tenerife and St. Thomas, West Indies; surface. One specimen.

April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface, night; surface temperature, $73^{\circ}\cdot7$. One specimen, male.

April 28, 1876, North Atlantic; lat. $17^{\circ} 47'$ N., long., $28^{\circ} 28'$ W.; surface; surface temperature, $73^{\circ}\cdot5$. One specimen.

Atlantic, surface. One specimen.

Remarks.—The specimen taken April 29, 1876, measured about seven-tenths of an inch in length; in the fifth peræopods the distal end of the first joint is rather flattened than rounded, not at all produced, and is followed by two minute joints, very narrow, about equal to one another in length; the postero-lateral angles of the third pleon-segment are a little outdrawn. Claus figures the fifth peræopods with only one appendicular joint, but this character is probably variable; the relative lengths of the joints of the lower antennæ are also most likely subject to some variation. The resemblance in almost all details is so exact between the Pacific and Atlantic specimens, that the very small points of difference do not seem to justify specific distinction.

Genus *Sympronoë*, n. gen.

Near to *Parapronoë*.

First Gnathopods simple, the wrist supplying no approach to a palm.

Second Gnathopods complexly subchelate, the process of the wrist short and more or less obtuse.

Fifth Peræopods with the first joint not much expanded above and distally much narrowed; the two terminal joints minute.

Uropods of the first and second pairs as in *Parapronoë* with the rami acute; the rami of the third pair short, broad, ending obtusely.

Telson very short.

The name is derived from the Greek $\sigma\acute{\nu}\nu$, with, and *Pronoe*, the name of the leading genus in the family Pronoidæ. Claus, in his observations on the genus *Parapronoë*, says that though the first gnathopods are simple, the wrist is so expanded that the limb might be characterised as complexly subchelate. This, which applies well to *Parapronoë crustulum*, is unsuited to the species of *Sympronoë*. Unfortunately Claus has not described the first gnathopods of his *Parapronoë parva*, which must undoubtedly be included in the new genus. He remarks of the first maxillæ of *Parapronoë* that the apex reaches far beyond the four submarginal teeth, which again is true of *Parapronoë crustulum*, but does not apply to *Sympronoë*.

Sympronoë parva (Claus) (Pl. CXII.).

- 1879. *Parapronoë parva*, Claus, Die Gattungen und Arten der Platysceliden, p. 31.
- 1887. " " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 42.
- 1887. " " Claus, Die Platysceliden, p. 55, Taf. xiv. fig. 13-18.

Length and depth of the head about equal; in a lateral view the lower part of the front curve of the head becomes a little concave, where the upper antennæ project; the rostral point is obtusely angled between the upper antennæ; the fifth is the longest of the peræon-segments; the first three segments of the pleon are large, squared at the postero-lateral angles; the coalesced fifth and sixth segments form one that is considerably longer than the fourth, narrowing gradually towards the distal end. The skin of the specimen with the usual hexagonal markings, but also more or less covered with larger and smaller circles as if of a crystalline coating, and spotted with orange in many parts.

The Eyes occupy most of the head, but do not reach the front or lower margin.¹

Upper Antennæ.—The first joint of the peduncle widening distally, as broad as long, the second and third joints incompletely developed; the first joint of the flagellum very

¹ This limitation, however, may not apply to living specimens.

strongly eonvex on the lower or outer side, the apex rounded, not produced, the fringing brush formed by some fifty rows of filaments, the much shorter upper margin having filaments only at the apex; the second joint small, twice as long as broad, with two groups of filaments on the upper margin; the third joint rather shorter and much narrower; the fourth linear, rather longer than the second or third.

Lower Antennæ.—The gland-cone prominent; the third (first free) joint long, bent near the base, distally widened; the fourth and fifth joints equal in length, each considerably longer than the third; the first joint of the flagellum slender, curved, more than half as long as the third joint of the peduncle, less than half the fourth or fifth; the second joint minute, but like the others fringed on one side with short filaments; at its tip there is, as in the species of the neighbouring genus *Parapronoë*, a much more minute third joint.

Mandibles.—The cutting edge forming the distal part of the sinuous lower margin, slightly eonvex, with a finely striated and denticulate edge, and a prominent blunt tooth at the upper or front apex; the secondary plate of the left mandible rounded at its front apex, but having a small projecting tooth at the hinder one; in each mandible there is as usual a small process on the inner surface to the rear of the cutting plate; it is in this species placed well forward and quite blunt; the first joint of the palp not much longer than the other two together; the second much thinner than the first, the third a little thinner than the second, subequal to it in length, rather more strongly curved than the other two. The cutting edge is rather shorter than the third joint of the palp.

First Maxillæ.—The four teeth on the inner margin are very blunt, and the distal one is very near to the apex of the plate.

Maxillipeds.—The boat-shaped outer plates arching over the inner plate, their sinuous inner margins leaving an oval space between their apices and the inner plate's distal border, each plate having on its outer surface a row of eight or ten small setules; the distal border of the inner plate sinuous, cleft at its centre down to the sockets of the embedded setules, on either side of which there are a couple of inward pointing spinules.

First Gnathopods.—Side-plates deeper before than behind, a little pointed in front below. The first joint almost free from the side-plate, both margins eonvex for nearly the whole length, the front of great tenuity, with some extremely minute pectination; the second joint as broad as long; the third widest distally, shorter than the wrist but about as long as the hand; the wrist not quite so wide as the third joint, narrowing a little distally, the pectination of the hind margin of this and the preceding joint extremely minute; the hand abruptly narrower than the wrist, but attached to the centre of its distal margin, so that there is only a small free portion of that margin on either side of it, and nothing in any way suggestive of a palm; the hand is narrow, a little curved, the front margin convex, the hinder slightly sinuous; the finger very small and slender, slightly curved, less than half the length of the hand.

Second Gnathopods.—Side-plates tending to oblong, but broader above than below. Branchial vesicles longer and much broader than the first joint, with the usual lateral accessory inflations. The first joint not dilated distally, the front margin tending to convex; the second joint as broad as long; the third larger than in the first gnathopods, its front margin considerably longer than that of the wrist, the hinder not quite so long as that of the wrist, the rounded apices finely pectinate, the front one being the broader, the hinder the more strongly pectinate; the wrist, which is widest at its junction with the hand, is produced behind in a rounded process about half the length of the hand; the hind margin is pectinate, very finely at first, but more boldly as the pectination approaches and passes round the process; the hand as in the first gnathopods, but a little broader at the base; the finger is scarcely so long as in the preceding pair.

First Peræopods.—The side-plates a little less regular than in the preceding pair; the branchial vesicles similar; the first joint rather longer, with both margins very slightly convex; the second joint rather longer than broad; the third joint decidedly broader and a little longer than the fourth, narrowing distally to a very slight extent, the rounded corners of the distal margin finely pectinate; the fourth joint narrowing a little distally, wider than, but scarcely so long as, the fifth joint, which narrows a good deal distally; the finger is slender, curved, acute, not a third the length of the fifth joint. The limb figured in the Plate does not agree with the above proportions, but was probably abnormal.

Second Peræopods similar to the first, but with the joints a little longer, the fourth as long as the third, the finger scarcely one-fourth the length of the fifth joint.

Third Peræopods.—Side-plates broader than deep, both lobes squared, the hinder one the larger; the triangular tooth-like process on the inner side has its lower margin convex. Branchial vesicles much broader above than below. The first joint oval, with a very regular hind margin, the front rather less so; the second joint short, some little way from the distal end of the first; the third joint subequal in length to the fourth, the two together not reaching back to the base of the first, each with closely pectinate front margin; the fifth joint narrow, a little curved, rather longer than the fourth, its front margin with the fine pectination oblique, not standing out as in the two preceding joints, the apex pectinate; the finger very small and slender.

Fourth Peræopods.—Side-plates not broader than deep, deeper behind than in front. Branchial vesicles with a second lobe above, the larger front division very much narrowed below. The first joint a little longer than that of the third peræopods, its upper half a little broader than that at the centre, but narrowing rapidly to the apex, the front margin almost straight, tending rather to concave than convex except at the two ends, the hind margin at first convex, then oblique; the distal margin is broken by the short longitudinal slit, behind which the joint forms an almost pointed apex, while in front it carries on the inner surface a blunt process, and below this a pointed process, reaching together

with the rounded front apex below the hinder apex ; at the top of the slit rises the short second joint, partially overlapped by a third process ; the third joint is long, with the front margin longer than the hind one, strongly pectinate, forming a triangular process with smooth hind margin nearly halfway along the front of the much narrower fourth joint, which is pectinate with much smaller teeth ; the fifth joint is minutely pectinate, narrower and shorter than the fourth, the two together equalling the length of the third ; the finger is quite minute, sharp, no doubt retractile within the pectinate apex of the fifth joint, not nearly reaching to the base of the first joint.

Fifth Peraopods.—Side-plates rather deeper than broad, deeper behind than in front. The first joint a good deal more than half as long, and less than half as broad as the first joint in the fourth peraeopods, the front margin nearly straight, the hinder at first parallel, then sinuously sloping to a very narrow apex ; there is a ridge nearer to the front than the hind margin, and nearly parallel with it, reaching below the middle of the joint ; the second joint is minute, with slightly convex front margin ; the third joint is about as long, but scarcely so broad as the second ; it curves backwards, with convex front and nearly straight hind margin.

Pleopods.—The two coupling spines are small, with the usual caps ; in the cleft spine the subapical dilatation is very small ; the joints of the rami number ten and eleven.

Uropods.—The first pair have the peduncles scarcely so long as the rami, the rami long, lanceolate, reaching a little beyond the second pair, and not quite so far as the apices of the third, the margins cut into teeth, those on the inner margin being rather longer than those on the outer, and not approaching quite so closely to the acute apex, the outer ramus like the peduncles three-edged ; the peduncles of the second pair are shorter than those of the first, but reach as far back, with the inner apex acutely produced ; the rami are not much shorter than those of the first pair, the inner longer and considerably broader than the outer, with both margins cut into teeth, the outer with only the inner margin so ornamented ; the peduncles of the third pair are very short, broader than long, the slightly produced inner apices of the two peduncles nearly meeting ; the rami are shorter than the preceding pairs, the outer scarcely shorter, but considerably narrower than the inner, having the lower two-thirds of its inner margin cut into long teeth, more than twenty in number, the apex narrowly rounded ; the inner ramus is oval, but with a flattened base and the greatest width near the base ; the edges are smooth ; the inner ramus of one pair partially overlaps that of the other pair.

Telson small, about as broad as long, about half an oval with a slightly convex base ; the distal portion overlaps the upper inner corners of the inner rami of the third uropods.

Length.—The specimen in the position figured, measured, in a straight line from end to end, one-fifth of an inch.

Localities.—February 6-7, 1875, south of Mindanao, Celebes Sea; lat. $6^{\circ} 20'$ N., long. $123^{\circ} 18'$ E.; surface at night; surface temperature, $81^{\circ}\cdot7$. One specimen, male.

Station 206, January 8, 1875; China Sea, off Luzon; lat. $17^{\circ} 54'$ N., long. $117^{\circ} 14'$ E.; surface; surface temperature, $75^{\circ}\cdot2$. Three specimens.

Remark.—The specimen described by Claus was from Zanzibar.

Sympnomoë propinqua, n. sp. (Pl. CXCIII., B.).

The postero-lateral angles of the first three pleon-segments not acute, the lower margin of the first excavate behind; the fourth segment much shorter than the following composite segment; the body flecked with numerous dark spots.

Upper Antennæ as in the preceding species.

Lower Antennæ.—Gland-cone prominent; third (first free) joint of the peduncle much curved, the fifth joint longer than the fourth; the first joint of the flagellum less than half as long as the last of the peduncle, the following joint minute.

Gnathopods and first four pairs of *Peræopods* closely resembling those of the preceding species.

Fifth Peræopods.—The first joint rather abruptly narrowed distally, the apex narrowly produced behind the little second joint, which in its turn is produced so as to overlap the upper half of the third joint; the third joint is scarcely so long as the second, bent backwards.

Pleopods.—The coupling spines and cleft spine as in the other species; the joints of the rami from ten to twelve in number.

Uropods scarcely differing from those of *Sympnomoë parva*, yet the inner ramus in the third pair broader, and a little more produced beyond the outer.

Telson less broadly rounded distally than in the species just named.

Length, about a fifth of an inch.

Locality.—October 5, 1873, South Atlantic; lat. $29^{\circ} 1'$ S., long. $28^{\circ} 59'$ W.; surface, night; surface temperature, $65^{\circ}\cdot2$. One specimen, male.

Remarks.—The specific name refers to the near approach which this species makes to *Sympnomoë parva* (Claus), from Zanzibar and the Pacific.

A specimen, three-tenths of an inch long, evidently belonging to this genus, was taken at Station 201, October 26, 1874; off Basilan Strait; lat. $7^{\circ} 3'$ N., long. $121^{\circ} 48'$ E.; surface; surface temperature, 83° . This specimen probably belongs to a species distinct from those that have been described, differing chiefly in the first joints of the third and fourth peræopods.

Family TRYPHANIDÆ, Boeck, 1870.

This family was instituted by Boeck in 1870 for the single genus *Tryphana*. Bovallius in 1887, altering the name of the genus to *Tryphæna*, at the same time calls the family Tryphænidæ, with the following definition: ¹—

“Head large, more or less globular, tumid. Eyes large, occupying the sides of the head. First pair of antennæ curved, fixed at the inferior side of the head, with the first joint of the flagellum tumid, the following subterminal, few-jointed. Second pair fixed at the inferior side of the head, angularly folded (in the male) or wanting (in the female). Mandibles with palp (in the male) or wanting palp (in the female). Seventh pair of pereiopoda [Fifth Peræopods] are not transformed. Peduncles of the uropoda normal.”

Claus in 1879 and 1887, not taking note of the genus *Tryphana*, which had been by some writers identified with *Lycæa*, named the family Lycæidæ, and in 1879 gave the following definition:—

“Body less broad [than in the Typhidæ], *Hyperia*-like, in the female more compact. Pleon powerfully developed, half flexing. The laminar first joints of the third and fourth peræopods relatively small and triangular, like one another, covering only a part of the ventral surface. Fifth peræopods weak, but with the full number of joints. In the female the hinder antennæ are for the most part completely obsolete. Maxillæ reduced. Two otolith-vesicles present.” In 1887 he adds the character:—“Branchial vesicles with lateral accessory compartments.”

Genus *Tryphana*, Boeck, 1870.

- 1870. *Tryphana*, Boeck, Crust. Amph. bor. et arct., p. 9.
- 1872. „ Boeck, De Skand. og Arkt. Amph., p. 91.
- 1882. *Lycæa*, Sars, Oversigt af Norges Crustaceer, pp. 20, 76.
- 1886. *Tryphana*, Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 489.
- 1887. *Tryphæna*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 30.
- 1887. „ Bovallius, Arctic and Antarctic Hyperids, Vega-Exped., Bd. iv. p. 572.

For the original definition of the genus, see Note on Boeck, 1870 (p. 397).

From Boeck's description of the lower antennæ, which in the character of the family he says are “parvulæ,” and for which he only mentions three joints in desribing *Tryphana malmii*, and from his statement that the mandibles are without palp, it may be presumed that he was acquainted only with a male specimen not fully adult, since according to the family character formulated by Bovallius the lower antennæ are wanting in the female, while on the other hand the mandibular palp is present in the adult male. Bovallius, in his Arctic and Antarctic Hyperids, observes:—“The genus

¹ Arctic and Antarctic Hyperids, p. 572.

is at once distinguished from the other Hyperidean genera by the form of the last joint of the flagellum of the first pair of antennæ and by the peculiar armature of the second pair of perciopoda [Second Gnathopods]. In other respects it forms a link between the Hyperidean and the Platyscelidean groups of the tribe." He does not, however, describe "the last joint of the flagellum of the first pair of antennæ," which is by no means the same in the new species, *Tryphana boecki*, as that described and figured by Boeck for *Tryphana malmii*. Gerstaecker, who in 1886 rightly kept this genus distinct from *Lycæa*, in his definition leaves the eyes doubtful "(Augen ?)," but this doubt was needless, since Boeck in the description of the type-species had expressly said that the eyes occupy the whole sides of the head.

Tryphana boecki, n. sp. (Pl. CXCIV.).

Head deeper than long, as long as the first three or four segments of the peræon; head and peræon together shorter than the pleon; first three segments of the pleon large, the postero-lateral angles almost right angles, the acute points being minute; all parts of the animal having dark spots very irregularly distributed, on the whole not very numerous.

Eyes occupying all the sides of the head, with large and elongate pigment-mass.

Upper Antennæ attached in front to the under side of the head; the first joint of the peduncle widening abruptly from a narrow attachment, widening distally, not longer than broad, the two following joints short, their outlines rather indistinct except at the upper edge; the first joint of the flagellum short and broad, little convex on the upper edge, otherwise almost circular, the filaments of the brush round the lower edge being longer than the joint; the second joint longer than the first, within the slightly projecting apex of which it is attached, slender, its width distally for a third (or sometimes more) of the length being abruptly reduced to less than half that of the proximal part, the long lower margin having ten little groups of setules, and the truncate apex a bunch of them; the shorter upper margin has at its apex a long spine with two little hairs at the blunt tip, this spine probably being the third joint; between this spine-like third joint and the produced lower part of the second joint there is a very small process, not longer than broad, its distal margin occupied by three filaments, which reach to the end of the third joint.

Lower Antennæ attached at the back of the head; the gland-eone only slightly projecting, the joint which bears it being partially free; the following or third joint of the peduncle visible outside the lower part of the hind margin of the head, broad, somewhat oval, two or three times as long as broad, the edges smooth; the fourth joint much narrower, not twice as long, narrowed a little from the base, the distal part widest, closely fringed with short filaments on the inner edge, and with nine or ten distant cilia

on the outer edge ; the fifth joint similar, of nearly equal length, narrower, with only one cilium on the outer edge near the distal end ; the first joint of the flagellum abruptly narrower than the last of the peduncle and considerably longer ; the second joint still more slender, folded closely back against the first and perhaps nearly half its length ; the two joints of the flagellum are so delicate and so closely fitted into a groove of the head that it is very difficult to draw them out without breaking them.

Epistome conical ; *Upper Lip* shallow, bilobed.

Mandibles with a narrow trunk bent about at a right angle in front, the cutting edge having a sharp produced tooth at the top and a sinuous front margin, part of which is very finely dentieulate ; the secondary plate on the left mandible a little widened distally with its front edge finely denticulate ; the bent front portion of the mandibles presents a fold or thickening of the inner surface, with a spine-like projection at the rear end ; the three-jointed palp is large, placed well forward on the top of the angle of the trunk, the first joint rather longer than the following two together, and except at the extremities much broader ; the seeond joint narrowly oval, a little wider, but rather shorter than the apically acute third joint ; these two joints are very easily detaehed from the first.

First Maxillæ.—A narrow rectangular lamina mueh longer than broad, apieally a little peetinate, and of very thin texture, appears to constitute the first maxilla.

Second Maxillæ.—These appear to be like the first pair, except that the plate is broader and not apieally pectinate. The delicacy of these organs makes it difficult to separate them from the maxillipeds and mandibles without injury or distortion, the bases of all being pretty firmly united.

Maxillipeds broadly boat-shaped, the first joint narrow, the second very broad ; the inner plate with a small depression in the centre of the distal margin, a small embedded spine on either side of and below the depression, and a little lower down a pair of spinules ; the outer margin of the plate, as also the margin of an inner ridge, is finely pectinate ; the outer plates are broad at the base, apically narrow, the outer margin convex, the inner very sinuous, minutely pectinate, except at a little emargination not far from the apex ; the surface shows three minute spinules.

First Gnathopods.—Side-plates small, with a downward produced lobe in front. First joint widely expanded in front, not mueh longer than broad, the hind margin nearly straight, but the front very eonvex ; the second joint small, not longer than broad ; the thirld joint not longer than the second, and as seen from the outer side not so long, apically pointed, the hind margin carrying two small distally feathered spines ; the wrist about half as wide as the first joint, but about twice as wide and nearly twice as long as the third joint, with three distally feathered spines at the apex of the straight hind margin, the front margin convex ; the hand, including the acutely produced feathered process which forms the hinder apex, is equal in length to the wrist, but much

narrower, having a feathered spine on each margin; the finger half the length of the hand, very narrow, feathered, with a very sharp nail; in one example the finger was bent as if impinging against the apical process of the hand, in the other examples it appears to be stiff and straight, but whether the curvature was accidental or the apparent straightness due only to an optical effect I am uncertain.

Second Gnathopods rather longer than the first. The side-plates small, wider than deep. The first joint as long as in the first gnathopods, but much less expanded, the front margin convex, the hinder a little sinuous; the second joint slightly longer than broad; the third joint longer than the second, armed as in the first gnathopods, but rather oblong than triangular; the wrist longer and broader than the third joint, broader but shorter than the hand, the front margin ciliated, nearly straight, the hind margin a little ciliated below, with three apical feathered spines; the hand two and a half times as long as broad, ciliated on both margins, carrying a feathered spine at the hinder apex; the finger as long as the hand, slender, a little curved, feathered with cilia except near the base, apically produced into two acute processes, one longer than the other both finely pectinate, with a slender spine or nail between them, which projects a little beyond the longer.

First Peræopods much stouter than the second gnathopods, but not nearly twice as long. Side-plates rather wide and shallow, a little deeper behind than in front. Branchial vesicles simple, more or less oval, easily detached, all the pairs very similar. The first joint widening distally, the front margin sinuous, the hinder convex; the second joint little longer than broad; the third joint widening distally, a little decurrent at the front apex; the fourth joint a little narrower than the third, with the muscles placed near the front, to make room for a glandular cavity, which exhibits the system of branched cuticular canals, leading from the gland-cells to the exits, as figured by Claus for *Phronima* (*Phronimiden*, Taf. iii. fig. 16); fifth joint as long as, or a little longer than, the third or fourth, a little bent, width almost uniform, the hind margin sinuous, with two minute cilia, and a tooth-like apex, within which there is a very small spine; the finger curved, very acute, more than half the length of the fifth joint.

Second Peræopods a little larger than the first, similar.

Third Peræopods.—Side-plates wider than deep, bilobed. First joint dilated, the lower half more than the upper, longer than broad; the second and following joints very similar to those of the preceding peræopods, but all on a somewhat larger scale, the third, fourth, and fifth joints subequal in length, the fourth with the front margin finely pectinate, the fifth with that margin rather more strongly and more decurrently pectinate.

Fourth Peræopods not very much shorter than the preceding pair; the first joint larger than in the preceding pair, its greatest width near the base, diminishing downwards; the following joints narrower than in any of the preceding peræopods, the fourth joint shorter than the third, with the glandular space either absent or much reduced, the

front margin finely pectinate; the fifth joint rather longer than the third, its front margin pectinate.

Fifth Peræopods.—The side-plates a little deeper behind than in front, with a generally semicircular appearance. The first joint widely expanded, rather longer than broad, the front margin sinuous, bowed out in the middle, the hind margin very convex and regular, the remaining joints small, together scarcely as long as the first, the second not longer than broad, the third and fourth nearly equal, two or three times as long as broad, the fifth longer than either; the finger not half the length of the fifth joint, broad at the base, the upturned tip very acute.

Pleopods.—The peduncles broad and thick; the eleventh spine on the first joint of the inner ramus having the serrate arm shorter than that with the subapical dilatation; the first joint of the outer ramus bearing a prominent, apically narrow, interlocking process; the joints of the rami from nine to ten in number.

Uropods.—Peduncles of the first pair rather longer than the inner ramus, pectinate round the outer apex; the inner ramus larger than the outer, its outer margin pectinate nearly to the apex, and the inner for a short space at a little distance from the apex; the outer ramus pectinate on both margins, more strongly on the inner; peduncles of the second pair not reaching so far as those of the first, not as long as the inner ramus; inner ramus longer and much broader than the outer, the outer margin pectinate and the inner near the apex, the outer ramus with only the inner margin pectinate; these rami respectively not reaching so far as those of the first pair; peduncles of the third pair a little longer than broad, widening distally so that their inner apices touch or overlap, shorter than the nearly equal rami; the inner ramus broader than the outer, rather strongly pectinate for a short space on the inner margin near the apex, and less strongly on the outer margin for a longer space, the pectination on the margins generally becoming very minute at the upper part; the outer ramus pectinate along almost all the inner margin but on that only; the peduncles and rami respectively of this pair reach beyond those of the other pairs.

Telson subequal in length to the peduncles of the third uropods, longer than broad, narrowing from near the base to an acute apex, with the sides very slightly convex, the tip just showing beyond the peduncles of the third uropods.

Length.—The specimen, in the bent position figured, measured one-fifth of an inch; the figures *a.i.A.*, *l.s.A.*, *m.A.*, *m.c.p.A.*, *gn¹A.*, were taken from parts of this specimen; the remaining figures from another specimen as nearly as possible similar.

Locality.—April 29, 1876, North Atlantic; lat. $18^{\circ} 8' N.$, long. $30^{\circ} 5' W.$; surface, night; surface temperature, $73^{\circ} 7.$ Eight specimens, apparently all males.

Remarks.—The specific name is given in honour of Boeck, the founder of the genus

Tryphana. From *Tryphana nordenskiöldi*, Bovallius, the present species differs in having the second gnathopods decidedly longer than half the first peræopods, the first peræopods not as long as the fourth, the third pereopods longer than the pereon, the telson not longer than, though projecting a very little beyond, the peduncles of the third uropods. Bovallius' species was taken "off the Faero Islands at lat. 65° N." at a great distance therefore further north than the locality of the present species. Bovallius in one description of *Tryphana nordenskiöldi* says,— "Dactylus of first pair of pereiopoda [Gnathopods] pedunculated," an expression which does not seem applicable to the Challenger species, but in the absence of a figure I do not clearly understand it. The type-species, *Tryphana malmii*, Boeck, was taken by Boeck in the Hardangerfjord, and by Sars somewhat further north at Folgerøen.

Genus *Brachyscelus*, Spence Bate, 1861.

- 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk Vetensk.-Akad. Handl., Bd. 11, No. 16. p. 30.
- 1887. " Bovallius, Arctic and Antarctic Hyperids, Vega-Exped., Bd. iv. p. 574.
- 1887. " Claus, Die Platysceliden, pp. 55, 56.

Dana's *Dairilia* being rejected for its inherent obscurity, the name next in order is *Brachyscelus*, Spence Bate, which was probably set aside by Claus as coming too close to the already occupied *Brachyscelis*, but, though it is no doubt a disadvantage to have names so nearly alike, it is still more confusing to make the law of priority subject to individual judgment upon the more or less similarity that one name may bear to another. For the original definition of *Brachyscelus*, see Note on Spence Bate, 1861 (p. 327); for that of *Thamyris*, Note on the same author, 1862 (p. 337). For a short definition by Claus of the same genus, see Note on Claus, 1879 (p. 492). It is more fully defined by Claus as follows:—

" Body with thick, anteriorly rounded head, moderately broad pereon, and narrower elongate pleon. Hind antennæ in the male with long shaft and short terminal joint,

in the female wanting. Limbs of the pereon short, with wing-like projecting side-plates. Both pairs of gnathopods with complex denticulate chelæ and very thick wrists dilated helmet-like. Large gland-cells in the first joint of the first three pereopods. The laminar first joints of the third and fourth pereopods comparatively small, triangular, and pretty much alike. Fifth pereopods similarly formed, but much feebler. Peduncles in the first and second pairs of uropods elongate, almost equal in length. Rami of the third pair of uropods broadly lanecolate (flossenförmig verbreitert)."

It may be observed that the epithet triangular does not very well suit the first joint of the third pereopods. Bovallius in defining the genus states that the third pereopods are not longer than the fourth, and that the peduncles of the first pair of uropods are longer than the rami, but the characters are not applicable to all the species.

Brachyscelus crusculum, Spence Bate (Pl. CXCV.). Specimen A.

1861. *Brachyscelus crusculum*, Spence Bate, Ann. and Mag. Nat. Hist., ser. 3, vol. viii. p. 7,
pl. ii. figs. 1, 2.

1862. " " " Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 333, pl. liii.
figs. 2, 3.

1887. *Thamyris crusculum*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk.
Vetensk.-Akad. Handl., Bd. 11. No. 16, p. 31.

The postero-lateral angles of the first two pleon-segments produced into small acute points, simply squared in the third segment. The heart shows several constrictions, the lateral orifices in the first two divisions appearing to be within the third and fourth segments of the pereon.

Eyes large, covering the sides of the head except a small strip at the back.

Upper Antennæ.—Terminal joint of the peduncle almost evanescent, first of the flagellum long, the brush on the convex side not developed in the specimen but in preparation, the opposite margin carrying many filaments almost from the base to the narrowly produced apex, this apex no doubt representing the second joint still in coalescence with the first; the following joint minute, abruptly narrower than the apex of the first; the termination broken.

Lower Antennæ.—The basal joint with the gland-cone not completely coalesced with the wall of the head; the following (third) joint of the peduncle long, curved, distally widened, the fourth joint similar, a little longer, the fifth narrower, not longer than the third; the first joint of the flagellum rather shorter than the last of the peduncle, much curved, and in our specimen obstinately doubled upon itself; the terminal joint scarcely half as long as the preceding. The joints were almost entirely smooth, though with indications, especially on the last, that the usual fringe of short filaments would be developed later.

Mandibles.—The trunk very small, especially narrow where the palp is attached,

with a triangular front, the lower side of which forms the striated cutting edge; the secondary plate on the left mandible nearly as large as the principal plate; the tooth-like process on the inner surface to the rear of the cutting edge is small and narrow; the palp set far back has very much of a four-jointed appearance, the small eminence on which it is placed looking like a distinct joint; of the three regular joints the first is longer and much broader than either of the others, with one margin straight, the other convex; the second joint is similar in shape; the third is a good deal longer than the second, slender, distally tapering, much curved.

First Maxillæ.—These appear to be short, thin in texture, with smooth edges and rounded apex, not nearly reaching the distal end of the inner plate of the maxillipeds.

Second Maxillæ.—Apparently represented by a pair of smooth oval plates partially overlapping one another, thin in texture, much shorter than those of the first maxillæ.

Maxillipeds.—The inner plate is much longer than broad, longitudinally ridged on the inner surface for some distance from the base upwards; the distal margin almost straight, having at the centre a pair of little embedded teeth; the outer plates very much larger than the inner, very broad at the base, the outer edge folding a little inwards, the inner margin sinuous, almost smooth or microscopically pectinate; there are some minute setules along the outer surface, and a strong longitudinal ridge rises from the base at some distance from the inner margin on the inner surface.

First Gnathopods.—The side-plates strongly produced forwards, with rounded front apex, and the top of the front margin folded. The first joint not strongly twisted, but sinuous, deeply channelled in front both at the proximal and distal ends, and behind forming a small elbow just below the side-plate; the much produced front apex of the large wrist is finely pectinate, its chela-forming process has seven teeth on the front and eight on the hind margin besides the apical tooth and many little denticles; there are nine teeth on the distal half of the hind margin of the hand; finger less than half the length of the hand. One of the limbs in this specimen is only three-jointed, the third joint being abnormal, oval.

Second Gnathopods.—Branchial vesicles large, both in this and the following pairs having many lateral pockets. The first joint almost straight, channelled in front, the front margin of the outer surface convex below; the front of the wrist with the apex not produced downwards, though standing out from the hand; the chela-forming process more produced than in the first pair, with nine teeth on the front and four on the hind margin, besides the apical tooth; the hind margin pectinate almost from the base to the four teeth just mentioned; the hind margin of the hand has nine teeth; finger much less than half the length of the hand.

First Peræopods.—Side-plates much wider below than above. First joint bent near the base; third joint a little wider but scarcely longer than the fourth, the hind margin faintly dentieulate; the fourth similar to the third, more strongly denticulate, the fifth

longer than the third or fourth, with the hind margin more strongly denticulate; finger small.

Second Peræopods.—Similar to the first, but third, fourth, and fifth joints longer, especially the fifth, and the denticulation of the third and fourth joints less apparent.

Third Peræopods.—Side-plates with the front lobe almost acute in front, the hinder squared; a squarely produced process on the inner surface has the lower hinder apex narrowly produced backwards. Branchial vesicles greatly widened above the centre. The first joint oval, not so long as the next four joints together, the front margin with ten or eleven distant shallow serration teeth, distally somewhat squarely produced beyond the convex hinder margin; the third joint longer and broader than the fourth, with little teeth along much of the front margin; the fourth also pectinate distally; the fifth joint longer than the third, almost smooth; the finger small.

Fourth Peræopods.—The first joint longer and broader than in the preceding pair, much wider above than below, very squarely produced in front below the hind margin, the distal margin finely but not uniformly pectinate, the front margin serrate with fifteen little spinule-bearing teeth, the joint longer than all the other joints together; the third joint decidedly longer than the fourth, and the fifth than the third, all three conspicuously denticulate with unequal teeth, those on the third joint the largest, standing straight out, those on the fifth joint somewhat decurrent; the finger small, not much curved, pectinate along much of the inner margin, with a larger denticle in the midst of the pectination.

Fifth Peræopods.—Side-plates nearly square. The first joint much dilated, much smaller than that of the preceding pair, much longer than the rest of the joints together, the united length of which about equals its breadth; the third joint is much wider than the fourth, longer than the fourth and fifth together, faintly pectinate on part of the front margin; the fourth joint is a little longer and much broader than the fifth, with the front margin pectinate; the little fifth joint is slightly produced in front; the minute finger has a triangular front division and a slender curved hinder one.

Pleopods.—Peduncles stout; in the cleft spine the arm with the subapical dilatation is the longer; the joints of the broad rami thirteen or fourteen in number; the interlocking process on the first joint of the outer ramus not very elongate, with sinuous lower margin.

Uropods.—Peduncle of the first pair prismatic, a little longer than the outer ramus, having a small pectinate distal lobe; the rami are also prismatic the outer with the outer margins smooth the inner closely denticulate; the longer inner ramus has the inner margin closely and the outer loosely denticulate; the peduncles of the second pair a little shorter than those of the first, which they resemble, but with the inner apex more produced, their length subequal to that of the outer ramus; the rami broadly lanceolate, the outer with the lower part of the inner margin denticulate; the inner ramus broader

and longer than the outer, not quite so long as the inner of the first pair, denticulate on the lower part of the outer, and more loosely on the lower half of the inner margin; peduncles of the third pair wide apart, much shorter than the rami; the rami widening greatly from the base, so as to be broadest below the centre, then narrowing to an acute apex, the outer ramus rather the shorter, with smooth outer margin, and the lower part of the inner denticulate, the inner ramus much the broader, denticulate on both margins below the widest part.

Telson reaching a little beyond the rami, subequal in length to the eleventh and twelfth segments, longer than broad, the breadth nearly three-quarters of the length, in outline forming an elongated inverted arch, the apex almost acute.

Length, in the position figured, two-fifths of an inch.

Locality.—April 3, 1875; North Pacific, lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E.; surface temperature, $71^{\circ} 5$. One specimen, male.

Remark.—The specimen described by Spence Bate from some unknown locality was three-quarters of an inch in length, therefore much longer than the Challenger specimens.

Brachyscelus cruscum, Spence Bate (Pl. CXCVI.). Specimen B.

This specimen was in the first instance figured and described as a distinct species, but I think it may be regarded as the adult male form of *Brachyscelus cruscum*. The head is not smoothly rounded as in specimen A; the angles of the first three pleon-segments are similar.

Upper Antennæ.—First joint of the peduncle cylindrical, longer than broad, the following joint or joints very small, imperfectly developed; the first joint of the flagellum large, and with a large brush of filaments on the convex side, the straight upper margin having a series of broader filaments, the apex narrow, not produced; the next joint narrow, a little bent, having five groups of filaments; the third joint shorter and abruptly narrower, with filaments at the apex.

Lower Antennæ.—The third joint of the peduncle elongate, the basal half curved, the distal end dilated, fringed like the remaining joints with numerous short filaments, the fourth joint decidedly longer than the third, straight, the fifth joint a little longer than the fourth, the first of the flagellum longer than the third, but shorter than the fourth or fifth joint of the peduncle, the second joint about a quarter the length of the first.

Mandibles.—Trunk elongate, narrow, the point of the distal triangle forming a blunt tooth at the top of the cutting edge; the first joint of the palp much longer than the third, which is itself longer than the second.

Above the figure of the maxillipeds, in the middle of the Plate, the head is figured

from below, showing the antennæ and mouth organs *in situ*; the appearance of these in a lateral view is given in the adjacent figure on the right; below the figure *mxp.* is a figure of the dilated stomach.

First Gnathopods.—Side-plates sharply produced forwards. First joint curiously twisted, narrow at the base, then greatly widened by the backward bend of the hind margin, this margin then crossing the surface to the lower apex of the sinuous front margin, the joint at the elbow being much wider than above or below it; as in the preceding specimen the second and third joints have some small spines on the hind margin; in this genus, as in many genera of the Hyperina, the third joint, having assumed the form of a small wrist, is an exception to Spence Bate's rule, that in the gnathopods the third joint always *underrides* the fourth; the much dilated wrist has the broadly produced front apex scarcely perceptibly pectinate; the chela-forming process has on the front or inner margin five teeth besides denticles, and on the hinder or outer margin eight teeth and a few denticles; the apical tooth is additional; the hind margin of the hand has nine teeth.

Second Gnathopods.—The first joint a little curved, the lower part of the front channelled; the front apex of the wrist not produced downwards, nor nearly so large as in the first pair, finely pectinate, and carrying three or four little teeth, the chela-process with seven teeth on the front margin, one of them being an accessory denticle to the apical tooth; the hind margin is pectinate for some distance from the base, and then divided into four or five teeth; the hind margin of the hand has eight teeth.

Third Peraopods with the first joint a long oval, not quite twice as long as broad.

Fourth Peraopods.—The first joint not at all longer than the first joint of the preceding pair, but with the upper part very much wider, the lower margin in front of the second joint scarcely or not produced below that joint; the third, fourth, and fifth joints with the front margin closely pectinate with large and small teeth; the finger having some small decurrent teeth along much of the inner margin.

Fifth Peraopods.—The first joint much longer than wide, widest at the centre, the width there exceeding the length of all the other joints together, those joints being nearly as in specimen A.

Pleopods.—The rami with fourteen or fifteen joints.

Uropods very similar to those of the species just named.

Telson as long as the third uropods, its breadth rather more than two-thirds of its length, more rounded apically than in specimen A.

Length, in the bent position figured, two-fifths of an inch.

Locality.—July 1875, North Pacific, between Japan and Honolulu; lat. 35° N.; surface. Male specimen.

Remarks.—A female specimen from the same locality has the first joint of the first

gnathopods straight, the upper antennæ like those figured by Claus for the female of *Thamyris globiceps*, and the telson with acute-angled though not outdrawn apex.

A species of this genus from "Ocean Beach, Dunedin," New Zealand, of which Mr. G. M. Thomson very kindly sent me detailed description and figures, is in the closest relationship to the specimen B here described, but with the head less rounded and the telson "acutely triangular." The differences between specimen A and specimen B consist chiefly in the shape of the head, the form of the first joint in the first gnathopods, and the more or less rounding of the apex of the telson. The first and third of these may, I think, be attributed to individual variation, the remaining and the most striking difference I have, after much hesitation, assumed to be a character of age and sex. The specimens with the strongly twisted joint have the antennæ of the adult male, those in which it is slightly twisted have the lower antennæ incompletely developed, and female specimens have only a suggestion of the twisted first joint. Spence Bate's figure of *Brachyscelus crusculum* ♀, Claus' figures of the gnathopods of *Thamyris mediterranea*, young male, and *Thamyris rapax* ♀, as well as Mr. Thomson's figure of the male specimen from New Zealand, all lend support to the supposition that in this genus the strongly twisted arm of the first gnathopod is a character only of the adult male.

Brachyscelus inaequipes (Dana ?).

1852. *Daira inaequipes*, Dana, U.S. Explor. Exped., vol. xiii. pt. ii. p. 993, pl. lxviii. figs. 5 a-c.

1862. *Dairinia inaequipes*, Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 310, pl. l. fig. 6.

1887. *Thamyris inaequipes*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 31.

A specimen with large head and great eye-pigment, a single pair of slender straight antennæ, in which the third joint is longer than the second or fourth, the mandibles without palp, the first joint of the first gnathopods not twisted, and the front process of the wrist not much produced, the lower margin of the first joint in the fourth peræopods produced below the second joint, the first joint of the fifth peræopods not so dilated as in the other two species here described, the telson narrower than in those species, apically almost acute.

Of the *Mandibles* one has a secondary plate with finely denticulate edge, resembling the principal plate but smaller, while the other has a spine-like process like that described for *Brachyscelus crusculum*; in each mandible the principal cutting edge has a minute tooth at the lower end and a larger obtuse one at the upper; the upper lip is broader than deep, embracing the distal triangular ends of the two mandibles. The mouth organs probably in all essential respects agree with those of the other species.

Locality.—February 6-7, 1875, south of Mindanao, Celebes Sea; lat. $6^{\circ} 20'$ N.,

long. $123^{\circ} 18'$ E.; surface, at night; surface temperature, $81^{\circ} 7$. The specimen female or young.

Remarks.—Dana's *Dairilia inaequipes*, two lines long, was taken "off south end of Mindoro." The specific name probably refers to the inequality in length between the third and fourth peræopods. In the third peræopods the second joint reaches below the first, and the first is not nearly as long as the following five joints; in the fourth pair the second joint does not reach below the first, and the first joint is scarcely if at all longer than the following five; it is however somewhat longer than the first joint of the preceding pair.

Brachyscelus latipes, ♀, n. sp. (Pl. CXCVII., B.).

Head large, deep and rounded, the triangular cavity which contains the antennæ and mouth-organs being entirely below, not at all in front, the hind margin sinuous laterally; the peræon narrowing a little backwards, the first two segments very short; the third segment of the pleon the longest. The integument both of head and body very firm, with conspicuous scale markings.

Upper Antennæ.—The first joint the thickest; the second about half the length of the first, the two together forming a curve; the third joint as long as the first or a little longer, carrying groups of filaments on the upper margin; the fourth and fifth joints together not so long as the third, the fifth very slender.

Lower Antennæ represented in the female only by the prominent gland-cone.

Epistome domed; the *Upper Lip* small, transversely oval.

Mandibles.—The trunk broad, especially near the front; the cutting edge broad, with a prominent tooth at the top, the border slightly convex, finely striated, without any tooth at the lower corner, on the right mandible there is a little upturned spine-like process, adjacent to the hind margin of the principal plate near the centre.

Maxillipeds.—The distal border of the inner plate flat, wider than the base, having two little central embedded spinules; the outer plates with their inner margins little dehiscent, minutely pectinate, the surfaces carrying some small spinules.

First Gnathopods.—The first joint scarcely at all bent, the lower part channelled in front; the second joint with a strong brush of spines along the hind margin; the third joint not longer than broad, also with several spines about the hind margin, but not closely grouped as in the second joint; the wrist very much wider than the third joint, wider than long, the front margin convex, smooth, the hind margin pectinate and divided into five teeth, to which succeeds the apical tooth, the broad distal margin on the other side of it being also pectinate and divided into four teeth; the hand shorter than either the length or breadth of the wrist, with front margin smoothly

eonvex, hind margin pectinate and divided into six teeth, sueeessively larger to the apieal; finger about half the length of the hand, with hind margin slightly peetinate.

Second Gnathopods very similar to the first, but the first joint more channelled, seeond and third joints with few spines, the wrist mueh more strongly produced, with three teeth on the hind margin above the apical tooth, and four on the front or inner margin of the process ; the hand not reaching beyond the apex of the wrist, its hind margin pectinate and divided into four teeth, suecessively larger to the apical ; the finger less than half the length of the hand, curved, the inner margin peetinate.

First Peræopods.—Side-plates broader than deep, produced both forwards and backwards beyond the base. The first joint long and slender, bent at the upper part; the second joint longer than broad; the third and fourth joints subequal in length, almost smooth; the fifth abruptly narrower but a little longer than the fourth, the hind margin a little spinulous ; the finger curved, smooth, little more than a quarter the length of the fifth joint.

Second Peræopods like the first, but with the third, fourth, and fifth joints conspicuously longer.

Third Peræopods.—Side-plates with the front lobe narrowly produced, the hinder broad, and having a sort of squared proeess on the inner side with the lower hinder angle slightly produced downwards. The first joint as long as the four following together, distinguished by its great breadth, the maximum being a little above the centre, the hind margin very eonvex, the front margin, the distal margin behind the seeond joint, and the whole surface of the joint also convex ; the third joint longer and broader than the fourth, whieh is in turn broader than the fifth ; the fifth slender, slightly curved, rather longer than the third; the armature of all these joints very ineonspicuous, the sinuous distal margins of the fourth joint finely pectinate on the inner and outer sides of the limb ; the finger not a fourth of the length of the preceding joint.

Fourth Peræopods.—The side-plates with the front lobe not produced forwards, much shallower than the hind lobe. The first joint very little longer than in the preceding pair and not so broad, the front margin nearly straight, with some slight serration and a few small spinules, the lower angle rounded and the distal margin in front of and below the second joint broad and almost flat, while the convex hind margin does not reaeh to the end of the second joint ; across the top of the seeond joint there is an inner surface margin, distally straight, with a small rounded lobe behind ; the third joint is longer and broader than the fourth, not apically produced, strongly pectinate along the front margin and front part of the distal margin ; the fourth joint is armed in like manner, and with pectination also at the apex of the hind margin ; the fifth joint straight, slightly tapering, narrower than the fourth, almost as long as the third,

pectinate with closer, finer, and more decurrent teeth along the front margin, the apex also pectinate and slightly produced behind; the finger nearly straight, pectinate on the inner margin, rather more than a quarter of the length of the fifth joint.

Fifth Peræopods.—First joint pear-shaped, longer than the other joints together; second joint not longer than broad, third straight, more than twice as long as the second; fourth shorter than the third, with convex front margin; fifth shorter than the fourth, with hind margin convex, and the front straight; the exceedingly minute finger forms a blunt triangle in front, with a slender curved process behind it, extending from near its base beyond the apex.

Pleopods.—Peduncles broad, not very long; coupling spines broad-headed, with some lateral teeth below the apical; the eleventh spine with the longer arm very slightly dilated, placed at the broad top of the first joint of the inner ramus, and followed by six or seven plumose setæ along the inner margin of the same joint; the first joint of the outer ramus has eight or nine plumose setæ on the outer margin; joints of the inner ramus eleven or twelve, of the outer twelve or thirteen.

Uropods.—Peduncles of the first pair shorter than the rami, the distal margin pectinate on the under surface; the rami elongate, three-sided, reaching beyond the other pairs, the outer rather shorter than the inner, pectinate along two edges, the inner margin near the base smooth, convex, the joint then narrowing rather abruptly, the inner ramus also pectinate on two edges; peduncles of the second pair longer than the outer, shorter than the inner, ramus; the outer ramus almost smooth on the outer margin, pectinate on the inner, much shorter and narrower than the inner ramus, which is pectinate on both margins, but smooth on the upper part of the inner; peduncles of the third pair not longer than the distal breadth; the outer ramus shorter and much narrower than the inner, pectinate on both margins of the narrow lower part; the inner ramus broad till near the apex, then almost abruptly narrowed, pectinate on the lower part of each margin.

Telson reaching about to the apex of the inner ramus of the third uropods, rather longer than broad, not quite so long as the preceding composite segment, the end broadly rounded.

Length, with pleon flexed, under three-tenths of an inch.

Locality.—October 1875, South Pacific, surface. One specimen, female, with numerous eggs.

Remark.—The specific name refers to the great size of the first joint in the third peræopods, which seems to distinguish this species from all others as yet described in this genus.

Brachyscelus bovalii, n. sp. (Pl. CXCVII., A.).

This species is closely allied to *Brachyscelus rapax* (Claus), but smaller and with the head rather more rounded. Claus gives a figure of the animal from the ventral side, showing the long broad groove which separates the eyes on the under side of the head. As this is a very unusual aspect to be figured, because of the difficulty of arranging a specimen suitably for the purpose, it may be mentioned that the specimen from which the new species is described attracted attention by spontaneously assuming the requisite position. Though, however, in this aspect the Challenger specimen closely resembles Claus' species, it is separated from it by various points of detail.

Upper Antennæ.—Peduncle short; first joint of flagellum long, not strongly curved, the apex little produced, the long convex under side with the usual brush of filaments, the upper margin not very short, carrying a dozen pairs of filaments; the small second joint twice as long as broad, with filaments at four or five points, the third joint linear.

Lower Antennæ.—Third (first free) joint of peduncle three-quarters the length of the next joint, proximally curved, distally widened, fringed like the following joints with short filaments; the fourth joint straight, distally widened, the next joint broken and the others missing.

First Gnathopods.—The lower front corner of the side-plates produced, rounded. The first joint twisted, the elbow behind a little more prominent than the distal convexity of the front margin; the second joint with two spines at the apex of the hind margin; the third joint small, very little longer than the second, but distally much wider, with two spines at the hinder apex and one spine on the margin above it; the wrist of the usual pattern, but with scarcely any pectination, while the teeth are long and slender, five in number above the apical tooth on each margin of the process; the hand has five teeth on the hind margin, graduated in size, the apical being the longest and reaching nearly halfway along the finger, close to which it lies; the finger curved, more than half the length of the hand. Claus' figure of the first gnathopod of "*Thamyris rapax*" shows three teeth on the hand, and on the wrist three teeth on one side and four on the other side of the apical tooth.

Second Gnathopods.—The first joint almost straight and parallel-sided; the wrist differing little from that of the first gnathopods, except as usual in not having the prominent rounded apex of the front margin; the upper part of the hind margin is straight and smooth; above the apical tooth there are four teeth on the hind margin of the process, and in one limb three, in the other five, on the front, with more serration than in the first gnathopods; the hand has five teeth on the hind margin besides some serration; the finger scarcely so long as in the first pair.

First and Second Peræopods very slender, smooth, except for the pectination of
(Zool. Chall. Exp.—Part LXVII.—1888.)

the hind margin of the fifth joint and some extremely minute pectination of the distal margin of the fourth.

Third Peraopods.—Inner process of the side-plates with the lower corner produced backwards, scarcely acute. The first joint shorter than the remaining joints together, moderately expanded, narrowing downwards, the front margin straight except at the two extremities, not apically produced, the hinder margin convex; the second joint reaching below the first; the third very little longer than the fourth, the fifth longer than the third, the finger not a third the length of the fifth, all these joints smooth.

Fourth Peraopods.—The inner process of the side-plates with a very irregular lower margin. The first joint not longer than the remaining joints together, similar in shape to the first joint of the third peraeopods, but rather longer and much broader, the apex of the front margin also being produced below that of the hinder margin as far as the apex of the short second joint; the third joint considerably longer than the fourth, pectinate except near the base along the front margin, and much more finely on the distal margin; the fourth joint similarly pectinate, but more strongly and irregularly on the distal margin; the fifth joint longer than the fourth, shorter than the third, pectinate on the front and distal margins; the finger about a third of the length of the fifth joint.

Fifth Peraopods.—First joint pear-shaped, not very widely expanded, the front margin much straighter than the hinder one; the remaining joints together more than two-thirds of the length of the first; the second joint as broad as its length; the third not very much longer or broader than the fourth; the fourth broader but not very much longer than the fifth; all of the joints smooth, the fifth produced in front into a small triangular process, round which the small slender finger curves, a small setule projecting between. In all the species there is such a setule, and in some it is a little doubtful whether the finger is really folded or only curved round a projecting apex of the fifth joint.

Pleopods.—The rami rather short, with nine joints to the inner, and ten to the outer ramus.

Uropods.—Peduncles of the first pair reaching rather beyond the base of the telson, equal in length to the inner ramus, the distal margin of the under surface pectinate; the rami carinate beneath, the outer much narrower and a good deal shorter than the inner, pectinate on both margins except at the widened part close to the base; the inner ramus reaching beyond the telson, pectinate on the outer margin, a little serrate on the lower part of the inner; peduncles of the second pair shorter than the inner ramus, the rami damaged, seemingly very similar to those of the first pair but a little smaller and not carinate; peduncles of the third pair not longer than the distal breadth, the outer ramus shorter and narrower than the inner, pectinate on the lower part of each margin; the inner ramus reaching beyond the telson, the outer margin pectinate on the lower half, the inner margin almost straight and smooth, the apex broad but worn, so that the true apex may be acute.

Telson longer than broad, with gently convex sides and a broadly rounded apex, so that it has nothing of the triangular appearance presented by many other species of the genus.

Length, one-fifth of an inch.

Locality.—October 1875, South Pacific; surface. One specimen, male.

Remarks.—The specific name is given out of respect to Professor Bovallius. *Brachyscelus rapax* (Claus), from the Cape of Good Hope, is said to have the third joint of the fourth pereopods not pectinate, and the first joint of the fifth pereopods equal in length to the remaining joints together; the peduncles of the first pair of uropods are described as little longer than the rami, but figured a little shorter; the length of the specimen described is given as about two-fifths of an inch, whereas the Challenger specimen, also an adult male, is only one-fifth of an inch long. *Brachyscelus latipes*, above described, which agrees with the present species in regard to the telson and more or less in regard to the uropods, is very different in the third and fourth pereopods. The present species is in some respects a connecting link between the genera *Braehyseelus* and *Thamneus*.

Braehyseelus aeuticaudatus, n. sp. (Pl. CXCVII., C.).

Back of pereon rounded, a little compressed laterally, side-plates small and shallow; first three pleon-segments with the sides angled.

Eyes occupying almost all the surface of the head, leaving free a small strip at the base; the upper division of the eye much smaller than the lower front one, closely contiguous to it; dorsally the head has a small space free where the four ocular divisions approach one another.

Upper Antennæ (of the female) forming a single bend, the first joint of the peduncle nearly three times as long as the second joint; the first of the flagellum as long as the first of the peduncle, with five groups of filaments on the slightly narrow distal half; the second joint narrow, not half the length of the first; the following joint broken off.

First Gnathopods.—The first joint straight, channelled in front; the short second joint with a strong brush of spines on the hinder distal margin; the wrist with seven teeth on either side above the tooth of the apical process; the hand with eight teeth on the hinder margin and one on the distal margin.

Second Gnathopods.—The wrist process with six teeth on the hind margin and nine on the front or inner margin; the hand with six teeth on the hinder and one on the distal margin.

First and Second Peraopods.—Only the fifth joint pectinate.

Third Peraopods.—Side-plates with the inner process produced acutely backwards. The first joint of the limb long oval, narrowest distally, the slightly serrate front margin being a little concave near the apex, which is produced a little below that of the hind margin.

Fourth Peraopods.—The first joint longer and much broader than that of the third peræopods, the greatest breadth above the middle, below which the joint narrows rapidly; the front margin nearly straight, shallowly serrate and carrying little spines, the squared apical lobe reaching considerably below the second joint; the hinder margin, of which the upper part only is strongly convex, has a rounded apex not reaching to the end of the second joint; the third joint is not longer than the fifth, each of them longer than the fourth, all the three being pectinate in the usual way along the front margin and round the apex.

Fifth Peraopods.—The side-plates with little semicircular marks, the lower hind corner a little outdrawn. The limb nearly as in *Brachyscelus crusculum*.

Pleopods.—The dilated arm of the cleft spine the longer; the rami long, joints of the inner ramus thirteen or fourteen in number, of the outer fourteen or fifteen.

Uropods.—Peduncles of the first pair about equal in length to the inner ramus, reaching to the base of the telson; the rami not very broad, carinate beneath, the inner a little longer than the outer, as long as the telson, closely pectinate on the outer margin, loosely serrate on the inner; the peduncles of the second pair reaching nearly as far as those of the first pair, the rami damaged; peduncles of the third pair short, the outer ramus slightly carinate, its outer margin smooth and almost straight, the inner margin very convex, with the lower part pectinate; the inner ramus missing.

Telson triangular, much longer than the breadth at the base, constricted a little near the acute apex, the sides having very little convexity.

Length, about two-fifths of an inch.

Locality.—August or September 1875, Pacific Ocean; surface. One specimen, female.

Remarks.—The specific name refers to the sharply narrowed tip of the telson, which is a distinguishing feature of the species; the shape of the first joint of the fourth peræopods is another well-marked character.

Brachyscelus mediterranea (Claus).

1887. *Thamyris mediterranea*, Claus, Die Platysceliden, p. 60, Taf. xvi. figs. 11–18.

The segments a little imbricated.

First Gnathopods.—The first joint almost straight, the wrist with five teeth on the hind margin, four on the inner margin of the process, and the apical tooth, the hand not reaching beyond the apical tooth of the wrist, having six teeth on the hind margin.

Second Gnathopods differing little from the first; the wrist with three teeth on the hind margin, five teeth on the inner margin of the process, and the apical tooth; the hand not quite reaching the tip of the wrist's apical tooth, having six teeth on its inner margin. The dentate margins in both gnathopods have as usual some pectination in addition to the dentation.

Fifth Peraopods.—The terminal joints as figured by Claus, but not bearing the same proportion to the first joint, which is much longer than all of them together.

Pleopods.—Coupling spines very small, without any but the apical teeth; joints of the rami nine to ten in number.

Uropods.—The inner ramus of the third pair is rather widened at a little distance from the acute apex, in this respect not entirely agreeing with Claus' figure.

Telson longer than broad, triangular, somewhat more acute at the apex than that figured by Claus.

Length, a quarter of an inch.

Locality.—April 26, 1876, off St Vincent, Cape Verde Islands; lat. $16^{\circ} 49'$ N., long. $25^{\circ} 14'$ W.; surface; surface temperature, $73^{\circ}.2$. One specimen.

Remark.—The differences are too slight to admit of any reasonable doubt that this is the species described by Claus from the neighbourhood of Naples.

The following table shows the distribution of the genus *Brachyscelus* as illustrated by the Challenger specimens:—

1. April 26, 1876, off St Vincent, Cape Verde Islands; lat. $16^{\circ} 49'$ N., long. $25^{\circ} 14'$ W.; surface. One specimen (*Brachyscelus mediterranea*, see p. 1556).
2. Station 351, April 12, 1876; Atlantic, off coast of Africa; lat. $9^{\circ} 9'$ N., long. $16^{\circ} 41'$ W.; surface; surface temperature, $81^{\circ}.8$.
3. Station 103, August 22, 1873; Tropical Atlantic; lat. $2^{\circ} 52'$ N., long. $17^{\circ} 0'$ W.; surface-net, 100 fathoms; surface temperature, 77° .
4. October 5, 1873, South Atlantic; lat. $29^{\circ} 1'$ S., long. $28^{\circ} 59'$ W.; surface, night; surface temperature, $65^{\circ}.2$.
5. Station 319, February 12, 1876; South Atlantic; lat. $41^{\circ} 54'$ S., long. $54^{\circ} 48'$ W.; surface; surface temperature, $59^{\circ}.5$.
6. February 6–7, 1875, south of Mindanao, Celebes Sea; lat. $6^{\circ} 20'$ N., long. $123^{\circ} 18'$ E.; surface at night. (*Brachyscelus inaequipes*, see p. 1549.)
7. April 3, 1875, North Pacific, south of Japan; lat. $24^{\circ} 49'$ N., long. $138^{\circ} 34'$ E.; surface. (*Brachyscelus crusculum*, ♂, see p. 1544.)
8. Station 230, April 5, 1875; North Pacific, south of Japan; lat. $26^{\circ} 29'$ N., long. $137^{\circ} 57'$ E.; surface; surface temperature, $68^{\circ}.5$. Young male, lower antennæ not fully developed, first joint of first gnathopods only slightly twisted.

9. July 1875, North Pacific, between Japan and Honolulu; lat. 35° N.; surface. (*Brachyseclus crusculum*, see p. 1547.)

10. August or September 1875, Pacific Ocean; surface. (*Brachyscelus aacuteicaudatus*, see p. 1555.)

11. October 1875, South Pacific; surface. Two specimens (one *Brachyscelus latipes*, see p. 1550, and one *Brachyscelus bovallii*, see p. 1553).

To complete the account of the distribution so far as at present known, it may be deduced that *Thamyris antipoda*, Spence Bate, was taken in lat. 58° S., long. 172° W.; *Thamyris rapax*, Claus, at the Cape; *Thamyris globiceps*, Claus, at Zanzibar; *Thamyris mediterranea*, Claus, near Naples; *Thamyris elegans*, Bovallius, in the Atlantic, and Dana's *Dairilia inaequipes*, at the Philippine Islands.

Genus *Thamneus*, Bovallius, 1887.

- 1852. *Daira* (?) (*pars*), Dana, U.S. Explor. Exped., vol. xiii, pt. ii. pp. 981, 992.
- 1852. *Dairilia* (*pars*), Dana, U.S. Explor. Exped., vol. xiii, pt. ii. pp. 1519, 1596, 1604.
- 1862. *Dairinia* (*pars*), Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 309.
- 1885. " (*pars*), Bovallius, Some forgotten Genera of Amphipoda, p. 9.
- 1887. *Thamneus*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk - Akad. Handl., Bd. 11, No. 16, p. 31.

For the definition of this genus, see Note on Bovallius, 1887 (p. 591). The first described species of the genus appears to be Dana's *Dairilia* (or *Dairinia*) *depressa*, but Dana's generic name may well be allowed to drop, as well for the doubtfulness of the spelling, as for the reason that Dana himself intended to identify it with Milne-Edwards' *Daira*, from which it differs, and included in it three species, of which two have already been assigned to other genera, and the third remains still doubtful. The name *Thamneus* itself comes rather awkwardly near to the earlier *Thamnus*.

Thamneus platyrrhynchus, n. sp. (Pl. CXCVIII.).

A very broad species, and also deep at the middle of the peræon; the head broader than long and considerably broader than deep; the front of the head, though broad from side to side, is very thin vertically, the rostral point not projecting but folded in on the under side between the antennæ; the peræon has its segments a little dimpled on either side; the fourth and fifth segments are the broadest; the first three segments of the pleon, which are scarcely half as broad as these, have their postero-lateral angles slightly rounded. The skin is covered with minute honeycomb markings. The outer margin of the liver-tubes is deeply corrugated as in *Simorhynchotus*.¹

¹ See Claus, Die Platysceliden, p. 65, Taf. xvii. fig. 18.

Eyes occupying nearly all the surface of the head, except a strip round the hind margin which projects into an angle at the centre. The thin front margin is also unoccupied at the centre.

Upper Antennæ (of the female) small, projecting from the under surface of the head, at some distance from the front. The first joint is about twice as long as the second; the first joint of the flagellum is tapering, longer than the peduncle, fringed with filaments; the second joint is about a third of the length of the first, and much narrower, not even at the base so broad as the distal end of the preceding joint; the terminal joint is almost linear, more than half as long as the preceding.

Upper Antennæ (of the male), fig. *a.s.B.* First joint of the peduncle distally widened, as broad as long, the second joint incompletely developed; first joint of the flagellum large, the strongly convex lower side covered with a thick brush of long filaments; the second joint attached at the upper end of the rounded apex of the first, much wider than the third joint, and as long as the third and fourth together, its upper margin fringed with filaments; the fourth joint shorter and much narrower than the third.

Lower Antennæ wanting in the female; in the male (fig. *a.i.B*) not longer than the upper antennæ; the second joint to some extent free from the wall of the head; the third joint subequal in length to the fourth, its margins smooth; the fourth joint forming an angle with the third and another with the fifth, as if partially adapted for folding, but these three joints are not elongated or linear; the fourth and fifth joints have short filaments along the straight margin; the flagellum consists of a single joint, shorter and narrower than the preceding joint, with short filaments at the blunt apex and at two points of one margin. It may be questioned whether these antennæ are the fully developed form, but the probability is that they are, since they are found in a specimen which has the upper antennæ and the mandibular palp of an adult male.

Epistome deep and broad, helmet-shaped, its lower margin forming a triangle over the upper edges of the trunks of the mandibles, the apex of the triangle occupied by the small *Upper Lip* over the cutting edges of the mandibles.

Mandibles.—The part of the trunk in front of the palp is narrow, the cutting edge narrow, with a small prominence at the upper angle; the palp is placed on a projection of the upper margin, its first joint much broader than the second or third, but not so long as those two together; the second joint shorter than the third; the third joint curved, apically almost acute.

The Maxillæ appear to be smooth-rimmed oval plates, the first pair much larger than the second, and coalesced along the centre except distally, while those of the second pair are free from one another.

Maxillipeds short and broad; the inner plate with convex sides, and two little embedded spinules close together at the centre of the slightly emarginate distal border;

the outer plates not reaching far beyond the inner nor meeting over it, their outer surface very convex, and broad except distally, carrying a few spinules.

First Gnathopods.—Side-plates small, the lower front corner rounded and a little produced forwards. The first joint for most of its length free from the side-plate, rather broader above than below, the front margin bent out a little near the base, and the hinder margin to a slight extent at some distance from the distal end; the second joint short, with some small spines at the apex of the convex hind margin, and on the distal margin of the inner surface; the third joint a little longer, distally widened in front, the hind margin serrate, carrying some small spines; the wrist wider than the length of the hand, the front margin slightly convex, the hind margin somewhat produced, in length nearly equaling the distal width of the joint, cut into minute teeth, among which are three much more prominent than the rest, the apical being the largest and in fact double though very slender; much of the distal margin facing the hind margin of the hand is also denticulate; the hand is oval, the front margin the more convex and scarcely serrate, the hind margin toothed like the wrist, with one prominent double tooth not far from the narrow distal end, which is occupied by the base of the very short, slightly curved, acute finger, the concave margin of which is not quite smooth. A comparison of specimens shows that the denticulation of wrist and hand in both pairs of gnathopods is subject to variation; indeed, it is not absolutely constant between the two limbs of a pair in one and the same specimen.

Second Gnathopods.—Side-plates broader than the preceding pair. Branchial vesicles longer than the first joint and much broader, with accessory lateral vesicles; the marsupial plates much longer and broader than the branchial vesicles. The limb similar to that of the first gnathopods, the first joint longer and rather broader, the wrist a little longer but not broader.

First Peraopods.—Side-plates wider than deep, the lower margin convex, extending beyond the upper margin both before and behind. The branchial vesicles and marsupial plates similar to those of the second gnathopods, but larger. The first joint for most of its length free from the side-plate, the front margin slightly convex, the hinder a little sinuous; the second joint short, with some spinules on the hind margin; the third joint a little longer than the fourth, a little shorter than the fifth, widened distally, with spinules on the front apex and along the hind margin; the fourth joint slightly narrowed distally, having spinules on the convex front and the straight hind margin; the fifth joint a little curved, tapering, the front margin convex, the hinder slightly concave, with some spinules; the finger minute, curved, acute.

Second Peraopods.—The side-plates deeper than the preceding pair. The branchial vesicles, marsupial plates, and joints of the limb scarcely differ from those of the first pereopods, but the third and fourth joints are a little longer.

Third Peræopods.—Side-plates bilobed, much broader than deep, the front lobe rather deeper and much broader than the hind one. Branchial vesicles similar to the preceding pairs, but larger, broader above than below. Marsupial plates scarcely so large as the preceding pair. First joint oval, with the narrower end at the base, the front margin very regularly convex, scarcely serrate, fringed with spinules; the hind margin with the convexity most developed at the lower end, smooth; second joint short, with spinules on the front margin; third joint rather longer than the fourth, scarcely shorter than the fifth, all three resembling the corresponding joints in the two preceding pairs, but slightly exceeding them in length; the finger also is similar.

Fourth Peræopods.—Side-plates less broad than the preceding pair, the front lobe much deeper than the hind one, and with a straight front margin. The branchial vesicles not quite so large as the preceding pair, much widened at the upper hind corner. The limb differing very little from that of the third peræopods, the hind margin of the first joint more regularly convex, the third joint a little longer, the fifth perhaps scarcely so long, and a little widened at the upper part so that its front margin is not concave, the fourth and fifth joints having their front margins minutely pectinate; the finger a little longer and straighter than in the preceding pair.

Fifth Peræopods.—Side-plates not bilobed, very little broader than deep. First joint as broad as in either of the two preceding pairs but not so long, suddenly narrowed distally, the front margin very slightly, the hinder for the most part very strongly, convex; at the distal end the hind margin is concave and channelled; the remaining joints together do not quite equal the length of the first, and but little exceed its breadth; the second joint short, with some spinules in front, the third joint longer than the second, a little shorter than the fourth, which has a convex front margin; the fifth is very little shorter than the fourth, with a convex hind margin, the front concave for the lower two-thirds; the finger, which is scarcely discernible except with a high power, has something of a horse-shoe shape, the lower point projecting forwards a little in advance of the upper.

Pleopods.—The two coupling spines have short slender shafts, the apical dome or cap having its rim cut into several teeth; the left spine is attached close to the top of the first joint of the inner ramus, the subapically dilated arm about as long as the other, the dilatation small; below it on the first joint there are four plumose setæ; the first joint of the outer ramus has a tongue-like interlocking process; the joints of this ramus are eleven in number, those of the inner ramus ten.

Uropods.—The peduncles of the first pair reach beyond those of the second; they are a little shorter than the rami; the outer ramus is scarcely so long as the inner; they are both lanceolate, carinate beneath, with finely pectinate margins, and reach beyond the other pairs; the peduncles of the second pair are shorter than the rami, and only

reach to the base of the peduncles of the third pair; the outer ramus is a good deal shorter than the inner, which in its turn is shorter than either ramus of the first pair; the third pair are similar to the second, and all three pairs agree in general structure.

The Telson is oval in shape, with the base truncate, not coalesced with the preceding segment; it reaches about halfway or rather further along the inner rami of the third uropods.

Length.—The specimen of which the lateral view is figured measured, in a straight line from the front of the head to the back of the second pleon-segment, rather more than a fifth of an inch. Fig. A was taken from a rather smaller specimen.

Locality.—April 3, 1874, off Cape Howe, Australia; lat. $38^{\circ} 7' S.$, long. $149^{\circ} 18' E.$; surface, night; surface temperature, $66^{\circ}.5$. Fifteen specimens, of which ten were probably (and some of them certainly) females, the other five being adult or young males.

Remarks.—The specific name is derived from *πλατύς*, wide, and *ρύγχος*, beak, in allusion to the breadth of the head.

This species is very like *Daira* (?) *debilis*, Dana, but in that species the joints of the antennæ are described and figured as all short, there is no rostral point on the under side of the head, the branchial vesicle of the second pereopod is figured as shorter than the first joint, the fifth and sixth coalesced pleon-segments are drawn as longer than the fourth, and the telson is represented as coalesced with the preceding segment; the back of the animal is drawn as if strongly imbricated. Dana's specimen, three lines long, was taken in lat. $2^{\circ} S.$, long. $175^{\circ} W.$ When Dana says that in the second gnathopods the carpus is hardly smaller than the hand, he is no doubt speaking of the third and fourth joints respectively, not of the fourth and fifth, but either way his remark is inapplicable to our species; he figures the wrist of the second gnathopods with the inner or front margin smooth. *Thamneus rostratus*, Bovallius, must also come near to the present species, but that has the "telson very broad, rounded, a little shorter than last pair of uropoda." It ought to be mentioned that among the Challenger specimens three of the female specimens were much bulkier than the rest, and lighter coloured, so that till the details were compared these three were considered specifically distinct from the others.

 1887. *Amphipronoë*, Giles, On Six new Amphipods from the Bay of Bengal, Journ. Asiat. Soc. Bengal, vol. lvi. pt. ii. No. 2, p. 220.

For the original definition, see Note on Dana, 1852 (p. 259). For a short definition by Claus, see Note on Claus, 1879 (p. 492). The fuller definition by Claus is to the following effect:—

"Body *Hyperia*-like, with great thick head, in the male elongate, with powerful pleon, in the female thick and compact. Anterior antennæ concealed in a deep frontal cavity, in the male with a three-jointed flagellum and thick, elongate peduncle, in the female five-jointed. The hinder antennæ of the male very long, folded zigzag, with short stem, very long fourth joint, and extremely short terminal joint. Oral cone thick and short, with compact mandibles and short maxillæ. Both pairs of gnathopods are complexly subchelate. Gland-cells in the third joint of the first, second, and third peræopods. The laminar first joints of the third and fourth peræopods elongate, comparatively not very broad. Third peræopods greatly elongated, having like the shorter fourth pair a strong first joint. Fifth peræopods with broad laminar first joint, (the limb) comparatively small, but with the full complement of joints. Peduncles of the first pair of uropods considerably elongated. Rami of the uropods lanceolate. Telson elongate. Inner ramus of the third pair of uropods coalesced with the peduncle."

The upper antennæ in my view should be spoken of as having a four-jointed flagellum, the first joint alone being massive; that which is in the definition spoken of as the fourth joint of the hinder antennæ is in my view the first joint of the flagellum of that pair.

Lycæa vincentii, n. sp. (Pl. CXCIX.).

Head rounded, first three segments of the peræon short, the second especially so, the seventh segment also very short; the skin sparsely spotted with pigment flecks.

Eyes covering the sides of the head, the ocular pigment very large.

Upper Antennæ.—The peduncle very short, the second and third joints almost evanescent; the first joint of the flagellum bulky, the convex lower margin long, the

thick brush of long filaments extending to its slightly produced apex, the upper margin making a very pronounced angle, so that its distal half might indifferently be reckoned as part of the apical margin; the second joint with a little basal lobe is inserted at the top of the true apical margin, and has near its apex seven or eight broad filaments; the third joint is narrower and rather shorter, with two filaments at a little distance from the apex; the fourth joint is of about the same length, much more slender, a little bulbous at the base, and carrying some setules at the tip.

Lower Antennæ.—The third joint of the peduncle nearly two-fifths of the length of the next joint, a little curved near the base, with little filaments along the margin as in the other joints; the fourth joint much more slender, clongate; the fifth in a slight degree exceeding the length of the fourth, more slender; the flagellum a little shorter than the last joint of the peduncle, its second joint being very short and the first very long.

Maxillipeds.—The inner plate is almost as broad as it is long, with two little embedded spinules at the centre of the distal margin; the broad apically rounded outer plates appear to have quite smooth edges.

First Gnathopods.—The first joint wider above than below, channelled in front; the second joint with convex hind margin; the third joint not underriding the fourth, much broader than long, its convex hind margin scarcely so long as that of the second joint; the wrist with very sinuous finely pectinate hind margin produced into a long sharp smooth tooth, the long sinuous distal margin having near this tooth a pectination of six or seven denticles; the hand, attached just within the apex of the wrist's front margin, folds upon its distal margin so as with its almost smooth hind margin nearly to reach the apex of the wrist's produced tooth; the distal margin of the hand has a close pectination of about thirteen little backward sloping denticles; the sharp curved finger is more than half the length of the hand and reaches considerably beyond its distal or palmar margin; it is bulbous at the base. Gland-cells show themselves in the first five joints of these and the five following pairs of limbs.

Second Gnathopods differing little from the first; the first joint longer and a little sinuous, the hinder apex of the wrist rather more strongly outdrawn, and the finger rather longer.

First Peraopods.—The branchial vesicles as in the other pairs very large, elongate oval, with many lateral accessory pockets. The first joint nearly straight, the second longer than broad, the third much broader and longer than the fourth, the fourth with its hind margin nearly smooth except round the distal part, the fifth joint narrower than the fourth, as long as the third or a little longer, its front margin pectinate; the finger small, smooth-edged.

Second Peraopods very similar to the first but longer, the increased length being chiefly noticeable in the third and fifth joints.

Third Peraopods considerably longer than the second. The first joint longer than

in the preceding pair, tending to oval, but with the hind margin flattened, almost entirely smooth edged, the other joints nearly as in the preceding pair, but the third and fifth joints are much longer, and the pectination of the fourth joint, especially round the distal margin, appears to be stronger.

Fourth Peraopods.—First joint not longer than in the preceding pair, but wider, with the hinder margin very convex; the third, fourth, and fifth joints scarcely so long as in the second peraeopods, all three pectinate along the front margin; the pectination is also strong on the narrow distal margin of the fifth joint, which has some likewise on the lower part of its hind margin.

Fifth Peræopods.—The first joint much dilated, the breadth more than two-thirds of the length, and much surpassing the length of all the other joints together; these are all smooth-edged, the third longer than the second or fourth, the fourth not longer than the second, the fifth a little longer than the third, tapering; the finger minute, its base broad, triangular, the terminal part longer than the base, and bent sharply and closely back upon it, forming an effective hook.

Pleopods.—The coupling spines minute, with only the apical hooks; the cleft spine with very short arms, that with the subapical dilatation being the longer; the interlocking process on the outer ramus not elongate; the joints of the rami numbering from ten to eleven.

Uropods.—Peduncles of the first pair very much longer than the rami, extending back beyond the peduncles of the third pair, the outer edge folded in near the base, and below this pectinate; the rami equal, about a third of the length of the peduncles, carinate below, reaching back beyond the telson, the edges pectinately toothed except just near the base; the peduncles of the second pair a little longer than the inner ramus; the outer ramus narrower and shorter than the inner, its edges denticulate like all the other rami, its length a little exceeding that of the rami of the first pair; the inner ramus reaching just to the end of the peduncles of the first pair; the third pair have the peduncles short, widely separated, the inner ramus curving outwards, coalesced with the peduncle; the outer ramus is narrow, broken in the specimen, but from what remains pretty evidently not very elongate.

Telson not quite reaching to the apex of the third uropods, equal in length to the peduncles of the second uropods, the breadth about three-quarters of the length, narrowing to the apex, which is rounded, by no means acute.

Length.—From the front of the head to the back of the third pleon-segment the specimen measured one-fifth of an inch.

Locality.—April 26, 1876, off St. Vincent, Cape Verde Islands; lat. $16^{\circ} 49'$ N., long. $25^{\circ} 14'$ W.; surface; surface temperature, $73^{\circ} 2$. One specimen, male.

Remarks.—The specific name is taken from the place of capture. There are three

other specimens from the same locality probably belonging to this species, one of them a female (mounted in Canada balsam), which is almost covered with large stellate pigment-markings, and has numerous young ones. From "*Amphipronoë longicornuta*," Giles, this species is distinguished by having all the segments of the peraeon distinct and by the curved rami of the third uropods.

Lycæa pauli, n. sp.

Upper Antennæ.—The upper margin of the large first joint of the flagellum not angled.

Lower Antennæ as in *Lycæa vincentii*.

Mandibles.—The cutting edge nearly straight, not broad, finely striated, with a slight prominence at the upper corner, the lower rounded; the secondary plate of the left mandible nearly as long as the principal. First joint of the palp longer than the two following together, and more than twice as broad as either; the third joint slightly longer than the second.

Gnathopods nearly as in *Lycæa vincentii*, but the distal or palmar margin of the wrists less hollowed, the serrate part of it being straight.

Third Peræopods.—The first joint broadly oval, narrow at the neck, distally broad, the much rounded and faintly serrate distal extremity of the hind margin projecting much behind the following joint; the third joint longer and broader than the fourth; the fourth strongly pectinate on its distal margin on the inner surface; the concave front margin of the fifth joint faintly pectinate.

Fourth Peræopods.—The first joint more regularly oval than that of the preceding pair, about the same length with that, but considerably narrower; the third, fourth, and fifth joints also narrower as well as shorter than in the third pair.

Fifth Peræopods.—The first joint longer than broad, nearly as broad as the first joint in the preceding pair, narrowed at the two extremities, the front margin straight, the hinder very convex; the second joint not longer than broad; the third a little longer; the fourth narrower than the third, longer than the second and third together; the fifth longer than the fourth; the finger very small, with a small protruding piece above, the bent tongue-like piece below extending much beyond this.

Pleopods with about ten joints to the rami.

Uropods.—Peduncles of the first pair scarcely twice as long as the rami, strongly pectinate on the outer margin; the rami reaching a little beyond the telson, the outer rather the longer, pectinate on both margins, the inner pectinate on the outer margin and lower part of the inner; inner ramus of the second pair pectinate on both margins, reaching much beyond the peduncle of the first pair; the outer ramus much shorter and narrower than the inner, pectinate on the inner margin; the coalesced inner ramus of

the third pair scarcely curved outwards, reaching a little beyond the rami of the first pair, pectinate on both margins; the much smaller outer ramus pectinate on the inner margin, more than half the length of the inner ramus.

Telson rather narrower at the base than in *Lycæa vincentii*.

Length, three-tenths of an inch.

Locality.—Station 108, August 27, 1873; off St. Paul's Rocks; lat. $1^{\circ} 10'$ N., long. $28^{\circ} 23'$ W.; surface; surface temperature, 78° . One specimen, male.

Remark.—The specific name is taken from the place of capture.

Lycæa pulex, Marion.

1874. *Lycæa pulex*, Marion, Ann. d. Sci. Nat., sér. 6, t. i. p. 13, pl. ii. fig. 2.

Locality.—Station 351, April 12, 1876; Atlantie, off coast of Africa; lat. $9^{\circ} 9'$ N., long. $16^{\circ} 41'$ W.; surface; surface temperature, $81^{\circ} 8$.

Remarks.—The specimen is in bad condition. The third uropods agree better with those which Claus figures for *Lycæa robusta* than with Marion's figure of these organs, but as Claus himself regards Marion's species as the young of his own *Lycæa robusta*, it seems correct to adopt Marion's specific name.

Genus *Paralycaea*, Claus, 1879.

1879. *Paralycaea*, Claus, Die Gattungen und Arten der Platysceliden, pp. 32, 40.

1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 486.

1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 33.

1887. " Claus, Die Platysceliden, pp. 56, 63.

For the shorter definition of the genus, see Note on Claus, 1879 (p. 493). Claus' fuller description is to the following effect:—

"The shape to a certain extent intermediate between *Lycæa* and *Eupronoë*. Anterior antennæ concealed in a deep frontal groove, in the male resembling those in *Lycæa*. Hind antennæ in the male with short thick basal joint and very long terminal joint. Oral cone strongly projecting, with compact mandibles and widely divided maxillipeds. Both pairs of gnathopods simple and elongate. Third peræopods elongate, with elongate oval laminar first joint. Fourth peræopods much shortened, with broad almost triangular laminar first joint. Fifth peræopods reduced to a narrow curved little laminar first joint, succeeded by the rudimentary remnant of the limb bent hook-like. Peduncle of the first pair of uropods long and broad, that of the second pair somewhat shorter, the leaf-like inner ramus coalesced with the peduncle."

Paralycea gracilis, Claus.

1879. *Paralycea gracilis*, Claus, Die Gattungen und Arten der Platysceliden, p. 40.
 1887. " " (?) Bovallius, Systematical List of Amph. Hyper., Bihang. till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 33.
 1887. " " Claus, Die Platysceliden, p. 64, Taf. xx. fig. 1-11.

Head obliquely oval, mouth-organs much produced below it; peræon much shorter than pleon, each of the first three segments much shorter than any one of the last four; first three segments of the pleon together much longer than the remainder of the pleon; scale-markings of the integument conspicuous.

Eyes covering most of the head, showing no external trace of the division of each eye into two groups of ocelli.

Upper Antennæ in the female very small; the peduncle seemingly short, one-jointed, the flagellum two-jointed, its first joint much longer than the peduncle, bent at the base, and having a group of three or four broad filaments almost at the apex, the second joint quite small, but longer than broad, tipped with long filaments.

Lower Antennæ not present in the female.

First Gnathopods.—Side-plates with convex front margin. The first joint much bent, concave in front, with a little hair or setule here and there; second joint longer than broad, the hind margin convex; the third joint longer than the second, broader than the fourth, the hind margin convex; the fourth joint perhaps slightly longer than the third, the distal margin projecting a little obliquely beyond the fifth joint or hand; the hand narrower than the wrist and a very little longer, the front margin convex, the hinder straight, with a minute setule below the centre; the finger curved, slender, rather more than half the length of the hand, squarely widened at the base, the hind margin then regularly concave except for a small interruption where a minute setule emerges high up on the margin.

Second Gnathopods like the first, but all the joints rather larger, except the finger. Branchial vesicles oval, simple, broader than the first joint, not longer. The concave front margin of the first joint seems to be without setules, the third and fourth joints are equal in length, and each of them little longer than the second, and little shorter than the fifth.

First Peraopods not very different in appearance to the gnathopods, but considerably larger. The side-plates convex in front, the lower hind corner produced a little backwards. The first joint wider than in the gnathopods and less concave in front; the third joint much larger than the second, widened distally, with convex front margin; the fourth joint longer than the third, wider than the fifth and nearly as long, with a slight narrowing near the apex; the fifth joint slender, slightly curved, with a few little setules along the hind margin and one at the apex of the convex front; the finger not half the

length of the fifth joint, shaped as in the gnathopods, but without setule or interruption of the concave part.

Second Peræopods like the first, but with the third, fourth, and fifth joints longer.

Third Peræopods.—Side-plates with convex front and hind margins and a narrow tongue-like backward-directed process on the inner side. Branchial vesicles shorter than the first joint and not broader. The first joint slightly channelled behind, about three times as long as broad, fully as long as the three following joints together, its sides nearly straight; the second joint longer than broad, the third considerably longer than the second, the fourth than the third, and the fifth than the fourth; the fourth joint straight, very finely pectinate along the front margin; the fifth much narrower, scarcely curved, still more minutely pectinate; the finger as in the preceding pairs, but much smaller, about a sixth of the length of the fifth joint.

Fourth Peræopods.—Branchial vesicles shorter than the preceding pair. The first joint much longer than all the remaining joints together, little shorter, but in the upper part much broader than, the first joint of the third peræopods, the lower end of the broad oval much narrowed and smoothly rounded; the second joint very small, scarcely capable of reaching the apex of the first; the third joint longer than the remaining joints together, its front margin pectinate with retroverted teeth, the apical prolongation narrow, almost acute, not quite reaching the middle of the next joint; the fourth joint much longer and broader than the fifth, armed like the third except at the narrowed apical portion; the fifth joint slender, nearly straight, with a setule at the apex of the hind margin, the lower part of which is a little concave; the finger small and blunt, abruptly narrower than the fifth joint, and about a sixth of its length.

Fifth Peræopods very feeble, the narrow first joint a little curved, about half the length of the first joint of the fourth peræopods, and a fifth or a sixth of its greatest breadth; the hook-like appendage obscurely divided into four joints of which the second forms the bend, the terminal one having a rounded apex.

Pleopods.—Peduncles produced downwards at the inner angle; coupling spines very short, with the usual apical cap; one arm of the cleft spine having a long narrow dilatation, the other arm nearly equal; inner ramus with five joints, outer with six.

Uropods.—Peduncles of the first pair longer than the rami, three-edged, the outer margin pectinate below; the outer ramus longer than the inner, three-edged, the outer margin more strongly pectinate than the inner; the inner ramus laminar, its margins less strongly pectinate than those of the outer ramus; peduncles of the second pair rather shorter than the outer ramus; the outer ramus three-edged, almost smooth on the outer margin, the inner pectinate; the inner ramus rather shorter than the outer, coalesced with the peduncle, both margins pectinate; peduncles of the third pair shorter than the outer ramus; the outer ramus considerably shorter and narrower than the inner, the outer margin smooth, the inner pectinate; the inner ramus coalesced with the

peduncle, reaching beyond the other rami and the telson, both margins pectinate, the apex narrowly rounded.

Telson a long narrow triangle, with the sides slightly concave, and the apex smoothly rounded, the length not much less than that of the third uropods.

Length about three-twentieths of an inch.

Locality.—March 16, 1874, south of Australia; lat. $39^{\circ} 22'$ S., long. $140^{\circ} 27'$ E.; surface; surface temperature, 61° . One specimen, female, with eggs.

Remarks.—There seems nothing to distinguish this specimen from Claus' *Paralyæxa græilis*, of which the locality was unknown to Claus. Bovallius describes a species, from "Tropical parts of Atlantic," under this name, to which he assigns "body smooth, head twice deeper than body," and "exterior ramus of last pair [of uropods] as long as the interior." These particulars do not suit the Challenger specimen, nor does the last of them agree with Claus' figure of the species.

Paralyæxa hoylei, n. sp. (Pl. CCX., E.).

Upper Antennæ as in the preceding species.

First Gnathopods.—First joint nearly straight, a little widened below, with half a dozen setules along the hind margin; the fourth joint or wrist decidedly longer than the third joint, with two minute setules on the almost straight hind margin; the fifth joint or hand slightly curved, narrower than the wrist and not longer, with a minute setule at the centre of the hind margin; the finger a little widened at the base.

Second Gnathopods.—Branchial vesicles simple, rather shorter than the first joint. Marsupial plates much larger than the branchial vesicles. The first joint longer and more sinuous than in the first pair, the second and third joints rather larger; the wrist not much longer than the third joint, rather shorter but broader than in the first gnathopods, the rather convex hind margin having a minute spinule below the centre and another at the apex which stands well clear of the hand; the hand rather longer than the wrist and longer than in the first pair, while the finger is rather shorter.

First and Second Peraopods nearly as in the preceding species; the first joint more curved than in the gnathopods; the fifth joint longer than the fourth.

Third Peraopods.—The first joint not widely expanded, about as long as the three following joints together, the second joint longer than broad, with convex front margin; the third joint much longer than the second, with straight hind margin and convex front; the fourth joint narrower than the third, not or scarcely longer, finely pectinate; the fifth joint narrower than the fourth and almost as straight, a little longer, finely pectinate; the finger small.

Fourth Peræopods.—The first joint longer than that of the third peræopods, widest above, with narrowly rounded apex, within and a little above which the small second joint is embedded; the third joint as long as the three following together, the produced apex of the inner surface being about half the width of the joint at its base and less than half the length of the following joint; the retroverted teeth of the front margin are graduated in size, the largest being within one or two of the small apical tooth; the fourth joint is oval, longer than the two following together, almost as broad as the third and pectinate like it, except that the channelled distal part of the front margin is free from teeth; the fifth joint about half the length of the fourth and not a third of its breadth; the finger scarcely half as long or as broad as the fifth joint, straight, not acute; the last five joints are together much shorter than the first.

Fifth Peræopods.—First joint about three times as long as broad, seemingly with both margins a little sinuous, the terminal appendage small, not well observed.

Pleopods as in the preceding species.

Uropods.—Peduncles of the first pair a little longer than the rami, the apex of the inner margin a little produced, the lower half of the outer closely pectinate; the rami as in the preceding species; peduncles of the second pair fully as long as the rami, shorter and much narrower than those of the first pair, with the lower part of the inner margin pectinate; the rami pectinate as in the preceding species, the inner very slightly the shorter, not at all coalesced with the peduncle; the third pair as in the preceding species, but a small indent on the inner margin marking the point of coalescence between the ramus and peduncle.

Telson as in the preceding species, but scarcely so long compared with the third uropods.

Length, one-tenth of an inch.

Locality.—Station 351, April 12, 1876; Atlantic, off coast of Africa; lat. $9^{\circ} 9' N.$, long. $16^{\circ} 41' W.$; surface; surface temperature, $81^{\circ}.8$. One specimen, female.

Remarks.—The species is named as a mark of respect to Mr. W. E. Hoyle of the Challenger Office, who has seen a large part of this Report through the press. From *Paralycaea newtoniana*, Bovallius, which also has the inner ramus of the second uropods free, this species is distinguished at once by the process to the third joint of the fourth peræopods.

Genus *Simorhynehotus* (*Simorhynchus*,¹ Claus, 1871).

1871. *Simorhynchus*, Claus, Unters. über den Bau und die Verw. der Hyperiden. Nachrichten der K. Gött. Soc., p. 156.
 1879. " Claus, Die Gattungen und Arten der Platysceliden, pp. 32, 42.
 1886. " Gerstaecker, Bronn's Klassen und Ordnungen, Bd. v. Abth. ii. p. 486.
 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 34.
 1887. " Claus, Die Platysceliden, pp. 56, 65.

For the shorter definition of this genus by Claus, see Note on Claus, 1879 (p. 493). The following is based upon the fuller account which he also gives both in 1879 and 1887:—

Upper Antennæ with four-jointed flagellum, the first joint very large, the others narrow.

Lower Antennæ.—The first free joint (in the male) curved, much shorter than any of the three following joints, which are long and linear, the terminal joint short.

Mandibles with three-jointed palp (in the male).²

Maxillæ degraded.

Maxillipeds with small inner plate and large outer plates.

First Gnathopods simple; *Second Gnathopods* tending to a subchelate form.

Third Peraopods longer than the *Fourth*, both pairs with expanded first joint.

Fifth Peraopods with expanded first joint, the remaining joints present but feeble.

Branchial Vesicles large, with accessory lateral compartments.

Uropods of the *Second* and *Third* pairs having the inner ramus coalesced with the peduncle, the outer movable, finger-like.

Claus states that the ganglia in the ventral chain (which he figures) are very closely set, with short longitudinal commissures; that the hepatic tubes (which he also figures) are broad, with secondary bulgings; and that the heart (Rückengefäß) is very wide. His description of the rodent-like head must no longer be included in the generic account, since Bovallius describes a species, "*Simorhynehus Lilljeborgi*," with "Head rounded, not rostrate."

Simorhynehotus antennarius (Claus) (Pl. CC.).

1871. *Simorhynchus antennarius*, Claus, Untersuch. über den Bau und die Verwandschaft der Hyperiden. Nachrichten K. Gött. Soc., p. 156.
 1879. " Claus, Die Gattungen und Arten der Platysceliden, p. 43.
 1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 34.
 1887. " Claus, Die Platysceliden, p. 65, Taf. xvii. figs. 9–19.

Head broad, produced a little in front, as if into a short blunt snout; the back broad, the segments of the peraeon together not so long as the first three of the pleon; the

¹ *Simorhynchus*, being preoccupied among birds (see Scudder, Nomenc. Zool., p. 292), has been changed into *Simorhynehotus*.

² Claus says "Mandibular-palp short, basal joint only a little longer than the following joints," whereas in the Challenger specimen the palp is relatively long, and its basal joint considerably longer than the second joint.

side-plates with the upper boundary not very distinct; the first three segments of the pleon large, with the postero-lateral angles not acute.

Upper Antennæ attached below near the front of the head; the first joint of the peduncle about as broad as long, the second very short, the third obscure or absent; the first joint of the flagellum large, strongly bent, the long convex margin surrounded by a dense fringe of long filaments, the apex produced about to the end of the second joint, with the margin facing that joint ciliated; adjacent to the upper margin of the joint there is a second brush of filaments and this margin has an elevated process at a little distance from the apex; the small second joint is longer than broad, with filaments near and at the apex; the third joint is much shorter and narrower, with filaments near the apex and setules at it; the fourth joint is as long as the two preceding together, at first a little bulbous, then filiform, tipped with setules. In Claus' figure the apex of the first joint of the flagellum is more strongly produced, the third joint is as long as the second, and the fourth is linear, little longer than either of the preceding joints.

Lower Antennæ attached at the lower part of the back of the head; the third (first free) joint of the peduncle curved, rather elongate, thickest near the base; the fourth joint narrower, broken in our specimen. Claus says that the fourth joint reaches almost to the pleon, and the following joint is equal to it in Claus' figure; according to that figure the first joint of the flagellum is nearly as long as the last of the peduncle, while the second or terminal joint is extremely short.

Upper Lip a small dome, rather wider than deep.

Mandibles.—The trunk very small, compared with the palp, the cutting edge with a slightly produced tooth at the top, the remainder very finely denticulate, straight; the first joint of the palp longer and broader than either of the others; the second a little widened at the base, curved, shorter than the third; the third more curved and narrower than the second, apically pointed. Claus, in the character of the genus, states that the first joint of the mandibular palp is only a little longer than the following joints, and in fact figures the third joint of nearly equal length with the first.

Maxillipeds.—The inner plate about as long as broad, not half the length of the outer plates, which are rather broad at the base, the apices rounded, not meeting over the inner plate, the margins smooth.

First Gnathopods.—The first joint longer than all the rest together, with the hind margin nearly straight, the front sinuous, the two ends of the joint being narrow, the middle a little dilated; the second joint not broader than long, the third a little longer, with one little setule on the hind margin; the wrist a narrow oval, longer than the hand, with a little setule and two hairs on the hind margin; the hand narrow, with the hind margin straight, armed below with three tiny setules, the front margin convex; the finger small, acute, less than a third of the length of the hand, with a minute setule on the hind margin.

Second Gnathopods very like the first, but the first joint longer and rather more slender, and the wrist widening distally, with straight or slightly concave distal margin forming the widest part of the joint and projecting much behind the hand, the hind margin furnished with five setules or spinules successively larger, and three submarginal hairs or setules, besides a little excessively fine furring.

First Peræopods.—The first joint narrowest at the neck, the front margin straight; the second joint longer than broad; the third joint subequal in length to the fourth, which is a little narrower and slightly curved; the fifth joint longer and narrower than the fourth, slightly curved, the concave hind margin of this and the preceding joint faintly furred; the finger bulbous at the base, very slightly curved, less than half the length of the fifth joint. There are microscopic setules on various parts of the limb.

Second Peræopods like the first, except that they are slightly stouter, and the third, fourth, and fifth joints are longer.

Third Peræopods much longer than the preceding pairs, the first joint not widely expanded, more than twice as long as broad, with some small spines along the upper part of the front margin which below is weakly serrate; the second joint longer than broad; the third and two following joints much more elongate than in the preceding pair, the third rather longer than the fourth; the fifth slender, curved, much longer than either of the two preceding joints, nearly as long as the first; the finger small, about a sixth of the length of the preceding joint.

Fourth Peræopods shorter than the third, the first joint rather longer and at the upper part much more widely expanded, the front margin produced a little below the hinder, and having a few spines, the convex hind margin smooth; the second and third joints rather larger than in the preceding pair, the third joint having its distal margin finely pectinate and armed on either side with a couple of spines; the fourth joint about half the length of the third, the distal armature similar, but the pectination much stronger, the front margin very minutely pectinate at the middle, but at a little distance from the apex carrying four short broad teeth; the fifth joint longer than the third, curved, the concave front margin strongly pectinate; the finger small.

Fifth Peræopods.—The first joint narrowly pear-shaped, not so long as the first joint of the third pair, but as broad at its broadest part; the second joint not longer than broad; the third about twice as long as the second; the fourth nearly twice as long as the third, but narrower; the fifth nearly as long as the fourth; the minute finger projecting in front of the fifth joint and strongly bent, so that the linear or setiform termination is brought very near to the base and projects in advance of it.

Pleopods.—Coupling spines minute; cleft spine having the arm with the subapical dilatation considerably longer than the other; the first joint of the inner ramus carrying five setæ below the cleft spine; the first joint of the outer ramus longer than

that of the inner, with six or seven plumose setæ on the outer and two or three on the inner margin; joints of each ramus numbering eight or nine.

Uropods.—Peduncles of the first pair reaching just beyond the bases of the third pair, a little longer than the outer ramus, probably a little shorter than the inner; the outer ramus narrower and no doubt shorter than the broken inner ramus, closely pectinate along both margins, curving a little inwards; the inner ramus curving a little outwards, more loosely pectinate on the inner than on the outer margin; both rami carinate on the under surface; the second pair altogether missing on one side and on the other perhaps incompletely developed, the peduncle much shorter and narrower than the peduncles of the first pair, on the inner side bluntly produced for less than half the length of the small outer ramus, which scarcely reaches to the end of the peduncle of the first pair; peduncles of the third pair completely coalesced with the inner ramus; the outer ramus, to judge by the one remaining stump, is evidently narrow and probably short; the inner ramus apart from the distally widened peduncle is rather shorter than the outer ramus of the first pair, the first half broad, with both margins convex, the terminal half narrow; the margins are pectinate, the under surface carinate, the terminal part of the ramus bending outwards, the whole ramus not quite twice as long as the peduncle, with which its inner margin is completely continuous.

Telson on the upper surface quite coalesced with the preceding composite segment, which it exceeds in length; the breadth at the base about equal to the length; the sides for much of the length convex, converging very slightly, distally a little concave, converging rapidly to an almost acute apex halfway down the narrow part of the inner ramus of the third uropods.

Length, in the somewhat bent position figured, a quarter of an inch.

Locality.—April 13–14, 1876, Atlantic, off coast of Africa; lat. $11^{\circ} 5'$ N., long. $18^{\circ} 15'$ W.; surface; surface temperature, $74^{\circ}\cdot 7$. One specimen, male.

Remarks.—The small differences in the upper antennæ and mandibular palp between this specimen and that described by Claus are evidently not of specific value. The first joint of the fourth peræopods and the finger in the fifth do not agree with Claus' figures, but he does not specially describe those parts; there are also differences in the uropods, but, as already observed, the Challenger specimen may be a little abnormal in this respect.

Family OXYCEPHALIDÆ, Spence Bate, 1862.

Dana in 1852 made the Oxycephalinae the third subfamily of the Typhidæ. Spence Bate in 1862 established the Oxycephalidæ as the fifth family of the Hyperina, including in it two subfamilies, the Synopiades and Oxycephalides. By later writers the Synopiades

have been classified elsewhere. In 1879 and 1887 Claus placed the Oxycephalidae as the fifth family of the Platyselidan group, and defined it to the following effect:—

“ Body more or less laterally compressed and elongate, with long rostrum, the pleon extensive, with stiliform uropods. The branchial vesicles are elongate, simple. The laminar first joints of the third and fourth peraeopods thin and comparatively weak. Fifth peraeopods very weak, but generally complete. The hinder antennæ of the female and both pairs of maxillæ degraded. Two otolith-vesicles are uniformly present.”

Claus includes in the family only the two genera, *Oxycephalus* and *Rhabdosoma*, for which Dana originally formed the subfamily Oxycephalinæ. Streets added the genus *Leptoetis* in 1877 and *Calamorhynchus* in 1878. Bovallius in 1887 added the genera *Glossoecephalus* and *Tulbergella*, changed the name *Rhabdosoma* into *Rabdonectes*, and gave the following diagnosis of the family:—

“ Head long, produced anteriorly into a rostrum. Eyes large, not occupying the whole head. First pair of antennæ fixed at the under-side of the head in a special groove between the rostrum and the eyes; first joint of flagellum tumid, the rest subterminal, few-jointed. Second pair fixed at the under hinder corner of the head, angularly folded (♂) or wanting (♀). Pereiopoda [Gnathopods and Peræopods] are walking legs. Seventh pair [Fifth Peræopods] complete or rudimentary.”

The expression “ pereiopoda are walking legs ” is rather obscure, and not applicable to the gnathopods.

For the original definition of the genus *Oxycephalus*, see Note on Milne-Edwards, 1830 (p. 143). For the definitions of *Orio*, see Note on Coeeo, 1832 (p. 145), 1833 (p. 150), and compare Note on Prestandrea, 1833 (p. 152). For the account of *Ornithorhamphus*, see Note on de Natale, 1850 (p. 239). For *Erpetoramphus* see Note on de Natale, 1850 (Appendix, p. 1623). For the definitions of *Natalius* and *Carcinornis*, see Note on Costa, 1864 (pp. 346, 347). For an independent definition of *Oxycephalus*, see also Note on Nielet, 1849 (p. 232). For a short definition by Claus, see Note on Claus, 1879 (p. 493). Those who have access to the specimens on which the Italian authors mentioned in this synonymy founded their genera may be able to uphold some of those genera as distinct, or to show that they have anticipated some of the genera more recently instituted. Claus' fuller definition of *Oxycephalus* is to the following effect:—

" Body elongate, in the female sex having the peræon widened. Head outdrawn in a tolerably triangular rostrum, the base of which receives the anterior antennæ in a deep groove-like excavation of the ventral surface. From this a flat channel extends on the under-side of the head to the mouth-organs for the reception of the long zigzag folded second pair of antennæ. The anterior antennæ end with a short two- to three-jointed flagellum, and in the male are strongly swollen, weakly curved, and carry a thick brush of close-set olfactory filaments. The hinder antennæ of the male are five-jointed, folded zigzag and end with a short terminal joint, while in the female they are completely wanting. Mandibles powerful, with sharp tooth-like projecting cutting edge, attached to the rim of the tumidly prominent epistome. In the female without palp, in the male they carry one that is elongated rod-like, reaching to the anterior antennæ; its two distal joints lie angularly curved and form a sort of hook-like termination. Maxillæ were not found. The maxillipeds are represented by a three-leaved under-lip. The two short pairs of gnathopods are complexly chelate; uniformly is the chela of the first pair shorter, more compact, and armed with sharper edge to the finger-joint. The first joints

of the third and fourth peræopods have a laminar expansion. The fifth peræopods more or less reduced, but having the full number of joints, the first triangularly laminar. The uropods with two lanceolate rami. The telson triangular."

Without being able to give any definite information as to the lower lip and maxillæ in this genus and the other genera of the same family, I may express an opinion that these organs are not absolutely unrepresented, but that they consist of delicate and more or less rudimentary plates, which are almost inevitably torn and disfigured when the mandibles are drawn away from the maxillipeds.

Oxycephalus clausi, Bovallius, ♀ (Pl. CCI.).

1879. *Oxycephalus piscator*, Claus, Die Gattungen und Arten der Platysceliden, p. 44.
 1887. *Oxycephalus clausi*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 35.
 1887. *Oxycephalus piscator*, Claus, Die Platysceliden, p. 69, Taf. xxii. figs. 1-9, Taf. xxiii. figs. 1-8.

The back carinate from the tip of the rostrum to the apex of the telson, the carina interrupted by depressions between the segments of the peræon and to some extent by depressions across the segments of the pleon; the proximal half of the head of a bulbous oval form, almost entirely occupied by the great eyes with their innumerable ocelli; the distal half a triangle much longer than broad, the end rounded except quite at the apex, which forms a small point; the outer margin of the whole head serrate; viewed laterally the outer or lower margin is sinuous, convex at the eye, concave at the rostrum which forms a sort of prismatic base, along the underside of which lie the two little antennæ. On either side of the central carina, a lateral carina is developed in a more or less disconnected manner, as well on the rostrum as on the segments of the peræon and the first three of the pleon; of these latter the postero-lateral angles are produced into sharp points, above and beyond each angle the hind margin being also produced into a sharp point, with a faintly serrate cavity below and a convex or sinuous tract above; the coalesced fifth and sixth segments are equal in length to the telson, and coalesced with it. Much of the animal is finely pubescent.

Upper Antennæ but little exceeding in total length the breadth of the wrist of the second gnathopods. The first joint about three times as long as broad; the second joint very short, twice as broad as long; the first joint of the flagellum longer than the peduncle, fringed on the outer side with about eighteen short filaments; the second joint about a fifth of the length of the first and much narrower, with a subapical pair of short filaments; the third joint shorter than the second, linear, a little curved, tipped with a spinule.

Lower Antennæ wanting (in the female).

Upper Lip transversely oval.

Mandibles small, the distal end triangular, the lower edge of the triangle being the striated cutting edge; the secondary plate of the left mandible is nearly as large as the principal, and similar except that it has not a projecting tooth at the top; on the right mandible there is a small process shaped like a broad broken spine.

Maxillipeds.—The inner plate and the joint to which it is attached carinate down the centre on the inner side, its distal margin arched; the outer plates curving over the inner one, with sinuous inner margins, at first convex, then concave, fringed with seven small tubercles, in each of which a short setule is planted.

First Gnathopods.—Side-plates much deeper than broad, produced below to a sharp point, the lower part of the concave front margin and all the lower margin serrate, the hinder margin rounded below. The first joint attached a little above the middle of the side-plate and not reaching much below it, the hind margin convex, the front still more bowed, except at its two extremities; the second joint very short, broader than long, with a spinule near the hinder apex; the third joint very little longer, somewhat broader than the second, with a spinule similarly placed but longer; the wrist broader than the first joint and behind about as long; the front margin convex, with a spinule near the apex, the wrist here attaining its greatest breadth; the hind margin much longer than the front, convex at the base, thence running in almost a straight line to form a long apical tooth, the inner margin of the process being cut into two or three smaller teeth, the outer surface carrying a few spines and the inner surface crossed by a large group; the hind margin is bordered with eight spinules, and along the distal half serrate, and minutely pectinate between the serrations; the very convex front margin of the small hand is not continuous with that of the wrist, but set considerably back, while the straight, finely but irregularly denticulate, hind margin overlaps without reaching beyond the inner margin of the process of the wrist; numerous spines planted on the surface of the hand within its hind margin antagonize with those on the inner surface of the wrist; the finger is very small, set on the front of the apex of the hand, curving over the short remaining part of the faintly produced apical margin and across the sharp apical tooth of the wrist; there are small spines on the front margin and distributed on both surfaces of the distal part of the hand.

Second Gnathopods.—Side-plates with the front margin almost straight and smooth, directed obliquely forwards, deeper than the hind margin; the lower margin serrate, slightly sinuous. Branchial vesicles oval, a little longer and much broader than the first joint, speckled over with little hairs. The limb not unlike that of the first gnathopods, but much larger; the first joint a little sinuous, not quite so long as the wrist; the second and third as in the preceding pair, but larger; the wrist very broad, and more than twice as long as it is broad, the proximal part muscular; the hind margin convex, fringed with spinules, the distal two-fifths forming a triangular thumb, the apex of which reaches beyond the hand, the inner or front margin of the process being slightly concave,

divided into blunt teeth, of which five or six are conspicuous, the rest near the apex being small; the front margin is only slightly convex, and has a sharp apex, a little bent, with a small cavity behind it containing a spinule; between this and the thumb the distal margin is nearly straight; the hand set on as in the preceding pair, widens beyond the neck, and then tapers to the truncate apex, the front margin being convex, the hinder gently erenate, scarcely convex; the finger very short, its base occupying nearly all the apex of the hand, its tip curving across the tip of the thumb; there are spinules along the hind margin of the wrist, and near the teeth of its distal process, also near the margins and on the surface of the hand. In both the first and second gnathopods there are gland-cells in the first five joints.

First Peræopods.—Side-plates deeper behind than in front, the front margin convex the other margins sinuous, the lower serrate. The branchial vesicles long oval, not so long as the first joint. The limb long and slender; the first joint concave in front, a little widened distally, almost free from the side-plate, as long as the three following joints united, having a longitudinal ridge on the under surface; the second joint not shorter than the breadth, carrying two spinules on the convex hind margin; the third joint rather longer than the fourth, with some very small spinules on the slightly convex front margin, the hind margin nearly straight, fringed with numerous outstanding spinules; the fourth joint not much narrower, similarly armed; the fifth subequal in length to the fourth, similarly armed, a little curved, distally tapering; the finger slender, acute, a little curved, scarcely more than a fifth of the length of the fifth joint.

Second Peræopods.—Side-plates rather broader than in the preceding pair, branchial vesicles and limbs similar, but the joints rather longer, except the second and the finger; the fourth joint not quite so long as the fifth.

Third Peræopods.—Side-plates a good deal broader than deep, the hind lobe the larger, with its lower margin flattened; on the inner side there is a narrow tapering process directed downwards. Branchial vesicles subequal in length to the first joint, but not so broad. The first joint greatly expanded, rather longer than the first joint of the preceding pair, irregularly oval, narrower at the base than distally, the hind margin very convex and regular, finely not deeply serrate, the front margin nearly straight in the upper part, carrying a few spinules, the lower part convex, strongly serrate, its apex produced into a sharp point, the distal margin sinuous; the rest of the limb slender, similar to the preceding pair, but with the third and fifth joints considerably, the second and fourth a little, longer and somewhat thicker, the second joint with a minute spinule in a notch above the front apex.

Fourth Peræopods.—The side-plates as deep as the preceding pair, not so broad, the front and hind margins nearly straight, but the front rounded at the lower corner, the hinder produced into a small projection. The branchial vesicles broadly oval, but not so

long or so broad as the first joint. The first joint tending to circular, a little shorter than the first joint of the preceding pair, but broader, similarly armed, the distal end the narrowest part, with a sinuous margin; the remaining joints similar in general shape to those of the preceding pair but shorter, the fourth and fifth much shorter, the third joint longer than the fifth; the front margin of the third, fourth, and fifth joints pectinate, the larger teeth interspersed with minute teeth, of which there are some also on the distal margins and a few on the inner margin of the almost straight finger near the base.

Fifth Peræopods.—The side-plates produced below and in front into a small lobe, the lower margin to the rear of the lobe nearly straight, forming a right angle with the slightly convex hind margin, above which the plate is separated from its segment by an incision extending for about one-third of the total breadth. The first joint papyraceous, pear-shaped, as long as the first joint of the fourth peræopods, and near the base two-thirds as wide, distally greatly narrowed; the remaining joints linear, together not quite so long as the first, the whole limb much more than half the length of any preceding pair; the second joint short, with a spinule on the convex front margin; the third as long as the three following united, narrowing a little distally, the front margin nearly straight, with some minute spinules, a long oval packet of gland-cells filling most of the joint; the fourth joint much narrower than the third, rather longer than the fifth; the fifth much narrower than the fourth, tapering to a very small sharp nail, which looks like the sharp point of a pencil cut with a narrow stalk.

Pleopods small in proportion to the size of the animal; the peduncles large in proportion to the rami, filled with strong muscles, the general appearance oval, but the front margin flattened, the hind margin double, strongly convex, the rim of the outer surfacee projecting a little beyond that of the inner; the coupling spines two in number, very short, the apex forming a circular cap of retroverted hooks; on one of the peduncles there were three coupling spines, but this might be abnormal; the eleventh spine having a broad subapical dilatation of the longer arm; the joints of the rami numbering from eleven to thirteen or fourteen, the inner ramus slightly the longer but with fewer joints.

Uropods.—Peduncles of the first pair considerably longer than the rami, both the upper edges pectinate, the outer margin at the base folded on to the upper surfacee; below there is a central longitudinal ridge or carina, with another on either side of it; the inner ramus is longer than the outer, with a narrower neck, and reaches back a little beyond the third uropods; both rami are acutely lanceolate, with pectinate edges, and carinate below; the outer edge of the outer, and the inner of the inner, nearly straight; the peduncles of the second pair widen till they reach the base of the rami, not extending quite to the base of the telson, on the inner side terminating in a small sharp point; the outer ramus is the shorter and much the narrower; the inner, which does not reach so far as the apices of either of the other pairs, is firmly coalesced with the peduncle, broadly lanceolate, acute, and like its fellows pectinate and ridged; the third uropods

are constructed like the second but are smaller, the peduncle proper about half the length of the telson.

Telson long, lanceolate, very acutely pointed, reaching just beyond the first uropods, the edges pectinate; the length is about equal to that of the preceding double segment, to which it is itself firmly coalesced.

Length.—The specimen, in the position figured, measured, in a straight line from the tip of the rostrum to the back of the second pleon-segment, seven-twentieths of an inch.

Localities.—Station 104, August 23, 1873; Equatorial Atlantic; lat. $2^{\circ} 25'$ N., long. $20^{\circ} 1'$ W.; surface to 100 fathoms; surface temperature, 78° . One specimen, female with eggs.

Station 347, April 7, 1876; Equatorial Atlantic; lat. $0^{\circ} 15'$ N., long. $14^{\circ} 25'$ W.; surface; surface temperature, 82° . One specimen, with a shorter rostrum.

Remarks.—The specimen above described is undoubtedly the same as Claus' *Oxycephalus piscator*. Claus gives for the synonymy of his species "*O. piscator* Edw., Ann. scienc. nat. l.c. [xx. p. 396] 1830. *O. oceanicus* Guérin, Mag. de Zool. l.c. [t. vi. Cl. vii.] 1836. *O. tuberculatus* Sp. Bate, Catalogue of the spec. etc. 1862. *O. tuberculatus* Streets, Proceedings of the Acad. of Nat. Sciences of Philadelphia 1878." It is quite possible that the specimens referred to, or some of them, may belong to the present species, but the evidence is defective. Guérin's species is apparently smooth-bodied and is said to have the telson longer than the preceding segment; in the Brit. Mus. Catal. Amph. Crust., pl. liv., figure 3. *s.t.u.z.* is probably taken from Guérin and by accident wrongly numbered as if belonging to *Oxycephalus piscator*, M.-Edw.; Milne-Edwards does not say that his species is tuberculated, nor does he show the character of the margins of the first three pleon-segments, a character which separates the species above described from *Oxycephalus edwardsii*, G. M. Thomson. *Oxycephalus tuberculatus*, Spence Bate, is figured as though the margins of the pleon-segments were not excavate, the fifth peraeopods are stated to be rudimentary, not so long as the first joint of the preceding pair, and the second uropods are said to have the margins of the rami smooth. Under the circumstances it seems necessary to adopt the name *Oxycephalus clausi*, Bovallius, both for the specimen here described and for those specimens which Claus has named *Oxycephalus piscator*, since the diagnosis given by Bovallius for *Oxycephalus clausi* is in essential agreement with the specimens in question, whereas the accounts accompanying the earlier names either differ from these specimens or leave points of importance undetermined. Bovallius assigns to Spence Bate's species from the Cape of Good Hope, "rami of second pair of uropoda serrated," but this is probably only a misprint for "not serrated." As the habitat of Milne-Edwards' species Bovallius gives "Atlantic, Mediterranean, Indian Ocean, Pacific," while Milne-Edwards only says "Parait avoir été trouvé dans l'océan Indien."

Oxycephalus clausi, Bovallius (?), (Pl. CCII.).

The rostral tract of the head much shorter than the ocular, with the edges scarcely serrate ; the head only slightly constricted at the base ; a faintly marked central carina along the back of the head and peræon, tuberculated along the peræon, and accompanied by two similar lines at intervals on either side ; the first three segments of the pleon have the lateral carinæ less conspicuous, the remaining segments being apparently without them ; the first segment of the pleon is the largest, the next three successively diminishing in length and depth ; the postero-lateral angles of the first three segments produced into a short sharp point, behind which, at some distance, the hind margin forms a similar point, from which in the third segment, it runs forward parallel to the lower margin ; the margins serrate near the produced points.

Eyes large, nearly twice as long as the portion of the rostrum beyond them, not meeting at the top of the head.

Upper Antennæ with their bases in front of the eyes, pointing backwards as they lie in the ventral cavity of the head ; the peduncle broad, the first joint widening from the base, scarcely longer than its greatest breadth ; the second joint as wide as the first, only about a third as long ; the first joint of the flagellum apically tapering, much longer than the peduncle, with transverse rows of filaments ; the three following joints linear, bending outwards, much shorter than the first joint, the second joint about equal in length to the two following united, much broader, with a setule near the apex on the outer side ; the third joint not half the length of the fourth ; the fourth tipped with three setules.

Lower Antennæ consisting of four stout joints folded upon one another, the first a little longer and stouter than either of the two following, the fourth a good deal shorter and thinner ; the first three widen a little distally with a slight curve, the fourth distally becomes narrow and straight, then tapering to a rounded end. This form does not represent the full development of these organs.

Mandibles small, of the same form as in the female, but with a palp, of which the first joint is not quite so long as the last of the lower antennæ, longer than the second and third joints together ; the second shorter than the third ; the third tapering to an acute apex, curving inwards.

Maxillipeds small, the outer plates not reaching far beyond the inner one.

First Gnathopods much smaller than the second, yet not so much so as in the Atlantic specimen, with which in general they agree.

Second Gnathopods similar to those of the Atlantic specimen, but the long hind process of the wrist has an almost smooth margin facing the hind margin of the hand, most of which is finely serrate ; the hand is as long as the front margin of the wrist. In the female specimen the process of the wrist has the inner margin tuberculated as in the

Atlantic specimen, though far less strongly ; the smoothness of the margin in question is probably a juvenile character.

First and Second Peraopods similar to those of the female already described. The branchial vesicles of these and the two following pairs having short transverse pockets or folds.

Third Peraopods differing from those of the previous description chiefly in the first joint which is elongate oval, more convex at the finely serrate hind margin than at the front, which is armed with two or three spinules in the upper part, and serrate at six points in the lower, the breadth being about the same at the proximal and distal ends.

Fourth Peraopods differing from those of the Atlantic form in the first joint, which is rather pear-shaped than circular, a little shorter than the first joint of the third pereopods, much broader above, but at the distal end a little narrower, both margins strongly convex at the upper part, especially the hind margin, the front margin in the lower half tending rather to concave, serrate at six or seven points.

Fifth Peraopods.—The pear-shaped first joint shorter as well as much narrower than that of the fourth pereopods, less strikingly narrowed before reaching the distal end than in the Atlantic specimen. The remaining joints feeble, together much shorter than the first ; the third not greatly longer than the fifth, the fifth a little longer than the fourth ; the nail very small, spine-like. In the female specimen these limbs are very nearly as in the Atlantic specimen, but the first joint has not the narrowed distal part so much prolonged.

Pleopods similar to those already described.

Uropods similar to those of the Atlantic form, but with the inner ramus of the first pair reaching just beyond the telson, the inner apex of the third pair being almost or quite level with the apex of the telson.

Telson shorter than the double segment, with which it is coalesced, not nearly twice as long as broad ; the lateral margin smooth or nearly so above, strongly pectinate below ; the apex acute. In the female specimen more elongate, yet not quite so long as the preceding segment.

Length.—The female specimen from which the full figure was taken, measured, in the position figured, in a straight line from the apex of the rostrum to the distal end of the first uropods, almost three-quarters of an inch, the full length when extended being rather over an inch. The male specimen from which the details were drawn was a good deal smaller, measuring about half an inch in a slightly bent position.

Locality.—July 1875, North Pacific, between Japan and Honolulu ; surface. Four specimens.

Remarks.—It will be noticed, as an example of the correlation of parts, that the short telson in the specimen here described goes with a short rostrum, as in the Atlantic

specimen a longer telson with a longer rostrum, but these parts are certainly variable within the species. It would no doubt be possible to make out a case for distinguishing the Pacific from the Atlantic specimens as different species, and on the other hand something might be said for grouping both sets under the name *Oxycephalus tuberculatus*, Spence Bate, or the older and still more vague title, *Oxycephalus piscatoris*, Milne-Edwards; another species, *Oxycephalus edwardsii*, G. M. Thomson, 1884, makes a very close approach to the forms which are here described, but there are some differences in the gnathopods, the first joint of the fifth peræopods is particularly slender, and the double segment in the pleon is very decidedly longer than the telson in Mr. Thomson's species.

A plate with the signature "R. v. W. del" contains the two figures, of which reduced copies are here given:—

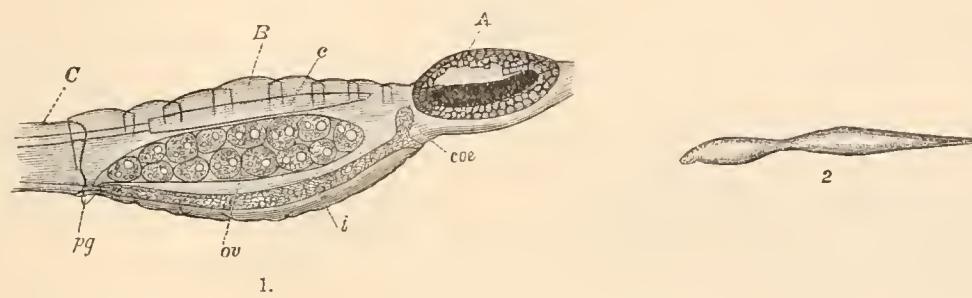

Fig. 29.

The accompanying explanation is:—

"Fig. 1. Thorax des ♀.
 A Kopf.
 B Thorax.
 C Abdomen.
 c Herz.
 coe Cœcum.
 i Darm.
 pg papilla genitalis.
 Fig. 2. Hoden des ♂."

It will be observed that the papilla genitalis of the female is placed in the seventh segment of the peræon instead of in the fifth as might be expected, but this is probably an error. The figures do not suffice to determine what species of *Oxycephalus* was under examination; apart from their scientific value, they have a special interest as being the work of the young and ardent naturalist who closed his life on board the Challenger, during the voyage to which he had looked forward with so much eager enthusiasm.

Another plate by von Willemoes Suhm contains the following figures:—

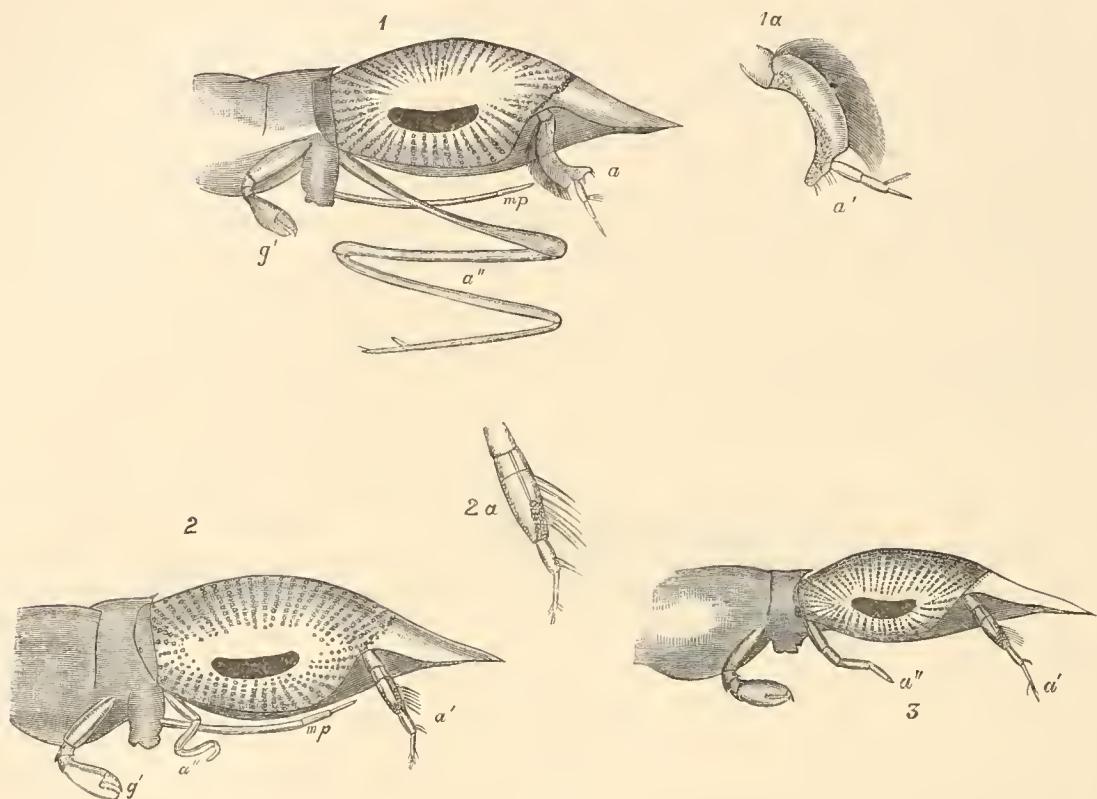

Fig. 30.

The account accompanying these figures is as follows:—

"*Oxycephalus oceanus* Guérin, 12–20 Febr. 75. Western Pacific, Nordküste von Neu-Guinea.

a' erste } Antenne.
a'' zweite }

mp. palpus mandibul.

g' erster Gnathopod.

Fig. 1. Kopf eines alten ♂ aus der melanesischen See.

Fig. 1a. Erste Antenne H. [Hartnack] 1/7.

Fig. 2. Kopf eines alten ♀.

Fig. 2a. Erste Antenne desselben H. 1/7.

Fig. 3. Kopf eines jungen ♀, das aber schon geschechtsreif. Zweite Antenne hat sich noch nicht zusammengelegt."

It is clear that all three figures are taken from male specimens, and from the nature of the case the name given them could only have been conjectural.

Oxycephalus porcellus, Claus (Pl. CCIIL.). Specimen A.

1879. *Oxycephalus porcellus*, Claus, Die Gattungen und Arten der Platysceliden, p. 48.
 1887. " " Bovallius, Systematical List of Amph. Hyper., Bilang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 36.
 1887. " " Claus, Die Platysceliden, p. 72, Taf. xxiv. figs. 7-9.

Head rather longer than the peraeon, thick at the base; the rostrum much less acute when seen from above than appears from a lateral view, shorter than the ocular region, the edges smooth; the first three segments of the pleon with the postero-lateral angles acute, a little produced; the fourth pleon-segment dorsally as long as the following composite segment measured to the base of the third uropods; the composite segment ventrally produced to the rami of the third uropods.

Eyes occupying the sides of the head to the base of the rostrum.

Upper Antennæ.—Peduncle short, the first joint not longer than broad, the second incompletely developed; first joint of flagellum long, curved, with a broad brush of filaments, the upper margin slightly concave, with the apex rather strongly but not extravagantly produced upwards; the small second joint a little longer and broader than the third, each with a small apical group of filaments; the fourth joint linear, a little longer than either of the preceding, tipped with setules.

Lower Antennæ.—Third (first free) joint of the peduncle very long, curved, distally dilated; fourth joint longer than the third; fifth a little longer than the fourth; first joint of the flagellum slender, fully as long as the third joint of the peduncle; terminal joint minute; the three joints of the peduncle and the first of the flagellum all closely fringed with short filaments, and the terminal joint tipped with them.

The Epistome appears to be helmet-shaped, with an *Upper Lip* of great tenuity, transversely oval, but a little excavate on the lower margin.

Mandibles.—Trunk very short compared with the palp; cutting edge with a produced tooth at the top, the rest of its margin straight, finely denticulate, the left mandible having a shallow secondary plate, with its edge nearly as long as that of the principal, the right mandible having a minute tubercle to the rear of the cutting plate; the first joint of the palp between three and four times as long as the two following joints together; the second joint a little longer than the third, the two together forming a hook, both much narrower than the first joint.

Maxillipeds small, the inner plate widening distally, with the usual embedded spinules at the centre of the front margin, the outer plates broad, with their broad apices almost meeting over the inner plate.

First Gnathopods.—The side-plates with the lower front angle produced forwards, almost acute, having a ridge on the under surface running to the apex. The first joint a little widened below the neck; the second joint scarcely so long as broad; the third distally widened, broader than long, with a subapical spine on the convex hind margin;

the wrist very broad, the greatest breadth a little less than the length; the produced part much broader than long, distally denticulate with eleven teeth, of which the central one is the longest, forming a kind of apex; the hinder margin is very faintly serrate and pectinate, and there are numerous spines of various sizes upon the inner surface, chiefly on or near the produced part, some of them being shown in the figure *gn.*¹ as seen through the partially transparent joint; the hand not nearly half as broad as the wrist, the length not equalling the wrist's greatest breadth; there are three spines on the lower part of the very convex front margin; the hind margin slightly concave or nearly straight, having a low serration alternating with sharp and distinct but little teeth, the adjacent inner surface set with numerons spines, and the apex produced nearly halfway along the finger; the finger slender, curved, more than half the length of the hand.

Second Gnathopods.—The side-plates convex in front. The wrist much larger than in the first pair, the hind margin much longer than the front, forming an acute apex, the distal margin oblique, very long, finely and regularly denticulate, the hind margin and inner surface carrying several slender spines; the hand longer than in the first gnathopods, scarcely so broad, its length not equalling the breadth of the wrist, having numerous spines on the inner surface; it is bent at the neck, below this the hind margin being slightly convex, dentieulate, the apex not projecting much behind the finger; the finger slender, curved, acute, considerably more than half the length of the hand, having a little tooth on the inner margin.

First Peraopods.—First joint with narrow neck, the front margin coneave; the seeond joint longer than broad; the third about as long as the fourth but broader, with a few small spines on the hind margin, which excepct near the base is straight; the fourth shorter but much broader than the slender fifth; the finger more than half the length of the preeeding joint.

Second Peraopods like the first, but the fifth and perhaps one or two other joints longer; the finger not half the length of the preeeding joint.

Third Peraopods.—The side-plates having a very narrow backward-directed proceess on the inner side. First joint about twice as long as the greatest width, which is a little above the centre, the front margin nearly straight, the hinder very eonvex; the second joint bent; the third rather longer than the fourth, each with slender spines along the front margin; the fifth joint slender, slightly curved, much longer than the third joint, the concave front margin fringed with a few spinules and minutely furred; the finger slender, rather more than a fourth of the length of the fifth joint.

Fourth Peraopods.—First joint not longer but much broader than in the preeeding pair, with very convex hind margin; the third joint longer than the fourth, strongly pectinate along the front margin, which is produced into a little apical lobe also pectinate and carrying a little spine; the fourth joint longer than the fifth, peetinate along the front margin, having a little spine not far from the apex which with the under surface of

the distal margin is more finely pectinate than the upper part of the joint; the fifth joint decurrently pectinate with teeth of various sizes along the front margin and with slender close-set teeth round the apex; the finger straight, acute, half the length of the preceding joint.

Fifth Peraopods.—First joint shorter than in the third peraeopods but not less broad, longer than the following joints together, the hind margin irregularly convex; the second joint as broad as the third, not longer than broad; the third a little longer than the fourth; the fourth rather longer than the fifth, slender, tapering; the finger minute, straight.

Pleopods.—The coupling spines very small, the arms of the eleventh spine short, and the subapical dilatation small; the joints of the rami about twelve in number.

Uropods.—Peduncles of the first pair rather longer than the rami, three-sided; the rami long, equal, three-sided, pectinate on two edges, reaching nearly to the apex of the telson; peduncles of the second pair much shorter than those of the first, shorter than the rami; the rami broadly lanceolate, the outer a little shorter than the inner, which is as long as those of the first pair, the edges pectinate below; the peduncles of the third pair little longer than broad, shorter than the rami; the outer ramus a little shorter and much narrower than the inner, the edges pectinate, more loosely on the outer than on the inner margin.

Telson triangular, much longer than broad, if reckoned from the base of the third uropods, the apex acute; the telson forms a shield under which the rami of the third uropods are neatly packed away, the rami in this position covering its whole under surface except the narrowed apex and a small triangular space at the base.

Length, a little over half an inch.

Locality.—South Pacific, between Api and Cape York; surface. One specimen, male.

Remarks.—Claus' specimen from Zanzibar was a female not fully adult, 8 mm. in length, and differing from the Challenger specimen in not having the hind margin of the hand of the first gnathopods produced along the finger, and in having the fifth peraeopods relatively much smaller, but in other respects the two specimens are so closely alike that it seems undesirable to separate them specifically. It is possible that this species may be the same as Guerin's *Oxycephalus oceanicus*, or that species may be the same as Claus' *Oxycephalus similis*, but it is not possible, I think, to determine such questions.

Oxycephalus porellus (Pl. CCIV., A). Specimen B.

Head as long as the peraeon, rostrum acute, nearly as long as the ocular region of the head, its margins sparsely and shallowly serrate; the coalesced fifth and sixth segments of the pleon not so long as the telson, but broader.

Upper Antennæ.—First joint of peduncle not very broad, second short; first joint

of flagellum longer than the peduncle, tapering, carrying some groups of filaments, the two following joints slender, small.

Lower Antennæ not fully developed.

Mandibles.—The palp small, almost straight, the jointing not fully developed.

First Gnathopods.—The side-plates with the lower front corner produced, rounded. The first joint reaching considerably below the side-plate; the third joint broader than long, with a slender spine at the apex of the convex hind margin; the wrist broad, with numerous spines on the inner surface, the hind margin very finely pectinate, the distal process broad, not very long, with three graduated teeth on each side of the long central one which is the longest and most produced; the hand in close agreement with that described for *Oxycephalus porcellus*, Claus, from the Pacific.

Second Gnathopods showing only such points of difference from those of the specimen just mentioned as might be expected in a younger specimen, the wrist having fewer spines, being less broad, with fewer teeth on the inner or front margin of the wrist's process; the denticulation of the almost straight hind margin of the hand is very similar without being absolutely alike in the two specimens.

First Peræopods.—Third joint shorter than fourth; fourth shorter but much wider than fifth. The peræopods in general as in the other specimen, but with fewer spinules, the finger in the third pair more than a third the length of the preceding joint, and in the fourth pair more than half.

Pleopods.—Cleft spine having an unsymmetrical subapical dilatation to the longer arm; eight joints to each ramus.

Uropods.—Peduncles of the first pair scarcely as long as the rami, which are sub-equal, with serrate margins, the inner slightly the longer, reaching as far back as the outer ramus of the third pair; peduncles of the second pair much shorter than those of the first, shorter than the rami; the rami rather shorter than those of the first pair, the outer narrower and a little shorter than the inner, the edges for the most part pectinate; peduncles of the third pair longer than broad, shorter than the rami; the outer ramus a little shorter and much narrower than the inner.

Telson more than twice as long as broad, the greatest breadth some distance below the base, the sides being convex at first, finally converging to a very acute apex that reaches beyond the uropods.

Length, at full stretch, about three-tenths of an inch.

Locality.—Station 106, August 25, 1873; Equatorial Atlantic; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; surface to 40 fathoms; surface temperature, $78^{\circ}.8$. One specimen, young male.

Remarks.—The narrower base of the telson and the narrower wrist of the second gnathopods as well as the smaller number of teeth in the wrist process of the first

gnathopods, may prove to be characters sufficiently constant to warrant the establishment of a distinct species, but in the meantime, as the specimen is not adult, the separation of it from the older species may await further information.

Oxycephalus longiceps, Claus (Pl. CCIV., B).

1879. *Oxycephalus longiceps*, Claus, Die Gattungen und Arten der Platysceliden, p. 48.
 1887. " " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 37.
 1887. " " Claus, Die Platysceliden, p. 72, Taf. xxiv. fig. 10.

Head considerably longer than the peræon, not showing any constriction at the neck while in position, the rostrum acute, not very much shorter than the ocular region, the edges smooth; the coaleseid fifth and sixth segments of the pleon about as long as the telson and scarcely broader, the postero-lateral angles of the first three pleon-segments acute, not much produced.

Upper Antennæ attached a little in advance of the eyes, straight in the specimen; the first joint of the peduncle more than twice as long as the second; the first joint of the flagellum a little longer than the first of the peduncle, narrowing distally, with a few apieal and subapieal filaments, the second joint not half the length nor nearly half the breadth of the first, the third as long but only half as broad as the second.

Lower Antennæ (of the young male), the three free joints of the peduncle subequal, short, smooth, comparatively thick, closely folded, indistinctly jointed; the flagellum of one joint, tapering, not acute, nearly as thick as the peduncle, but shorter than any of its joints.

Mandibles.—The palp not as yet distinctly jointed.

First Gnathopods.—Side-plates with the lower front angle acute, not produced. The first joint reaching a little below the side-plate; the second joint broader than long, with one subapical spinule on the convex hind margin; the third joint little longer than the second, distally widened, with three spinules on the convex hind margin; the wrist much longer and broader than the hand, with numerous spines on the inner surface and along the minutely peetinate hind margin, which is apically only a little outdrawn but into a very acute point; the hand with numerous spines on the inner surface, the front margin very convex, the hinder nearly straight and smooth, with a little apical tooth; the finger short, very acute.

Second Gnathopods.—Side-plates with the lower front angle acute and a little outdrawn. The branchial vesicles simple. The third joint considerably longer than the second, with one spinule at the apex of the hind margin; the wrist much more widened than in the first pair, with few spines on the inner surface and hind margin, the latter apically outdrawn almost to the end of the hand, the process at first broadly triangular,

but the apex linear, spine-like; the hand longer than in the first pair, longer than the front margin of the wrist, with eight or nine spines on the inner surface, and three or four little spinules adjacent to the hind margin which is smooth and nearly straight; there is here no toothed apex or palmar margin. The finger curved, acute, not half the length of the hand, having above the centre a little spinule on the inner margin.

First Peraopods.—First joint slender, curved; second joint longer than broad, with one spinule on the hind margin; third longer than fourth, which is only a little wider than the fifth and scarcely shorter; the finger about a third of the length of the fifth joint; the third joint has two slender spines on the hind margin, the fourth four, the fifth two.

Second Peraopods like the first, but with the fifth joint longer, the finger only a fourth of the length of the preceding joint.

Third Peraopods considerably the longest; the side-plates with a tongue-shaped process on the inner surface; the brachial vesicles with a constriction near the narrowed apex; the first joint not greatly widened, widest at the centre, the hind margin convex, the front almost straight; the second joint short, with rounded front apex; the third considerably longer than the fourth and a little longer than the fifth; the finger about a quarter as long as the fifth joint, slender like the three preceding joints.

Fourth Peraopods.—First joint as long as in the preceding pair, at the upper part considerably wider, the hinder apex rounded, produced behind the short second joint; the third joint considerably longer than the fourth or fifth, with the front margin and apex strongly pectinate; the fourth joint shorter than the fifth, both pectinate along the front, but much more delicately than the third joint; the finger nearly straight, very acute, more than a third of the length of the fifth joint.

Fifth Peraopods.—Side-plates with rounded angles, partly distinct from the segment. The limb longer, if outstretched, than the first joint of the preceding pair; the first joint not very widely expanded, longer than the remaining joints together; of these the third is the longest; the finger minute, spine-like.

Pleopods.—The cleft spine with short arms, that with the subapical dilatation the longer; the joints of the rami six in number.

Uropods.—Peduncles of the first pair reaching to the base of the telson, rather longer than the rami; the slightly longer inner ramus reaches as far back as the apex of the outer ramus of the third pair; the edges of all the rami are pectinate with long decurrent teeth; the peduncles of the second pair are longer than the outer, shorter than the inner, ramus; the inner ramus is subequal to those of the first pair; peduncles of the third pair much longer than broad, shorter than the rami, the inner margin having a little apical tooth; the outer ramus is shorter and narrower than the inner.

Telson fully twice as long as the breadth at the base, triangular, with gently convex sides, the produced and sharply pointed apex reaching a little beyond the uropods.

Length, fully extended, two-fifths of an inch.

Locality.—July 4, 1875, North Pacific; lat. $36^{\circ} 42'$ N., long. $179^{\circ} 50'$ W.; surface, night; surface temperature, $69^{\circ}\cdot2$. One specimen, young male.

Remarks.—Claus' specimen from Zanzibar was a young male, only 6 mm. in length; the representation of the first gnathopods in Claus' figure is not suitable to those of the Challenger specimen, but, as they are not separately figured, I have not allowed this difference to outweigh the general agreement between the two forms.

Genus *Leptocotis*, Streets, 1877.

- 1871. *Oxycephalus (pars)*, Claus, Unters. über den Bau und die Verwandschaft der Hyperiden, Nachrichten K. Gött. Soc., p. 155.
- 1877. *Leptocotis*, Streets, Bulletin U.S. Nat. Mus., No. 7, p. 136.
- 1878. " Streets, Proc. Acad. Nat. Sci. Philad., p. 283.
- 1879. *Oxycephalus (pars)*, Claus, Die Gattungen und Arten der Platysceliden, p. 48.
- 1887. *Leptocotis*, Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 38.
- 1877. *Oxycephalus (pars)*, Claus, Die Platysceliden, p. 71.

For the original definition of the genus, see Note on Streets, 1877 (p. 470). In the definition given the following year Dr. Streets omits the statement that the constricted portion of the head is "not narrower than the thorax," and applies the term "thoracic legs" to the gnathopods and pereopods in common, instead of to the pereopods alone as in the earlier definition. The first species clearly known of this genus is Claus' *Oxycephalus tenuirostris*, which Claus retains under *Oxycephalus*, making *Leptocotis spinifera*, Streets, a synonym of it. The differences, indeed, between *Oxycephalus* and *Leptocotis* as defined by Dr. Streets resolve themselves almost entirely into the comparative stoutness of the former and slenderness of the latter genus. Of *Oxycephalus* Dr. Streets says, "body moderately long, robust; head narrow, produced anteriorly in a broad, triangular rostrum, short, grooved below;" "the last three pairs [of Peræopods] with the basal joint broadly dilated;" "the sixth abdominal segment broad, not elongated; the caudal appendages short, broadly lanceolate; telson broadly triangular." For *Leptocotis* he says, "body long and slender; head produced anteriorly to the superior antennæ in a long, slender rostrum;" "the last three pairs [of Peræopods] with the basal joint dilated;" "the sixth abdominal segment (the fifth and sixth fused) elongated; the caudal appendages long, linear; telson long, triangular at apex." In regard to *Oxycephalus* he also says, "extremity of the sixth pair [Fourth Peræopods]—articulating with the broad basal joint—finely serrated along the anterior margin," but this equally applies to *Leptocotis*. Of *Leptocotis* he says that the upper antennæ are "curved in the male," but this also applies to

Oxycephalus. He does not mention the extreme development of the upturned apex of the first joint of the flagellum in the male upper antennæ of *Leptocotis*, except in the description of the type-species; nor would the character be of much use, since it probably only belongs to a limited portion of the animal's life.

Leptocotis ambobus, n. sp. (Pl. CCV.).

Head as long as peræon with the first two segments of the pleon, the neck depressed, more than half the total length of the head in front of the eyes, the rostral tract in front of the upper antennæ narrow and slightly arched, rather more than a third of the total length of the head; the first three segments of the pleon with the lower margins finely serrate, the postero-lateral angles of the first two segments not outdrawn, but those of the third segment much outdrawn and acute, those of the fourth segment acute, but only little outdrawn; the double segment elongate, with sharp lateral edges and two dorsal ridges traversing its whole length.

Eyes not nearly reaching the point at which the upper antennæ are inserted, the front ocelli the smallest, the ocular pigment long, but the principal point from which the ocelli appear to radiate situated low down and much behind the centre of the eye.

Upper Antennæ attached considerably in advance of the eyes, at about a fourth of the whole distance between these and the apex of the rostrum; the first joint of the peduncle much longer than broad, the second short and imperfectly developed; the first joint of the flagellum very much longer than the peduncle, the convex side carrying a thick brush of filaments, the apex upturned at a right angle with the main portion of the joint, forming a prominent, tapering process with a few filaments on the almost straight outer margin; the three following joints are very small and narrow, lying back against the first joint, in line with the apical process, but pointing in the opposite direction.

Lower Antennæ.—The third (first free) joint of the peduncle elongate, curved near the base, distally thickened, fringed with short filaments; the fourth joint a little but decidedly longer than the third, more slender, with each end a very little thickened; the fifth joint of about the same length as the fourth; the first joint of the flagellum very slender, nearly as long as the third joint of the peduncle; the second joint minute, with the fringing filaments only at two points.

Epistome apparently almost semicircular in outline, but bent so that the two divisions of the front surface produce an angular projection down the centre.

Mandibles.—The trunk very short compared with the length of the palp; the secondary plate on the left mandible similar to the principal, but smaller; the first joint of the palp slender, a little shorter than the first joint of the flagellum of the

lower antennæ, more than three times as long as the two following joints together, which are subequal to one another, and curved so as in combination to be sickle-shaped.

Maxillipeds.—The inner plate short and broad, with the usual pair of embedded spinules at the centre of the distal margin, the outer plates apically narrowed. Between the mandibles and maxillipeds there is a space which is certainly not empty, and may be presumed to contain the other mouth-organs though in a more or less rudimentary condition.

First Gnathopods.—The side-plates with the lower front corner produced forwards, well rounded. The first joint scarcely or not reaching below the side-plates, widened at the centre for the gland-cells; the second joint broader than long; the third joint longer than the second, but small, with a spinule at the apex of the hind margin; the wrist large, widening to the attachment with the hand, the hinder process broadly triangular, with a spine-like apex, both margins of the process being finely denticulate, the hind margin of the wrist carrying in all about a dozen denticles and the inner margin half a dozen; the hand narrow at the neck, with very convex front margin, the hind margin nearly straight and when the hand is closed upon the wrist not reaching the tip of its spine-like apex; the hand is broader distally than at the neck, the little palm being cut into two denticles; the finger is very small and slender, yet more than half the length of the hand, reaching a little beyond the palm, and having a small denticle on the inner margin; there are spinules on the surface of both hand and wrist, but they are not very conspicuous.

Second Gnathopods longer than the first; the side-plates widened below. The first joint longer and more slender than in the first pair; the wrist also longer and with the process more withdrawn so as to make the limb complexly chelate rather than subchelate, the denticles on the hind margin not so closely set; the hand longer than in the first pair, with the palm margin cut into three or four denticles; the finger not more than half the length of the hand.

First Peraopods with all the joints slender, the third a little longer than the fifth and both considerably longer than the fourth. The gland-cells conspicuous in the first and third joints.

Second Peraopods like the first, but with longer joints, and the fifth longer than the third.

Third Peraopods.—The hind lobe of the side-plates deeper than the front and deepest just behind the attachment of the first joint, the inner process being almost linear. The first joint longer than the three following together, widest a little below the base, the front margin nearly straight, the convexity of the hind margin little developed except above; the third joint much longer than the fourth, about equal in length to the much narrower and slightly curved fifth; the front margin of the third

and two following joints faintly furred; the slender, slightly curved, and very acute finger more than a third the length of the fifth joint.

Fourth Peraopods.—The first joint broader than in the preceding pair and nearly as long, with some convexity of the front as well as of the hind margin, which is produced beyond it both above and below; the third joint elongate, as long as the remaining three together, pectinate with retroverted teeth along the front margin and its slightly produced apex; the fourth joint shorter than the fifth, both pectinate; the finger short, straight, acute.

Fifth Peraopods.—The side-plates with the hinder angle a little produced, rounded. The first joint about two-fifths as long as the first of the third pereopods, as broad as the length, about one and a half times as long as the feeble remaining joints together; the second joint with very convex front margin; the third joint also with convex front; the fourth much narrower but only a little shorter than the third; the fifth a little longer than the third; the finger minute, sharp-pointed.

Pleopods.—Coupling spines slender in the shaft, with the usual denticulate caps; the cleft spine with unsymmetrical subapical dilatation of the longer arm; the joints of the rami eight or nine in number.

Uropods.—Peduncles of the first pair subequal in length to the double segment, three-edged, the inner margin more closely denticulate than the outer, nearly two and a half times as long as the long outer ramus, which is also three-edged, denticulate, and finely pectinate; the inner ramus only about a quarter the length of the outer; the peduncles of the second pair very similar to those of the first and not much shorter, rather more than twice as long as the inner ramus; the outer ramus about three-quarters the length of the inner, both of them denticulate and pectinate; the peduncles of the third pair longer than broad, coalesced with the inner ramus, the inner margin of which is much more strongly denticulate and pectinate than the outer; the outer ramus is less than half the length or breadth of the inner, with pectinate teeth on the inner margin, the outer margin smooth.

Telson coalesced with the preceding double segment of which it is less than half the length, its breadth at the base about a third of the length, the apex very acute and outdrawn considerably beyond the uropods.

Length of the outstretched animal eleven-twentieths of an inch.

Locality.—Station 287, October 19, 1875; South Pacific; lat. $36^{\circ} 32' S.$, long. $132^{\circ} 52' W.$; surface; surface temperature, $57^{\circ} 8$. One specimen, male.

Remarks.—This species comes exceedingly near to *Leptocotis (Oxycephalus) tenuirostris*, Claus, and to *Leptocotis lindströmi*, Bovallius, hence the specific name. Claus says that in his species the postero-lateral angles (die Seitenflügel) of the pleon-segments are unarmed, yet he figures that of the third segment sharply pointed, as

it is in the present species, and as Streets states it to be in his *Leptocotis spinifera*, since regarded as a synonym of Claus' species. Streets also says that the inferior margins of the first three segments of the pleon are finely serrated, and they are so in the present species. Claus says that the coalesced fifth and sixth segments are three to four times as long as the telson, here they are little more than twice as long; the peduncles of the first and second uropods, he says, are four to five times as long as the rami, while here they are only a little more than twice as long. Of the diminutive inner ramus to the first, and diminutive outer ramus to the third, uropods, neither Claus nor Streets make any mention. The character of the afterpart of the pleon brings the species near to Bovallius' species, but in that the second gnathopods as well as the first are said to be subcheliform, whereas in our species the second pair deserve to be called chelate; again Bovallius states that the fifth pereiopods are in his species a little shorter than the first joint of the fourth pair, a description which would not naturally be applied to the very short fifth pereiopods of the present species, in which the first joint is as broad as long, considerably less than half as long as that of the preceding pair, but much longer than the upturned remaining joints. Streets says in the description of *Leptocotis spinifera*, "the last pair of legs diminutive, not half as long as the basal joint of the preceding," but he is perhaps only taking into account the first joint, not considering what the total length of the limb would be with the remaining joints outstretched.

Claus' species was taken in the Gilolo-Passage; Streets' specimen in the "North Pacific Ocean. Latitude 29° north; longitude 157° west;" Bovallius' species was taken in "tropical parts of Atlantic." It is possible that, notwithstanding some differences in the specimens and descriptions, *Leptocotis tenuirostris*, *Leptocotis spinifera*, *Leptocotis lindströmi*, and *Leptocotis ambobus* may be the synonyms of a single species, but this must be left for future research to decide.

A plate with the signature "R. v. W. del" contained the figures here reproduced on a smaller scale:—

Otolith (ot) mit seinem Nerven."

It may be presumed that at least fig. 2 belongs to the genus *Leptocotis*, but to which of the specific names it should be assigned cannot be decided from the figure of the head alone. That which v. Willemoes Suhm designates as the shaft or peduncle of the upper antennæ includes what is here considered to be the first joint of the flagellum, the letter *x* in the figure being at the almost monstrously upward-produced apex of that joint.

Leptocotis mindanaonis, n. sp. (Pl. CCIV., C).

Head as long as the peræon and first four segments of the pleon, the neck narrow, ocular region dilated, rostrum curved, acute, narrowly elongate, yet not nearly so long as the remainder of the head, with a line of orange spots along each side, its margins a little serrate near the eyes, smooth near the apex; the third segment of the pleon with the postero-lateral angles acutely produced, the first and second having these angles squared; the coalesced fifth and sixth segments considerably longer but very little wider than the telson.

Upper Antennæ.—The first joint of the flagellum considerably longer than the small two-jointed peduncle, its upper margin carrying four sets of filaments; the two terminal joints minute.

The Gnathopods nearly as in *Oxycephalus longiceps*, Claus, but with the wrist in the second pair less dilated, longer in proportion to the breadth, and the spine-like apex of the process not nearly reaching the apex of the hand.

First and Second Peræopods with slender joints.

Third Peræopods.—The side-plates with a short and narrow inner process, not of uniform breadth. The branchial vesicles with a constriction near the narrowed apex. The first joint slenderly pear-shaped, the greatest width being near the base; the third

joint longer than the fifth; the fifth than the fourth; the finger straight, about a fifth of the length of the preceding joint.

Fourth Peraopods.—The third joint as long as the fourth and fifth together, all three pectinate along the front margin, the third having large teeth alternating with sets of three or sometimes two or four minute ones, at the slightly produced apex having only little ones.

Fifth Peraopods.—The rounded end of the side-plate is separated from the segment by an open notch. The first joint is as broad and as long as in the preceding pair, as long as all the remaining joints together; the third is slender, straight, longer than the fourth; the fourth about equal to the fifth; the finger straight, very minute.

Pleopods.—The peduncles not very stout; in the cleft spine the subapical dilatation is unsymmetrical, the arm that carries it reaching a little beyond the other; the joints of the rami six in number, the first joint long.

Uropods.—Peduncles of the first and second pairs elongate, longer than the rami, reaching back nearly on a level; the rami having the margins pectinate with long decurrent teeth; the rami of the first pair equal, in the second pair the outer ramus a little shorter than the inner, the latter reaching a little beyond the rami of the first pair, but not so far as either apex of the third pair; peduncles of the third pair a little shorter than the rami, about a third as long as the peduncles of the first pair; the outer ramus shorter than the inner, the edges of both pectinate like those of the other pairs.

Telson three times as long as broad, with a very acute apex reaching beyond the uropods. The telson and uropods are slightly spotted with orange.

Length, about two-fifths of an inch.

Locality.—Off Mindanao, Philippines, surface.

Remarks.—The specific name is taken from the locality. From *Oxycephalus longiceps*, Claus, it is well distinguished by the narrow neck, the more prolonged double-segment of the pleon, the much longer peduncles of the second uropods, besides the minuter details connected with the gnathopods and pereopods.

Genus *Calamorhynchus*, Streets, 1878.

1878. *Calamorhynchus*, Streets, Proc. Acad. Nat. Sci. Philad., p. 285.

1887. " Bovallius, Systematical List of Amph. Hyper., Bihang till K. Svensk. Vetensk.-Akad. Handl., Bd. 11, No. 16, p. 39.

For the original definition of the genus, see Note on Streets, 1878 (p. 485). The character there given, "superior antennæ with the peduncle three-jointed; in the female straight," does not entirely suit the Challenger species, in which these antennæ are curved or sinuous; that which the definition regards as the third joint of the peduncle

is in this Report considered to be the first of the flagellum. The expression "first and second pairs of thoracic legs" refers to the gnathopods; by "the sixth segment of the abdomen" is meant the double-segment composed of the fifth and sixth segments of the pleon coalesced. The character, "telson short, triangular," is rather vague, since those epithets, however applicable to the type of the genus, do not convey the idea of a telson about four times as long as its greatest breadth, which are its dimensions in the Challenger species.

Calamorhynchus rigidus, n. sp. (Pl. CCVI.).

There appears to be a very close similarity between this remarkable species and the type of the genus, *Calamorhynchus pellucidus*, Streets. The description of the head given by Dr. Streets is almost exactly applicable to the present species, "head long, nearly one-third of the total length, its breadth twice that of the thorax [peræon]; the portion containing the eyes oblong, convex above and below when viewed in profile, elevated above, in the median line, into a sharp ridge, which terminates at the apex of the rostrum; below the eyes form two long and rounded lobes separated by a broad, shallow groove; rostrum flattened, posteriorly broader than the eyes, commencing on either side of the eyes in a broad, rounded wing-like expansion, and tapering forward to a long and acute apex." The whole animal is sharply angled along the median dorsal line. The middle segments of the peræon rather longer than those at the two extremities; the whole length of the peræon subequal to that of the first three segments of the pleon together; the third segment of the pleon has the postero-lateral angles very acutely produced, the second segment has them produced in a less degree than the third, and the first than the second; the fourth segment is much shorter than either of the three preceding, and little more than a third of the length of the coalesced fifth and sixth segments.

Upper Antennæ slender, first joint of the peduncle much longer than the second, which is not longer than broad; the first joint of the flagellum is in the present species twice as long as the first of the peduncle (not, as in the type-species, subequal to it), somewhat curved, with filaments at seven or eight points along the convex margin and a couple at the apex of the opposite margin; the second joint very much thinner than the preceding, shorter than the first joint of the peduncle, with apical filaments; the third joint about half the length and breadth of the second, with apical setules.

Lower Antennæ wanting in the female.

Upper Lip.—The upper margin not evenly convex but with a little lobe in the centre.

Mandibles.—The cutting edge very oblique, finely striate and denticulate, having a narrow, slightly produced tooth at the upper corner; the secondary plate of the left

mandible similar to the principal, but without the produced tooth ; the little process behind the cutting plate on the right mandible extremely minute ; palp wanting in the female.

Lower Lip and *Maxillæ* appear to be represented but they are difficult to determine.

Maxillipeds strongly bent.

First Gnathopods.—The first joint little longer than the wrist and not half as broad ; the second joint broader than long ; the third widening distally, rather longer than broad, with a spine at the apex of the hind margin ; the wrist very large, broadest at the base of the hand, longer than broad, the hind margin longer than the front, carrying a few small spines, the broad process not so long as the proximal part of the wrist, nor reaching quite to the extremity of the hand, its front or inner margin cut into several teeth and bordered on each surface with a thick brush of spines, the apical tooth much the longest, the short hind margin of the process having one tooth between the long apical tooth and the short tooth which forms the apex of the hind margin proper ; the hand is shorter than the front margin of the wrist, with numerous spines on both surfaces, most numerous distally and near the hind margin ; the hind margin nearly straight, toothed and serrate, the apical tooth the largest, produced some way along the finger ; the finger slender, a little curved, scarcely half as long as the hand, having a small tooth at about the centre of the hind margin.

Second Gnathopods.—The first three joints nearly as in the first pair, the wrist of similar type but with the proximal part much more elongate, the hind margin continuous to the long apical tooth, and the inner margin of the process cut into about fifteen teeth which are larger and much closer together than those in the first pair, with comparatively few spines on the adjacent surface ; the hand reaches a little beyond the process of the wrist, but is very much shorter than the front margin ; it has spines as in the first pair, and the hind margin is cut into a dozen close-set decurrent teeth, resembling those of the wrist ; the finger is slender, bent, more than half the length of the hand, having a tooth near the centre of the hind margin.

First, Second, Third, and Fourth Peræopods.—There are numerous spinules along the hind margin of the third, fourth, and fifth joints in the first and second pairs ; the second pair are the longer ; the third pair are longer than the second, and have the same joints furnished along the front with spinules ; the shorter fourth pair have the third joint pectinate with short straight teeth, the fourth with longer straight teeth, the fifth with unequal decurrent teeth, the finger finely pectinate. The side-plates of the third pair have on the inner side a narrow tongue-like process pointing directly backwards.

Fifth Peræopods.—Side-plates with rounded front angle, only the hinder half disjoined from the segment, this half shallow, with the upper and lower margins nearly straight and parallel. The first joint slender, pear-shaped, somewhat longer than the first in the preceding pairs and rather longer than the remaining joints together, apically

much narrowed; the second joint short, the third very slender, considerably longer than the fourth, and the fourth than the almost linear yet tapering fifth; the finger minute, rather like the nib of a pen. This limb, instead of being, as in the type-species, "diminutive, barely exceeding the basal joint of the preceding pair," is nearly as long as the whole limb in that pair.

Pleopods.—Peduncles narrow, elongate; coupling spines small; cleft spine as in *Streetsia challengerii*; rami having about a dozen joints apiece; the interlocking process on the first joint of the outer ramus not sinuous.

Uropods.—Peduncles of the first pair prismatic in transverse section, elongate but not reaching the end of the double segment, more than twice as long as the outer, not twice as long as the inner, ramus, the inner margin denticulate, the rounded apex of the outer finely pectinate; the rami prismatic, denticulate on both margins, more strongly on the inner; peduncles of the second pair as broad as but a little shorter than those of the first and not reaching quite so far back, more than twice as long as the rami, the inner margin slightly serrate and distally forming with the apical margin a small produced triangle; the rami similar to those of the first pair but respectively shorter; the peduncles of the third pair longer than the outer ramus, nearly as long as the inner, with which the peduncle is coalesced; the outer ramus denticulate only on the inner margin, the inner on both margins, the denticulation of the inner margin being continued some way up the peduncle. In the type species the first uropods are described as "stouter than the second, equal in length."

Telson between three and four times as long as broad, produced to a sharp apex some way beyond the uropods; the length more than three-fifths of that of the coalesced fifth and sixth segments, equal to that of the first segment of the pleon; there are some very minute submarginal setules, and a little faint serration is visible near the middle of the lateral margins.

Length, nine-tenths of an inch.

Locality.—Station 330, March 8, 1876; South Atlantic; lat. $37^{\circ} 45' S.$, long. $33^{\circ} 0' W.$; surface; surface temperature, $64^{\circ} 2$. One specimen, female, with young in the pouch.

Remarks.—The specific name refers to the rigid straightness of the specimen as preserved. A specimen, one-third of an inch long, probably belonging to this species, was taken in Simon's Bay, Cape of Good Hope, November 10, 1873. The type species of the genus was obtained in the Pacific, "lat. $28^{\circ} 06' N.$, long. $140^{\circ} 12' W.$," Dr. Streets' specimen being also a female. The remarkable differences between the adult, with its pointed head and tail, and the young first taken from the pouch, with both ends blunt, may be seen from the figures.

Genus *Streetsia*, n. gen.

Head not constricted at the base, much longer than the peræon, the rostrum very elongate and the eyes still more so.

The Gnathopods complexly subchelate.

The Second Peræopods longer than the *First*.

The Fourth Peræopods with the hinder apex of the first joint acutely produced.

The Fifth Peræopods with dilated first joint exceeding in length the other five joints together; the outstretched limb exceeding in length the first joint of the fourth pair.

The Uropods with the rami distinct from the peduncles; the *Third Uropods* with peduncles much longer than broad.

The Telson produced far beyond the uropods, much longer than the coalesced fifth and sixth segments of the pleon.

The generic name is given in compliment to Dr. Streets who instituted the genera *Calamorhynchus* and *Leptocotis*.

Streetsia challengerii, n. sp. (Pl. CCVII.).

The Head is deeper than broad, but cylindrical in general appearance from the base to the rostrum; the latter is tapering, dorsally carinate, with serrate edges, and though of great length, shorter than the proximal part of the head; the peræon is dorsally rounded, the segments differing little from one another in length, with rather deep side-plates, of which the upper boundary is distinctly marked, except in the case of the seventh pair, where as so commonly the dividing line is limited to the hinder part of the plate; the pleon is more or less sharply carinate or dorsally angled, its second and third segments having the postero-lateral angles acutely produced.

Eyes of great length, occupying the whole sides of the head as far as the front antennæ, which are fixed just behind the base of the rostrum.

Upper Antennæ very small and slender, first joint of peduncle much longer than the two following together, each of these being broader than long; the first joint of the flagellum tapering, as long as the first of the peduncle, carrying two groups of filaments; the second joint not half the length or breadth of the first, with an apical group of filaments; the third joint narrower and shorter than the second, tipped with setules; there are some setules or cilia on the peduncle and first joint of the flagellum.

Lower Antennæ attached near the base of the head within its channelled lower side; the gland-cone is conspicuous; in addition to this, there is a triangular process of great tenuity, and near to it a little round-headed process, one or both of which may be antennary.

The Mandibles are very short, with a tolerably broad striated cutting edge, the secondary plate of the left mandible nearly as long as the principal, but without the projecting tooth at the upper angle.

The Maxillipeds are very small, not elongated; the inner plate short, distally beset with little setules; the outer plates arching over it are almost as broad at the base as their length; their sinuous inner margin has a wrinkled or striated appearance.

First Gnathopods.—The side-plates deeper than wide; serrate about the lower front angle, which is pointed forwards. The first joint broader above than below, the second very short, the third broader than long, wrist-like; the wrist very large, the convex front margin projecting a little in front of the hand, not apically produced, the hind margin set with small, unequal, partially feathered spines, much of it finely pectinate, the distal part cut into seven teeth, the apex strongly produced, the broad almost straight or slightly sinuous palmar margin within the apex cut into six or eight unequal straight teeth, submarginal to which on both surfaces are rows of many spines of various sizes; the hand shorter than the wrist and not half the width, widening a little from the neck and contracting again near the finger, with the front margin convex, at first smooth but distally set with spines, of which there are many on the surfaces and adjoining the straight, crenulate, and denticulate hinder margin, the apex of which is acute and produced to about half the length of the finger, its inner margin having one or two denticles; the finger is little curved, and has a denticle near the middle of the inner margin.

Second Gnathopods.—Branchial vesicles broader and longer than the first joint. The first joint with the hinder apex strongly outdrawn; second and third joints as in the first pair; the wrist much larger, similarly armed, except that the very elongate hind margin is not pectinate or toothed, the inner margin within the very elongate apex is cut into five or six teeth; the hand though not dissimilar to that of the first pair is narrower in appearance and much longer; the finger is also rather longer and the produced apex of the hand does not reach the middle of it; the much greater length of the apical tooth of the wrist and its oblique distal margin give to these gnathopods a claim to be regarded almost as complexly chelate instead of subchelate.

First Peraopods.—Side-plates with the front margin convex. Branchial vesicles longer and much broader than the first joint, with two lateral accessory poekets, rather longitudinal than transverse, in the upper half. The first joint not quite so long as the third and fourth joints together; the fourth rather longer than the third, the fifth much narrower than the fourth, as long as the third, curved, having like the two preceding joints outstanding spinules along the hind margin, but small ones; the finger slight, less than a third of the length of the fifth joint.

Second Peraopods like the first, but with all the joints longer, and the third rather longer than the fourth.

Third Peraopods.—Within the large bilobed side-plates, just above the attachment of the first joint, there is a very narrow, curved, round-ended process. The first joint widest near the middle, about two and a half times as long as broad, the front margin almost straight, shallowly serrate with a minute setule in each indent, the apex produced into a small tooth, the hind margin convex, carrying small setules, very shallowly serrate below the centre; the second joint with spinules along the front margin; the third joint much longer than the fourth; the fifth a little longer than the third, having a few spinules along the hind margin, and like the two preceding joints several along the front; the finger slender, nearly straight, little more than a fifth of the length of the fifth joint.

Fourth Peraopods.—Branchial vesicles much shorter than the first joint, the upper part much produced behind. The first joint with the greatest breadth near the base, longer and broader than in the preceding pair, considerably longer than all the remaining joints together, the front margin rather sinuous, a little serrate below and produced into a small tooth, the hind margin convex, rising much above and descending much below the front, the lower part shallowly serrate, the produced triangular apex reaching considerably below the second joint; the second joint short, its front margin straight, with an apical tooth, behind which is a second much longer tooth; the third joint as long as the three following joints together, pectinate with strong outstanding teeth along the front margin, and smaller teeth about the apices, of which the front one is a little more produced than the hind one; a spine projects a little above the front apex in this and the next joint; the fourth joint narrower than the third, shorter than the fifth, with varied pectination of the front and apical margins; the fifth joint very little curved, the pectination varied, decurrent; the finger not a third of the length of the fifth joint.

Fifth Peraopods.—The first joint nearly as broad as in the third pair, but much shorter, the muscles occupying a very small portion of the expanse; the second joint a little longer than broad; the third joint as long as the two following together, narrow and narrowing distally; the fourth straight, subequal in length to the fifth; the fifth apically narrowed; the finger not a quarter of the length of the fifth joint.

Pleopods.—Peduncles large and powerful. The coupling spines short, round-headed, with retroverted points; the cleft spine with short nearly equal arms, of which the shorter is a little apically dilated and appears to form a hook, while the longer arm is greatly but unsymmetrically dilated; the joints of the rami number from twelve to fourteen, the first joint of each ramus being long, with several setæ.

Uropods.—Peduncles of the first pair about as long as the coalesced fifth and sixth segments of the pleon, longer than the rami, which are elongate, the outer shorter than the inner, both with denticulate margins, the inner margin being more strongly toothed than the outer; peduncles of the second pair shorter than the rami, which are respectively as long as those of the first pair, with the inner margins much less strongly denticulate; the peduncles of the third pair very little shorter than the outer ramus,

which is nearly smooth on the outer margin, dentieulate on the inner; the inner ramus longer than the outer, denticulate on both margins; the inner margin of the peduncles is shallowly serrate and has three teeth at the apex. The peduncles of the first and second pairs have the apex of the inner margin acutely produced; the apices of all the rami are produced into long sharp points.

Telson apparently coalesced with the preceding double segment, carinate, nearly half the length of the head, longer than the first uropods, about four and a half times as long as its greatest breadth, tapering far beyond all the uropods to an acute point. It should be mentioned that fig. *T.*, representing the telson, is drawn to a larger scale than fig. *C.D.*, representing the dorsal aspect of the head.

Length of the outstretched animal a little over an inch.

Locality.—June 20, 1875, North Pacific; lat. $35^{\circ} 35'$ N., long. $150^{\circ} 50'$ E.; surface temperature, $69^{\circ} 7$. One specimen, female.

Genus *Rhabdosoma*, Adams and White, 1847–48.¹

For the original definition of *Oxycephalus*, see Note on Milne-Edwards, 1830 (p. 143). For *Rhabdosoma*, see Note on Adams and White, 1848 (p. 225). For the definition of *Macrocephalus*, see Note on Spence Bate, 1858 (p. 307). For the definition of *Rhabdonectes*, see Note on Bovallius, 1887 (p. 591), and for a short definition of *Rhabdosoma*, see Note on Claus, 1879 (p. 493).

Claus' fuller account of the genus is to the following effect:—

"The proximal section of the head is elongate, linear, swollen in front to the

¹ Bovallius, in his Systematical List, 1887, says with regard to *Rhabdonectes*, "the name has been substituted for the old name *Rhabdosoma*, as this latter was already preoccupied by Duméril for an Ophidian genus," but Duméril's genus is *Rabilosoma* and its date 1853, see *Mém. Acad. des Sciences*, Paris, t. xxiii. p. 440.

strongly widened ocular region, which is followed by the long rostral spine. The anterior antennæ, which can be laid within a deep groove, end in the male with single flagellum-joint, which in the female is lost, while on the other hand the third joint of the peduncle of the female antennæ is dilated (bauchig aufgetrieben) and furnished with numerous olfactory filaments. The antennæ of the second pair are similar to those in *Oxycephalus*, five-jointed, the terminal joint extremely small. The three-jointed mandibular palp of the male is elongate, linear, reaching to the front antennæ. The mouth-organs in general are as in *Oxycephalus* only that the movable part of the upper lip projects shield-like, and the mandibles armed with cutting edge are more considerably shortened. The front limbs are short, complexly chelate. In the third and fourth, and even the fifth,¹ pereopods the first joint is narrow and linear, only the first joint of the fifth is a broad plate of pear-shaped outline, to which I uniformly failed to find any terminal joints attached. Curiously in the male only the third and fourth pereopods have branchial vesicles, while in the female also the branchiæ of the three preceding pairs are retained. Also another obviously striking sexual distinction is observable in the appendages of the peræon, in that especially the first and second pereopods, but also the following pairs, in the female have much stronger and thicker first and third joints. The first three segments of the pleon are very extensive and at least of the length of the whole peræon. The pleopods are distinguished in the male by the thickness and strength of their peduncles, which in the female are weaker and more slender. The following hinder section of the pleon is linear, in the female far more elongate. The eggs are developed in the pouch of the breast protected between the side-wings of the peræon-segments."

The large third joint of the upper antennæ, which Claus regards as part of the peduncle, in this Report is considered to belong to the flagellum. It will be seen in the account of *Rhabdosoma brevicaudatum* that in that species the fifth pereopods appear to have a minute appendage to the first joint. The first three pleon-segments may occasionally be shorter than the peræon.

Rhabdosoma armatum (Milne-Edwards). Specimen A.

- 1840. *Oxycephalus armatus*, Milne-Edwards, Hist. Nat. des Crustacés, t. iii. p. 101.
- 1847. *Rhabdosoma armatum*, White, List of Crust. in Brit. Mus., p. 130.
- 1848. " " Adams and White, Zool. of Voy. of H.M.S. "Samarang," p. 63, pl. xiii. figs. 7, 8.
- 1858. *Macrocephalus longirostris*, Spence Bate, Ann. and Mag. Nat. Hist., ser. 3, vol. i. p. 361.
- 1862. *Rhabdosoma armatum*, Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 344, pl. liv. fig. 6.

¹ As this seems contradictory to what immediately follows, I may be mistranslating the original, which is, "An dem fünften und sechsten, auch siebenten Beinpaare, bleiben die Schenkelglieder schmal und stabförmig, nur das Schenkelglied des siebenten Beines ist eine breite Platte von birnförmiger Umgrenzung." It will be remembered that the fifth, sixth, and seventh limbs of the original correspond respectively to the third, fourth, and fifth pereopods of the nomenclature used in this Report.

Rostrum seven-tenths of an inch long, the total length of the head being one inch; the peraeon four-tenths of an inch long, with the first segment very short, and the seventh like the second much shorter than any of the intermediate segments; the first three segments of the pleon together not so long as the peraeon, in their slightly curved position measuring three-tenths of an inch; the remainder of the animal to the apex of the telson three-quarters of an inch long; the fourth segment much longer than any of the preceding, longer than the following double segment; the postero-lateral angles of the third pleon-segment very acute, much more produced than those of the two preceding segments.

Lower Antennæ and Mandibular Palps not present. The *Second Gnathopods* and first four pairs of *Peræopods* with branchial vesicles. The third and fourth joints in the *First* and *Second Peræopods* rather dilated, this being the case also in a less degree in the *Third Peræopods*, in which the first joint is noticeably longer than the third; the *Fourth Peræopods* are rather shorter than the *Third*, with none of the joints dilated; the lower part of the seventh segment of the peræon corresponding with the side-plate of the fifth peræopods forms behind a forward-directed hook such as Claus figures for this part of the female.

Uropods.—Peduncles of the first pair much longer than the double segment, many times longer than the one remaining ramus; peduncles of the second pair shorter than those of the first, but longer than the double segment, the outer ramus more than half the length of the inner, the inner coalesced with the peduncle and less than a quarter of its length; peduncles of the third pair more slender than those of the first, about as long; the outer ramus rather more than half the length of the inner, longer but more slender than the inner ramus of the second pair; the inner ramus about a third of the length of the peduncle and coalesced with it.

Telson linear, elongate, a little but quite distinctly longer than the third uropods,

¹ *R. curvicorne* on Plate.

uropods, about equal in length to the fourth and coaleseed fifth and sixth segments of the pleon together, the apex acute.

Length, in a bent position, two inches and a tenth, fully outstretcheded about two inches and a half.

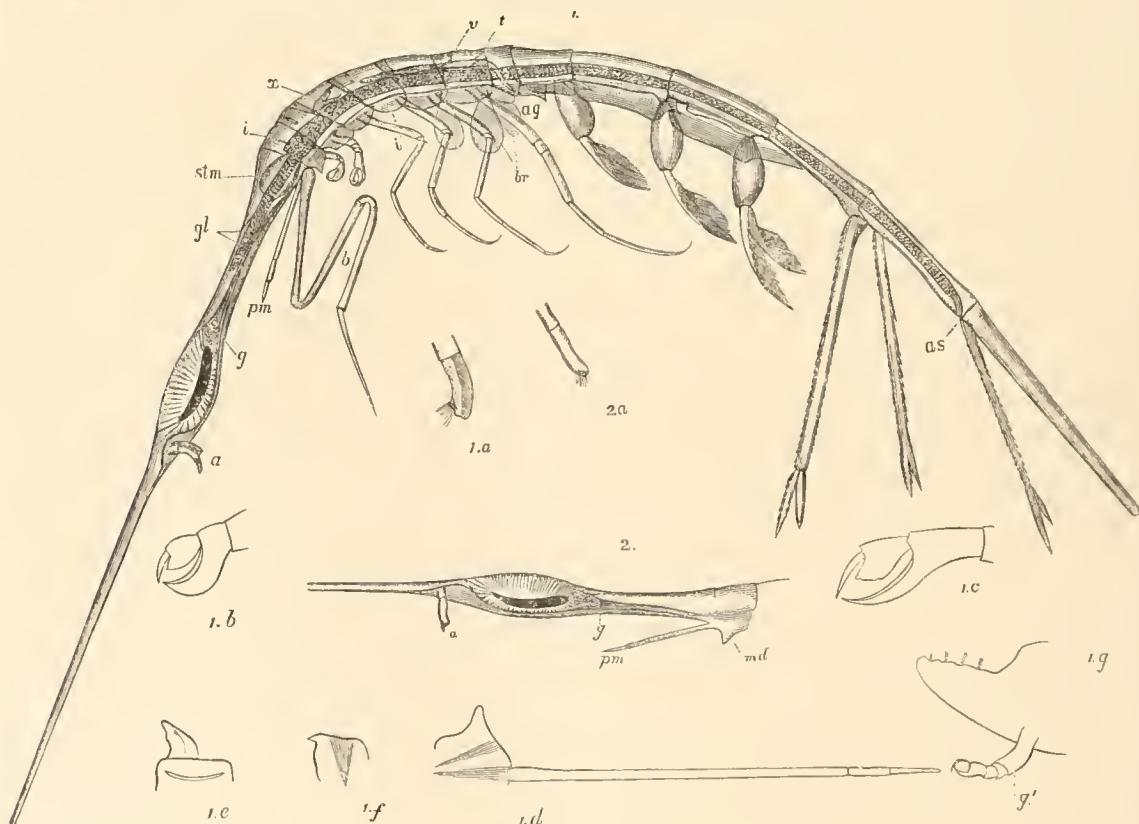

Locality.—Station 347, April 7, 1876; Equatorial Atlantie; lat. $0^{\circ} 15'$ S., long. $14^{\circ} 25'$ W.; surface net; surface temperature, 82° . One specimen.

Remarks.—The synonymy of this species is given under reserve, since there was only a single specimen for examination, while other writers have been able to compare several examples. The type described by Milne-Edwards was evidently a male; its length is said to be about an inch, with the head as long as all the rest of the body, and the telson, "un stylet impair," as long as the body. The expressions are vague, since "all the rest of the body" may or may not include the "stylet impair," which is itself said to be as long as the body, the body in this instance probably meaning the peræon and pleon together. Spence Bate describes a female speeimen under the name "*Rhabdosoma armatum*," and a male under the name "*Rhabdosoma Whitei*." Claus both in 1879 and 1887 deelares that these are the two sexes of one species. Streets in 1878, under the name "*Rhabdosoma whitei*, Bate," deseribes a male, and figures a female, and further describes and figures, under the name "*Rhabdosoma armatum* (Edw.), Adams and White," a young male, taken at the same place with six out of his seven specimens of "*Rhabdosoma whitei*." In the synonymy he states that "*Rhabdosoma armatum*, Adams and White, Voyage of the 'Samarang,' 1850 [1848], Zoology, Crust., p. 63, pl. 13, fig. 7," is not "*R. armatum*, Bate, Catalog. Amphi. Crust., 1862, p. 344, pl. 54, fig. 6," though he recognises that White and Spence Bate are apparently deseribing the same specimen.¹ Bovallius in 1887 distinguishes "*Rabdonectes armatus*" from "*Rabdonectes Whitei*," but whether from his own observation or relying only on published accounts he does not indicate. Dr. Giles gives a beautiful figure of a male specimen, under the name *Rhabdosoma investigatoris*, the measurements of which agree very fairly with those given by Claus for one of his male specimens. In the peræopods of Dr. Giles' specimen the seeond joint is shown with a very acute apex, and it is so figured by v. Willemoes Suhm in the first three pairs of peræopods, but neither Dr. Giles nor any other author deseribes this feature, nor could I detect it in the specimen above deseribed. The more obvious and exeedingly striking peculiarities of this genus have so much absorbed attention, that comparatively little has been paid to minuter details. A tooth on the hind margin of the wrist of the first gnathopods is figured both by Claus and Spence Bate for the female of "*Rhabdosoma armatum*"; Spence Bate gives no such tooth in his figure of the first gnathopods of *Rhabdosoma whitei (curvicorne)*; Streets does not give it

¹ The specimen had clearly suffered some damage before it came into Spence Bate's hands, but even so the pleon in his figure of it cannot easily be reconciled with that in White's.

either for his *Rhabdosoma whitei* or his *Rhabdosoma armatum*. Dr. Giles says of the first and second gnathopods of his species that, unlike those of the forms described by Spence Bate, Streets, and Claus, they "are subequal and very closely resemble each other." When these small appendages are observed with a low power, such a statement would be readily applied to them, and in describing the type-specimen Milne-Edwards is content to say, "pates des deux premières paires extrêmement petites," without the slightest distinction between them, yet in all probability all the forms have the first gnathopods easily distinguishable from the second when highly magnified. The comparative lengths of the segments, the uropods, and the telson would seem to be highly variable according to the age or sex, but other characters when more completely examined than they have hitherto been may suffice for establishing specific distinction between some of the forms included in the synonymy here discussed.

Rhabdosoma armatum (Milne-Edwards). Specimens B, C.

The woodcuts here given are reproduced on a reduced scale from a plate drawn by the late R. v. Willemoes Suhm during the voyage, and accompanied by the following explanation in his handwriting:—

"Rhabdosoma Whitei Sp. Bate, Catal. Amph. Crust, pg. 345, Pl. 54, fig. 7. 12 Febr. 75. Western Pacific (δ); lat. $4^{\circ} 19' N.$, long. $130^{\circ} 15' E.$, between the Tulus and Warren Hastings Isl.
 ♀ in der Melanesian sea, auf dem Wege von Api--Cap York, lat. $14^{\circ} 7' S.$, long. $153^{\circ} 43' E.$

The specimens referred to have not come into my hands, but it is clear that in fig. 1 the small fifth peræopod by a very natural mistake has been marked as one of the branchial vesicles; the ostia of the heart are placed in the second, fourth, and sixth segments of the peræon, no lateral opening being shown in the third segment; the third and fourth peræopods are drawn with the fingers directed backwards just as in the first and second pairs, instead of forwards, which is their ordinary position; the fourth peræopod is represented as considerably larger than the third, but it may be taken for granted that the two have been transposed, probably owing to an accidental crossing of these delicate appendages in the specimen itself.¹ Fig. 1g is said to represent the Unterlippe, that is, the maxillipeds, with the first gnathopod, but the part spoken of as the Unterlippe is more probably the lower part of the first segment of the

¹ Spence Bate in his description of *Rhabdosoma whitei*, loc. cit., says, "pereiopoda gradually increasing in length posteriorly, the fourth pair being the longest." Streets also says in his account of "*Rhabdosoma whitei*," Bate, in reference to the pereiopods, "the remaining thoracic legs simple, first joint not dilated, as slender as the preceding, increasing in length to the sixth," meaning by the sixth thoracic legs the fourth pereiopods. Nevertheless it seems to me altogether improbable that the form should differ in this respect from all the rest of the Oxycephalidae, whether in this genus or in other genera of the family. When for convenience of delineation the legs are stretched out in the figure apart from one another below the body, mistake seems impossible, but in the specimen itself the limbs are apt to get very mixed in appearance, so that in the entanglement an observer, guided by an earlier description, might readily adopt an error which in the first instance was easy enough to make. This consideration lessens the weight which would necessarily be attributed to the agreement on the point in question between Spence Bate, Streets, and v. Willemoes Suhm.

pereon answering to the side-plate. Fig. 2 is stated to be the head of the female, ten times the natural size, with the mandible. Since, however, the mandible has a three-jointed palp, the specimen was no doubt a male, although, to judge by the anterior antennæ, a young one. In both specimens the mandibular palp is figured as perfectly straight, not with the two short terminal joints forming a sickle-like curve, the curvature probably being developed only at a more advanced period of life than that which either of these specimens had attained.

Rhabdosoma brevicaudatum, n. sp. (Pl. CCVIII.).

Rostrum broken, the remaining portion with the neck and ocular region a quarter of an inch long, the neck being by itself one-tenth of an inch; in front of the mouth organs there is a strongly projecting tooth or process on the ventral surface at the base of the head; the pereon about three-twentieths of an inch in length, with the dorsal outline convex, the first segment short, the second longer than the first, but shorter than any of the following, the seventh not much shorter than any of the four preceding segments; the first three segments of the pleon together as long as the pereon, the postero-lateral angles of the first acute, but not produced backwards, those of the second very slightly produced, those of the third very acute and much produced backwards, the lower margin of the third segment being much more convex than that of the two preceding segments; the remainder of the pleon to the end of the telson equal in length to the first three segments, but to the end of the uropods measuring a quarter of an inch; the fourth segment about half the length of the following double-segment.

Upper Antennæ placed in the ventral groove of the head just in front of the oval ocular region; the first joint of the peduncle considerably longer than the second; the one-jointed flagellum longer than the peduncle, the distal margin carrying a few filaments.

Lower Antennæ wanting.

Mouth Organs not well observed; the *Maxillipeds* appear to have the outer plates apically pointed; the *Mandibles* without palp.

First Gnathopods very short; the first joint with sinuous front and convex hind margin; the second joint broader than long; the third joint a little longer than the second, distally widened; the wrist large, widest where it joins the hand, the hind process longer than the proximal part of the joint, and longer than the hand, ending in a sharp apical tooth, a little way above which a piece of the hind margin is finely denticulate, the inner or front margin of the process being similarly denticulate; the hand has a very convex front margin, the hind margin beyond the neck being slightly convex and distally a little denticulate, the distal margin finely pectinate and supplying

a small convex palm; the finger curved, small, yet more than half the length of the hand and reaching much beyond the palm, having a little denticle on the concave margin.

Second Gnathopods longer than the first, with all the joints longer, but very similar; the pectinate palm of the hand is more strongly convex, while the front margin of the hand is much less so; the finger is much more than half the length of the hand.

First Peraopods.—First joint widening distally, with concave front margin, not very elongate; the second joint not longer than broad, with a little pectination of the convex hind margin; the third joint oval, broader and scarcely shorter than the first joint, almost filled with gland-cells, the front margin fringed with little spinules; the fourth joint a little broader than the fifth, but much shorter; the fifth narrow, slightly curved, shorter than the third, both this and the fourth joint having spinules along the front margin; the finger long and slender, more than half the length of the fifth joint, curved at the tip.

Second Peræopods differing little from the first except in their greater size, which chiefly depends on the longer third joint, the fifth joint also being rather longer than in the preceding pair, but very decidedly shorter than the third joint.

Third Peræopods.—Branchial vesicles lying parallel to the body, much larger and more conspicuous than the three preceding pairs. This pair of limbs the longest; the first joint very moderately dilated, the front margin faintly serrate and still more minutely pectinate on the front margin; the second joint scarcely longer than broad, with the convex front margin slightly pectinate; the third joint narrower than the first and a little shorter, having a very small portion of its space occupied by muscles; the fourth joint little more than half as long as the third; the fifth slender, a little curved, nearly as long as the third, having like the two preceding joints small spinules along the front margin; the finger slender, about a third as long as the fifth joint.

Fourth Peræopods very similar to the third, but considerably shorter, the first joint rather longer and broader, but the third shorter and much narrower, the fourth joint also smaller in proportion, and the fifth joint not very much longer than the fourth; the finger straight, acute, about half the length of the fifth joint.

Fifth Peræopods.—The lower part of the segment (corresponding to the side-plate) having the angles rounded both before and behind, the front part of the lower margin a little excavate. The first joint of the limb small, scarcely reaching below the margin of the segment, expanded so as to form a sort of triangle, with the sides nearly equal and more or less convex; the apex below seems to be formed by a partially coalesced second joint, from which projects an extremely minute two-jointed appendage, of which the terminal joint is acute.

Pleopods.—The peduncles long and slender; coupling-spines not perceived; cleft spine having a small subapical dilatation to the longer arm; the interlocking process on the first joint of the outer ramus much bent; the joints of the rami numbering from six to eight.

Uropods.—The first pair long and slender, prismatic in section, the peduncle longer than those of the other two pairs, much longer than the rami and also longer than the double segment, the outer and inner margins pectinate, the teeth on the inner margin being shorter, much more numerous and less decurrent than those on the outer; both members of this pair are unfortunately broken, but the fragment of one is preserved, and shows an outer ramus probably half the length of the peduncle, with long decurrent teeth on the inner margin, some also on the under margin, and the outer margin serrate; the inner ramus about a third of the length of the outer, with short decurrent teeth on the outer margin, the series not reaching to the apex, the inner margin very closely pectinate, the apex slightly curved, with a spine-like ending; the second pair are much more slender than the first, the peduncles reaching a little beyond the double segment, near to the base of which they are attached; the upper and inner margins have slender decurrent teeth, the outer margin being sparingly serrate; the inner ramus is more than half the length of the peduncle, coalesced with it and similarly armed; the outer ramus minute, not a sixth as long as the inner, having two or three long decurrent teeth on each margin; the third pair are more slender than the first, but less slender than the second, the peduncles shorter than the double segment, with smooth outer margin and spine-like rather distant teeth on the inner; the inner ramus nearly as long as the peduncle with which it is coalesced, longer than the rami of the other pairs, having both margins armed with decurrent teeth; the inner ramus slender, minute, perhaps a tenth as long as the outer, carrying one decurrent tooth on the inner margin.

Telson coalesced with the preceding segment, but abruptly narrower, about a third as long as the peduncles of the third uropods, very little broader at the base than at the apex, which is neatly rounded and finely pectinate with little teeth which are longest at the centre of the margin.

Length.—The specimen outstretched measured four-fifths of an inch, the rostrum being broken.

Locality.—Station 352, April 13, 1876; North Atlantic; lat. $10^{\circ} 55'$ N., long. $17^{\circ} 46'$ W.; surface; surface temperature, $77^{\circ}.7$. One specimen, female.

Remarks.—The specific name refers to the shortness of the telson, which is unique among the species hitherto named as belonging to this genus. It may, I think, be presumed that the specimen is a female, since not only are the lower antennæ and mandibular palps wanting, but the third joint in the peræopods has the dilatation

which appears to be a distinctive character of the female in this genus; the first three pairs of branchial vesicles, which are wanting in the male, were also here faintly discerned.

The following table shows the distribution of the Oxycephalidae as illustrated by the Challenger specimens:—

1. Station 13, March 4, 1873; between Tenerife and St. Thomas; lat. $21^{\circ} 38'$ N., long. $44^{\circ} 39'$ W.; surface temperature, 72° . (*Leptocotis*.)
2. April 29, 1876, North Atlantic; lat. $18^{\circ} 8'$ N., long. $30^{\circ} 5'$ W.; surface, night; surface temperature, $73^{\circ} \cdot 7$. (*Oxycephalus*.)
3. April 28, 1876, North Atlantic; lat. $17^{\circ} 47'$ N., long. $28^{\circ} 28'$ W.; surface; surface temperature, $73^{\circ} \cdot 5$. (*Oxycephalus*.)
4. April 27, 1876, North Atlantic; lat. $17^{\circ} 18'$ N., long. $26^{\circ} 32'$ W.; surface temperature, $73^{\circ} \cdot 5$. (*Oxycephalus*.)
5. April 26, 1876, off St. Vincent, Cape Verde Islands; lat. $16^{\circ} 49'$ N., long. $25^{\circ} 14'$ W.; surface temperature, $73^{\circ} \cdot 2$. Four specimens. (Three specimens are probably *Oxycephalus clausi*, and one probably *Oxycephalus porcellus*.)
6. Station 352, April 13, 1876; North Atlantic; lat. $10^{\circ} 55'$ N., long. $17^{\circ} 46'$ W.; surface; surface temperature, $77^{\circ} \cdot 7$. One specimen (*Rhabdosoma brevicaudatum*).
7. Station 104, August 23, 1873; Equatorial Atlantic; lat. $2^{\circ} 25'$ N., long. $20^{\circ} 1'$ W.; surface; surface temperature, 78° . (*Oxycephalus clausi*.)
8. Station 106, August 25, 1873; Equatorial Atlantic; lat. $1^{\circ} 47'$ N., long. $24^{\circ} 26'$ W.; surface to 100 fathoms; surface temperature, $78^{\circ} \cdot 8$. One specimen, in Canada balsam (*Leptocotis*, ♂, with the upper antennæ having only a small upward produced point), and one specimen, in Canada balsam (*Leptocotis*, ♀).
9. Station 347, April 7, 1876; Equatorial Atlantic; lat. $0^{\circ} 15'$ S., long. $14^{\circ} 25'$ W.; surface net; surface temperature, 82° . One specimen (*Rhabdosoma armatum*), and one specimen (*Oxycephalus*).
10. Surface, Atlantic. One specimen (*Oxycephalus*).
11. "Oxycephalus ♂, Atlantic, surface." Two separately mounted specimens.
12. October 5, 1873, South Atlantic; lat. $29^{\circ} 1'$ S., long. $28^{\circ} 59'$ W.; surface temperature, 66° . "Oxycephalus, ♀."
13. November 10, 1873, Simon's Bay, Cape of Good Hope; "Vibiliia and Oxycephalus." The two specimens are mounted in Canada balsam, the "Oxycephalus" evidently belonging to the genus *Calamorhynchus*.
14. Station 330, March 8, 1876; South Atlantic; lat. $37^{\circ} 45'$ S., long. $33^{\circ} 0'$ W.; surface; surface temperature, $64^{\circ} \cdot 2$. One specimen (*Calamorhynchus rigidus*).
15. "Oxycephalus oceanus, ♀," off Kandavu, Fiji Islands. Two specimens in Canada balsam.

16. "Oxycephalus, Aleiope, Euphausia larva, West Pacific." One specimen, in Canada balsam, with others not Amphipoda.
17. "Oxycephalus, ♀, West Pacific." One specimen, in Canada balsam.
18. Station 227, March 27, 1875, West Pacific; lat. $17^{\circ} 29' N.$, long. $141^{\circ} 21' E.$; surfacee; surface temperature, $79^{\circ} 2.$ (*Oxycephalus*).
19. Station 180, August 24, 1874, between Api and Cape York; lat. $14^{\circ} 7' S.$, long. $153^{\circ} 43' E.$; surfacee temperature, $80^{\circ}.$ One specimen (*Rhabdosoma armatum*, ♂).
20. South Pacific, between Api and Cape York; surface. One specimen (*Oxycephalus porcellus*). One specimen, in Canada balsam. "Oxycephalus oceanus, ♀."
21. Station 215, February 12, 1875, Western Pacific; lat. $4^{\circ} 19' N.$, long. $130^{\circ} 15' E.$; surfacee temperature, $81^{\circ} 8.$ One specimen (*Rhabdosoma armatum*, ♂).
22. February 12–20, 1875, Western Pacific, off the north coast of New Guinea. "Oxycephalus oceanus, Guérin."
23. February 9, 1875, West Pacific; lat. $5^{\circ} 33' N.$, long. $125^{\circ} 33' E.$; surface temperature, $80^{\circ}.$ One specimen, in Canada balsam, young male (probably *Leptocotis mindanaonis*).
24. Off Mindanao, Philippines; surfacee. One specimen (*Leptocotis mindanaonis*).
25. April 3, 1875, North Pacific; lat. $24^{\circ} 49' N.$, long. $138^{\circ} 34' E.$; surfacee; surface temperature, $71^{\circ} 5.$ Five specimens (*Oxycephalus clausi*?).
26. Station 230, April 5, 1875, North Pacific; lat. $26^{\circ} 29' N.$, long. $137^{\circ} 57' E.$; surfacee; surface temperature, $68^{\circ} 5.$ Several specimens (*Oxycephalus clausi*?), and one specimen (*Oxycephalus porcellus*).
27. Pacific, between Admiralty Islands and Japan. "Oxycephalus." Two specimens, ♂, in Canada balsam. The lower antennæ not fully developed.
28. June 20, 1875, North Pacific; lat. $35^{\circ} 35' N.$, long. $150^{\circ} 50' E.$; surface temperature, $69^{\circ} 7.$
29. Station 241, June 23, 1875; lat. $35^{\circ} 41' N.$, long. $157^{\circ} 42' E.$; surface; surface temperature, $69^{\circ} 2.$ (*Oxycephalus*.)
30. July 4, 1875, North Pacific; lat. $36^{\circ} 42' N.$, long. $179^{\circ} 50' W.$; surfacee, night; surfacee temperature, $71^{\circ} 5.$
31. July 1875, between Japan and Honolulu; surface. (*Oxycephalus clausi*?).
32. Station 271, September 6, 1875; Mid Pacific; lat. $0^{\circ} 33' S.$, long. $151^{\circ} 34' W.$; surface temperature, $78^{\circ} 7.$ One specimen (*Oxycephalus porcellus*), and one specimen, imperfect (*Oxycephalus clausi*?).
33. Station 287, October 19, 1875, South Pacific; lat. $36^{\circ} 32' S.$, long. $132^{\circ} 52' W.$; surface; surfacee temperature, $57^{\circ} 8.$

To the distribution of the family thus shown, must be added from other sources the Indian Ocean, the Mediterranean, the Caribbean Sea, and New Zealand. The range may therefore be considered to encircle the globe from east to west, but, so far as at present known, not to extend into the colder waters either north or south.

APPENDIX TO THE BIBLIOGRAPHY.

1775. FABRICIUS, J. C.

Systema Entomologiæ.

For the definition of the Agonata see Note on Fabricius, 1775 (p. 40). In this group, at page 415 of the Systema, is placed the species *Astacus crassicornis*, of which Fabricius' description has been already quoted in the discussion of the genus *Scinà*, p. 1271. As already noticed, Herbst in 1796 described the same species under the name "Cancer (Gammarellus) *crassicornis*;" but while by the name "Cancer (Gammarellus)" he led the way to the inclusion of this species among the Amphipoda, he at the same time shut the gate against it by retaining the erroneous characters of the original description. Hence the species has passed through a long period of neglect; but that Herbst was right in the matter of classification is made clear by the figures in the unpublished *Museum Banksianum*, which have attached to them the name *Cancer crassicornis*, and the signature "Sydney Parkinson pinx^t. 1768." It is quite possible that the original description was made, not from an actual specimen, but from Parkinson's drawing, which is certainly suggestive of eight pairs of limbs. The eighth segment attributed to the thorax, I now think, is not so well to be accounted for by the inclusion of the head, as by the supposition that the fold of the skin between the peraeon and pleon has been converted into an eighth segment to meet the exigencies of an extra pair of legs.

The volume containing the figures just referred to is preserved at the British Museum in Cromwell Road. An inscription at the beginning reads as follows:—"Zoological drawings by Sydney Parkinson in Capt. Cook's First Voyage 1768–1771." Besides the *Cancer crassicornis* it contains the following Amphipoda:—

"Onidium spinosum. Sydney Parkinson pinx^t. 1768.," three figures, respectively dorsal, ventral, and lateral, about five inches long, intended apparently for life-size, and evidently representing the *Cystisoma* which Fabricius describes as *Oniscus spinosus*.

"Onidium gibbosum. T. 15. P. Sept. 7. 1768.," with a monogram, seven figures which no doubt refer to the *Oniscus gibbosus* of Fabricius, but the enlargement is not sufficient to help out the description to any important extent. The fifth peraeopods are very small.

"Onidium oblongatum. T. 16. P. Sept. 7. 1768.," with a monogram, two figures representing one of the Hyperina, but without sufficient enlargement to show clearly the position of the species. The magnified figure gives the two pairs of gnathopods and the last peraeopods as very much smaller than the intermediate feet.

"Onidium quadricorne. Sydney Parkinson pinx^t. ad vivum. T. 2. P. 2. August 28. 1768.," two figures, which no doubt represent the *Oniscus quadricornis* of Fabricius, a species identified with *Hyperia medusarum* (O. F. Müller).

Dr. Günther kindly made search at my request for the specimens from which Sydney Parkinson's drawings were made, but the Amphipoda could not be found among the specimens still preserved in the cabinets of the "Banksian Museum."

1793. FABRICIUS, J. C.

Entomologia Systematica. (See p. 59.)

In the account of this work it should have been mentioned that the Amphipods include, besides
 "Astacus Homari," *Astacus crassicornis*, Fabricius, a species which has been already
 discussed, pp. 1271, 1617.

The new genus *Cymothoa* is thus defined, p. 503 :—

"Os absque palpis et mandibulis. Antennæ sæpius quatuor æquales, sessiles.

"Cymothoæ corpus oblongum, glabrum, iumarginatum, tardum, segmentis quatuordecim
 transversis, brevibus : posticis minoribus, antico sive capite minore, oculis ovatis, lateralibus,
 antennis brevibus, sub capite insertis, cauda foliolis quatuor, pedibus quatuordecim, brevibus,
 unguiculatis, colore obscuro."

The Amphipods which Fabricius includes in this genus are 12. *Cymothoa bicaudata*, 17.
Cymothoa spinosa, and 21. *Cymothoa Ceti*. *Cymothoa bicaudata* has the synonym
 "Oniscus bicaudatus. Mant. Ins. 1.241.11. Linn. Syst. nat. 2.1060.8. Fn. Sv. 2062.,"
 a species which Pallas in 1766 identifies with his own *Oniscus volutator*, while Fabricius
 here as elsewhere makes Pallas' species a synonym of his own *Gammarus longicornis*.
Cymothoa spinosa is a new name for the *Oniscus spinosus*, of which the description has
 been quoted at page 40. *Cymothoa* as originally constituted must have been tolerably
 comprehensive, since the three species of Amphipoda placed in it have since been referred
 respectively to genera so remote as *Corophium*, *Cystisoma*, and *Cyamus*. In the Supple-
 mentum, 1798, Fabricius assigns four species instead of twenty-four to *Cymothoa*, adding,
 "Cymothoæ reliquas mihi minus notas ad ulteriorem disquisitionem sepono;" of the
 remaining twenty he assigns ten to *Idotea* (*Idothea*, Index, p. 27, 1799), one to *Ligia*, and
 one (*Cymothoa ceti*) to *Pycnogonum*, leaving eight to be accounted for.

1802. BOSC, L. A. G.

Histoire Naturelle des Crustacés. (See p. 67.)

In the Introduction, at page 79, Bosc names a new genus, which he places between *Gammarus*
 and *Cyamus*, and defines as follows :—

"Genre XXXIV. Liparis, *Liparis*. Corps filiforme, long; pattes alongées. (Ovaires placés
 sous le troisième et quatrième anneau.)

"Exemp. du genre. *Squilla lobata*, Fab."

He takes no further notice of this genus in his subsequent descriptions. The reference to *Squilla*
lobata of O. F. Müller and O. Fabricius shows that *Liparis* is a synonym of *Caprella*,
 Lamarck, 1801.

1824. PARRY, WILLIAM EDWARD.

Journal of a second voyage for the discovery of a north-west passage from the
 Atlantic to the Pacific; performed in the years 1821–22–23, in his Majesty's
 ships Fury and Heela, under the orders of Captain William Edward Parry,
 R.N., F.R.S., and Commander of the expedition. London, MDCCCXXIV.

In the Bay of Shoals, lat. 66° 31' 59" N., long. 83° 48' 54" W., he notices that "there were con-
 siderable flocks of the long-tailed duck feeding on the innumerable shrimps (*cancer nugax*, of
Phipps's Voy.) with which the sea swarmed in all this neighbourhood," p. 113.

At page 126 he says, "I have before mentioned the myriads of small shrimps (*cancer nugax*),
 which for some weeks past had been observed near the surface of the sea. These insects
 were found to be still as numerous as ever [October] in any hole we made in the ice ;

and such was the extreme avidity with which they immediately seized upon any meat put overboard to thaw or soak for the sake of freshness, that Captain Lyou to-day sent me a goose to look at, belonging to the officers of the Hecla, that had been thus deposited within their reach only eight and forty hours, and from which they had eaten every ounce of meat, leaving only a skeleton most delicately cleaned. Our men had before remarked that their meat suffered unusual loss of substance by soaking, but did not know to what cause to attribute the deficiency. We took advantage, however, of the hunger of these depredators to procure complete skeletons of small animals, for preservation as anatomical specimens, enclosing them in a net or bag with holes, to which the shrimps could have access, but which prevented the loss of any of the limbs, should the cartilage of the joints be eaten. For want of this latter precaution some specimens were at first rendered imperfect."

This account of the voracity of the Arctic Amphipoda tallies with what is said by Holboell, 1842, Sutherland, 1852, and Goës, 1865.

1824. SABINE, E.

A supplement to the Appendix of Captain Parry's Voyage for the discovery of a north-west passage, in the years 1819–20. Containing the zoological and botanical notices. London, MDCCCXXIV. Marine Invertebrate Animals, by Captain Edward Sabine. pp. ccix–ccxxxix.

The zoological part of this work had already appeared in 1821 without any variation from the present edition except in the numbering of the pages; thus, for example, in a list of synonyms, " *Gammarus loricatus*, Sabine, Appendix to Capt. Parry's Voyage of Discovery, p. 58, 1821," and " *Gammarus loricatus*, Sabine, Supplement to the Appendix of Captain Parry's Voyage, p. ccxxxi. 1824," are practically one and the same reference. See Note on Sabine, 1821.

1828. ROSS, J. C.

In Narrative of an attempt to reach the North Pole, in boats fitted for the purpose, and attached to his Majesty's ship Hecla, in the year MDCCCXXVII., under the command of Captain William Edward Parry, R.N., F.R.S. London, MDCCCXXVIII. Appendix. Zoology. By Lieutenant (now Commander) James Clark Ross, R.N., F.L.S.

Under the heading "Marine invertebrate animals," the following notices of Amphipoda are given on pages 203–205.

"9. CAPRELLA SCOLOPENDROIDES.

"Caprella Scolopendroides. Lam. v. p. 174. App. to Parry's Third Voyage, p. 118.

"*Gammarus Quadrilobatus*. Zool. Dan. iii. p. 58, Plate 114, fig. 11, 12, Female.

"*Squilla Quadrilobata*. Zool. Dan. ii. p. 21, Plate 56, fig. 4, 5, 6, Male.

"*Squilla Lobata*. Fabr. Faun. Groenl. p. 248.

"The specimens of this species, which were taken in a net to the northward of Low Island, are of a size intermediate between those figured by Müller and those obtained, during Captain Parry's Third Voyage, at Port Bowen. The spines along the back were hardly visible without the aid of a microscope; and the second pair of legs are inserted in the anterior part of the second segment of the body, and not in the centre of it, as in the plates referred to.

- "10. GAMMARUS LRICATUS. (Sabine.)
 "Gammarus (Gen.) *Lamarck*, v. p. 179.
 "Gammarus Loricatus. *Supp. to Parry's First Voyage*, p. cxxxii. Plate 1, fig. 7. *App. to Parry's Third Voyage*, p. 118.
 "Found on the shores of Walden Island amongst sea-weed.
 "11. GAMMARUS SABINI. (Leach.)
 "Gammarus Sabini. *Leach, in Ross's Voyage*, octavo edit. ii. p. 178. *Supp. to Parry's First Voyage*, p. cxxxii. Plate 1, fig. 8-11. *App. to Parry's Third Voyage*, p. 118.
 "Taken in a net from a depth of 80 fathoms, in the Polar Sea, in lat. $81^{\circ} 6' N.$
 "12. GAMMARUS BOREUS. (Sabine.)
 "Gammarus Boreus. *Supp. to Parry's First Voyage*, p. cxxix. *App. to Parry's Third Voyage*, p. 119.
 "Abundant on the shores of Low Island and in Hecla Cove. A dead specimen was found on the ice in lat. $82^{\circ} \frac{1}{4} N.$
 "13. GAMMARUS AMPULLA.
 "Gammarus Ampulla. *Supp. to Parry's First Voyage*, p. cxxix.
 "Cancer Ampulla. *Phipps's Voyage*, App. p. 192, Plate 12, fig. 2.
 "Taken from the stomach of a young seal which was shot in lat. $82^{\circ} \frac{1}{2} N.$ It is rather difficult to determine whether this animal belongs to the genus *Gammarus* or *Talitrus*; but this difficulty may possibly arise from the antennae of many of the individuals being imperfect.
 "14. TALITRUS NUGAX.
 "Talitrus Nugax. *App. to Parry's Third Voyage*, p. 119.
 "Gammarus Nugax. *Supp. to Parry's First Voyage*, p. cxxix.
 "Cancer Nugax. *App. to Phipps's Voyage*, p. 192. Plate xii. fig. 3.
 "Taken off Low Island, and in Hecla Cove, abundantly.
 "15. TALITRUS EDWARDSII. (Sabine.)
 "Talitrus Edwardsii. *Supp. to Parry's First Voyage*, p. cxxxii. Plate ii. fig. 1, 4. *App. to Parry's Third Voyage*, p. 119.
 "Abundant in the Polar Sea; great numbers were taken in a net from a depth of eighty fathoms, in latitude $81^{\circ} 6' N.$, and some dead specimens were found on the loose ice to the northward of the Seven Islands, in lat. $82^{\circ} N.$ "
- The *Caprella scolopendroides* of this and of Ross's earlier Appendix is perhaps the same as *Aegina spinosissima*, Stimpson (see Note on Ross, 1826, p. 130, and Note on Miers, 1877, p. 468). The reference to *Cancer ampulla*, Phipps, mentions fig. 2, instead of fig. 3, which is the number in the original both in the text and on the Plate. This error in the reference to Phipps' species is, for some reason, of common occurrence.

1841. VALLOT, JEAN NICOLAS.

Observations sur la chevrette, crevette des ruisseaux, crevette puce, (*gammarus pulex*). Sciences physiologiques et médicales. pp. 171-183. (Actes de l'Académie des Sciences de Bordeaux pour 1841.)

This author thinks that it is the same species which occurs in brooks and wells, variously coloured, and known by many different names, of which he gives derivations; chevrette from the Latin *caprella*; crevette, from *crabette*, petit crabe; gammarus from caris marina, "un nom hybride formé de grec et de latin" [!]; agrouelle or égrouelle from Gesner's *scrophulæ aquaticeæ*. The three pairs of pleopods, he says, are called *pattes branchiales*. In regard to the branchial vesicles, of which he does not admit the brauchial function, he curiously says that he has never been able to find them. He denies that the males carry about the females between their feet, though he allows that some of these

animals may often be seen carrying others about in this manner, but he adds, "elles finissent par les ronger sur le dos, jusqu'à ce que les ayant tuées elles abandonnent le cadavre." After referring to the statements of Baster, Roesel, Cuvier and others, with regard to the eggs being carried in the mother's ventral pouch, he owns that he has seen nothing of all this, but he says, "je me suis assuré que les crevettes pondent une espèce de frais gélatineux pareil à celui de plusieurs testacés univalves d'eau douce."

Besides the above rather singular statements, some useful criticisms are given on the figures in Roesel and Baster and the authors who copied directly or indirectly from Roesel. Vallot says that *Squilla fluviatilis*, Merret, Pin. p. 192, has nothing to do with la crevette des ruisseaux, as supposed in l'*Encycl. méthod. ins.*, t. vi. p. 187, No. 7, and le *Dict. des Sc. nat.*, t. 28, p. 354, for that Merret is not speaking at all of *Gammarus pulcher*, but only of the larva of *Dytiscus marginalis*, "signalée par Rondelet, de *piscibus fluviatil. lib.*, Cap. xxxvii. p. 112, sous la rubrique de *squilla fluviatili*."

He refers to M. Flourens, *Act. Diviron.*, 1838, p. 83, for evidence that the crevette swallowed alive would perish at once in the stomach; to M. Hippolyte Cloquet, *Enc. méthod. syst. anatom.*, t. iv. p. 498, for the capacity of these animals to clear the skeletons of moles, rats and the like; to Thulis and Bernard, *Journ. de phys.*, 1786, t. xxviii. p. 67; *Journ. d'hist. nat.*, 1787, No. 21, p. 320; *Iethyol. de la France*, Suppl., p. 34, for the phosphorescence of the fresh-water shrimp, observed at midnight in June; and lastly, states that of six crevettes frozen into a mass of ice, which was allowed to thaw slowly, three regained animation and lived for more than a month afterwards.

1844. ÖRSTED, A. S.

De regionibus marinis. Elementa topographiæ historiconaturalis freti Öresund. Hauniæ, MDCCCXLIV.

In the "Regio Trochoideorum" extending from the shore to seven or eight fathoms, Örsted found "*Talitrus saltator* Edw.—*Orchestia littorea* Leach.—*Metocetus Medusarum* Kr. in *Medusa aurita*.—*Hyperia* sp. nov. ? cum præcedente in Med. aur.—*Gammarus Sabbini* Leach, Hellebaek—Hveen.—*Gammarus Locusta* Fabr." (p. 67). *Corophium longicorne* mentioned on p. 64 seems to have been omitted from the general list by an oversight. In the "Regio Gymnobranchiorum" he includes "*Caprella linearis* Latr. Kullen—Hellebaek—*Leptomera pedata* Latr. Hellebaek" (p. 73). In the "Regio Buccinoideorum. Profunditas," the Amphipoda are "*Amphioe* sp. nov. ? Kullen—*Podocerus Laechii* Kr. Hellebaek" (p. 78). Of the *Amphioe* he gives no description, but merely says in a footnote, "Tentaculis longis circumagendis efficit planum depressius rotundum, ex cuius centro solum caput rubrum, cetero corpore latente, prominet." He makes some incidental remarks on the adaptation of the species to their respective localities.

1850. DE NATALE, GIUSEPPE.

Su pochi Crostacei del porto di Messina. *Lettera del Dottor Giuseppe de Natale socio corrispondente dell' Academia giornia di Catania al Sig. Achille Costa con una tavola in rame.* Napoli, 1850. pp. 1–16.

The discovery of two species of Crustacea, which, as he supposes, belong to the "Iperini Gammaroidi a piccol capo," the Vibiliidae, which had hitherto included only a single genus *Vibilia* and a single species *Peronii*, leads de Natale to the discussion of the organic value of the Crustacean chela and its modifications, in regard to which he says, "questi passagi graduati

dalla mano didattila [chela] al gancetto, e da questo all'ugna rigida immobile, sono così insensibili, che io non mi so con quanta ragione, in quest'ultimi tempi vi si dice tanto valore da fondar su di essi caratteri uon specifici ma genericci." Now to *Vibilia peronii*, he observes, Milne-Edwards assigns "una mano didattila ai piedi del secundo pajo, e quelli del primo si terminano, secondo lui, per una mano subcheliforme, che risponde quasi ad un gancetto. Or il primo Crostacco che nella stessa famiglia io metto, e che da me fu detto *Orattrina* e che tu ravviserai disegnato al microscopio uella fig. 1^a. non presenta chela di sorta alcuna, e offre la miglior semplicità immaginabile in tutti gli arti suoi, che son tutti terminati da semplici ugnette e che uemmeno son frangiati di peli." Had this been the only difference between *Vibilia* and *Orattrina*, he would have been content to have instituted at most a new species, science being, he thought, still in its infancy in the matter of distinguishing variations truly specific from those which are merely climatic. The other and more important characters which led him to establish the new genus *Orattrina*, he gives as follows:— "Essa è allungata, ingrossata un pochin sul mezzo, ristretta a punta verso il capo e la coda. Il capo, distinto come primo ancello, porta due paja d'antenne; le superiori sono cortissime, larghe, laminari, non cilindriche come uella *Vibilia*, e ci danno l'apparenza della lamina che giace come sostegno del peduncolo delle antenne superiori nelle Astacidi e Palemonidi. I loro articoli son due; il primo è corto, globoso; il secondo, doppio di lunghezza del primo, è terminale e laminare. Le antenne inferiori son pur cortissime, impiantate immediatamente sotto le precedenti; hanuo tre soli articoli distinti, e appena escon fuor delle superiori in avanti. L'animale, nell'acqua, mentre che è vivo, le spiega, le divarica ai lati e in sopra; ma dietro morte, compariscono come una mobile punta che corre dal capo in avanti. Gli occhi risaltano pel color nero, come un rettangolo ai lati del capo, lasciando fra essi un breve spazio lineare. La bocca sorge come lieve tubercolo, ai fianchi e dentro a cui le mascelle son come d'ordinario disposte; i palpi che le stan dietro sono picciolini, triarticolati e gracili. Tutti i piedi toracici son simili tra essi, unguicolati tutti, ambulatori, ad articoli gracili e cilindrici. Il primo, il quinto e settimo pajo sono cortissimi, ma i tre articoli del primo pajo son gracili tutti, mentre i basilari del quinto e settimo pajo sono un pochino ingrossati. I piedi del secondo, terzo e quarto pajo sono più lunghi, ma tutti i loro articoli, eccettuato il basilare che è grosso, son gracili e cilindrici. Il sesto pajo è più forte di tutti, e presenta esso solo un dente rilevato sull'orlo posteriore dei suoi articoli."

"Io non ho potuto ravvisarvi i grandi palpi articolati che Edwards attribuisce alla *Vibilia*; la mano subcheliforme al primo pajo di piedi, e la chela al secondo pajo mancano qui egualmente. I primi falsi piedi addominali si fanno, come nella *Vibilia*, rilevare per la grossezza del lor peduncolo basilare, a capo a cui s'inscrisce un altro articolino, e poi una vera lamina triangolare membranosa, liscia, non orlata né di peli né di dentelli. Sai tu bene, che simili piedi nella *Vibilia*, sono dentellati e frangiati di lunghi peli agli orli. Finalmente la miglior differenza che ho potuto ravvisare tra la *Vibilia* e l'*Orattrina* mia, è negli ultimi falsi piedi che in quest'ultima costituiscono una notatōja molto complessa. Il quarto falso piede è gracile e terminato da due stiletti cilindrici a tre articoli diretti in dietro orizzontalmente; il quinto pajo è cortissimo ed ha due articoli indistinti; il sesto pajo finalmente è il più robusto di tutti; porta di fatti un potente articolo basilare fiancheggiato dai piedi seguenti, con due stiletti terminale, e con un appendice ibiliforme¹ ai lati suoi. Il corpo poi si termiuva per un segmento picciolissimo di forma conica."

Fig. 2 shows the *Orattrina*, as seen from above, with the uropods spread out, and the back as it were tri-lobed. After calling attention to this appearance of the back, de Natale sums up the differences which he found between *Orattrina* and *Vibilia*, and gives the reason for the specific name.

¹ What *ibiliforme* means I have no idea; it occurred to me at first that it might be a misprint for *vibiliforme*, with the meaning as in *Vibilia*, but the explanation would still need explaining.

"I suoi caratteri specifici sono :

"Orattrina *Pulchella* (Nobis) : *Corpo erythrino, antice posticeque subulato; longitudine altitudinis sextuplum fere æquante; segmento terminali corporis conico brevissimo, articulis pedum thoracorum sextæ seriei postice unidentatis, reliquis pedibus glabris edentulis.*"

The length is not more than seven lines, and the specimens occur in abundance in company with *Orio zancleus*, *Phrosine*, *Typhlis*, *Phronima*, etc. Very much rarer is the next species, which he at first thought was a little fish.

"Erpetoramphus Costæ : fig. 3." "Il nome di Erpetoramphus che io gli diedi per questo te ne darà la ragione. Il suo capo, di fatti, somiglia, quando è di troppo ingrandito, a quello acuto di una Lucertola, terminasi per un lungo rostro affilato a punta, rigido, immobile, all'estremo di cui mostrasi una membranella con appendice membranosa, e credo che questa osservata con ingrandimenti maggiori, ci darebbe due piccolissime antenne, e di queste produzioni di fatti non ha traccia alcuna altrove, ond'io sono portato a crederle antenne vere. Gli occhi son piccoli, rotondetti, neri e posti ai fianchi del capo, alla parte posteriore del quale ove s'immette esso coll'anello primo del torace ed in sotto, risalta come lieve tubercolo la bocca, i cui pezzi mandibolari sono secondo l'ordinario disposti e costrutti. I piedi mascellari, che qui li chiameresti palpi, son esilissimi, gracilissimi, a tre articoli indistinti. Gli anelli toracici son lisci, non solcati come nell'Orattrina. Ma il primo pajo di piedi deve dare a quest'animaluzzo grand'ajuto nelle sue prede, poichè esso è cortissimo e robusto di troppo a paragone della sua taglia, a due articoli peduncolari brevissimi, ma il terzo è largo, trapezoedro, compresso, e terminato da una mano didattila dentellata agli orli. Il secondo pajo di piedi toracici lo vedrai gracile, cilindrico, a tre articoli ben conformati, l'ultimo de' quali presso a poco eguale al precedente si termina a punta senza mostrare ugnetta accessoria. Gli articoli basilari dei piedi del terzo, quarto, quinto e sesto pajo si dilatano in una lamina ovoidea diafana, e tutte queste lame nel riposo copronsi imbricate a vicenda; il terzo ed il quinto pajo sono i più lunghi, e tutti terminansi unguicolati. Il settimo pajo è quasi simile al secundo, ma presenta un'ugnetta terminale. I primi tre anelli addominali sono larghi quanto i toracici, i falsi piedi che ne pendono in giù sono analoghi a quelli dell'Orattrina, ma vanno più brevi quanto più corron dietro, e l'ultimo ne è piccolissimo.

"I tre ultimi auelli addominali restringonsi un pochino, e l'ultimo convertesi in una coda inarticolata terminale; i loro piedi son trasformati in notatoja codale di tre lamelle, di cui le due anteriori sono lamellose e terminate a puuta, l'ultima più o men cilindrica e subulata.

"È pur picciolino quest'Erpetoramphus, e tien fra gli altri caratteri anco la statura, ed i colori dell'Orattrina, e con essa si accompagna ma è molto raro, ed i due soli che ne tengo li conservo con assai cura presso di me. Come ti dissi, io ne consacrai a tuo padre la scoperta; ne vuoi i caratteri della specie? Eccoteli :

"Erpetoramphus Costæ (Nobis). *Corpo erythrino, antice posticeque subulato, longitudine decuplum altitudinis fere æquante; oculis rotundatis nigris; pedibus edentulis, segmento caudæ terminali conico.*"

After deciding that *Vibilia*, *Orattrina*, and *Erpetoramphus* are certainly animals of the same family, he proceeds to consider the species called *Bivonia culicina* by Cocco in 1832. Having compared a specimen of this with Milne-Edwards' description of *Phronima*, he says,

"Ti penserai già la meraviglia che mi ebbi quando trovai una Fronima in tutti suoi caratteri generici, il capo, i palpi, i piedi tutti, il torace, l'addome erano similissimi; l'unica differenza che vi rimarcai era nella presenza di due paja di lunghe e filiformi antenne, così sottili come un capello.

"Il pajo superiore come vedrai nella fig. 4, è nel suo coto e grosso peduncolo simile all' inferiore, ma nel primo pajo al di là di quest'articolo basilare corre un altro gracile, cilindrico, inarticolato, a corpo a cui s'innestano molti articoletti piccolissimi, fino all'ultimo che diventa

veramente microscopico. Le antenne iuferiori però al di là del peduncolo corrono capillari, mollissime, inarticolate. Il disegno che ne offro te ne mostrerà chiaro il fatto. Eccoti adunque una Fronima con due paja di lunghe, e gracilissime antenne."

De Natale fancies that all specimens of *Phronima* hitherto observed may have had the antennæ mutilated. Nature, he says, rarely introduces one modification of an animal without correlated variations. "Possibile che conservati i caratteri tutti d'una Fronima, la natura avesse voluto innestarvi due paja di corna senz' altro? Io ci stento a crederlo, e inclino troppo a credere che le Fronime hanno sempre due paja di gracilissime antenne, che la Bivonia *culicina* di Cocco è una Fronima. Terrai come ti agrada questa mia maniera di pensare, il fatto è che io tengo presso di me una Fronima con 2 paja d'antenne gracilissime. La specie che te ne dò, la chiamo *Coccoi* ad onore del suo scopritore; essa è una specie distinta. Picciolina di 3 a 4 linee al più, cristallina con punti aranciati disseminati, distinguesi dalla *Phronima sedentaria* perché non ha come questa un sol dente sul taglio interno del dito della mano didattila, ma ne ha 5 c. conspicui, e non presenta come questa l'antipenultimo articolo dei piedi delle due prime paja prolungato sotto del gancetto. Non è la Ph. *Atlantica* che ha due denti al gaucetto della chela. Sarà la Ph. *sedentaria* di Risso? Ma quest' ultima è così mal nota, tanto informe il disegno, che non se ne può tener conto. Abbiti adunque la "Phr. *Coccoi* (Nobis). *Hyalina, punctis aurantiacis adpersa; dentibus quinque conspicuis in manu didactyla.*"

The figure and the description of *Phronima coccoi* alike make it clear that de Natale had obtained the male of some species of *Phronima*, of what species it might not be easy to decide even if we had his specimen. His *Orattrina pulchella* beyond doubt belongs to the genus *Vibiliia*, and is probably a synonym of *Vibiliia jeangerardii*, Lucas, with which it agrees at any rate so far as the antennæ and the colour are concerned. It is pretty evident from the figures that de Natale's account of the gnathopods was based on insufficient examination, and the trilobation which he ascribes to the body was most likely due to accidental wrinkling of his specimen. It may be, however, noticed that Lucas says of his species, "le cinquième segment abdominal [in the Latin by mistake septimo segmento abdominiis] paraît comme trilobé en dessus. *Erpetoramphus costæ* comes perhaps as near to *Oxycephalus similis*, Claus, from Messina, as to any other of the hitherto described Oxycephalidae. It is rather singular that de Natale should not have noticed its affinity to his own recently described *Ornithoramphus*.

Boeck's account of this paper is, that its author describes "two Hyperids, namely, *Orattrina pulchella*, Natali, which seems to be a *Vibiliia*, and *Reptoramphus Costæ*, which looks like a *Platycheles*. His description of them is very short, and the figures are inadequate." Why Boeck changes *Erpetoramphus* into *Reptoramphus* is not explained, nor is it clear what he means by the comparison with *Platycheles*, a genus unknown among Amphipoda.

The genus *Seba*, which, from the reference in the Brit. Mus. Catal. Amph. Crust., p. 159, might have been expected to occur in this pamphlet, is not mentioned in it, and I hear from Prof. A. Della Valle that A. Costa, to whom Spence Bate attributes the genus, expressly denies having established it.

1854. BATE, C. SPENCE.

The Annals and Magazine of Natural History. Ser. 2. Vol. XIII. London,
1854. p. 504.

The name *Bellia*, Sp. Bate, 1851, as preoccupied, is here changed to *Sulcator*; itself a synonym of *Haustorius*, P. L. S. Müller.

1856. THOMPSON, WILLIAM, died February 17, 1852 (R. Patterson in Preface).

The Natural History of Ireland. In four volumes, 1849–1856. Vol. IV. London, 1856.

Pages 395 to 400 give lists of Amphipoda and Læmodipoda, with a long note on *Chelura terebrans*, Philippi, and some short notes on other species. Of "Gammarus fluviatilis, Edw.", he says, "I have found the stomach of the *Salmonidae*, from Lough Neagh, often entirely filled with it." One entry is "*G. longimanus*, Leach (sp.). *Mæra longimana*, Leach MSS. A single one taken with last [*G. campylops*, Leach]:—same as Leach's unique specimen in the British Museum." He has also found "*Gammarus punctatus*, Johnst.," and "*Amphithoe fucicola*, Leach (sp.)," meaning by the latter Leach's *Pherusa fucicola*. He gives the size and colouring of the Belfast species of *Anonyx*, "which," he says in a parenthesis, "is well worthy of the name of *elegans*." His list of Gammarina contains seventeen species, of Hyperina three, "*Hyperia galba*, Mont. (sp.)," "*H. Latreillii*, Edw.," and "*Lestrigonus*, sp." The Læmodipoda include nominally seven species.

1860. RENTSCH.

Homoio genesis. Beitr. z. Natur- u. Heilkunde. 1860. (Nervous system of *Gammarus ornatus*.)

I am indebted for this reference to A. S. Packard's Bibliography of the nervous system of Crustacea.

1861. SILL, VICTOR.

Beitrag zur Kenntniss der Crustaceen, Arachniden und Myriopoden Siebenbürgens. Verhandlungen und Mittheilungen des siebenbürgischen Vereines für Naturwissenschaften zu Hermannstadt. XII. Jahrgang. Hermannstadt, 1861. N^o. 1. Januar, 1861. p. 3. Zweiter Beitrag zur Kenntniss der Crustaceen und Arachniden Siebenbürgens. N^o. 11. November, 1861. pp. 181, 182.

On page 3 descriptions are given of "Gammarus puteanus Koch" and "Gammarus fossarum Koch," quoted without material alteration from Koch's work (see Note on Koch, 1835, p. 159).

At page 181 Sill makes the following observations:—

"Gammarus pulex Fabr. (Koch : Heft 36. Nro. 21). Er ist $\frac{3}{4}$ " lang, von derselben Gestalt wie G. fossarum, doch an den scharfen, zahnartigen Spitzen des 8., 9. und 10. Körperringes leicht zu erkennen; es ist nämlich der Hinterrand dieser Ringe in ein scharfes, stachelartiges Zähnchen verlängert. In Wassergräben (Grossscheuern).

"Vergleichen wir nun Gammarus pulex mit Gamm. fossarum und puteanus (S. Verh. und Mitth. Nro. 1 Jahrg. 1861) so finden wir als charakteristisches Unterscheidungszeichen das Fehlen oder Vorhandensein der Dornen. Daher unterscheidet auch M. Edward's Gamm. pulex (ohne Dornen) und Gamm. fluviatilis (mit starkentwickelten Dornen); während Koch dem mit Dornen der Namen Gamm. pulex gab und aus dem ohne Dornen Gamm. puteanus und fossarum machte.

"Die Herrn Cornel Chyzer und Alexander Tóth in Pest¹) vereinigen aber Gammarus fluviatilis Miln. Edw. mit Gammarus pulex F. und stellen den mit Dornen als Varietät mit dem Namen Gamm. spinosus auf.

¹ Siehe der Naturfreund Ungarns, herausgegeben von Dr. J. von Nagy und A. F. Láng, IV. Heft. Neutra 1857.

(ZOOL. CHALL. EXP.—PART LXVII.—1888.)

“ Die Dornenlosen unterscheiden sich nämlich von den mit Dornen auch durch die Form der Augen, welche bei den Letztern deutlich nierenförmig, bei den Erstern oval sind. Dieser Charakter ist so constant, dass man von der Form der Augen auf das Vorhandensein oder Fehlen der Dornen und umgekehrt schliessen kann. Es gibt aber auch Individuen bei welchen die Dornen sehr schwach ausgeprägt sind, ja sogar nur ein einziger ganz schwacher Dorn vorhanden ist.

“ Diese Uebergangsformen sind wohl geeignet, die vielleicht unrichtige Benennung und Unterscheidung von Gamm. puteanus fossarum und pulex Koch—dahin zu berichtigen, dass blos Gamm. pulex Fabr. mit der Varietät spinosus beizubehalten sei.”

From the reference here given to Dr. Cornel Chyzer, it may be surmised that he takes notice of some fresh-water species of *Gammarus* in his work “ Ueber die Krustaceenfauna Ungarns. Verhandl. des Zool. Bot. Vereines 1858,” which is mentioned in a bibliographical list by Dr. Anton Frič.

1862. WALKER, DAVID.

Notes on the Zoology of the last Arctic Expedition under Captain Sir F. L. M'Clintock, R.N. [Read Friday Evening, April 27, 1860.] The Journal of the Royal Dublin Society. Vol. III. 1860–61. Dublin, 1862. pp. 61–77.¹

An introductory observation states that, “ with a very few exceptions, none of the species of birds, fishes, mollusca, crustacea, and insecta are strictly confined to the Arctic regions.” The Amphipoda are recorded as follows on page 68 :—

- “ † ‡ *Gammarus loricatus* (Sab.).—Numbers found swimming about in Port Kennedy.
 - “ † ‡ *Gammarus locusta* (Mont.).—Associated with the former and following species at Port Kennedy.
 - “ † ‡ *Gammarus boreas* (Sab.).—Ditto.
 - “ † ‡ *Amphitoe Edwardsii* (Sab.).—Near Cape York, 15 fathoms.
 - “ † ‡ *Amphitoe Sabini* (Leach).—Caught in a garbage net in numbers at Port Kennedy.
 - “ † ‡ *Acanthosoma lystris* (Owen).—Near Cape York, 15 fathoms.
 - “ ‡ *Lysianassa rahlili*
 - “ † ‡ *Lysianassa appendiculata* } (Kroyer).—Found at Port Kennedy.
 - “ ‡ *Stegocephalus ampulla* (Kr.).—Two very fine specimens obtained at 10 fathoms in Port Kennedy.
 - “ † ‡ *Themisto Arctica* (Kr.).—Found in the stomach of a seal at Port Kennedy.”
 - “ Specimens of species marked thus † are deposited in the Museum of the Royal Dublin Society.
 - “ Specimens of species marked thus ‡ are deposited in the Queen's College, Belfast.”
- Page 69 contains “ a comparative table, showing the number of crustacean species brought home by the several expeditions under Parry, Ross, Penny, Belcher, and M'Clintock.” Seventeen species of Amphipods are named, including besides those already mentioned, “ *Gammarus Sabini* (Leach)”; “ *G. Kroyeri* (Bell)”; “ *G. nugax* (Fabr.)” said in a foot-note to be “ now usually referred to genus *Lysianassa*”; “ *Amphitoe Jurinii* (Kr.)”; “ *A. laxiuscula* (Kr.)”; “ *Lysianassa sagenae* (Kr.)”; “ *Metoecus Cyanex* (Sab.).” *Gammarus sabini* (Leach) and *Amphitoe sabini* (Leach) are both of them credited to Ross' Second Voyage and to Penny's, while the two names are divided between the other voyages, Parry's first and second and Belcher's receiving *Gammarus sabini* and M'Clintock's the synonymous *Amphitoe sabini*. *Lysianassa appendiculata* is attributed only to M'Clintock's voyage, and to that with a note of interrogation.

¹ Attention is called to this paper in the Nat. Hist. of Greenland, 1875, and in Hansen's Malac. mar. Groenl. occid., 1887.

1864. GRUBE, A. E.

Ueber ein neues Crustaceum; *Iceridium fuscum* Grube, pp. 58-59 (read February 18), and Ueber die Crustaceen-Fauna des adriatischen und Mittelmeeres, pp. 59-64 (read April 1). Einundvierzigster Jahres-Bericht der Schlesischen Gesellschaft für vaterländische Cultur. Enthält den Generalbericht über die Arbeiten und Veränderungen der Gesellschaft im Jahre 1863. Breslau, 1864.

As to *Iceridium fuscum*, see Note on Grube, p. 348. In the second paper Professor Grube briefly describes the following new species:—

“*Allorchestes stylifer*, der *Amphithoe Prevosti* ähnlich, aber mit verhältnissmäßig längeren obereu Antennen und einem ansehnlichen Fortsatz am drittletzten Gliede des zweiten Fusspaars beim Männchen, wie bei *A. australis*. (See p. 365.)

“*Iphimedia multispinis*, sehr auffallend gezeichnet, blassröhlich mit Querreihen orangegelber Flecken, der Endrand des 7. und der drei nächsten Segmente mit 1 Paar langer Rückenzähne, des 8., 9. und 10. ausserdem mit 1 unpaaren Zahne vor jenen, sonst aber nicht bewaffnet, die Hüftplatte der vier vorderen Beinpaare in eine spitze Zacke auslaufend, Augen oval, im Uebrigen der *I. nodosa* ähnlich.” (See pp. 348, 353.)

“*Protomedieia guttata*, am meisten mit *Pr. pilosa* übereinstimmend, aber mit 3 Rückenzähnchen auf dem 11. Segment, auch ganz anders gefärbt: chamois mit Querreichen brauner Tropfen.” (See p. 366.)

“*Cerapus latimanus*, von *C. abditus* besonders durch die Bildung der Hand des zweiten Fusspaars abweichend, die hinten nur $\frac{1}{3}$ schmäler als der *Carpus* und hier am Unterrand ausgeschnitten ist, ebenso durch die längeren Zähne des *Carpus* und durch die viel längere und allmälig zugespitzte Klaue.” (See p. 349.)

“*Caprella quadrispinis*, von der Gestalt von *C. phasma* (Mont.), mit 1 Zahn auf dem Kopf und dem 1. Segment und 2 nebeu einander auf dem zweiten, welches so lang als jene zusammen ist. Das 2. sehr lange und vor der Mitte angesetzte Fusspaar hat an der gestreckten Hand einen dreizackigen Unterrand, sie ist so lang als der Schenkel, viel länger als das zweite Segment selbst.” (See p. 1244.)

“*Caprella gracilipes*. Der Körper sehr schlank, das 1. Segment kürzer als der Kopf; das 2. sehr gestreckt und über der Insertion seines Fusspaars, nahe am Hinterrande, knotig verdickt, der Schenkel dieses Fusspaars äusserst dünn und lang, die Hand dagegen kurz und breit mit vorderem unteren Ausschnitt, vor und hinter welchem 1 Zahn.” Mayer pronounces this description insufficient for the recognition of the species, but evidently based on a male specimen.

1869. NORMAN, A. M.

Last Report on dredging among the Shetland Isles, by J. Gwyn Jeffreys, F.R.S., Rev. A. Merle Norman, M.A., W. C. M'Intosh, M.D., F.L.S., and Edward Waller. In Report of the thirty-eighth meeting of the British Association for the Advancement of Science; held at Norwich in August 1868. London 1869.

The Amphiopoda, by Norman, are reported on pages 273 to 288, with a postscript, pp. 335-336. The new species described are *Probolium serratipes*, which in 1886 Norman still leaves

under that title, probably awaiting an examination of the mandibles for its transfer to *Metopa* or *Stenothroë*; *Ediceros æquicornis*, which "comes near to *E. brevicalcar* of Goës"; *Syrrhoë hamatipes*, of which Norman says, "I place this species provisionally in the genus *Syrrhoë*; the head having been crushed, I am unable to speak with precision respecting the eyes and rostrum;" *Atylus macer*, a species not mentioned in the Museum Normanianum, 1886, and almost certainly not belonging to *Atylus*, since the fifth and sixth pleon-segments are apparently not coalesced; *Megamphopus cornutus*, "species typica"; *Protomediea pectinata*; *Cyrtoplium armatum*, of which Norman says, "the sixth and seventh segments of the perion appear to be coalesced. It approaches *Lætnatophilus tuberculatus* of Bruzelius, but is much more strongly tuberculated, and the gnathopods of different structure, the first smaller, the second larger, the hand broader, and the basos spined"; in 1886 he names it *Lætnatophilus armatus*; *Corophium tenuicorne*, the female only observed, and that "resembling in general characters the same sex of *longicorne* and *crassicorne*." The new genus *Megamphopus* is defined as follows:—

"Antennæ slender (imperfect), the insertion of the lower so much behind that of the upper that the end of the third joint of the peduncle is only on a level with the end of the head. First segment of pereion produced forwards and downwards on each side into a remarkable horn-shaped process. Both pair of gnathopods greatly developed, of equal size, and subchelate. First three pereiopods short, last two much longer. Telson tubular."

There are numerous notes on species not new, referring principally to the synonymy. On page 275, "*Anonyx ampulla* (Phipps). *Cancer ampulla*, Phipps," is given by mistake for *Cancer nugax*, Phipps. Descriptions more or less complete are given of the species named "*Probolium Alderi* (Bate)=*Montagui Alderi*, B. & W."; "*Amphelisca æquicornis*, Bruzelius"; "*Ampelisca tenuicornis*, Lilljeborg"; "*Ampelisca carinata*, Bruzelius, . . . = *Ampelisca Gaimardi*, Bate, . . . (but not *A. Gaimardi* of Kröyer and Bruzelius)"; "*Ampelisca levigata*, Lilljeborg"; "*Ampelisca macrocephala*, Lilljeborg," with the remark that "the *Ampelisca Belliana* of Bate appears to be referable to this species"; "*Eusirus Helvetiae*, Bate=*Eusirus bidens*, Heller"; "*Aora gracilis*, Bate=*Autonoë punctata*, Bruzelius"; "*Microdeuteropus anomalus* (Rathke). *Gammarus anomalus*, Nova Acta Leop. 1843, p. 63, pl. iv. fig. 7, = *Autonoë anomala*, Bruzelius, Skand. Amphip. Gammarid. p. 25, pl. i. fig. 4 (but scarcely *Microdeutopus anomalus*, Bate & Westwood, Brit. Sessile-eyed Crust. p. 289), = *Microdeutopus gryllotalpa*, Bate & Westwood, l. c. p. 289 (but not of Costa)"; "*Microdeuteropus versicolatus*, Bate"; "*Microdeuteropus Websteri*, Bate," with the remark, "I question whether there are sufficient grounds for separating the genus *Aora* from *Microdeuteropus*"; "*Protomediea (?) Whitei*, Bate," with the suggestion that it is the female of "*Lilljeborgia Shetlandica*"; "*Protomediea hirsutimanus*, Bate," which in 1886 Norman calls *Ptilochirus hirsutimanus*, Bate; "*Hyperia obliqua*, Kröyer, Grönlands Amphipoder, p. 298, pl. iv. fig. 19 (but not *H. obliqua*, Bate & Westw. vol. ii. p. 16)"; "Bate and Westwood's '*H. obliqua*,' which has not the propodos of the gnathopods at all produced, cannot be Kröyer's species nor that here described;" "I would propose for it the name of *H. gracilipes*"; "*Metoëcus medusarum*, Kröyer, Grönlands Amphip. p. 288, pl. iii. fig. 15 (not *Hyperia medusarum*, Bate, Cat. Amphip. Crust. Brit. Mus. p. 295)." The specimen for which the name *Hyperia gracilipes* is here suggested more probably, however, belongs either to *Parathemisto* or (on the supposition of its not being full grown) to *Euthemisto* (see p. 1420).

The Postscript, besides remarks on other species, says of Bate and Westwood's *Hyperia tauriformis*, "this is the *Metoëcus medusarum* of Kröyer and of this Report. B. & W.'s specimens were from Banff, forwarded by Mr. Edward, to whom I am also myself indebted for specimens." The species is now named *Hyperoche medusarum* (Kröyer).

On *Syrrhoë hamatipes* and *Megamphopus cornutus*, see pp. 788, 1108.

1872. BOECK, A.

Bidrag til Californiens Amphipode fauna. (See p. 410.)

A separate copy of this paper lent me by a friend was devoid of the illustrative plate, which my friend assured me had never been published. The volume of the "Forhandlinger i Videnskabs-Selskabet i Christiania Aar 1871. Med 3 lithographerede Plader," containing Boeck's paper, possessed three plates as promised on the title-page, but none of the three had anything to do with the species which Boeck describes. Mayer, Die Caprelliden, p. 12, also says that he is indebted to G. O. Sars for the information that the plate in question was never printed. In May, however, of this year to my surprise I was able to obtain from Oswald Weigel iu Leipzic a separate copy of the paper with the missing plate.

The figures confirm the view taken in my account of *Caprella scaura*, Templeton, p. 1267, that the *Caprella californica* described by Boeck is one of the synonyms of that species. The rounded apex of the hand in the second gnathopods is rather conspicuously produced in Boeck's figure, and the tooth on the inner margin of the finger near its hinge has an appearance slightly differing from what is found in other figures and specimens which I have regarded as belonging to Templeton's species, but these small variations are of no great weight in themselves, and may, I think, be in part attributed to the accidental condition of the specimen figured.

The species named *Caprella verrucosa*, which Mayer thought might possibly be the young of *Caprella acanthifera*, Leach, is shown by the figures to come nearer to one or other of the forms that have received the specific name *tuberculata*. It is distinguished from *Caprella acanthifera* by the very prominent frontal tooth or horn, and from all other species of *Caprella* by the considerable size of the process of the hand in the second gnathopods of the male, a deep cavity being formed between this process and the distal part of the hind margin which is slightly concave. Boeck himself says that the species "is so peculiar by its short antennae and its body beset with large, finely tuberculated warts, and lastly by the slight difference in the structure of the body in the two sexes, that it cannot be confused with any other described species."

1873. FRIČ, ANTON (see Note on Frič, 1872, p. 415).

Die Krustenthiere Böhmens. Archiv für die naturwissenschaftliche Landes-durchforschung von Böhmen. Zweiter Band. Zweiter Theil. Mit 1 lithogr. Tafel und 126 Holzschnitten. Prag, 1873. pp. 201-271.

The preface is dated "Prag im Juli 1871." The account of the Amphipoda is given on pp. 264, 265. It contains the following descriptions:—

"Gatt. *Gammarus*. Die oberen längeren Fühler tragen an der Spitze ihren 3gliedrigen Stielcs, neben der langen Geissel, einen kurzen 5gliedrigen Faden; die beiden vorderen Fusspaare in beiden Geschlechtern Greiffüsse, deren hakiges Endglied sich gegen das verdickte Fussblatt einschlägt. Die Afterfüsse der beiden letzten Hinterleibsglieder und die beiden Endanhänge des Schwanzes sind gabelige Springstiele."

"*Gammarus pulex*, Fabr. [Fig. 99]. Das vorletzte Glied des ersten Fusspaars ist birnförmig und nach vorne in eine kurze Spitze ausgezogen. Die Augen rund, die unteren Fühler sind mit kurzen Haaren verschen. Jedes der 3 hintersten Leibessegmente hat am Hinterrande 3 Borstenbüscheln, von denen die seitlichen zu 2-3 Borsten zu erhalten pflegen. Die Farbe ist gelblich grün oder bräunlich. Länge 10-15 mm. Leben in reinen Quellen und

den darans entstehenden Bächen, wo sie den Fischen und namentlich den Forellen eine gute Nahrung liefern. Bei Prag kommen sie am nächsten im Cibulkabache vor und haben Exemplare von dort häufig in ihrem Darmkanal einen *Echinorhynchus*."

"*Gammarus puteanus*, Koch. [Fig. 100]. Das vorletzte Glied des ersten Fusspaars ist schief viereckig, vorne viel breiter als hinten. Augen fehlen. An dem hinteren Rande der ersten drei Leibessegmente sehr feine Stacheln, an den letzten drei fehlen die Borstenbündel. Farbe stets weiss."

The figures would require discussion, only that they seem to be of a conventional character. In the definition of the genus *Gammarus*, it can scarcely be necessary to give the number of joints in the accessory flagellum of the upper antennæ.

1873. GODET, PAUL.

Bulletin de la Société des Sciences naturelles de Neuchatel. 1870 à 1873.
Tome neuvième. Neuchatel, 1873. *Séance du 21 décembre 1871.* pp. 153–155.

Of three specimens of *Gammarus* found in a well at Neuchatel, the largest measured, without the antennæ, 32 mm. in length, the smallest about 12 mm. The largest was distinguished by the extraordinary length of the last uropods. "The species is distinguished," Godet says, "from our *Gammarus fluviatilis* by the following characters:—absence of eyes: penultimate joint [hand] of the two pairs of anterior feet [gnathopods] of triangular shape, almost as broad as long: upper antennæ very long, of about 51 joints." He compares it with the somewhat obscure *Gammarus puteanus* of Koch, and with the *Gammarus puteanus* of La Valette. To judge by the figure, it cannot be far remote from *Niphargus aquilex*, Schiødte.

1873. HESSE, EUGÈNE.

Mémoire, &c., see Note on page 417.

There are some difficulties connected with M. Hesse's description and figures of his species of *Ichthyomyzoculus*, which require discussion. The dorsal view, fig. 3., of "*Ichthyomyzoculus Morrhuæ*" is strongly suggestive of *Lafystius sturionis*, Kröyer, 1842, a species which has been taken, according to Bruzelius, on *Gadus morrhua*, *Acipenser sturio*, and *Galeus canis*, according to S. I. Smith, in the mouth of a goose-fish (*Lophius americanus*), and which is labelled in the Challenger collection as taken parasitic on *Cottus*. There seems a strong improbability that the cod should have two parasitic Amphipods so like one another in general appearance, in the head, antennæ, claws, and uropods, as *Lafystius sturionis* and *Ichthyomyzoculus morrhua*, if these are to be considered distinct species. On the other hand, if they are the same, M. Hesse's account is open to much criticism. Of the seven rings of the thorax (peræon-segments), he says that "aucun d'eux ne présente de pièces épimériennes sur les côtés," whereas in *Lafystius sturionis* all these segments have the usual side-plates. He represents the first three pairs of thoracic legs as practically all alike in form and direction, and similarly the last four pairs, whereas in Kröyer's species the two pairs of gnathopods differ as usual to some extent from the first two pairs of peræopods, and, though all the five pairs of peræopods are very much alike, the first two pairs according to rule face the last three, not one another. *Ichthyomyzoculus morrhua* and *Ichthyomyzoculus lophii* are placed under the heading "B.—"Abdomen formé de cinq articles et terminé par trois paires de tiges," yet in the specific description of the former we read "l'abdomen contient aussi sept anneaux,"

and of the latter "l'abdomen se compose aussi de sept anneaux." *Ichthyomyzocus squatinæ* stands under the heading "C.—Abdomen formé de deux articles et terminé par deux paires de tiges," and for this the specific description, without any inconsistency, says, "la partie abdominale est relativement extrêmement courte, puisqu'elle ne se compose que de deux anneaux." But, to compensate for this diminished abdomen, M. Hesse assigns ten segments to the thorax, which would at once remove the species from the Amphipoda and the Edriophthalma altogether. The figure, however, shows plainly that three of these ten thoracic segments belong to the abdomen or pleon. It is a little perplexing that, though fig. 19 gives to this species only two pairs of uropods in accordance with the text, fig. 26, on the contrary, depicts three pairs. *Ichthyomyzocus ornatus* is placed under the heading "A—Abdomen formé de cinq articles et terminé par trois tiges." Fig. 1 represents this species with a very narrow pleon, carrying a pair of uropods at the distal corners of the fifth segment; between these is what looks like a very narrow segment coalesced with the preceding and having the two rami of a uropod attached to its distal end not quite centrally. It is clear that M. Hesse's single specimen was defective. The absence of the telson from this and the preceding species can scarcely be accepted without corroboration. To determine the true position of all these species, further details must be awaited, and their peculiarities seem well worth a careful investigation.

1874. DALL, W. H.

On New Parasitic Crustacea, from the N.W. Coast of America. (Published in advance, March 3d, 1874.) Proceedings of the California Academy of Sciences, Volume V. 1873–1874. San Francisco, June, 1875. pp. 254, 255.

"On examination," Mr. Dall says, "of a small collection of parasites, in the collection of the Academy (presented by Captain C. M. Scammon, and reported to have been procured from a Pacific Right Whale, near the Island of Kadiak, Alaska, in 1873) I find that it contains two species, both apparently undescribed." The first he describes as *Cyamus tentator*, n. sp., which, he says, "is readily distinguished from *C. mysticeti*, Dall, by its spiked 'hands' and knobby branchial segments; and from *C. Scammoni* by its straight unequal brauchiæ, long antennæ, knobs, and the shape of the head." The second he describes as *Cyamus gracilis*, n. sp., and says that "the prominent features of this species are its slender and compact form, short antennæ, and weak and inconspicuous posterior limbs."

Lütken decides that *Cyamus gracilis* is the same as the species already so named by Roussel de Vauzème, and *Cyamus tentator* the same as de Vauzème's *Cyamus ovalis*.

1874. SCAMMON, CHARLES M.

The marine mammals of the North-western Coast of North America, described and illustrated: together with an account of the American Whale-fishery. San Francisco, 1874.

Of the Californian Gray Whale (*Rhachianectes glaucus*, Cope), he says, p. 21, "both sexes are infested with parasitical crustaceans (*Cyamus Scammoni*), and a species of barnacle (*Cryptolepas rhachianecti*), which are chiefly upon the head and fins." In a footnote Dall's description of "*Cyamus Scammoni*, n. sp." is quoted from "Proceedings Cal. Acad. Sci., Nov. 9th, 1872." A footnote to the description of the Humpback Whale (*Megaptera versabilis*, Cope), p. 38,

quotes Dall's description of "*Cyamus suffusus*, n. sp." from "Proc. Cal. Acad. Sci., Dec. 18th, 1872." In the description of the Bowhead or Great Polar Whale (*Balaena mysticetus*, Linn.), it is remarked, p. 57, that "the Arctic Bowhead is comparatively free from parasitic crustaceans, as well as barnacles. Occasionally, however, a species of *Cyamus* is present about the head or fins," and a footnote quotes Dall's description of "*Cyamus mysticeti*, n. sp.," including by an obvious misprint "Length 33 inches; breadth (of body) 16 inches." The species of *Cyamus* are also referred to in Dall's Appendix, at pp. 301, 302, 305, on the latter page *Cyamus tentator*, Dall, and *Cyamus gracilis*, Dall, being mentioned as parasites of *Balaena sieboldii*.

In describing the gambols of the Sperm Whale (*Physeter macrocephalus*, Linn.), at p. 77, Seammon says, "These singular antics of the Sperm Whale are said to be performed in order to rid itself of a troublesome parasite, known among the whale-fishers by the name of 'Suckfish'; but the animal is seldom infested with the parasitic crustacea, which are indigenous to the rorquals and Right Whales."

On this point and on the species of *Cyami* here mentioned, compare Note on Lütken, 1887.

1875. ALLMAN, G. J.

Instructions on the Construction and Method of Using the Towing Net, and Notes on the Animals which may be obtained by its employment. In Instructions for the use of the Scientific Expedition to the Arctic Regions, 1875. London, 1875.

Under *Arthropoda*, at p. 57, Dr. Allman says, "Among the invertebrate life which abounds in Arctic seas, and which from the concurrent testimony of Arctic voyagers constitute a characteristic feature of their fauna, will be found the *Amphipodous Crustacea*. These are small active animals, most familiarly known to us by the 'sand hoppers' of our own shores. In Arctic regions they are often attracted in countless multitudes by fragments of offal thrown into the sea. To such an extent do they abound there that the carcass of a seal has been in a few hours reduced by them to the condition of a clean skeleton. They frequent various depths from the surface downwards, and may be all well preserved in spirit."

1875. BARCELÓ Y COMBIS, FRANCISCO.

Apuntes para la Fauna Balear. (Sesion del 3 de Febrero de 1875.) Anales de la Sociedad Española de Historia Natural. Tomo cuarto. Madrid, 1875.

In the "Catálogo de los crustáceos marinos observados en las costas de las islas Baleares," at page 67 the "Hedrioptalmos" comprise two Amphipods, "*Orchestia* Leach. *O. Montagui* And. [Aud.]. *Pugó* en Mallorca!," and "*Gammarus* Fabr. *G. locusta* Fabr. Mallorca."

1875. LOCKINGTON, W. N. (see p. 443).

Observations on the genus *Caprella*, and Description of a New Species. Proceedings of the California Academy of Sciences. Volume V. 1873–1874. San Francisco, June 1875. pp. 404–406, pl. xi.

The new species is named *Caprella spinosa*. It was taken in Hakodadi Bay, Japan, and is thus described:—

“ *Male.* Body very slender; segments elongate, second thoracic segment more than one-half longer than the first, and very slender. No spine on dorsal surface of head. Superior antennæ longer than half the body; first joint little more than half the length of second; third joint nearly as long as second; flagellum rather longer than basal joint. Inferior antennæ reaching to about the first third of the second joint of the superior antennæ. Hand of second pair of legs very narrow, with three teeth on the underside, one a short distance behind the claw, a second close to the first, and a third posterior to the middle. The third and fourth segments have a sharp spine on each side, above the branchiaæ and near the hinder margin, and the three posterior segments are furnished with similar spines.

“ Length of body, 1 11-16 inch. Length of superior antennæ, about 1 inch.

“ *Female.* Body less elongated than in the male; third and fourth segments swollen at the sides, and both these segments armed with a long, sharp spine, the point curving towards the head; fifth and sixth segments armed with a straight spine. Second pair of legs about as long as the second segment of the body, the basal joint armed with a sharp spine on the upper side of distal end; hand shorter than basal joint, with a single acute tooth on the posterior third of the under side. Superior antennæ about half the length of the body, the second joint about one-third longer than the basal; flagellum as long as second joint. Inferior antennæ about equal in length to the first two joints of the superior antennæ.

“ Length of body, about 1 7-16 inch; of superior antennæ, $\frac{3}{4}$ inch.”

In the preliminary observations Mr. Lockington observes that “ the male somewhat resembles the *C. attenuata* of Dana, the chief differences being the spines upon the five posterior segments, and the absence of the spine upon the head.” He further says, “ The females differ so greatly from the males in the comparative lengths of the several joints of the body and antennæ, that I was at first inclined to believe they belonged to another species; but since the two forms were always dredged in company, and the specimens of one form are all males while those of the other are all females, it is evident that they are the two sexes of the same species.”

Already (p. 1259) I have suggested that Mr. Lockington’s species might be the same as *Caprella scaura*, Templeton, of which Dana’s *Caprella attenuata* is a synonym, and now that I have seen Mr. Lockington’s descriptions and figures, little doubt remains in my mind that *Caprella spinosa* should be added to the synonymy of *Caprella scaura*. In regard, however, to the “ long, sharp spine, the point curving towards the head,” which Mr. Lockington figures on each side of the third and fourth segments of the female, it is reasonable to suspect some misapprehension, since, in regard to the branchial vesicles of these two segments in the *Caprella*, he says, “ in the females these branchiae are modified in form and function, becoming four broad plates,” to form the marsupial sac. It is probable, therefore, that, as he considered the marsupial plates to be modified branchiae, he regarded the actual branchiae as spinous processes.

1875. LÜTKEN, CHR. FR.

The Crustacea of Greenland. *In* Manual of the Natural History, Geology, and Physics of Greenland and the neighbouring regions; prepared for the use of the Arctic Expedition of 1875, under the direction of the Arctic Committee of the Royal Society, and edited by Professor T. Rupert Jones, F.R.S. London, 1875. pp. 146–165.

It is stated that “ this list is chiefly a revised copy of that given by Prof. Reinhardt in Rink’s ‘Greenland,’ containing the corrections and additions published of late years.” “ The (Zool. Chall. Exp.—Part LXVII.—1888.)

synonyms given are principally taken from authors on Arctic or Scandinavian Zoology." For the Note on Reinhardt, 1857, see p. 301.

"Amphipoda (et Læmidopoda)," pp. 151-159, include the numbers 50 to 128, a note adding "Species dubiae: *Oniscus arenarius*, F. Gr. 234; *O. Stroemianus*, F. Gr. 235 (*Gr. Kingupek*); et *O. abyssinus*, F. Gr. 236." The species are named as follows:—50. *Pontoporeia femorata*, Kr.; 51. *Opis typica*, Kr.; 52. *Lysianassa gryllus* (Mandt.); 53. *Socernes Vahlii* (Rhdt.); 54. *Anonyx lagena* (Rhdt.); 55. *Anonyx gulosus* (Kr.); 56. *Aristius tumidus* (Kr.); 57. *Hippomedon abyssi* (Goës); 58. *Hippomedon Holboelli* (Kr.); 59. *Orchomene minuta* (Kr.); 60. *Onisimus Edwardsii* (Kr.); 61. *O. plautus* (Kr.); 62. *Onisimus littoralis* (Kr.); 63. *Cyphocaris anonyx*, Ltk.; 64. *Stegocephalus ampulla* (Phipps); 65. *Metopa Bruzelii* (Goës); 66. *Metopa clypeata* (Kr.); 67. *Metopa glacialis* (Kr.); 68. *Syrrhoë crenulata*, Goës; 69. *Odius carinatus* (Sp. Bate); 70. *Vertumnus cristatus* (Owen); 71. *Vertumnus serratus* (Fabr.); 72. *Vertumnus inflatus* (Kr.); 73. *Paramphithoë glabra*, Boeck; 74. *Paramphithoë panopla* (Kr.); 75. *Paramphithoë bicuspis* (Rhdt.); 76. *Paramphithoë pulchella* (Kr.); 77. *Atylus carinatus* (Fabr.); 78. *Atylus Smitti* (Goës); 79. *Pontogeneia crenulata* (Rhdt.); 80. *Tritropis fragilis* (Goës); 81. *Tritropis aculeata* (Lepechin); 82. *Calliopus larvusculus* (Kr.); 83. *Amphithopsis longimana*, Bk.; 84. *Cleippides tricuspidis* (Kr.); 85. *Halirages fulvocinatus* (Sars); 86. *Paramphithoë megalops* (Buchh.); 87. *Acanthozone cuspidata* (Lep.); 88. *Ædicerus saginatus*, Kroyer; 89. *Ædicerus lynceus*, Sars; 90. *Ædicerus borealis*, Bk.; 91. *Monoculodes affinis* (Bruz.); 92. *Monoculodes norregicus*, Boeck; 93. *Monoculodes latimanus* (Goës); 94. *Monoculodes borealis*, Bk.; 95. *Tiron acanthurus*, Lillj.; 96. *Harpina plumosa* (Kr.); 97. *Phoxus Holboelli*, Kr.; 98. *Haploöp tubicola* (Lilljeborg) (var.); 99. *Ampelisca Eschrichtii*, Kr.; 100. *Byblis Gainardi* (Kr.); 101. *Pardalisca cuspidata*, Kr.; 102. *Eusirus cuspidatus*, Kr.; 103. *Melita dentata* (Kr.); 104. *Gammarus locusta* (Linn.); 105. *Gammaracanthus loricatus* (Sabine); 106. *Amathilla Sabini* (Leach); 107. *Amathilla pinguis* (Kr.); 108. *Autonoë macronyx* (Lilljeb.); 109. *Protomedea fasciata*, Kr.; 110. *Photis Reinhardti*, Kr.; 111. *Podocerus anguipes* (Kr.); 112. *Podocerus latipes* (Kr.); 113. *Siphonocoetes typicus*, Kr.; 114. *Glaucome leucopis*, Kr.; 115. *Themisto libellula* (Mandt); 116. *Th. bispinosa*, Boeck; 117. *Parathemisto compressa* (Goës); 118. *Hyperia medusarum* (Müll.); 119. *Tauria medusarum* (Fabr.); 120. *Dulichia spinosissima*, Kr.; 121. *Caprella septentrionalis*, Kr.; 122. *Cereops Holboelli*, Kr.; 123. *Ægina longicornis*, Kr.; 124. *Æ. elevata*, Boeck; 125. *Cyamus mysticeti*, Ltk.; 126. *Cyamus boopis*, Ltk.; 127. *Cyamus monodontis*, Ltk.; 128. *Cyamus nodosus*, Ltk.

The synonymy of "Acanthozone cuspidata (Lep.)" is followed by the note "Obs.—*Amphithoë Jurinii?*, Kröy., Bell, l. c., p. 406. I am not aware that Prof. Kröyer ever described a species of that name."

To the synonymy of "Hyperia medusarum (Müll.)" is appended a footnote, "As *Hyperoödon rostratus* and *Globiocephalus melas* are occasionally seen in Baffin's Bay, their parasites (*Platycyamus Thompsoni*, *Pennella crassicornis*, *Xenobalanus gl.*, and *Cyamus globicippitis*) might also be enumerated among the Crustacea of Greenland; but they are omitted here because they have not actually been sent down from Greenland."

To "Cyamus nodosus, Ltk." is appended a footnote, "Quid est *Talitrus cyaneæ*, Sabine, Suppl. App. Parry's Voy., t. I., f. 12-18?"

It may be remarked, in reference to these notes, that "*Amphitoë Jurinei*, Milne-Edwards," is by Spence Bate made a synonym of *Pherusa fucicola*, Leach; that *Pennella* and *Xenobalanus* are only mentioned incidentally, not with any intention of including them among the Amphipoda; that to the question "quid est *Talitrus cyaneæ*, Sabine," the answer given by Boeck and Bovallius seems reasonable that it is a synonym of *Hyperia medusarum* (Müller). "*Paramphithoë bicuspis* (Rhdt.)" has for its synonyms *Amphithoe bicuspis*, Kr., *Paramphithoë*

bicuspidis, Bruzel., *Pherusa bicuspis*, Sp. Bate, and *Pherusa cirrus*, Sp. Bate; but Mr. A. O. Walker has called my attention to the circumstance, which I take this opportunity of mentioning, that *Pherusa bicuspis*, Sp. Bate, is clearly a distinct species from Kroyer's *Amphithoe bicuspis*.

The Manual also contains separate lists of Amphipods under the following headings:—

Page 503. "Marine Invertebrates of the Parry Islands, &c. By Sabine, Kirby, J. C. Ross, Fleming, Leach, and R. Owen, 1824, 25, 26; 1819; 1835." In a footnote to this contribution a reference is given to a mention of "*Gammarus Sabini*" by Dr. Wallich, in "The North-Atlantic Sea-bed," Part I. p. 79 (London, 1862).

Page 508. "Arctic Crustacea and Pycnogonida, collected by the English Expeditions. By Dr. Walker, 1860."

Page 512. "The Results of some Dredgings made at Goodhaab, West Greenland, by Dr. G. C. Wallich in 1860. 'The North-Atlantic Sea-bed,' &c., by G. C. Wallich, M.D., F.L.S., F.G.S., 1862 (4to, London), p. 102." "*Gammarus arcticus*" and "*Caprella linearis* (on Algae)" are the only Amphipods mentioned.

Page 561. "The Crustacea of E. Greenland. By Dr. R. Buchholz, 1874."

These lists, with the exception of Dr. Wallich's, have been already discussed in earlier Notes on the works from which they are drawn.

1880. STOSSICH, MICHELE.

Prospetto della Fauna del Mare Adriatico. Parte III. Crustacea. Bollettino della Società Adriatica di Scienze Naturali in Trieste. Volume sesto. Trieste, 1880. pp. 178–271.

In this Catalogue the Amphipoda extend from page 230 to page 247. The suborder Læmodipoda contains the family Caprellidae, with one genus, *Caprella*, to which are assigned eight species. The suborder Crevettina contains the family Cheluridae, with one genus and species; fam. Corophiidae, with the subfam. Corophiinae, in which *Corophium* has two species, *Cyrtophium* one, *Cratippus* two, *Icridium* one; subfam. Podocerinae, in which *Microdeutopus* has two species, *Cerapus* two, *Podocerus* five, *Amphitoe* four; fam. Orchestiidae, in which *Talitrus* has one species, *Orchestia* four, *Allorchestes* three, *Nicella* eleven; fam. Gammaridae, with the subfam. Atylinæ in which *Atylus* has one species, *Protomedieia* three, *Pherusa* one, *Dexamine* five, *Iphimedia* two, *Isza* one, *Ampelisca* one, *Kroyera* one; subfam. Leucothoinæ, in which *Eusirus* has one species, *Leucothoe* one; subfam. Gammarinæ, in which *Gammarus* has six species, *Melita* three, *Mæra* seven, *Eurystheus* one, *Amathilla* one; subfam. Lysianassinae, in which *Lysianassa* has seven species, *Probolium* two, *Ichnopus* two, *Anonyx* seven, *Callisoma* one. In all a hundred and one species are given, with synonyms, references to authorities, and localities. Stalio's Catalogue (1877) is quoted for almost every species.

1881. EXNER, SIGMUND.

The Mode of Action of Facetted Eyes. Popular Science Review, Vol. XX.
1881. p. 337. From Biologisches Centralblatt, Jahrg. I. p. 272, 1881.

1881. RATHBUN, RICHARD.

The littoral marine Fauna of Provincetown, Cape Cod, Massaehusetts. Proceedings of the United States National Museum. Vol. III. 1880. Washington, 1881. pp. 116–133.

It is stated that the Amphipods have been identified by Professor S. I. Smith. They are named as follows on pages 120, 121; “*Orchestia agilis* Smith”; “*Talorchestia longicornis* (Say) Smith”; “*Talorchestia megalopthalma* (Bate) Smith”; “*Hyale littoralis* (Stimp.) Smith”; “*Calliopius lœviusculus* (Kroy.) Boeck”; “*Gammarus locusta* (Linné) Fabr., with a reference to “Gould, Inv. Mass., ed. I. p. 334, 1841,” and the synonym “*G. ornatus* Edwards, Ann. des Sci. Nat., tome xx. p. 367, 1830”; “*Gammarus annulatus* Smith”; “*Gammarus mucronatus* Say”; “*Mæra levis* Smith”; “*Microdeutopus grandimanus* Smith,” with the synonyms “*Autonoë grandimana* Bruz., Skand. Amphip. Gamm., p. 26, 1859.—*Microdeutopus minax* Smith, Inv. V. S., p. 562, 1874”; “*Amphithoë longimanus* Smith”; “*Corophium cylindricum* (Say) Smith”; “*Chelura terebrans* Philippi”; “*Caprella geometrica* Say.” A few short notes are given in regard to localities, and the statement is made that “a comparison of European with American specimens has enabled Professor Smith to establish the identity of *G. ornatus* and *G. locusta*.” *Autonoë grandimana*, Bruzelius, had been already named *Microdeutopus grandimanus* by Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 378.

1881. THOMSON, GEORGE MALCOLM, born October 2, 1848 (G. M. T.).

Recent Additions to and Notes on New Zealand Crustacea. [Read before the Otago Institute, 11th May, 1880.] Transactions of the New Zealand Institute, Vol. XIII. pp. 204–221. Pls. VII., VIII.

A discussion on the genus *Orchestia* leads up to the conclusion that the New Zealand species of that genus thus far known are only five, *Orchestia aucklandia*, Sp. Bate, *Orchestia telluris*, Sp. Bate, *Orchestia chilensis*, M.-Edw., *Orchestia serrulata*, Dana, and *Orchestia sylvicola*, Dana. The last species is regarded as including *Orchestia novæ-zealandiae*, Sp. Bate, and *Orchestia tenuis*, Daua. The terminal part of a second gnathopod is figured. From the examination of 163 specimens, Mr. Thomson is “strongly of opinion that they all belong to one variable species, the males of which have at least two forms of gnathopoda, and the females of which differ considerably in those very characters which have hitherto had specific importance attached to them.” It is “a strictly terrestrial form.”

The other species discussed in this paper have been already mentioned in the Notes on Thomson, 1879 (p. 500) and 1880 (p. 524).

On Plate vii., fig. 5A. is the head, 5B. a gnathopod, of *Amphilochus squamosus*, Thomson; fig. 6. is *Amphilumotus levis*, Thomson. On Plate viii., fig. 7A. represents the antennæ, 7B. a mandible, 7C. the telson and third uropods of “*Microdentopus maculatus*,” Thomson; fig. 8. is “*Cyrtophium cristatum*,” Thomson; fig. 9. is “*Corophium contractum*, Stimpson.”

1882. BELLESME, JOUSSET DE.

Sur les anastomoses des fibres musculaires striées chez les Invertébrés. In Compt. rend., Tome 95. pp. 1003, 1004.

“Jousset de Bellesme verbreitet sich über die bereits bekannten Anastomosen der Musculatur an den ‘glandes gastriques’ (Hepatopancreas) der Amphi- und Isopoden (vergl. Bericht f. 1880. II. p. 12).” P. Mayer in Zool. Jahresbericht für 1882.

1882. COSTA, ACHILLE.

Rapporto preliminare e sommario sulle ricerche zoologiche fatte in Sardegna durante la primavera del 1882. (Adunanza del dì 14 Ottobre 1882.) Rendiconto dell' Accademia delle Scienze fisiche e matematiche. Anno XXI. Napoli, 1882. pp. 189–201.

The only remark upon Amphipoda is, at page 193, that to genera previously collected there are added some species of *Gammarus*, still awaiting examination.

1882. THOMSON, G. M.

Additions to the Crustacean Fauna of New Zealand. [Read before the Otago Institute, 22nd November, 1881.] Transactions of the New Zealand Institute, Vol. XIV. pp. 230–238. Pls. XVII., XVIII.

Prior to describing *Anonyx corpulentus*, n. sp., pl. xvii. figs. 1a–f, Mr. Thomson remarks that the characters on which the genus *Anonyx* "is separated from *Lysianassa* are very insufficient, being mainly subchelate nature of the first pair of gnathopoda, and secondly the cleft telson." The new species, he says, "is an *Anonyx* in all respects, except that its telson is entire, which is the case also with *A. plautus*, Kröyer, an European species." *Anonyx plautus* is transferred by Boeck to *Onisimus*. "*Anonyx exiguum*," Stimpson, is described and partly figured, pl. xviii. figs. 2a–e. *Phoxus batei*, Haswell, is described and partly figured, pl. xvii. figs. 2a–e. This species appears to come near to *Phoxus bassi*, n. sp., of this Report, but to be distinguished from it by the differently shaped first joint of the fifth pereiopods, the more unequal rami of the third uropods, and the shorter telson; the differences in the antennæ are probably due only to age or sex, and the very considerable difference between the second gnathopods of the two forms is not necessarily specific. *Polycheria obtusa*, n. sp., pl. xvii. figs. 3a–d, is in my opinion, as elsewhere stated, a synonym of *Tritæta antarctica*, Stebbing. *Leucothoë traillii*, n. sp., pl. xviii. figs. 1a–d, is described. Three varieties of Dana's Fiji species, *Gammarus quadrimanus*, are noticed under the name "*Moera quadrimanus*, Sp. Bate," with figures of the second gnathopod of two of the forms, pl. xvii. figs. 4a, 4b. *Moera petriei*, n. sp., pl. xviii. figs. 3a–c, is described, a species afterwards identified by Mr. Chilton with *Megamoera sub-carinata*, Haswell, and in this Report transferred to the genus *Elasmopus*, Costa, see p. 1024. In the family Corophiidae, the new genus *Iphigenia* is thus described:—

"Body much depressed and flattened. Antennæ short and thick, subequal. Coxæ of the first four segments of the pereion very large, those of the succeeding segments small. Basa of the three pairs of posterior pereiopoda dilated. Gnathopoda simple, ungnathiate. Three posterior pairs of pleopoda very small, curved inwards, with minute simple rami. Telson single, entire."

"The very remarkable Crustacean (Amphipod) for which this genus has been formed, appears on first inspection to be an Isopod. It is only after closer examination that it is seen to be allied to *Icilius* [*Icilius*], Dana, one of the most anomalous forms of the Corophiidae. From this genus it is, however, at once distinguished by the very large coxæ of the four anterior segments of the pereion, and by its short, thick, subequal antennæ."

The type species, *Iphigenia typica*, n. sp., is described and figured, pl. xviii. figs. 4a–g. As already pointed out by Dr. v. Martens, the name *Iphigenia* is preoccupied and requires to be changed. In many respects this curious little species seems to approach the equally curious little *Phlias serratus* of Guérin, but while the latter is laterally much compressed,

the former is strikingly flattened out; on the other hand, *Pereionotus testudo* (Montagu) and *Iceridium fuscum*, Grube, which come very near to Guérin's species, agree with *Iphigenia typica* in having the depressed Isopod-like body; the maxillipeds of *Iceridium fuscum* are said to have a three-jointed palp, agreeing in this respect with the maxillipeds figured by Mr. Thomson for his species, but not agreeing with a specimen of *Iphigenia typica* sent me by Mr. Chilton, in which the maxilliped-palps are four-jointed; the mandibles in this specimen agree with those which Grube describes, in having four teeth to the cutting edge and no visible palp; in regard to the pleon Grube's species is very distinct from Thomson's; until, however, the mouth organs of the genera referred to have been more fully described and figured, and the anomalous character of the pleon in Grube's *Iceridium* has been either established or disproved, the relation of these remarkable forms to one another must remain very uncertain.

1883. GRAEFFE, ED.

Biologische Notizen über Seethiere der Adria. Ueber die Fauna der Sehlamm-region der Adria. Bolletino della Società adriatica di scienze naturali in Trieste. Volume ottavo. Trieste, 1883. pp. 85-89.

The two species of Amphipods recorded from this mud-region are " *Ampelisca Gaimardi* Kroyer," and " *Phoxus plumosus* Kroyer." Professor Graeffe regards these two species as strongly supporting his view that the mud-dwellers have suffered degradation of the visual organs owing to the character of their habitat.

" The Crevettines or Gammaridae," he says, " to which division these Amphipods belong, generally exhibit sessile eyes, that is, the pair of eyes is situated wholly in the cephalothorax. A part of the chitin-layer of this is bulged out, and provided with facets, which are more or less clearly developed. Behind this faceted corneal-surface there is a pigment-layer, which envelops the elements of the arthropod-eye, crystal-coue, and rhabdom-layer of the retina. The optic-nerves which provide for this eye, are derived from a special cerebral-knot or ganglion.

" In *Ampelisca* this corneal-part of the eye is only provided with two facets, which points to an arrested development of it, as these facets, to which the refracting and sentient retina-rods correspond in number are multiplied with the development, the growth of the animal. In *Ampelisca Gaimardi*, moreover, the pigment of the eye is little developed, so that one may well maintain that this species possesses a degraded pair of eyes.

" In *Phoxus plumosus* this degradation has advanced still further, since here no corneal part whatever is to be seen, and in the place of the eye there is only a faint yellowish pigment-fleck remaining. This species is to be reckoned among the totally blind animals."

On the subject of the eyes in *Ampelisca*, see Note on Della Valle, 1888 (p. 1651).

1883. HERRMANN, G.

Sur la spermatogénèse chez les Crustacés édriophthalmes. In Compt. Rend. Tome 97. pp. 1008-1012. Also in Journ. Mier. Paris. Année 7. pp. 588-590.

According to this author " verläuft die Spermatogenese bei *Ligia*, *Idotea*, *Sphæroma*, *Gammarus*, *Talitrus* in ganz anderer Art als bei den Podophthalmen und erinnert bis auf das sehr frühe Verschwinden des 'nodule céphalique' in auffallender Weise an die der Selachier. Das Spermatozoid bleibt unbeweglich (vergl. Bericht f. 1879. p. 418 u. 1882. II. p. 21)." Zool. Jahresbericht für 1883.

1884. GIESBRECHT, W.

Zoologischer Jahresbericht für 1883. II. Abtheilung. Leipzig, 1884. Crustacea, pp. 9-50.

1884. MÖBIUS, KARL.

Nachtrag zu dem im Jahre 1873 erschienenen Verzeichniss der wirbellosen Thiere der Ostsee. In 4. Ber. Comm. Unt. d. Meere Kiel. 7.-11. Jahrg. 3. Abth. pp. 61-70.

The Gammaridæ mentioned are (on p. 68), *Pontoporeia furcigera*, Bruz., "7 m. tief, todtes Seegras"; *Bathyporeia pilosa*, Lindström; "*Dexamine spinosa*, Montag.>"; *Cheirocratus brevicornis*, Hoek, "10-14 m. tief"; and (on p. 69), *Protomediea pilosa*, Zadd.; *Microdeutopus gryllotalpa*, Costa, "in geringen Tiefen zwischen Miesmuscheln"; *Amphithoe podoceroides*, Rathke; *Podocerus falcatus*, Mont., "stoller Grund, 18 m. tief."

1884. THOMSON, G. M.

Descriptions of new Crustaceans. [Read before the Otago Institute, 31st October, 1882.] Transactions and Proceedings of the New Zealand Institute, 1883. Vol. XVI. Issued May, 1884. Wellington. pp. 234-240, Pls. XII., XIII.

"*Allorchestes recens*, n. sp. Pl. xiii., figs. 2-5," is described, and of the locality Mr. Thomson says, "Numerous specimens of this species were sent me from Wellington by Mr. J. C. Gully, who obtained them in a small stream into which several drains ran."

"*Corophium excavatum*, n. sp., Pl. xii., figs. 1-8," is described, from "Brighton Creek (salt water), near Dunedin," and the remark added, "This species is very distinct from any hitherto described, the form of the meros [third joint] of the 2nd gnathopod being quite remarkable; a tendency towards a similar development of structure occurs apparently in *C. longicorne*, which is, however, a very different species in many respects." The third uropods are represented with two rami, "internal ramus very minute." This feature is inconsistent with the definition of the genus *Corophium* by Spence Bate and of the family Corophidæ by Boeck, according to which the third uropods are uniramous.

A definition of the genus *Oxycephalus* is followed by descriptions of the two sexes of "*Oxycephalus edwardsii*, n. sp. Plate xii., figs. 14-21; pl. xiii., fig. 1." Of this species Mr. Thomson says, "I found numerous individuals washed up on the Ocean Beach near Dunedin on two different occasions: they appear to come ashore in fine clear calm weather." The approximation of this species to the form designated in this Report as *Oxycephalus clausi*, Bovallius, has been already noticed (pp. 1582, 1585). Mr. Thomson says of the maxillipeds, that they "are of very simple structure, consisting each of an oval smooth plate, without any trace of hairs or teeth," but the specimens which he has very kindly sent me show that

these minute organs are of the form usual in the genus and indeed in the whole group, having a small inner plate between the two outer plates, the latter having the outer margin convex and the inner sinuous.

1886. BROOK, G., and CALDERWOOD, W. L.

Report on the Food of the Herring. Appendix to Fourth Annual Report of the Fishery Board for Scotland. Edinburgh, 1886. pp. 102–128.

In allusion to this Appendix the Introduction to the Report states (p. xix) that "during winter and spring herring feed chiefly on *Hyperia Galba*, *Nyctiphantes norvegica*, and *Sagitta*."

In regard to *Hyperia galba* the Appendix itself says, "This species must be reckoned as one of the most important forms of herring food. Judging from its frequency in the stomach of the herring, this form must exist in myriads off the east coast of Scotland. The male is smaller than the female and leads an active pelagic existence. In structure it is so different that it has been described as a distinct genus (*Lestrigonus*). The males occur in much greater abundance than the females in the stomachs which we have examined, an occurrence which is doubtless to be attributed to the difference in habit of the two sexes. The female occurs plentifully in the summer time under the umbrella of *Aurelia*, *Rhizostoma*, and other Medusæ. We are not, however, acquainted with its habit during the colder months, that is during the period in which it is found as herring food." In the notes on the distribution of the species it is stated that "the statistics given for the area between Peterhead and Cromarty appear to show that *Hyperia* is frequent in that part in December, more abundant in January, while in February and March the supply gradually diminishes and the herring then seeks other food. A careful comparison, however, shows that so far as our material goes, *Hyperia* is by no means so abundant in this area as in those to the south of it." "This species," the authors say, does not "appear to form such an important part of the herring's food in the Wick district at any time, as it does in the waters south of Peterhead." They are also "of opinion that *Hyperia* cannot be a common form on the west coast."

Since the authors speak of *Hyperia* as a species, it may be presumed that they did not intend to lay any special stress on the specific name *Hyperia galba*, which has so long exercised and still continues to exercise the minds of writers on the synonymy of the Amphipoda. Indeed the herrings must be delicately sensitive in the matter of taste if they can discriminate the various closely connected species of the family Hyperidae, let alone those of the genus *Hyperia*. The opinion of Thomas Edward as to the stay of *Hyperia galba* and *Hyperia obliqua* respectively at Banff, may be seen in the Note on that author, p. 382. Unless, however, some distinguishing marks are given, it is of little use to argue about the distribution of species, since authors may be referring to different species under the same name, or to the same species under different names. No great stress should, I think, be laid on the negative evidence regarding the occurrence of *Hyperia* on the west coast of Scotland, but it is corroborated by Mr. David Robertson's experience with regard to "*Parathemisto obliqua*," recorded in his Catalogue of the Amphipoda of the Clyde, 1888.

"With reference to the food of the east coast herring," the authors say, "it may be stated generally that the relative frequency of *Hyperia* and [the Schizopod] *Nyctiphantes* depends on the month during which the fish were captured. *Hyperia* is extremely abundant during January and February, and the stock then gradually diminishes, or at any rate the herring do not feed on this form to such a great extent after that time." But as the *Hyperia* become rare, the stock of *Nyctiphantes* increases. "The quantity of the one appears to be inversely proportional to that of the other."

1887. BONNIER, JULES, born August 31, 1859 (J. B.).

Catalogue des Crustacés Malacostracés recueillis dans la baie de Concarneau. Paris, 1887. Extrait du Bulletin scientifique du Département du Nord publié sous la direction de M. Alfred Giard. 2^{me} série.—X^{me} année.—1887.

The Amphipoda occupy pages 67–127 (pp. 296–356 of the Bulletin itself),¹ and a part of pages 189, 190. The "Index bibliographique des ouvrages cités" extends from page 167 to page 184. In the classification of the Amphipoda Boeck's latest work is followed; no new species are recorded or described; some brief notes are given on some of the known species, of which sixty-four are enumerated, with an elaborate synonymy, the discussion of which would involve too much repetition of remarks already made in earlier notices.

1887- BOVALLIUS, C.

1888.

Contributions to a monograph of the Amphipoda Hyperiidea. Part I. Division 4: The families Tyronidæ, Lanceolidæ, and Vibiliidæ (with 10 Plates). Svenska Vetenskaps-Akademiens Handlingar. Ny Fjöld. Band 21: 1884 oeh 1885. Häftet I. Stockholm 1887 (auf dem Titel 1884).

For the preliminary notice, see Note on Bovallius, 1887 (p. 587). The present instalment of Bovallius' larger work has not yet come into my hands. The title is quoted from Friedländer's Natura Novitates for June 1888.

1887. CHEVREUX, E.

Crustacés Amphipodes nouveaux dragués par l'*Hirondelle*, pendant sa campagne de 1886. Extrait du Bulletin de la Société Zoologique de France, t. xii. 1887. Paris, 1887. 15 pages.

Off Cape Finistère, at a depth of 510 mètres, the Hirondelle obtained specimens of "*Nicippe tumida* Bruz," "*Ampelisca anomala* G. O. Sars," and "*Urothoe abbreviata* G. O. Sars," and the following new species, of which descriptions are given—(1) *Opis hispana*, (2) *Harpinia excavata*, (3) *Amphithopsis grandimana*, (4) *Tritropis Grimaldii*, (5) *Ampelisca uncinata*, (6) *Ampelisca spinimana*, (7) *Byblis Guernei*, (8) *Podoceropsis abyssi*. Of these the species numbered 1, 2, 5, and 8 are said to be without eyes. *Opis hispana* should be called *Opisa hispana*, the preoccupied *Opis* having been changed by Boeck, and *Tritropis grimaldii* should be called *Rhachotropis grimaldii*, S. I. Smith having substituted *Rhachotropis* for the preoccupied *Tritropis*. In *Podoceropsis abyssi* there is a rudimentary secondary

¹ Juillet-aout 1887.

flagellum to the upper antennæ, and M. Chevreux says that he has always found one in the different forms of the genus *Podoceropsis* which he has had occasion to examine; on this subject I may refer to what is said on p. 1108, in confirmation of M. Chevreux's remark.

Lists are given of the species of Amphipods obtained at various stations off the west coasts of France and Spain, and among others M. Chevreux notices that "*Melita gladiosa* Sp. Bate" and "*Gammaropsis erythrophthalma* Lillj." were obtained from a depth of 250 mètres.

1887. GILES, G. M.

On Six new Amphipods from the Bay of Bengal. Natural History Notes from H.M.'s Indian Marine Survey Steamer "Investigator." No. 6. [Reprinted from the *Journal of the Asiatic Society of Bengal*, Vol. LVI. Part II. No. 2, 1887.] [Received and Read March 2nd, 1887.] pp. 212-229. Plates III.-VIII.

The first section of the paper is headed, "A Description of two new Species of the Amphipod Family Phronimidae with some Remarks on the Genera of the Family." In stating that the finger of the third pereopod in *Phronima* is not, as Spence Bate supposed, either fused with the preceding joint or obsolete, Mr. Giles is, I think, quite right. He describes and figures (pl. iii. figs. 1 and 2), a new species, *Phronima bucephala*, which, he says, "differs from the genus as defined by Claus in the following points:—1st., in my one female specimen, I can make out no trace whatever of inferior antennæ; 2nd., the subchela of the '5th' (6th) thoracic appendage [third pereopod] cannot be said to be slender, the fixed ramus being very stout and almost quadrate; 3rd., there are two extra small gill-sacs on the 2nd and 3rd thoracic segments, a character extremely abnormal, but of the reality of which I carefully satisfied myself. To avoid, however, the necessity of manufacturing a new genus, I describe it as a member of the genus *Phronima*, as defined by Spence Bate, under the name of *P. bucephala*."

There is certainly no need for a new genus; the specimen is a small one, "5·75 mm." in total length, so that the failure to discover the lower antennæ can be easily understood; the objection that the grasping part of the third pereopods cannot be said to be slender rests on an accidental misreading of Claus' generic definition, which states that this part is powerful (mit mächtiger Scheerenhand), not slender (schmächtig in the previous line referring to the gnathopods); lastly, the two extra pairs of gill-sacs are probably not gill-sacs but marsupial plates in process of development, at least I have never met with them except in small specimens of *Phronima*. The telson in this genus is as a rule so difficult to observe, that too much stress must not be laid on the remark in the specific description, "the telson appears obsolete." The fourth joint of the third pereopod is thus described—"The carpopodite is triangular, its inferior border being nearly as long as the lateral. The antero-inferior angle is prolonged into a powerful spine, and the inferior border is armed with three dentations, between which are a corresponding number of small, isolated tufts of hair." According to the figure, however, the antero-inferior spine is not very strong compared with what is found in adult specimens of the female in this genus. In the "Explanation of the Plates" the specimen by a misprint is said to be a male.

The second species described and figured (pl. iii. fig. 3) is named *Phronimella hippocephala*, n. sp., which appears from the antennæ to be a young male, but whether it is distinct from species already described it may be difficult to decide. The first pereopods are as usual much longer than the second, and this peculiarity made Mr. Giles hesitate whether he could include his species in the genus *Phronimella*. Claus, unfortunately, in *Der Organismus der*

Phronimiden, on which Mr. Giles has relied, repeats the erroneous statement which he had already himself corrected, that the second pereopods are longer than the first.

The third species, "*Rhabdosoma investigatoris*, n. sp. Pl. IV.", is briefly compared with the descriptions of *Rhabdosoma armatum*. Whether the species here discussed is really new may need some further enquiry. It is said that two specimens were obtained, one male and the other female, "the latter being that shown in the figure." Mr. Giles remarks that "It is probably an adult, as the broad pouch, although empty, is well-marked and of considerable size." The figure, however, shows the characteristic upper and lower antennæ of the male, as well as the long mandibular palp of that sex. Since the specimens were respectively only an inch and half an inch long, the small differences from Claus' figure and description of *Rhabdosoma armatum*, ♂, may be accounted for by individual variation or difference in age. Mr. Giles considers that Claus has proved the specific identity of *Rhabdosoma armatum* (Milne-Edwards) and *Rhabdosoma whitei*, Spence Bate.

The fourth species, "*Amphipronoë longicornuta*, n. sp., Pl. V.", is called in the "Explanation of the Plates" *Amphipronoë longicornutus*. It is said that "the animal agrees well with all the characteristics of the genus as given in Spence Bate, though the 8th thoracic appendage [fifth pereopods] would perhaps be better described as stunted than as rudimentary." The difficulty connected with the genus *Amphipronoë* is here overlooked, for in the definition of that genus Spence Bate includes the character, "First pair of gnathopoda complexly subchelate; second pair not subchelate," whereas in the new species the two pairs of gnathopods "closely resemble each other" and "they are provided with a curious complex subchela." The species clearly belongs to the genus *Lycæa*, Dana, as interpreted by Claus. The muscles of the antennæ and gnathopods are here discussed by a competent observer.

The fifth species "*Lestrigonus bengalensis*, n. sp., Pls. VI. & VII.", is referred to *Lestrigonus*, not on the ground that *Lestrigonus* is distinct from *Hyperia*, but on the supposition apparently that it is the older name. The new species is extremely small, males with antennæ indicating the adult stage being only 2·5 mm. long. It bears some resemblance to *Hyperia dysschistus* of this Report, but is distinguished from it by the telson and uropods.

The sixth species "*Eurystheus hirsutus*, n. sp., Pl. VIII.", should perhaps rather be named *Gammaropsis hirsutus*. The side-plates as figured are remarkably shallow.

1887. GUERNE, J. DE.

Sur la faune des îles de Fayal et de San Miguel (Açores). Comptes Rendus Hebdomadiers des séances de l'Académie des Sciences. Tome CV. No. 17 (24 October 1887). Paris, 1887. pp. 764–767.

Allusion is made to the Amphipod soon afterwards named *Orchestia chevreuxi*, found in the Caldeira of Fayal.

1887. GUERNE, J. DE.

Notes sur la faune des Açores : Diagnoses d'un Mollusque, d'un Rotifère et de trois Crustacés nouveaux. Le Naturaliste. Revue illustrée des Sciences Naturelles. Paris, 1887. (Extract, 7 pages.)

Orchestia chevreuxi, nov. sp. is thus described ;— "Femina. Antennæ superiores paulo ultra articulum pedunculi penultimum antennarum inferiorum porrectæ. Pedes secundi paris articulo quarto aculeis duobus armato; carpo elongato. Pedes quarti paris perbreves

Telson breve, ovatum, emarginatum. *Mas ignotus*. Longit. 15 mm. Localité. Cratère de Fayal, 16 juillet 1887." Compare Note on Barrois, 1888 (p. 1648), and Note on de Guerne, 1888 (p. 1652).

M. de Guerne observes that while the species of *Orchestia* from the sea-shore are numerous, the only species hitherto known under conditions like those of *Orchestia chevreuxi* is *Orchestia tahitensis*, Dana, found on an extinct volcano in Tahiti, several miles from the sea and 500 mètres above its level; for a correction of this statement see Note on Barrois, p. 1649.

1887. HANSEN, H. J.

Malacostraca marina Groenlandiae occidentalis. Oversigt over det vestlige Grønlands Fauna af malakostrake Havskrebsdyr. Særtryk af "Vidensk. Meddel. fra den naturh. Foren. i Kjøbh. 1887." Kjøbenhavn, 1887.

Besides various notices in the introductory part of this valuable work, the Amphipoda occupy pages 55 to 177, pages 217 to 222, and pages 225, 226. Plates II. to VI. are concerned with this group. A hundred and fifty-one species are named, some with corrected synonymy, some with notes of locality, and some with more or less full discussion, the new species being described in Latin and in general figured. The new species are named—*Aristias neglectus* (Tab. II. fig. 4) of which see below; *Anonyx groenlandicus* (Tab. II. figs. 5-5g); *Tryphosa pulchra* (Tab. II. figs. 6-6e); *Prinassus Nordenskiöldii* (Tab. II. figs. 7-7f, Tab. III. figs. 1-1c); *Amphilochus oculatus* (Tab. III. figs. 2-2c); *Metopa latimana*, of which however Dr. Hanseu begins his description by saying "Specimeu singulum vix adultum vidi.—*Met. affini* Boeck valde similis, structura pedum primi et secundi parium diversa," *Metopa groenlandica* (Tab. III. figs. 7-7e); *Metopa neglecta* (Tab. III. figs. 9-9b), with the synonymy "*Metopa longimana* Boeck Skand. og Arkt. Amph. Pl. XVII. figs. 5-5n (figura 6 et descriptio ad *Met. longimanum* pertinent)"; *Metopa carinata* (Tab. IV. figs. 3-3e); *Oediceros curvirostris* (Tab. IV. fig. 4) with the synonymy "*Oediceros lynceus* Boeck, Skand. og Arkt. Am. Pl. XIII. fig. 4 (Descriptio ad *Oed. lynceum* pertinet)"; *Monoculodes crassirostris* (Tab. IV. figs. 5-5f); *Monoculodes simplex* (Tab. IV. figs. 6-6h); *Halimedon obtusifrons* (Tab. V. figs. 1-1e); *Aceros distinguendus* (Tab. IV. fig. 8) with the synonymy "*Oediceros obtusus*, 'alia forma, Goës, Op. cit. p. 527, Tafl. XL. fig. 24'"; *Paramphithoë Boeckii* (Tab. V. figs. 3-3b) with the synonymy "*Pleustes pulchellus* Boeck, Skand. og Arkt. Amph., Pl. XXIII. fig. 1 (Descriptio ad *Par. pulchellam* referenda est)"; "*Amphithopsis Olrikii*" (Tab. V. figs. 5-5b); *Amphithopsis glacialis* (Tab. V. figs. 6-6c); *Tritropis oculata* (Tab. V. figs. 7-7e), the description of which is followed by the observation, "Haæ species nova a speciebus ceteris affinibus hujus generis imprimis differt oculis permagnis superne valde inter se approximatis, antennarum primi paris articulo basali perlato quam articulo secundo longiore, articulo tertio perbrevi, pedum septimi paris articulo secundo perpaulo longiore quam atiore"; *Melita amoena* (Tab. VI. figs. 1, 1a); *Podoceropsis Lindahlii* (Tab. VI. figs. 2, 2a); *Podocerus nanoides* (Tab. VI. figs. 4-4b); *Unciola crassipes* (Tab. VI. figs. 6, 6a); *Unciola laticornis* (Tab. VI. figs. 7-7b). There is also a named variety, "*Caprella microtuberculata* G. O. Sars, var. *spinigera*."

The new genus *Prinassus* is launched without distinction between the generic characters and those of the type-species, except that the author says, "this new and interesting form shows in the shape of the antennæ and limbs and in the coalescence of the fifth and sixth segments of the pleon so much difference from its nearest relations, *Pontoporeia* and *Priscilla*, that I have been forced to institute a new genus for it." The mouth organs are not described. The antenuæ (in the female) are short, with no accessory flagellum; the gnathopods are

subchelate, the hand not longer than the wrist; in the first and second pereopods the fourth joint is much shorter than the third; the third pereopods are longer than the fourth, and the fourth than the fifth; in the fifth the first joint is very large and the third and fourth joints are strongly plumose; the telson is rather longer than broad, cleft almost to the base. The name of the type-species is variously given as *Nordenskiöldii*, *Nordenskiöldii*, and *Nordenskjöldii*.

To *Hyperia latreillei*, Milne-Edwards, the synonyms given are *Lestrigonus exulans*, Krøyer, ?? *Hyperia obliteria*, Krøyer, ?? *Hyperia medusarum*, Boeck, ?? *Hyperia latreillei*, Bovallius, ?? *Parathemisto obliteria*, Bovallius; to " *Hyperoche medusarum* (Krøyer)" the synonyms are *Metoecus medusarum*, Krøyer, *Tauria medusarum*, Boeck, " *Hyperoche Kroeyeri*," Bovallius, " *Hyperoche Luetkeni*," Bovallius; *Parathemisto compressa*, Boeck, and *Themisto hispinoosa*, Boeck, are both assigned to *Euthemisto compressa* (Goës); " *Euthemisto Nordenskiöldii*," Bovallius, is made one of the synonyms of *Euthemisto libellula* (Mandt); *Hippomedon denticulatus* (Sp. Bate) (Tab. II. figs. 2-2b) is separated from *Hippomedon Holbølli* (Krøyer); on " *Aristius tumidus* (Kr. non aut.) (Tab. II. figs. 3-3b)," the remark is made, " *Anonyx* (*Aristias*) *tumidus* aut. cet. (Bruzelius, Boeck, Lilljeborg, Heller) non ad speciem a Krøyer descriptam referendus est. Speciem ab autoribus descriptam *Arist. neglectum* appello.)" (Tab. II. fig. 4); on *Amphilochus concinnus*, Stebbing, the remark is made "(*Amph. manudens* Boeck non ad *Amph. manudens* Sp. Bate referendus est)," while the identity of *Amphilochus manudens*, Boeck, with *Amphilochus concinnus*, Stebbing, is thought possible but a little doubtful; " ? *Metopa borealis* G. O. Sars" (Tab. III. figs. 4, 4a) is 7 mm. long in contrast with the 3 mm. of Sars' specimen; on *Metopa longimana*, Boeck, (Tab. III. figs. 8-8b), it is observed that in Boeck's work, Pl. XVII. fig. 5 does not belong to this species, and Pl. XVIII. fig. 3 probably does not; *Metopa nasuta*, Boeck, is given with a query, since the Greenland specimens differ by elongate fourth segment of the peræon and the slightly carinate back; under *Monoculodes crassirostris*, n. sp., a discussion is given on *Monoculodes affinis* and some other species of that difficult genus; to *Paramphithoë pulchella* (Kr.), " ? *Paramphithoë eucaantha* G. O. Sars" is given as a synonym; of " *Melita Goësii* H. J. Hansen" (Tab. V. fig. 8) the second gnathopod is figured; " *Amathilla arenaria* (O. Fabr.)" is a new name for *Amathilla sabini* (Leach), this species being identified with *Oniscus arenarius*, O. Fabricius, 1780, but the name *Amathilla homari* will take precedence for the reasons given in the Note on J. C. Fabricius, 1779 (p. 45); see also Note on O. Fabricius, 1780 (p. 47). On " *Euthemisto compressa*," see p. 1409.

In the "Kort Oversigt over de af O. Fabricius i 'Fauna Groenlandica, 1780' omtalte højere Krebsdyr," pp. 223-226, Dr. Hanseeu says that the reference of *Caprella septentrionalis*, Krøyer, to *Squilla lobata*, Müller, may be regarded as well grounded; that " *Oniscus Medusarum* (Müll.)" is certainly the same as " *Hyperia Latreillei* M. Edw. "; that " *Oniscus Cicada* O. Fabr." is perhaps, as Krøyer supposes, the same as " *Anonyx gulosus* Kr." but more probably, the greedy " *Onisimus Edwardsii* (Kr.)" so common in Greenland; that " *Oniscus arenarius*, O. Fabr." is certainly the same as " *Amathilla Sabini* (Leach)," on which see above; that " *Oniscus Stroemianus* O. Fabr." may be an *Orchestia*, probably *Orchestia litorea* (Mont.), but that, since no Orchestiid appears to have been since found in Greenland, the whole matter is doubtful; that " *Oniscus abyssinus* O. Fabr." partly suits *Pontogeneia inermis* (Kr.), and partly *Calliopius læviusculus* (Kr.), but neither of these entirely, nor yet any other species known from Greenland; and lastly, that " *Oniscus serratus* O. Fabr." is as already suggested by Krøyer the same as *Acanthonotosoma serratum* (O. Fabr.).

1887. HOLM, TH.

Beretning om de paa Fylla's Togt i 1884 foretagne zoologiske Undersøgelser i Grønland; Meddelelser fra Grønland, B. viii, pp. 153–171.

This work is mentioned by Hansen in his "Malacostraea marina Groenlandiae occidentalis," p. 216. Professor Hansen had himself supplied the lists of Crustacea for it, and in his own work takes the opportunity of correcting two names, *Monoculodes norvegicus*, Boeck (pp. 167 and 155), a wrong determination for *Monoculodes simplex*, n. sp., and *Caprella dubia*, Hansen (pp. 168, 157, and 158), which he now describes as "*Capr. microtuberculata*, G. O. Sars, var. *spinigera*."

1887. KOEHLER, R.

Recherches sur la structure du cerveau du *Gammarus pulex*. (Aus der internationalen Monatsschrift f. Anat. u. Phys. 1887. Bd. IV. Heft. 1.) Avec pl. I. 16 pages. Leipzig.

Microtome sections in various directions through the head of *Gammarus pulex* are described and figured. Since the upper antennæ carry the olfactory cylinders, the nerves which run to them are called, by Bellonci's term, the olfactory nerves. Two groups of cells which extend all along the dorsal face of the brain are designated the upper longitudinal bands; in these one cell is met with of considerable size (la cellule géante). The brain is divided into three regions; the upper including the group of the upper lobes and of the optic ganglia with the cells annexed (cells of the upper bands, of the upper lobes, and the nervous sheath of the optic ganglia), the middle including the median lobes with the median and central cells; the lower including the group of the olfactory lobes and ganglia. The middle region has its two lobes united by a commissural band which separates them from the upper region. In the central region there is a small empty space.

In comparing his own results with Bellonci's description of the brain of *Sphaeroma serratum* Dr. Koehler finds that the four cellular groups attached to the upper lobes of the brain of the Isopod (the first containing the giant-cell), have their equivalents in *Gammarus*, but with less distinctness in the grouping. The optic ganglion is constituted by two distinct lobes, but has not the hinder reticulated swelling, which Bellonci found well developed in *Ilotea* and rudimentary in *Sphaeroma*. As in the Isopods, the nerve destined for the antenna which carries the olfactory cylinders rises in an olfactory lobe to which is annexed a swelling with special structure, besides various cellular groups. The nerve of the lower antenna springs, as in the *Sphaeroma*, from the oesophageal commissure, but the group of cells connected with it at its origin is in *Gammarus* above instead of below the point of origin of the nerve. The bundles of fibrillæ coming from the olfactory region form a chiasma in the central region of the brain. These bundles penetrate into the upper, that is to say, the optic region, presenting an incomplete intercrossing, since certain vertical fibrillæ pass directly into the optic region of the same side.

The brain of *Gammarus*, therefore, Dr. Koehler says, appears to come closer to that of the Isopods than to that of the Phronimidae as described by Claus. "Ce savant a reconnu aussi chez les Phronimides un chiasma central, mais la signification de ce chiasma comme entrecroisement de faisceaux optico-olfactifs, est moins nette que chez les Isopodes et le *Gammarus*, puisque le nerf olfactif ne paraît pas prendre son origine chez les Phronimides dans la même région centrale que chez les autres Edriophtalmes étudiés. La région que j'ai décrite sous le nom de région moyenne ne paraît pas exister chez les Phronimides. Le

renflement annexé au lobe olfactif chez les autres Crustacés fait également défaut chez ces Amphipodes aberrants."

Dr. Koehler inclines to believe that the upper longitudinal bands in the brain of *Gammarus* are homologous with the hinder lobes of the brain of the Phronimidae, and with the fugiform bodies in the higher Arthropods, "d'autant plus qu'elles présentent avec les faisceaux optico-olfactifs les mêmes relations que chez les Arthropodes supérieures."

In the midst of the fibrillæ and of the medullary substance there are strongly coloured nuclei as to which he is doubtful whether they belong to nerve-cells, or are simple connective nuclei.

1887. KOEHLER, R.

Recherehes sur la strueture des fibres musculaires chez les EDRIOPHTALMES (Isopodes et Amphipodes). Journ. de l'anatomie et de la physiologie normales et pathologiques. Tome XXIII. Paris, 1887. pp. 113-123. Pl. XI.

The Amphipods selected for this investigation were "*Gammarus pulux*, *Talitrus saltator*, *Amphioë littorina*, *Mæra grossimana*, *Anonyx Edwardsii*, *Dexamine spinosa*, *Phronima sedentaria* et *Thyropus ovoïdes*." The sections were made through the same group of muscles in the various species, and the principal result arrived at is thus expressed:—"La substance contractile est située dans la région centrale de la cellule musculaire du faisceau primitif, et se trouve entourée d'un manchon plus ou moins épais de protoplasma qui s'étend entre la substance contractile et le sarcolemme. Ainsi donc chez les Isopodes et les Amphipodes, les relations respectives des éléments contractiles et du protoplasma de la cellule myogène se trouvent être inverses de ce qu'elles sont dans les fibres musculaires des autres animaux. Il ne s'agit ici, bien entendu, que des fibres musculaires epithéliales, les fibres mésenchymateuses des Crustacés ayant une disposition bien différente et qui est conue de tout le monde." If, however, the relations of position are constant in the Amphipoda and Isopoda, between the contractile element and the protoplasm of the muscular cellule, "on observe en revanche des variations assez importantes dans la taille des cellules musculaires et des cylindres primitifs, dans le nombre de ces cylindres, dans la forme, le développement et l'importance de l'élément contractile relativement à la taille de la cellule musculaire et à l'épaisseur de la couche de protoplasma périphérique; et enfin dans le nombre, la grosseur et la distribution des noyaux."

1887. LÜTKEN, CHR. FR.

Tillaeg til "Bidrag til Kundskab om Arterne af Slægten *Cyamus* Latr. eller Hvallusene." Med en Tavle. Avec un résumé en français. Vidensk. Selsk. Skr., 6. Række, Naturvidenskabelig og mathematisk Afd. IV. 4. Kjøbenhavn, 1887.

Of the five species of *Cyamus* named by Dall in 1872-1874, Lütken identifies *Cyamus mysticeti* from the *Balaena mysticetus* and *Cyamus gracilis* from the *Balaena sibboldii* with the species so named in his own work; *Cyamus tentator* from the *Balaena sibboldii* he identifies with *Cyamus ovalis*, R. de V., and *Cyamus suffusus* from the *Megaptera versabilis* with his own *Cyamus pacificus*, and both of these he thinks should become synonyms of *Cyamus boopis*, Fabr., seeing that *Megaptera versabilis* is only another name for *Megaptera boops*.

Of "*Cyamus Scammoni* Dall" Lütken gives figures, description, and the following definition:—
"Differt a C. ovali (cui similis præcipue branchiis duplicitibus appendicibusque branchialibus feminarum nullis, marium longiusculis) branchiis in utroque sexu spiraliter contortis, appendicibus branchialibus marium posterioribus quoque bicornibus."

Lütken has not been able to find any confirmation of the statements of Bennett and Seaman that there are Cyami on the Cachalot (*Physeter macrocephalus*). He now thinks it may be doubtful whether the same species of *Cyamus* ever lives on different closely related species of Whale, though it is certain that the same species of Whale may play the host to two or three species of *Cyamus*.

1887. MONACO, LE PRINCE ALBERT DE.

Sur les recherches zoologiques poursuivies durant la seconde campagne scientifique de l'Hirondelle, 1886. Note du Prince Albert de Monaco, présentée par M. A. Milne-Edwards. Comptes rendus Hebdomadaires des séances de l'Académie de Sciences, par MM. les Secrétaires perpétuels. Tome CIV. No. 7 (14 Février 1887). Paris, 1887. pp. 452-454.

It is mentioned that, in dredging between the latitudes of Belle-Isle and la Gironde,
 " Sur les pentes de sable fin plus ou moins vaseux qui s'étendent au large des côtes de France et
 par 130^m à 166^m de profondeur ;
 " Parmi les Amphipodes, trois formes, non signalées en ces parages, ont été recueillies : *Eusirus longipes* Boeck, *Epimeria cornigera* Fabr., *Tryphosa longipes* Sp. Bate."

1886- PACKARD, A. S.

1887. The American Naturalist. Vol. XX. pp. 889, 973, Vol. XXI. p. 279.

In these papers referring to the organs of smell in the Arthropoda, the views of various writers are briefly compared.

1887. STEBBING, T. R. R.

On some new Exotic Amphipoda from Singapore and New Zealand. Received November 12th, 1885, read January 19th, 1886. *From the Transactions of the Zoological Society of London*, Vol. XII. part. vi. 1887. Plates XXXVIII., XXXIX.

See Note on Stebbing, 1886 (p. 586). *Amphithopsis cærulea* (Thomson), is here named *Pherusa cærulea* as Mr. G. M. Thomson had originally proposed that it should be called. This species and *Talorchestia tumida*, Thomson, are figured, as also *Byblis kallarthrus*, Stebbing.

1887. WHYMPER, EDWARD.

Several specimens of Amphipods taken by Mr. Whymper at various localities in Ecuador have proved on examination to be the species named *Hyalella inermis* by Professor S. I. Smith. See Note on de Saussure, 1858, and on Philippi, 1860. Some of the specimens, Mr. Whymper informs me, were taken at Antisana, at a height of 13,300 feet above the sea. This, so far as I can discover, is the highest point from which Amphipoda have been obtained.

1888. BARROIS, TH.

Note sur l'histoire naturelle des Açores.—De l'adaptation de l'*Orchestia littorea* Montagu à la vie terrestre. Bulletin de la Société Zoologique de France pour l'année 1888. t. xiii, séance du 10 janvier 1888. Paris, Janvier 1888. pp. 19-22.

After recalling the observations on the terrestrial habits of various species of *Orchestia* recorded by Dana, Heller, Hoek, Spence Bate, von Martens, Fritz Müller, Bate and Westwood,

Blanc and Chevreux, Professor Barrois mentions instances of *Orchestia littorea* occurring in the Azores at various heights from 15 to 80 mètres above the sea-level, and concludes that this species is a marine type tending more and more to withdraw from its primitive habitat and to become adapted to life on land. He thinks it not improbable that "*Orchestia Chevreuxi*," de Guerne, found at the bottom of the crater of Fayal, may be the same species and not a new one. He also points out that Dana recorded two terrestrial species of *Orchestia*, *Orchestia sylvicola* from the crater of Taiamai in New Zealand, and *Orchestia tahitensis* in Tahiti 1500 feet above the sea level.

1888. BARROIS, TH.

Note préliminaire sur la Faune Carcinologique des Açores. Lille, 1887.
(Preface dated "Lille, le 15 Février 1888."?)

Reference is made to "H. Drouet, Éléments de la Faune Açoréenne (*Mém. de la Soc. d'Agric., des scienc., arts et belles-lettres du départ. de l'Aube*, 2^e sér., t. xii, 1861)." The only Amphipod included in the Crustacean fauna of the Azores by Drouet was *Phronima sedentaria*, Forskål. Professor Barrois here adds seven and twenty. Of the names here given, in his subsequent report he changes "*Proto Goodsiri* Spence Bate" into "*Proto ventricosa* O. F. Müller," and "*Cyamus Thompsoni* Gosse" into "*Cyamus globicipitis* Lütken;" and for some unexplained reason changes the correct spelling of *Mera* into *Mæra*.

1888. BARROIS, TH.

Remarques sur le dimorphisme sexuel chez quelques amphipodes du genre *Mæra* (*M. scissimana* Costa = *M. integrimana* Heller, *M. grossimana* Montagu = *M. Donatoi* Heller). Extrait du Bulletin de la Société Zoologique de France, t. xiii, séance du 28 février 1888. 2 pages.

Professor Barrois, having examined the types of Heller's species, concludes that *Mæra scissimana* (Costa), and *Mæra blanchardi*, Spence Bate, are the male, and *Mæra integrimana*, Heller, the female, of one species, while *Mæra grossimana* (Montagu), and *Gammarus Impostus*, Milne-Edwards, are the male, and *Mæra donatoi*, Heller, the female, of another species.

1888. BARROIS, TH.

Catalogue des Crustacés marins recueillis aux Açores durant les mois d'Août et Septembre 1887. (Avec 4 Planches et 8 Figures dans le texte.) Lille, 1888.

In the descriptive part the Amphipods occupy pp. 30–59. Thirty-five species are named, beginning with *Phronima sedentaria*, Forskål, and ending with *Cyamus globicipitis*, Lütken, these two species, however, not being included in the number obtained by Professor Barrois himself. In the addenda at p. 100, he remarks that "l'*Orchestia Chevreuxi* de Guerne paraît être une forme véritablement nouvelle, d'après les dernières observations de de Guerne et de Chevreux." With a fuller discussion of the synonymy of *Mæra scissimana* (Costa), Professor Barrois now thinks that *Amphithoe inaequipes*, Costa, should be included in it, as in fact representing the female of the species. He gives the name "*Moera rapax*, Costa" to take precedence of the following synonyms "♂ *Elasmopus rapax* Costa," "♀ *Gammarus brevicaudatus* Spence Bate," "♀ *Megamoera brevicaudata* Spence Bate," "♂ et ♀ *Moera brevicaudata* Heller," "♀ *Elasmopus latipes* Boeck," "♂ et ♀ *Elasmopus latipes* Chevreux." This reduction of the genus *Elasmopus* under *Mæra* is supported

incidentally by a reference to "*Moera crassipes*," Haswell, a species which I myself from another point of view had been led to place under *Elasmopus*. Pl. III. gives figures of "*Moera scissimana* Costa," and of "*Moera grossimana* Montagu," Pl. IV. gives figures of "*Moera rapax* Costa" and of "*Gammarella brevicaudata* Milne-Edwards." The details of the two species of *Moera* are also illustrated by figures incorporated in the text.

1888. CHEVREUX, E.

Troisième campagne de l'*Hirondelle*, 1887. Sur quelques crustacés Amphipodes du littoral des Acores. Bulletin de la Société Zoologique de France pour l'année 1888. t. xiii, séance du 24 janvier 1888. Paris, Janvier 1888. pp. 31-35.

1. From "Horta, île de Fayal, marée basse," ten species of Amphipods are recorded, with notes on "*Hyale Nilsoni* Rathke," "*Hyale Schmidtii* Heller," and "*Hyale Stebbingi* nov. sp."; of the last a description is given, and the observation is made that "les épines crochues et dentelées des cinq dernières paires de pattes thoraciques ne se retrouvent que chez une seule autre espèce du genre: *H. Lubbockiana* Sp. Bate; mais cette dernière diffère bien nettement de *H. Stebbingi* par ses antennes inférieures plus courtes, presque glabres, et par les petites dents que portent ses épimères, et le premier article de ses pattes des trois dernières paires."
2. From "Rade de Horta, île Fayal, profondeur, 15 mètres," eight species are named.
3. "Au large de Pouta Delgada, île San-Miguel, 8 juillet, 9 h. 30 du soir, surface," "*Urothoe Pouchetii* nov. sp." was obtained. This species is described, and the observation made that "cette espèce, assez voisine d'*Urothoe elegans* Sp. Bate, en diffère par sa forme moins obèse, la grandeur et l'aspect particulier de ses yeux, et surtout par ses pattes sauteuses des deux premières paires, qui sont plus développées que chez les autres espèces du genre."
4. "Au Snd de Pico, 14 juillet, 8 h. du soir, surface," two specimens were obtained of *Corophium crassicornis*, Bruzelius.

1888. CHEVREUX, E.

Sur quelques crustacés Amphipodes provenant d'un dragage de l'*Hirondelle* au large de Lorient. Extrait du Bulletin de la Société Zoologique de France, t. xiii, séance du 28 février 1888. 4 pages.

A dredging about eighty miles south-west of the île de Groix, lat. $46^{\circ} 3'$ N., at a depth of 100 fathoms on ground covered with Annelid-tubes, yielded twenty-seven species of Amphipoda, four of them being new species and four of them species not previously recorded from French waters. Latin descriptions are given of the new species, which are named *Lepidepecreum clypeatum*, *Phoxus maculatus*, *Amphilochus longimanus*, *Monoculodes gibbosus*, in each case the female only having been obtained. The four species new to the locality are "*Ichnopus spinicornis* Boeck," "*Stegocephalus Christianiensis* Boeck," "*Metopa rubrovittata* G. O. Sars," and "*Unciola Steenstrupi* Boeck." A footnote mentions that "*Gitana Sarsi* Boeck" has for a synonym "*Amphilochus Sabrinæ Stebbing, teste G. O. Sars,*" which is no doubt a correct determination.

Phoxus maculatus appears to come near to *Phoxus oculatus*, G. O. Sars, but to differ from it by having the body elongate and narrow, instead of short and thickset, the eyes oval instead of round, the telson short instead of long, and perhaps also by the colouring. A male specimen of *Phoxus*, with dark oval or reniform eyes, has recently been taken by Mr. David Robertson in the Clyde, but this differs from both the described species in the shape of the first gnathopods.

1888. CHEVREUX, É.

Note sur la présence de l'*Orchestia Chevreuxi* de Guerne, à Ténérife, description du mâle de cette espèce et remarques sur la locomotion de l'*Orchestia littorea* Montagu. Extrait du Bulletin de la Société Zoologique de France, t. xiii, séance du 27 mars 1888. 5 pages.

The antennae, second gnathopods, and fifth pereopods of the two species named in the title are compared, with illustrative figures, the conclusion being that the specific distinction of the two forms should be maintained.

1888. CHEVREUX, E., and GUERNE, J. DE.

Sur un Amphipode nouveau (Cyrtophium chelonophilum), commensal de Thalassochelys caretta L. 4 pages.

The chelonian was captured in the waters of the Azores, between Pico and São Jorge, and yielded seventy-seven specimens, male, female, and young, of the Amphipod. The authors say, "Cette espèce diffère bien nettement des formes déjà connues du même genre par la brièveté de ses antennes. Elle se rapproche de *C. lave* Heller par l'aspect lisse de la partie supérieure du corps; mais, en dehors du caractère mentionné ci-dessus, sa tête très courte et la forme de ses gnathopodes ne permettent pas de la confondre avec l'espèce de l'Adriatique." They consider Haswell's genus *Dexiocerella* a synonym of *Cyrtophium*, and, since *Cyrtophium lave* is preoccupied, they give to Haswell's species of that name the new title "*Cyrtophium Haswelli*." They notice that *Cyrtophium tuberculatum* of the British Museum Catalogue ought to resume the name "*Læmatophilus tuberculatus* Bruz.," and that "*C. armatum* Norman" is certainly also a *Læmatophilus*. On *Dexiocerella* see p. 566.

1888. DELLA VALLE, A.

Sopra le glandole glutinifere e sopra gli occhi degli Ampeliscidi del Golfo di Napoli. Estratto dagli *Atti della Società dei Naturalisti di Modena—Memorie Originali—Serie III.—Vol. VII.—Modena, 1888.* 6 pages.

In *Ampelisca*, it is stated, there are many large gland-cells in the connective tissue of the thoracic region; the side-plates of the gnathopods and first two pairs of pereopods are glandular, with ducts opening on the lower margin; in the first two pairs of pereopods moreover all the joints are glandular except the long awl-shaped finger, which has openings in its walls for the emission of the cement; in the fifth pereopod the excretory ducts from the gland-cells of the upper joints lead to little openings arranged along the front margin of the two terminal joints. It is no doubt to these series of duct-openings that I have referred in the description of *Ampelisca abyssicola*, p. 1051, and of *Ampelisca fusca*, p. 1056, without knowing their true meaning. Professor Della Valle mentions that Hoek had already noticed the glandular apparatus in *Ampelisca*, but it was observed still earlier by S. I. Smith. See Note on the latter author, 1874 (p. 432).

In *Haploops* the gland-cells are said to be found in the side-plates and in the first¹ and third joints of the first gnathopods, not in the side-plates but in the first four joints of the second gnathopods, in the side-plates and first three joints of the first two pairs of pereopods, and to a small extent in the first joint of the fifth pair, while in the interior of the body, both pereon and pleon, the cement-producing apparatus attains a very great development the

¹ Or second and fourth, as Professor Della Valle numbers them.

excretory ducts of the pleon-cells having their openings along the convex margin of the outer ramus of the first uropods.

In all the Ampeliscide of the Gulf of Naples, Professor Della Valle says, the number of the eyes is four, while the *Ampeliscæ* besides the two principal pairs have a third pair of rudimentary eyes. In a vertical section of the eye of *Ampelisca* the following strata are distinguished:—(1) the lenticular cornea; (2) the hypodermis with elongate or short cells; (3) external rhabdoms (bastonecelli); (4) crystalline cones; (5) internal rhabdoms; (6) reticulated membrane; (7) retinal cells. All the eye is surrounded in its distal part by a fine capsule of connective tissue, across which pass the fibres of the optic nerve, which before entering the ganglion form a true chiasma.

Between the eyes of *Ampelisca* and *Haploops* the principal differences are said to be, (1) the hypodermis in *Ampelisca* in the periphery of the cornea has some very long cells, but in *Haploops* only short ones; (2) in *Haploops* true crystalline cones are wanting, or rather these are represented by the dicotyledonous body [previously described], which is without doubt the union of the crystallogenous cells (nuclei of Semper); (3) the retinal cells are less elongate in *Haploops* than in *Ampelisca*, and do not as in *Ampelisca* segregate the internal rhabdom.

1888. GUERNE, J. DE.

Excursions Zoologiques dans les Iles de Fayal et de San Miguel (Açores). Paris, 1888.

At page 46, “*Orchestia Chevreuxi*, nov. sp.,” is described.

1888. GUERNE, J. DE.

Remarques au sujet de l'*Orchestia Chevreuxi* et de l'adaptation des Amphipodes à la vie terrestre. Extrait du Bulletin de la Société Zoologique de France, t. xiii, séance du 28 février 1888. 8 pages.

The suggestion having been made that *Orchestia chevreuxi* might be the same as *Orchestia littorea*, M. de Guerne here discusses the differences in detail, and besides giving comparative figures of various parts, supplies a fresh Latin definition, that which had previously appeared having suffered from errors of the press; it is as follows:—

“Femina.—Antennæ superiores paulo ultra articulum pedunculi penultimum antennarum inferiorum porrectæ. Pedes 2nd paris articulo 3rd aculeis 2 armato, carpo elongato; pedes 5th parvæ perbreves; pedes 7th parvæ et pedes saltatorii 1st et 2nd paris valde elongati. Telson breve, ovatum, emarginatum. Animal roseo-violaceascens. Mas ignotus. Longit. 15 mm.”

M. de Guerne observes that, with the exception of *Orchestia carimana*, Hoek, all the terrestrial *Orchestiæ* are insular forms.

1888. PEREYASLAWZEWA, S., and ROSSIISKAYA, M.

Etudes sur le développement des Amphipodes. Partie I. Le développement de *Gammarus poccilurus*, Rathke. Moscow, Bull. Soc. Nat., 1888. 38 pages, 4 plates.

This work is mentioned in Friedländer's *Naturæ Novitates* for August, 1888.

PFEFFER, GEORG.

Die Krebse von Süd-Georgien naeh der Ausbeute der Deutschen Station 1882-83. 2. Teil. Die Amphipoden. Mit 3 Tafeln Abbildungen. Aus dem Jahrbuch der wissenschaftlichen Anstalten zu Hamburg. V. Beilage zum Jahresberichte über das Naturhistorische Museum zu Hamburg für 1887. Hamburg, 1888.

Very detailed descriptions are given of the following Amphipods from South Georgia, an island lying in the south-west Atlantic, lat. $54^{\circ} 0'$ S., long. $36^{\circ} 30'$ W.

1. " *Allorchestes georgianus* nov. spec. (Taf. I, Figs. 1 a-n.)"
2. " *Metopa Sarsii* nov. spec. (Taf. II, Figs. 3, 8 und Taf. III, Fig. 2.)"
3. " *Anonyx Zschauii* nov. spec. (Taf. II, Fig. 1.)"
4. " *Anonyx femoratus* nov. spec. (Taf. II, Fig. 2.)"
5. " *Bovallia gigantea* nov. spec. (Taf. I, Fig. 5.)"
6. " *Eurymera monticulosa* spec. nov. (Taf. I, Fig. 3.)"
7. " *Stebbingia gregaria* nov. spec. (Taf. II, Fig. 7.)"
8. " *Calliopius georgianus* nov. spec. (Taf. II, Fig. 6.)"
9. " *Megamoera Miersii* nov. spec. (Taf. III, Fig. 3.)"
10. " *Leucothoe antarctica* nov. spec. (Taf. II, Fig. 4.)"
11. " *Podocerus ingens* nov. spec. (Taf. III, Fig. 1.)"
12. " *Caprellina Mayeri*, nov. spec. (Taf. III, Fig. 4.)"
13. " *Schraderia gracilis* nov. spec. (Taf. II, Fig. 5.)" is figured, but the description is reserved for the continuation of the work.

The descriptions of new genera are as follows :—

" *Bovallia gen. nov. Atylidarum.*

" Körper zusammengedrückt; Rücken vorn zusammengedrückt-rundlich, an den letzten Mittelleibs- und an den drei ersten Nachleibs-Ringen gekielt und in kräftige Spitzen ausgezogen. Die Epimeren sind sehr gross, höher als die dazu gehörigen Segmente, nirgends bewimpert. Augen schmal und hoch, schlank bohnenförmig. Fühler mit starken Stammgliedern und ziemlich kurzer Geissel; keine Nebengeissel. Oberkiefer mit kräftigem, dreigliedrigen Taster, mit Borstenreihe und gezähnter Kausspitze. Rand der Innenlade des 1. Unterkiefers reichlich mit gefiederten Haaren bestanden, Aussenlade mit gesägten Stacheln; Taster zweigliedrig, mit Stachelborsten am distalen Ende. Innenrand der Innenlade des 2. Unterkiefers mit gefiederten Haaren, Distalrand beider Leden mit Borsten. Kieferfüsse stark, mit kräftigen Leden und sehr kräftigem Taster mit spitzer Endklaue. Innenlade am Distalrande mit dicken Zähnen, Aussenlade am Rande mit kleinen Stiftstacheln. Die beiden ersten Beinpaare mit Halbscheeren von etwa gleicher Entwicklung; 5., 6. und 7. Beinpaar mit länglich blattförmigen Hüften. Die beiden seitlichen hinteren Kanten jedes Stammgliedes der beiden ersten Haltopoden-Paare sowie jedes Spaltastes aller dreier Paare mit kleinen Dornen besetzt. Die Spaltäste der beiden ersten Paare tragen am Ende zwei kräftige hochrichtbare Dornen; die des letzten Paars gehen in kräftige Dornenspitzen aus; an den ersten beiden Paaren ist der Aussenast kürzer, beim letzten Paar sind beide Äste gleich lang, kräftig. Schwanzschild schmal, blattförmig, bis über die Mitte gespalten."

" *Eurymera gen. nov. Atylidarum.*

" Körper nur hinten zusammengedrückt, der Rücken ganz ausserordentlich breit und flach gewölbt. Epimeren ganz ausserordentlich gross, hoch und breit. Der Stirnvorsprung ist nur ein Winkel. Auge klein, glänzend, rund, auf einen kräftig vorspringenden Höcker liegend. Telson gespalten. Fühler von mässiger Länge, die oberen ziemlich stark; der Stamm der unteren etwas länger; keine Nebengeissel. Die Aussenschneide des Oberkiefers gezähnt, ebenso die Innenschneide des linken Kiefers; eine grössere Anzahl nicht gefiderte Borsten.

Innenrand der Innenlade des 1. Unterkiefers mit vielen Fiederhaaren; Ansenlade proximal mit schwach gefiderte Stacheln; Taster länger als die Aussenlade, das Endglied beborstet. Laden des 2. Unterkiefers gleich lang, die innere schmäler. Proximalrand der Innenlade der Kieferfüsse mit gefiderten Borsten; an der inneren Ecke mit einigen Stacheln; Proximalrand der Aussenlade mit schlanken Stacheln. Die Handglieder der beiden ersten Paare nur ganz schwach ausgebildet, beim 1. Paare etwas lüger und kräftiger als beim 2.; die drei hinteren Mittelleibsbeine wachsen nach der Reihe an Länge, die Coxalglieder an Länge und Breite."

"*Stebbingia gen. nov. Atylidarum.*

"Gestalt schlank. Körper zusammengedrückt, nirgends gekielt. Die Nachleibs-Segmente schwach eingesattelt, nirgends sknlpiert oder in Spitzen ausgezogen. Die Epimeren sind ziemlich gross, höher als die dazu gehörigen Segmente. Augen bohnenförmig. Fühler von mässiger Länge, die oberen etwas länger, nicht so lang wie der Mittelleib. Die Stämme sind etwa gleich lang, ziemlich schlank; die Geisseln etwa doppelt so lang wie die Stämme. Keine Nebengeissel. Oberkiefer wie bei den Atylidern überhaupt, gezähnt; die Borsten kurz, hyalin, und ungefiedert. Wenige längere Borsten am Tasterende. 1. Unterkiefer wie bei *Bovallia*. Inneuladen des 2. Unterkiefers etwas kürzer und breiter als die Aussenlade; die Distalenden mit Borsten. Innenlade der Kieferfüsse mit Borsten und wenigen Stachelhöckern; Ausseulade am Distalrande mit gebogenen Stacheln, am Iunenrande mit knrzen Borstenstiften. Die beiden ersten Beinpaare mit schwacher, wenig verdickter Halbschere; das 1. Paar ganz ausserordentlich viel schwächer als das 2. Paar. Die Coxalglieder der drei letzten Mittelleibs-Beinpaare weuig verbreitert. Telson bis zur Hälfte gespalten."

In the species *Stebbingia gregaria*, for which this genus is instituted, there is said to be no accessory flagellum to the upper antennæ and the telson is said to be a little dehiscent, but in other respects the agreement is so great with the species described in this Report as "*Atyloides australis* (Miers)" that there is strong reason for supposing them to be the same. In that case the generic name *Stebbingia* will take precedence of *Atyloides* by priority of publication, though its own title may be open to challenge from the earlier *Paramoera*, Miers (see p. 913). If *Paramoera* be legitimately discarded, the species would become *Stebbingia australis*, bnt again perhaps snbjct to some doubt as to its distinctness from *Atylus austromus*, Spence Bate (see p. 918).

At page 107 there is a discussion upon the line of demarcation hetween the maxillipeds and the maxilliped-segment, and on the morphological relations of the inner plate of the maxillipeds. In this paper the joints of the limbs are numbered from one to seven, the seventh however being spoken of as the finger (die Klaue). The pleopods are "die Nektopoden" and the uropods "die Haltopoden." The genus *Schraderia* is not described. The work having only come into my hands at the last moment, it is impossible for me to discuss it with the fnlness which its importance deserves.

1888. ROBERTSON, DAVID.

A contribution towards a catalogue of the Amphipoda and Isopoda of the Firth of Clyde. Reprinted from the Transactions of the Natural History Society of Glasgow, vol. ii. pp. 9-99. Glasgow, 1888. pp. i-iv, 5-95.

One hundred and seven species of Amphipoda are named in the body of the work, and to this number nineteen are added in the Appendix. "A few Amphipods, little known or new to

science, together with some doubtful species that are reserved for further investigation, are intended to form the subject of another small supplement to the list." Some valuable hints on methods of collection are given in the introduction. Very useful notes are also interspersed throughout the work in regard to the localities frequented by the different species, and in many instances the colouring and movements of the living animals are described. These observations which are evidently the fruit of long and careful study of the Amphipoda give the work a far higher value than that of a mere catalogue. Of "*Parathemisto obliqua*, Kröyer," taken in Sanda Bay, Mr. Robertson remarks, "only a single specimen was obtained, and it is the only one that I remember of meeting with in the Firth of Clyde. I had lately, from Dr. John Murray of the *Challenger* Expedition, some gatherings taken by the tow-net in the Firth of Forth, where this species was in great abundance at the surface, and at depths of 30 and 40 fathoms." (See Note on Brook and Calderwood, p. 1640.) Mr. Robertson explains the value of tow-nets as used on board the steam yacht "Medusa," "not only as surface-nets, but attached to the dredging-line at various depths, thus giving a tolerably correct idea of the minute inhabitants of the various zones in the water, to what extent they were distinct or intermixed, and whether those found at the surface by night were met with in the under zones by day."

1888. ROLLESTON, GEORGE, and JACKSON, W. HATCHETT.

Forms of Animal Life, a manual of Comparative Anatomy with descriptions of selected types. Oxford, M.DCCC.LXXXVIII.

Pages 531–543 contain the account of the Crustacea. Claus' classification is followed. The "Class Crustacea" is thus defined:—"Aquatic Arthropoda with cutaneous or branchiate respiration: with two pairs of antennæ, a limb-bearing thorax, either free or united more or less to the head, and as a rule a segmented abdomen which may or may not carry limbs."

Among many other remarks of value the following occur:—"The second antenna may become uniramous, or the outer branch may be reduced to a scale or squame (many *Thoracostraca*).

It is minute in *Apus* and is lost in all *Cirripedia* and *Hyperida* (*Amphipoda*). But that the second antenna is lost in all Hyperidae can by no means be admitted.

"The primitive type of limb is probably that of the *Copepoda*, which closely resembles the *Nauplius* appendage. It has a basal stem carrying a more or less jointed or lamellate exo- and endo-podite. Such a limb is seen in the thoracic appendages of *Cirripedia* and of the *Schizopoda* among *Malacostraca*, and is generally found in the abdominal region."

The class is divided into Entomostraca and Malacostraca, the latter thus defined:—"Head composed of five, thorax of eight, and abdomen of six somites."

The Malacostraca are divided into Leptostraca, Arthrostraca, and Thoracostraca, the definition of the Arthrostraca being, "seven, rarely six free thoracic somites; eyes sessile; no cephalothoracic shield."

The Arthrostraca are subdivided into Amphipoda and Isopoda, the Amphipoda being defined as follows:—"body laterally compressed; branchiae on thoracic limbs; first three pairs of abdominal feet natatory: e.g. *Caprella*, *Cyamus*, *Talitrus*, *Orchestia*, *Gammarus*, *Hyperia*, *Phronima*." To the lateral compression of the body here mentioned there are several exceptions. The characters given are generally applicable, but *Caprella* is little suited to stand as the leading illustration, since in that genus the body is rather cylindrical than compressed, the thoracic limbs are missing from the segments which carry the branchiae, and there are no natatory abdominal feet.

1888. WALKER, ALFRED, O.

Report on the Crustacea of Liverpool Bay, 1886–1887. [From Proc. Biol. Soc., L'pool. Vol. II. 1888.] pp. 171–181, with Plate XIII.

Twenty-eight species of Amphipoda are recorded. Of *Tryphosa ciliata*, Sars, figs. 1–4, it is remarked that “the colour, whieh is milk white, is very proteetive among broken shells,” from among which the speemens were obtained. “*Pleustes bicuspis*, Kröyer,” figs. 5–9, is deseribed, being distinguished from *Pherusa bicuspis*, Spence Bate, and identified with the following synonyms, *Pleustes bicuspis*, Kröyer; *Paramphithoe bicuspis*, Bruzelius; *Paramphithoe bicuspis*, A. Boeck; *Amphithopsis bicuspis*, A. Boeck; *Calliopius bidentalus*, Norman. To these names *Pleustes bicuspis*, Boeck, should have been added. The observations show that in the synonymy *Pleustes bicuspis*, Kröyer, has been printed by mistake for *Amphilhoe bicuspis*, Kröyer. Reference is made to Norman and Chevreux, with regard to an undescribed species, *Eiscladus brevicaudatus*, having the third uropods shorter than in “*Photis (Eiscladus) longicaudatus*, Bate.”

Notes on colouring are given as to “*Pontocrates Norvegicus*, Boeck, = *Kroyera arenaria*, Bate”; “*Urothoe elegans*, Bate;” “*Pleustes bicuspis*, Kröyer”; “*Atylus Schwammerdamii*, M. Edwards”; “*Calliope leviuscula*, Kr.”; “*Cheiocratus Sundevalli* = *Lilljeborgia Shetlandica*, Bate”; “*Gammaropsis erythrophthalmus*, Lillje. *Eurystheus erytkrophthalmus*.”

1888. WRZEŚNIOWSKI, A.

O trzech kielzach podziemnych. De tribus Crustaceis Amphipodis subterraneis, commentatio zoologica.

Professor Wrześniowski has very obligingly sent me the following brief resumé of the above-mentioned work, whieh is to appear almost immediately:—

“Histoire détaillée des travaux sur les Amphipodes souterrains et des grandes profondeurs : *Niphargus*, *Eriopis* et *Crangonyx*.

“Deseriptio: *Niphargus tatrensis* nov. sp. et *Boruta tenebrarum* gen. et sp. nov. d'un puit à Zakopane (village au pied des montagnes Tatra), ainsi que eelle du *Niphargus puteanus* var. *Vejdovskyi* var. nov. d'un puit à Prague en Bohème.

“Comparaison avec les formes connues.

“Distribution des Amphipodes souterrains et des grandes profondeurs d'eau douee.”

“Ce travail contiendra aussi 11 tables lithographiées.”

¹ On p. 573, line 1, this form is suggested as the proper one in case the Dexaminæ are distinguished as a family from the Atylidae.

² On p. 559, line 25, for *Duchilidæ* read *Dulichiidæ*.

³ On p. 1182, line 24, for Family DULICHIDIÆ read Faunily DULICHIDIÆ.

⁴ In the Errata to Boeck's work the remark is made, "Instead of *Divisio Gammaridae* read *Gammarida*."

⁵ The earliest use of this term embraced the Amphipoda at large.

⁶ In the Errata to Boeck's work it says "Instead of *Divisio Hyperida* read *Hyperida*."

¹ For Phronimidae, in the Table, p. 290, read Phronomidae.

² On p. 805, line 3, for Pontoporeidæ read Pontoporeides.

³ Boeck, in quoting Lilljeborg's classification, gives the form *Pontoporina* by mistake for *Pontoporeina*.

⁴ On p. 393, it should have been noticed that in the index to his work Boeck adopts the form Prostomatidae in place of Prostomatae.

INDEX OF GENERIC NAMES.

NOTE.—The names held to be valid are printed in black letters, those of which I have been unable to find any published description are in ordinary type, and synonyms and preoccupied names in italics. When the author of a generic name has himself given or indicated the derivation of it, his own statement in the original language or translated appears between marks of quotation. The derivations of new generic names, having already been given in the text, are not repeated here. Dark numerals refer to the page on which the definition of a genus occurs.

Acanthechinus , Stebbing, 1888,	461, 547, 574, 883
<i>Acanthonotosoma</i> , alteration of <i>Acanthonotozoma</i> , Boeck, to suit the derivation,	599
Acanthonotozoma , Boeck, 1876. “ἀκανθα, spine, νῶτος, back, σῶμα, body.” Instead of <i>Acanthonotus</i> ,	162, 395, 453
<i>Acanthonotus</i> , Owen, 1835. ἀκανθα, spine, νῶτος, back. Preoccupied (see <i>Acanthonotozoma</i>),	161, 186, 200, 228, 242, 243, 258
	283, 296, 328, 256, 395, 561, 581
	582
<i>Acanthosoma</i> , Owen, 1835. ἀκανθα, spine, σῶμα, body. Preoccupied (see <i>Acanthozone</i>),	162, 179, 229
Acanthostephia , Boeck, 1870. “ἀκανθοστεφής, surrounded by spines,”	356, 394, 400 , 581
<i>Acanthostephia</i> , misspelling of <i>Acanthostephia</i> , Boeck,	508, 523
Acanthozone , Boeck, 1870. “ἀκανθα, spine, ζώνη, belt.” Instead of <i>Acanthosoma</i> ,	50, 395, 401 , 567
Aceros , Boeck, 1860. “α, without, κέρας, horn.” Preoccupied? <i>Accros</i> , Hodgson, 1844. A genus of birds, is derived from α, without, κέρας, wax, according to Agassiz,	322, 323 , 395
<i>Aceropsis</i> , Stuxberg, 1880. <i>Accros</i> , another genus, and ψηψις, appearance,	523
<i>Acerus</i> , misspelling of <i>Aceros</i> , Boeck (Forsstrand, 1886).	
Acidostoma , Lilljeborg, 1865. “From ἄκης, a point, and στόμα, mouth, because the mouth and its appendages form a long projecting point,”	362, 393, 568, 580, 709
Acontistoma , Stebbing, 1888,	709
<i>Ædicerus</i> , misspelling of <i>Oediceros</i> , Krøyer.	
<i>Egina</i> , Krøyer, 1843. “A sea-nymph, daughter of Asopns.” Preoccupied (see <i>Eginella</i>),	202, 212, 256, 261, 265, 281, 329
	396, 535-537, 571
Æginella , Boeck, 1860. “Diminutive of <i>Egina</i> .” Now to include <i>Egina</i> , Krøyer,	322, 325 , 397, 535-537, 1248
	1249
<i>Aerope</i> , Leach, 1818. Aerope, the wife of Atreus,	107, 123
<i>Aglaura</i> , Rafinesque, 1815. ἀγλαυρος, brilliant,	88
Alibrotus , Milne-Edwards, 1840. ἀλιβρωτος, swallowed by the sea,	186, 228, 258, 263, 296
<i>Allorchestia</i> , misspelling of <i>Allorchestes</i> , Dana,	321
	172, 228 , 235, 254, 257, 262
Allorchestes , Dana, 1849. ἄλλος, another; <i>Orchestia</i> , another genus. (?= <i>Hyale</i> , Rathke),	266, 313, 328, 365 , 455, 501
	560
<i>Allorchestina</i> , J. F. Brandt, 1851. Subgenus of <i>Orchestia</i> ,	245, 313
<i>Amanonyx</i> , Spence Bate, 1856. ἄμα, together with, <i>Anonyx</i> , another genus,	290
Amaryllis , Haswell, 1880. A girl's name in classical poetry,	511, 514, 581, 607, 698
<i>Amathia</i> , Rathke, 1837. “Called after a sea-nymph,” in Greek, Αμάθεια, see Homer, Iliad, xviii. 48. Preoccupied,	171, 229, 258, 328, 581, 583
<i>Amathilinella</i> , Grimm, 1880. Diminutive of <i>Amathilla</i> ,	509
Amathilla , Bate and Westwood, 1862. Diminutive of <i>Amathia</i> ,	171, 341, 381, 395, 435, 581
Amathillopsis , Heller, 1875. <i>Amathilla</i> , another genus, ψηψις, appearance. “This new genus stands intermediate between <i>Amathilla</i> and <i>Gammareacanthus</i> ,”	442, 547, 569, 581, 859
Ambasia , Boeck, 1870. “Name of a river,”	366, 393, 397 , 580, 694
<i>Ampelina</i> , misspelling of <i>Ampelisca</i> , Krøyer,	369

Ampelisca , Kröyer, 1842. "Nomen mulieris apud Plantum in Rudente,"	{ 199, 228, 258, 285, 293, 295, 296 314, 328, 395, 432, 570, 581, 601 1035 , 1651
<i>Ampeliscus</i> , misspelling of <i>Ampelisca</i> , Kröyer,	344
<i>Ampelisia</i> , misspelling of <i>Ampelisca</i> , Kröyer,	217
Amphilochus , Spence Bate, 1862. A Greek proper name, Ἀμφίλοχος. (Not to be confused with <i>Amphilocus</i> , among the Coleoptera),	{ 328, 333, 349, 394, 484, 581 743
Amphipronoë , Spence Bate, 1862. ἀμφί, about, <i>Pronoe</i> , another genus,	59, 337, 470, 492, 591, 1563
Amphithoe , or Amphithoë , or Amphithöe , alteration of <i>Ampithöe</i> , Leach, to suit the derivation,	{ 123, 148, 170, 184, 228, 229, 249 258, 270, 283, 294, 296, 307, 312 328, 349, 377, 396, 463, 580, 1113
Amphithoides , Kossmann, 1880. <i>Amphithoë</i> , another genus, εἶδος, likeness,	349, ¹ 367, 516, 517 , 580, 1115
1. <i>Amphithonotus</i> , Costa, 1851. <i>Amphithoë</i> , another genus, νῶτος, back. (= <i>Dexamine</i> , Leach, and <i>Atylus</i> , Leach),	{ 49, 249, 250 , 296, 297 , 581
2. <i>Amphithonotus</i> , Stimpson, 1854. Preoccupied,	278, 352
Amphithopsis , Boeck, 1860. <i>Amphithoë</i> , another genus, ὕψις, appearance. (?= <i>Pherusa</i> , Leach),	{ 322, 324 , 395, 569, 581, 913
Amphithyrus , Clans, 1879. ἀμφίθυρος, with a door on both sides,	491, 591, 1485
<i>Amphitoë</i> , or <i>Amphitöe</i> , misspelling of <i>Amphithoë</i> ,	{ 176, 187 , 231, 251, 255, 281, 311 342
<i>Amphitonotus</i> , misspelling of <i>Amphithonotus</i> , Costa,	560
<i>Amphitopsis</i> , misspelling of <i>Amphithopsis</i> , Boeck,	573
Amphithöe , ² Leach, 1814. Ἀμφιθόη, a Nereid, see Homer, Iliad, xviii. 42,	84, 86 , 90
<i>Anceus</i> , Riso, 1816. (= <i>Gnathia</i> , Leach, an Isopod genus),	96, 192
Anchylomera , Milne-Edwards, 1830. ἀγκύλος, crooked, μηρός, thigh,	{ 143, 170, 175, 184, 190, 192, 239 259, 426, 450, 487, 589, 593, 1432
<i>Anchylonyx</i> , Streets, 1877. ἀγκύλος, crooked, ὄνυξ, nail. (= <i>Phronimella</i> , Claus),	470
Andania , Boeck, 1870. "A town in Messenia,"	394, 399 , 461, 580, 582, 730
<i>Anisopus</i> , Templeton, 1836. ἀνισός, unequal, πόντος, a foot. Preoccupied (see <i>Sunamphithoe</i>),	166, 187, 228, 258, 294, 580, 582
Anonyx , Kröyer, 1883. "From ἀ, without, ὄνυξ, nail," referring to the absence, real or supposed, from the second gnathopods of a nail or finger,	{ 178, 228, 229, 257, 270, 283, 291 328, 361 , 393, 568, 580, 607 621 , 1637
<i>Anthia</i> , misspelling of <i>Amathia</i> ,	193
Aora , Kröyer, 1845. "Name of a nymph,"	{ 211, 228, 233, 258, 294, 328 396, 520, 551, 562, 580, 586 1072
<i>Apseudes</i> , Leach, 1814. ἀψευδῆς, without deceit. Not usually considered an Amphipod genus, 192, 1462
<i>Arancops</i> , A. Costa, 1853. "From aranea, spider, and ἄψ, eye." (= <i>Ampelisca</i> , Kröyer),	274, 296 , 314, 581
Argissa , A. Boeck, 1870. "A town in Thessaly,"	393, 399 , 580, 582
Aristias , A. Boeck, 1870. "A Greek poet,"	215, 367, 393, 398 , 580
<i>Asope</i> , Rafinesque, 1815,	88
Aspidophoreia , Haswell, 1880. ἀσπῖς, shield, φέρω, I bear,	514, 533, 564, 581
<i>Astacus</i> , ἀστακός, applied by the Greeks to lobster-like Crustaceans; used of Amphipods by Gronov, 1762, Fabricius, 1775, aud by Pennant, 1777,	{ 1, 23, 26 , 44, 1617
Astyra , A. Boeck, 1870. ? From Ἄστυρα, Astura, name of a river in Asturia,	394, 400 , 581
Atyloides , Stebbing, 1888,	913, 1654
Atylopsis , Stebbing, 1888,	924
Atylus , Leach, 1815. ἀ, without, τύλος, protuberance,	{ 89, 90, 122, 127, 142, 144, 148 170, 176, 184, 189, 228, 249, 258 296, 297, 328, 395, 459, 573, 581 601, 907
<i>Audouinia</i> , A. Costa, 1851. Named after Audouin, the eminent French naturalist. (Probably = <i>Corophium</i> , Latreille), 249, 250
Autonoe , Brzelius, 1859. "A daughter of Nereus and Doris," see Hesiod, Theogonia, 258,	312, 396, 570, 580, 1081
Batea , Fritz Müller, 1865. Evidently named in honour of Mr. Spence Bate, the English carcinologist, 362, 581

¹ Compare the remark on *Amphithoe* sp., by Fritz Müller, p. 349.

² This form competes with the later, generally accepted, and philologically better, form *Amphithoe*.

<i>Bathyporeia</i> , misspelling of <i>Bathyporeia</i> , Lindström,	295
<i>Bathyporeia</i> , Lindström, 1855. <i>βαθός</i> , deep, <i>πορεία</i> , passage. "Af denna nya form har jag hittills endast funnit några få exemplar på sand-botten med 18-24 farnars djup	286, 291, 294, 305, 328, 393, 581
utanför Wisby,"	
<i>Bathyporeja</i> , misspelling of <i>Bathyporeia</i> , Lindström,	296
<i>Batyporcia</i> , misspelling of <i>Bathyporeia</i> , Lindström.	
<i>Bellia</i> , Spence Bate, 1851. Named after Thomas Bell, the English carcinologist. (= <i>Hau-</i> <i>storius</i> , P. L. S. Müller),	243, 244, 263, 581, 1624
<i>Bircenna</i> , Chilton, 1884. "Bircenua, the daughter of the Illyrian Bardyllis, was one of the wives of Pyrrhus,"	551
<i>Bivonia</i> , Cocco, 1832. "Ho voluto intitolarlo al mio compatriota barone A. Bivona Bernardi delle cose naturale della Sicilia illustratore amplissimo." (= <i>Phronima</i> , Latreille),	146, 1624
<i>Boeckia</i> , O. Grimm, 1880. Preoccupied by Malm, 1870,	509
<i>Boeckia</i> , Malm, 1870. Named after the Norwegian zoologist, Dr. Axel Boeck, so distinguished in connection with the Scandinavian Amphipoda. (= <i>Leptocheirus</i> , Zaddach),	404
<i>Bornta</i> , Wrześniowski, 1888. "Boruta est le nom d'un diable, qui, d'après une vieille légende polonaise, habite les caves souterraines et garde les trésors, qui y sont accumulés,"	1656
<i>Boscia</i> , Leach, in Desmarest, 1825, as synonym of <i>Melita</i> , Leach. A name derived from Bosc, the French naturalist,	122
<i>Bovallia</i> , Pfeffer, 1888. Evidently named after C. Bovallius, the carcinologist,	1653
<i>Brachyscelus</i> , Spence Bate, 1861. " <i>βραχύς</i> , short, <i>σκελος</i> , leg,"	327, 337, 350, 492, 1543
<i>Brandtia</i> , Spence Bate, 1862. Named after J. F. Brandt, the carcinologist,	247, 309, 334, 581
<i>Bruzelia</i> , A. Boeck, 1870. "Named in honour of R. Bruzelius, author of Skand. Amphipoda Gammaridea,"	394, 400, 569, 581
<i>Byblis</i> , A. Boeck, 1870. "Βυβλίς, a daughter of Eidothea,"	395, 402, 570, 581, 601
<i>Calamorhynchus</i> , Streets, 1878. <i>κάλαμος</i> , reed, <i>φύγχος</i> , snout or beak,	484, 591, 1599
<i>Callianira</i> , Leach, MS., White, 1847. (= <i>Hypcria</i> , Latreille),	223
<i>Callimerus</i> , Stebbing, 1876. "The generic name refers to the beauty of the denticulate membranaceous thighs." <i>καλός</i> , beautiful, <i>μηρός</i> , thigh. (= <i>Amphilochus</i> , Spence Bate),	460, 484, 581, 583
<i>Calliope</i> (Leach, MS.), Sp. Bate, 1856-7. Καλλιόπη, one of the Nine Muses. Preoccupied among Mammals and Birds in 1836,	294, 328, 360, 581, 583
<i>Calliopius</i> , Lilljeborg, 1865. Altered from <i>Calliope</i> , Sp. Bate,	294, 360, 395, 573, 581
<i>Callirhoe</i> , Rafinesque, 1815. Name of a fountain, and of a daughter of Oceanus,	88
<i>Callisoma</i> , A. Costa, 1851. (Named, but not described, by O. G. Costa, 1840.) "From the Greek words <i>καλός</i> , beautiful, and <i>σῶμα</i> , body,"	183, 247, 248, 270, 293, 296, 328, 362, 393, 580
<i>Camacho</i> , Stebbing, 1888,	1178
<i>Cancer</i> , ancient comprehensive genus, no longer including Amphipoda,	11, 12, 13, 17, 18, 29
<i>Cancer</i> (<i>Gammarellus</i>), Herbst, 1796,	60
<i>Cancer</i> (<i>Gammarus</i>), Montagn, 1808,	54, 69, 79
<i>Caprella</i> , Lamarck, 1801. A diminutive from <i>capra</i> , a she-goat,	66, 79, 84, 88, 90, 95, 96, 123, 126, 135, 157, 171, 175, 183, 191, 192, 194, 202, 231, 249, 256, 265, 274, 282, 316, 328, 329, 343, 375, 397, 426, 477, 535-537, 566, 571, 1251, 1268
<i>Caprellina</i> , G. M. Thomson, 1878. An ally of <i>Caprella</i> , another genus. Preoccupied as name of a group (see <i>Caprellinopsis</i>),	233, 499, 535, 537
<i>Caprellinoides</i> , Stebbing, 1888,	1237, 1268
<i>Caprellinopsis</i> , 1888. New name for <i>Caprellina</i> , Thomson, preoccupied as the name of a whole group of genera,	233, 1237, 1268
<i>Caprocola</i> , 1825. Mistake for, or intended correction of, <i>Caprella</i> ,	121
<i>Carcinococcus</i> , de Natale, 1850. <i>Καρκίνος</i> , a crab, <i>κόκκος</i> , a kernel or berry. Included by mistake among the Amphipoda,	248
<i>Carcinornis</i> , A. Costa, 1864. <i>Καρκίνος</i> , a crab, <i>Ὥρνις</i> , a bird. In allusion to the rostrum in this genus,	347, 562
<i>Carcinus</i> , Latreille, 1796. Greek <i>καρκίνος</i> , a crab. No species were assigned to this genus, which according to Desmarest in 1825 is a synonym of <i>Gammarus</i> , Fabr.,	1, 62, 63, 123
<i>Cardenio</i> , Stebbing, 1888,	806

<i>Cephalaspis</i> , A. Costa, 1851. Κεφαλή, head, ἄσπις, shield. Preoccupied among fossil fishes in 1835,	249
<i>Ceradocus</i> , A. Costa, 1853. "From the Greek words κέρας, horn, antenna, and δοκός, beam." (= <i>Mæra</i> , Leach),	206, 274, 296, 298, 561, 581, 583
<i>Cerapodina</i> , Milne-Edwards, 1840. A name formed from that of the genus <i>Cerapis</i> , Say. (= <i>Cerapus</i> , Say),	168, 188, 202, 228, 257, 261, 296 559, 580 100, 123, 148, 170, 176, 184, 188
<i>Cerapus</i> , Say, 1817. "From κέρας, a horn, and πούς, a foot, in allusion to the animal employing its antennæ as feet,"	192, 207, 228, 257, 261, 283, 296 307, 328, 349, 350, 375, 390, 396 522, 559, 563, 571, 580, 581, 1157
<i>Cercops</i> , Kröyer, 1843. Κέρκωψ, candatus. In this genus of the Caprellina, the pleon or cauda has five segments,	202, 256, 329, 396, 535, 537 1226, 1268
<i>Cerophas</i> , Rafinesque, 1815,	88
<i>Cesapodina</i> , misspelling of <i>Cerapodina</i> , M.-Edw.,	426
<i>Charybdis</i> , Cocco, 1832. A whirlpool in the Mediterranean. Altered by the author to <i>Orio</i> , as <i>Charybdis</i> was preoccupied by Rafinesque among the Podophthalma,	145
<i>Cheirimedon</i> , Stebbing, 1888,	638
<i>Cheirocratus</i> , Norman, 1867. "χέλη and κρατεω, strong in the hand,"	370, 395, 581, 582
<i>Cheiropristis</i> , de Natale, 1850. χέλη, hand, and probably πλοστης instead of πιστης, a saw,	236, 237, 239, 248
<i>Chelura</i> , Philippi, 1839. χηλή, claw, οὐρά, tail,	{ 181, 217, 228, 256, 307, 328, 375 383, 396, 580
<i>Chiropristis</i> , Cocco, 1832. Undescribed, afterwards described as <i>Cheiropristis</i> by de Natale, 1850,	145, 233, 562
<i>Chloris</i> , Haswell, 1880. A mythological name. Twice preoccupied, the name afterwards changed to <i>Harmonia</i> ,	514, 528
<i>Chosroës</i> , Stebbing, 1888,	1208
<i>Cleippides</i> , A. Boeck, 1870. Κλειππίδης, name of a Greek,	216, 395, 401, 569
<i>Cleistotoma</i> , O. G. Costa and A. Costa, 1840. Preoccupied,	183
<i>Cleonardo</i> , Stebbing, 1888,	498, 959
<i>Clidippides</i> , by mistake for <i>Cleippides</i> .	
<i>Clydonia</i> , Dana, 1849. "The name of the genus is from κλυνδων, a wave, and alludes to the place of occurrence of the species." (= <i>Scinà</i> , Prestandrea),	{ 228, 229, 255, 256, 265, 558, 580 582
<i>Colomastix</i> , Grube, 1861. κόλως, stunted, μάστιξ, lash, flagellum,	329, 348, 391, 460, 517, 580, 582
<i>Constantia</i> , Dybowski, 1874. Preoccupied among Mollusca in 1860 (see <i>Costantia</i>),	427, 428, 581
<i>Corophia</i> , misspelling of <i>Corophium</i> , Latreille,	142, 184
<i>Corophium</i> , Latreille, 1800. According to Agassiz from κόπος, curvus, but there is no such meaning to the word κόπος, nor would it be applicable to this genus if there were. Bailey's Faceiolati in the following passage shows that it is useless to seek for a derivation of this name:—"Colnthis, orum. Murium genus sunt, quae vocant Graeci colnthis, alii corythia, turbinata aequa, sed minora multo, efficaciora etiam, et oris halitum custodientia. Haec Plin. l. 32, c. 7. ed. Hard. Antea v. g. in ed. Elzev. legebatur colycia. Adde c. 11. ed. Hard. ubi antea colycia vel corophia legebatur,	{ 79, 84, 88, 90, 123, 135, 148, 170 176, 184, 189, 192, 228, 249, 255 256, 265, 283, 296, 307, 312, 328 375, 396, 580
<i>Corophium</i> , misspelling of <i>Corophium</i> ,	86
<i>Costantia</i> , misspelling of <i>Constantia</i> , Dybowski, adopted instead of <i>Constantia</i> , preoccupied,	427, 428
<i>Crangonyx</i> , Spence Bate, 1859. κραγγών, a shrimp, νύξ, night,	311, 328, 414, 581, 1656
<i>Cratippus</i> , Spence Bate, 1862. Κράτιππος, a Peripatetic philosopher. (= <i>Colomastix</i> , Grube),	328, 336, 391, 517, 580, 582
<i>Cratippus</i> , misspelling of <i>Cratippus</i> , Sp. Bate.	
<i>Cratophium</i> , Dana, 1852. κράτος, strength. (= <i>Podocerus</i> , Leach),	257, 261, 580
<i>Cressa</i> , A. Boeck, 1870. Κρήσσα, a Cretan woman. (= <i>Danaia</i> , Spence Bate, which is preoccupied),	{ 293, 394, 400, 570, 581, 582, 747
<i>Cuvieria</i> , Leach, in Desmarest, 1825, as synonym of <i>Leucothoe</i> , Leach. After the celebrated naturalist Cuvier,	122
<i>Cyamus</i> , Latreille, 1796. κύαμος, a beau. "Ce nom, qui signifie en grec fève, avoit été donné à des eloportes, parce qu'ils ressemblent en quelque sorte à cette semence lorsqu'ils sout dans un état de contraction. Les crustacés dont il s'agit ici sont peu éloignés des eloportes, et c'est même dans ce genre que Linnæus les a placés." (Latr. II Hist. Nat., tome vi. p. 328),	{ 2, 63, 66, 72, 79, 88, 92, 96, 98 105, 124, 126, 134, 135, 155, 163 169, 171, 175, 191, 192, 194, 208 227, 249, 256, 281, 282, 306, 316 325, 328, 329, 397, 419, 426, 450 477
<i>Cychreus</i> , Rafinesque, 1815,	88
<i>Cyclocaris</i> , Stebbing, 1888,	664

<i>Cyllias</i> , ¹ Bovallius, 1887. The name was probably chosen to indicate an affinity with the neighbouring genus <i>Cylopus</i> ,	588
Cylopus , Dana, 1852. κυλλός, crooked, maimed, πούς, foot. "Feet of seventh pair nearly rudimentary,"	1296
<i>Cymadusa</i> , Savigny, 1816. κῦμα, a wave, δύω, I enter. (= <i>Amphithoe</i> , Leach),	93, 120, 123
<i>Cymothoa</i> , J. C. Fabricius, 1793. Cymothoe, one of the Oceanides, see Hesiod, Theogonia,	59, 85, 1618
245. An Isopod genus in which three species of Amphipoda were at one time included,	
Cyphocaris , Lütken and Boeck, 1870. "κύψος, hump, κάρα, head,"	393, 398, 580, 656
<i>Cypridoidea</i> , alteration of <i>Cypridea</i> , Haswell, to suit the derivation, see Scudder, Nom. Zool., p. 366.	
Cypridea , ² Haswell, 1880. See <i>Cypridida</i> ,	514, 581
Cypridida , Haswell, 1880. From its likeness to <i>Cypris</i> , an Entomostracan genus,	441, 512, 513, 514, 539, 574
Cyrtopodium , Dana, 1852. κυρτός, curved,	257, 261, 265, 328, 349, 518, 521 563, 580, 581, 1651
<i>Cysteosoma</i> , a variation in the spelling of <i>Cystisoma</i> , Guérin,	575
Cystisoma , Guérin, 1842. κύστις, a bladder, σῶμα, body (not to be confused with <i>Cystosoma</i> , Westwood, among the Hemiptera),	196, 259, 452, 575, 1269, 1318
<i>Cystosoma</i> , misspelling of <i>Cystisoma</i> , Guérin,	440, 444, 452, 471, 487, 580
<i>Dactylocera</i> , Latreille, 1829. δάκτυλος, finger, κέρας, horn. (= <i>Phrosina</i> , Risso),	125, 137, 142, 143, 144, 170, 175 184, ³ 191, 259, 487
<i>Dactylocerus</i> , a variation in the spelling of <i>Dactylocera</i> , Latreille. See Desmarest, 1825,	122
<i>Daira</i> , Milne-Edwards, 1830. Mythological name (Agassiz). Preoccupied,	143, 170, 175, 184, 190, 258, 264 558, 580, 1336
Dairella , Bovallius, 1887. Diminutive of <i>Daira</i> ,	589, 1269, 1342
Dairilia , Dana, 1852. Altered from <i>Daira</i> , Milne-Edwards,	264, 268, 337, 590, 1543
<i>Dairinia</i> , a misprint in Dana's work for <i>Dairilia</i> ,	264, 558, 580
<i>Danaia</i> , Spence Bate, 1857. "The genus is named after Professor Dana, to whom science is indebted for a valuable work on Crustacea." Preoccupied, ⁴	293, 328, 394, 570, 581, 582, 747
<i>Darwinia</i> , Spence Bate, 1856. Described as <i>Darwinia</i> , 1857.	
Darwinia , Spence Bate, 1857. "This genus is named in compliment to the distinguished author of the Monograph on the Cirripedia." (= <i>Lafystius</i> , Kröyer),	294, 328, 581
<i>Derothoe</i> , Dana, 1852. "The name of the genus, from δέρκω, to look, alludes to the projection forward of the eyes on a prominence of the front margin on either side of the head,—a frequent, if not universal, characteristic of the species." (= <i>Ericthonius</i> , Milne-Edwards),	258, 267, 268, 375, 580, 581
Dermophilus , E. van Beneden and Bessels, 1870. δέρμα, skin, φίλος, attached to. Perhaps a synonym of <i>Lafystius</i> , Kröyer, 1842,	392, 464
<i>Desmophilus</i> , misspelling of <i>Dermophilus</i> ,	463
Dexamine , Leach, 1814. Δεξαμένη, a Nereid, see Homer, Iliad, xviii. 44,	86, 89, 90, 122, 148, 170, 176 192, 229, 249, 258, 328, 379, 395 573, 581, 845
<i>Dexiocrella</i> , Haswell, 1885. δεξιός, ready, nimble, κέρας, horn, antenna, with a diminutive termination. (= <i>Platophium</i> , Dana),	566, 1184, 1651
<i>Dinoa</i> , Rafinesque, 1815,	88
<i>Diphyicola</i> , A. Costa, 1862. <i>Diphya</i> , an Aealeph genus, colo, I inhabit,	340, 1348
<i>Dithyrus</i> , Dana, 1852. διθύρος, with two doors. "Pedes 5ti 6tique articulo 1mo lati lamellati,"	259, 269, 327, 490, 591, 1471
Dodecas , Stebbing, 1883. δωδεκάς, a number of twelve. "Six pairs of feet attached to the pereion, the fourth segment having none,"	461, 547, 1232
<i>Dryope</i> , Spence Bate, 1862. Δρυόπη, a nymph. Preoccupied in 1830,	328, 336, 580, 1145
Dryopoides , Stebbing, 1888,	1145

¹ This genus was instituted doubtfully by Bovallius to receive the single species *Hyperia cuspidata*, Streets, but as the species in question belongs, I think, clearly to the genus *Paraphronima*, Claus, the name *Cyllias* will not be needed.

² On p. 514, l. 11, for *Cypridida* read *Cypridea*. The latter form is given in the *Annals and Magazine of Natural History* for January 1880, but precedence may perhaps be allowed to the form *Cypridida*, which in the same year 1880 appears in the *Proc. Linn. Soc. N. S. W.*, since Mr. Haswell would have had the opportunity of correcting the press in Australia but not in England.

³ For *Dactylocerus*, p. 184, line 6, read *Dactylocera*.

⁴ In 1849 Milne-Edwards and J. Haime, *Comptes rendus*, t. xxix. p. 261, gave the name *Dania* to a genus of fossil Corals; this name they spell *Danaia* in the general index to their Monograph of the British Fossil Corals, Palaeont. Soc. vol. for 1854, published 1855. *Danaia*, Spence Bate, must therefore give way to the later *Cressa*, Boeck, with which a specimen of the type species, recently obtained and dissected, proves it to be certainly synonymous. Compare the earlier footnote, p. 747.

Dulichia , Krøyer, 1845. "Formed from δούλιχός, long, with regard to the specially elongated form of the animal, the long antennæ, &c. The Ionic form is used to keep the name the more distinct from <i>Dolichus</i> already employed for the name of an Insect,"	213, 228, 256, 294, 295, 306, 328 396, 571, 580, 601
Dyopcdos , Spence Bate, 1857. Perhaps from δύο, two, and πούς, foot, because in this genus the sixth and seventh pairs of feet are attached to one compound segment. (= <i>Dulichia</i> , Krøyer),	
Egidea , a misspelling of <i>Egidia</i> , A. Costa.	294, 295, 580
Egidia , A. Costa, 1853. Proper name. Compare Latin <i>Egidius</i> . (= <i>Urothoe</i> , Dana),	274, 296, 561, 580, 582
Eiscladus , Bate and Westwood, 1862. "εἰς, one, κλάδος, branch, in allusion to the structure of the posterior pair of pleopoda." (= <i>Photis</i> , Krøyer),	341, 396, 581
Elamis , Leach, MS., in White, 1847. (= <i>Amphithoë</i> , Leach),	222
Elasmocerus , A. Costa, 1851. ἐλασμός, lamina, κέρας, horn, antenna,	248, 1278
Elasmodopus , A. Costa, 1853. "From the Greek words ἐλασμός, lamina, and πούς, foot,"	274, 298, 296, 395, 580, 582, 1649
Enone , Risso, 1826. ? from Οὐρώνη, (Enone, the nymph beloved by Paris,	128, 249
Ephippiphora , White, 1847. ἐφίππια, the trappings of a horse, φέρειν, to bear. Preoccupied, 1834,	177, 224, 270, 393, 500
Epidesma , a misspelling of <i>Epidesura</i> , Boeck.	
Epidesura , Boeck, 1860. From ἐπιδέης, deficient, οὐρά, tail, the fifth and sixth segments of the pleon or tail being united into one. (= <i>Atylus</i> , Leach),	322, 324, 581
Epimera , A. Costa, 1851. Probably so called from the epimera or side-plates, "Epimera quarti et quinti articuli thoracis maxima, simul clypeum semilunare formantia,"	249, 250, 296, 297, 395, 475 569, 877
Erataea , Rafinesque, 1815, .	88
Erichthus , Latreille. Not an Amphipod genus,	134, 135, 148
Erichthoncus , misspelling of <i>Erichthonius</i> , Milne-Edwards.	
Erichthonius , an alternative spelling for <i>Erichthonius</i> , Milne-Edwards, to correspond with the Greek original of the word,	170, 176, 200, 228, 255, 257, 258 268, 559, 571, 580, 581
Erichtonius , misspelling of <i>Erichthonius</i> , Milne-Edwards,	184, 312, 375
Erichthonius , Milne-Edwards, 1830. Ἐριχθόνιος, Erichthonius, a king of Athens,	142, 188, 285, 296, 299, 390, 396
Eriopis , Bruzelius, 1859. "A daughter of Jason and Medea." Preoccupied. (= <i>Niphargus</i> , Schiødte),	313, 395, 581, 1656
Erpetoramphus , de Natale, 1850. ἐρπετόν, a creeping thing, βάμφος, a crooked beak,	248, 1623
Erysthocetus , misspelling of <i>Eurystheus</i> , Spence Bate,	583
Erysthreus misspelling of <i>Eurystheus</i> , Spence Bate,	566
Erythrocephalus , Tilesius, 1819. ἐρυθρός, red, κεφαλή, head. "Rothkopf." Au obscure genus of the Hyperina,	109, 135
Etione , misspelling of <i>Enone</i> , Risso (M.-Edw., 1830).	
Euone , misspelling of <i>Enone</i> , Risso,	560
Euonyx , Norman, 1867. εὖ, well, ὄνυξ, nail. In the second gnathopods, unlike <i>Anonyx</i> , "nail large and strong,"	370, 668
Eupheus , Risso, 1816. εὖ, well, φαιός, dusky? (Agassiz), but more probably from εὖφυής, well fitted. (Synonym of <i>Apseudes</i> , generally reckoned an Isopod genus),	97, 129, 134
Eupronoë , Claus, 1879. εὖ, well, <i>Pronoe</i> , name of another genus,	241, 492, 591, 1509
Eurymera , Pfeffer, 1888. εὐρύς, broad, μηρός, thigh; "Epimeren ganz ausserordentlich gross, hoch und breit,"	1653
Eurysteus , misspelling of <i>Eurystheus</i> , Spence Bate,	544
Eurystheus , ¹ Spence Bate, 1856-7. A king of Mycenæ, the taskmaster of Hercules. (= <i>Gammaropsis</i> , Liljeborg),	286, 294, 328, 335, 580, 1092
Eurytenes , Lilljeborg, 1865. "From the Greek εὐρυτενής, which signifies widely stretched." Preoccupied in 1862,	360, 393, 580
Eurythenes , ² S. I. Smith, 1884, either an accidental misspelling or intentional alteration of the preoccupied <i>Eurytencs</i> , Lilljeborg,	557
Eurytheus , misspelling of <i>Eurystheus</i> , Spence Bate.	
Eusceliotes , 1888, in place of <i>Eusculus</i> , Claus.	
Eusculus , Claus, 1879. εὖ, well, σκέλος, leg. Preoccupied,	491, 591
Eusinus , misprint for <i>Eusirus</i> , Krøyer (Scudder, Nomenclator Zoologicus, p. 123).	
Eusirooides , Stebbing, 1888,	969

¹ On the question of the priority of *Eurystheus*, see p. 1092.

² In the Note on S. I. Smith, 1884, p. 557, I have not reproduced the spelling *Eurythenes*, having regarded it as a casual missprint, but the same spelling is given in Scudder's Nomenclator Zoologicus on Professor Smith's authority.

Eusirus, Kröyer, 1845. "Εὐσίρος, Eusirus, a son of Poseidon and Idlothea, a daughter of Ocean,"	213, 229, 258, 328, 394, 581, 964
Euthemisto, Bovallius, 1887, altered from Themisto, Guérin,	589, 593, 1407
Eutyphe, alteration of Eutyphe, Claus,	591
Eutyphe, Claus, 1879. Altered from Typhis, Risso. (=Platyseulus, Spence Bate),	269, 490, 561, 591, 597, 1463
Exunguia, Norman, 1869. "From ex and unguis, without a nail." (=Colomastix, Grube, 1861),	391, 517, 580
Galanthis, Spence Bate, 1856-7. A maid-servant of Alemene, turned into a weasel for deceiving Lucina. Preoccupied,	172, 293
Gamarus, misspelling of Gammarus, Fabricius,	12, 14
Gammaracanthus, Spence Bate, 1862. Gammarus, another genus, ἄκανθα, spine,	335, 395, 581
Gammarella, Spence Bate, 1857. Diminutive from Gammarus, another genus,	294, 328, 581
Gammarellus, Herbst, 1796. Diminutive of Gammarus, used by Herbst in combination with Cancer,	59, 1617
Gammarius, misspelling of Gammarus Fabricius,	416
Gammropsis, Liljeborg, 1855. Gammarus, another genus, ὁψις, appearance. (See note on Eurystheus),	285, 286, 294, 396, 550, 580 1092 4, 5, 11, 12, 40, 43, 53, 56 62, 66, 78, 79, 84, 86, 88, 90 92, 99, 123, 135, 148, 162, 170 175, 184, 187, 192, 194, 228 249, 255, 258, 283, 285, 294, 296 308, 313, 316, 328, 331, 353, 359 375, 378, 384, 391, 392, 395, 428 477, 563, 581, 601, 1005, 1225 1629
Gammarus, J. C. Fabricius, 1775. καμμαρος, Latin cammarus or gammurus, applied originally to various Crustacea, other than Amphipods	353, 472
Gampsonyx, Jord., 1847. γαμψωνυξ, with crooked talons. A genus among fossils doubtfully connected with the Amphipoda,	394, 400, 581
Gitana, A. Boeck, 1870. The Spanish word for a Gipsy,	394, 400, 581
Glaucome, Kröyer, 1845. "One of the Nereids." Preoccupied among Polyps 1826 and Mollusca, 1828. (=Urociola, Say, 1818),	212, 229, 263, 396, 571, 580 1163
Glossocephalus, Bovallius, 1887. γλωσσα, tongue, κεφαλη, head,	590
Glycera, Haswell, 1880. Γλυκερά, sweet, the name of a woman in Horace, Tibullus and Martial. Preoccupied among the Vernes, 1817,	512, 514, 528, 533, 580, 582
Glycerina, Haswell, 1882. "Altered from Glycera,"	512, 533, 643
Goësia, A. Boeck, 1870. "Named in honour of Goës, author of 'Crust. Amphip. maris Spetsbergiam alluentis,'"	358, 396, 402, 580
Goplana, Wrześniowski, 1879. From "Goplany, Polish for a Water-nymph,"	360, 472, 501, 581, 583, 601
Gossea, ¹ Spence Bate, 1862. "The genus is named in compliment to Mr. Gosse, in consideration of his valuable contributions to marine zoology,"	334, 580
Grammarus, a mistake for Gammarus,	317
Graya, misprint for Grayia,	473
Grayia, Spence Bate, 1862. "It is named in compliment to the Keeper of the Zoological collections of the British Museum,"	266, 328, 332, 435, 581
Grubia, Czerniavski, 1868. Named in honour of Grube the naturalist,	377, 517, 560, 566, 1115
Guerinia (Hope), A. Costa, ² 1853. Named after Guérin, the eminent French naturalist. Preoccupied in 1830,	272, 561
Guernea, E. Chevreux, 1887. "Je prie mon excellent ami, M. Jules de Guerne, d'accepter la dédicace de ce genre nouveau." In place of Helleria, Norman, preoccupied,	386, 595
Halibrotus, alteration of Alibrotus, M. Edw., to suit the derivation (Costa, 1853).	
Halice, A. Boeck, 1870. ἀλική, a briny maid,	394, 400, 581
Halicreion, A. Boeck, 1870. "ἄλις, sea, κρέων, ruler,"	395, 401, 581
Halicrion, misspelling of Halicreion, Boeck (Scudder, Nom. Zool., p. 139).	
Halimedon, A. Boeck, 1870. "ἄλις, sea, μέδων, lord,"	356, 394, 400, 581, 838
Halirages, A. Boeck, 1870. "ἄλις, sea, φέγγυνη, I break,"	395, 401, 569, 573, 581, 900
Halirhages, alteration of Halirages, Boeck,	523
Haplocheira, Haswell, 1880. ἀπλοῦς, simple, χεῖρ, hand. "Both pairs of gnathopoda simple,"	500, 512, 514, 565, 580, 1171

¹ Gossea appears to have been used by Agassiz also in 1862 for a genus of Coelenterata.

² The name Guerinia being preoccupied will become a synonym of Trischizostoma, Esmark and Boeck, 1860.

Haploops , Liljeborg, 1855. "From ἀπλοῦς, simple, and ὄψ, eye, because the eyes are simple, not compound,"	{ 270, 285, 385, 386, 395, 454 581, 1651 }
Haplochira , variation in spelling of <i>Haplocheira</i> , Haswell (Seudder, Nom. Zool., p. 369).	513
Harmonia , misspelling of <i>Harmonia</i> , Haswell,	512, 513, 514, 565
Harmonia , Haswell, 1880. Ἀρμονία. Harmony, personified in mythology. Preoccupied,	466
Harmophia , Boeck, MS., 1877,	
Harpina , A. Boeck, 1870. ἄρπη, a sickle. Preoccupied among the Coleoptera (Dejean) }	394, 400, 581
Burmeister, 1844,	
Harpinia , A. Boeck, 1876. "A Greek feminine name." Altered from <i>Harpina</i> , Boeck,	394, 568, 819
Harpinoides , Stebbing, 1888,	936
Harpilia , Boeck, MS., 1877,	466
Haustorius , P. L. Statius Müller, 1775. Haustor, one that draws or drains, water or the like,	39, 229, 244, 394, 474, 1624
Heiscladius , variation in the spelling of <i>Eiscladus</i> , Spence Bate,	430
Heiscladus , a variation in the spelling of <i>Eiscladus</i> , to suit the derivation.	
Hela , A. Boeck, 1860. "A northern, mythological name." Preoccupied (see <i>Neohela</i>),	322, 325, 396, 530, 580, 1215
Helella , attributed to Smith by Sars, probably by mistake for <i>Neohela</i> ,	1215
Helleria , Norman, December 1868. "I have dedicated it to Prof. Heller, who has done so much to elucidate the Crustacea of the south of Europe." Preoccupied earlier in the same year among Isopoda. (See <i>Guernea</i> , Chevreux),	386, 389, 581, 595
Hemityphis , Claus, 1879. ἡμι (in composition) half, <i>Typhis</i> , another genus. (? = <i>Dithyrus</i> , Dana),	491, 591, 1471
Heterelos , Rafinesque, 1815. Probably from ἔτερος and ἡλος, meaning with strange or uneven nails,	88
Hexona , Risso, 1826. ? from ἔξ, six. "Thorax sexarticulatus." An Isopod genus placed by Riso among the Læmodipoda,	127, 129
Hiella , Straus-Dürckheim, 1828-1829. Proper name (Agassiz). (= <i>Hyperia</i> , Latreille),	134, 139, 143, 145, 232, 580
Hieraconya , Guérin, 1836. "From ἱέραξ, ἄκος, hawk, ὄνυξ, nail." (= <i>Anchyliomera</i> , M.-Edw.),	164, 175, 184, 259, 426, 487
Hippias , Rafinesque, 1815. Name of a Greek,	88
Hippomedon , A. Boeck, 1870. "Ἴππωμέδων, name of a Greek,"	393, 397, 568, 580, 625
Hircella , Mayer, 1882, suggestion adopted by Haswell, 1885. A feminine diminutive of <i>hircus</i> , a he-goat. A genus among the Caprellidae,	535, 564
Hora , a misspelling of <i>Aora</i> , Krøyer,	494
Hyale , Rathke, 1837. "Benanut nach einer Nympfe aus dem Gefolge der Diana,"	{ 171, 174, 193, 258, 263, 293, 393 433, 460, 500, 512, 560, 564 }
Hyalella , S. I. Smith, 1874. Diminutive of <i>Hyale</i> , Rathke. "This genus seems to be closely allied to <i>Hyale</i> ,"	172, 174, 263, 433, 455
Hyalosoma , Nicol Wagner, 1868. Included by mistake among Amphipoda,	387
Hyperia , Latreille and Desmarest, 1823. Hyperia, a fountain at Pheræ in Thessaly,	{ 122, 127, 137, 139, 142, 144, 170 175, 184, 189, 191, 194, 207, 232 258, 263, 282, 328, 382, 426, 436 437, 452, 456, 469, 476, 477, 487 558, 580, 588, 593, 1377 }
Hyperiella , Bovallius, 1887. Diminutive of <i>Hyperia</i> ,	589, 593, 1403
Hyperiosis , G. O. Sars, 1885. <i>Hyperia</i> , another genus, and ὄψις, appearance,	567, 572, 576, 1269
Hyperoche , Bovallius, 1887. Closely related to <i>Hyperia</i> . (A substitute for <i>Metoccus</i> , Krøyer),	179, 588, 593, 1398
Jassa , Leach, 1814. Another spelling of <i>Jassa</i> , Leach,	86
Ichnopus , A. Costa, 1853. "From the Greek words ιχνός, slender, and πόδις, foot." }	274, 296, 393, 580
No doubt ισχνός, which means "thin," was intended, not ιχνός, which means a "footstep," }	
Ichthyomyzoculus , Hesse, 1873. "De ιχθύοις, poisson ; μύζω, je suine,"	417, 444, 464, 1630
Icilius , Dana, 1849. A Roman of note,	{ 228, 229, 255, 257, 265, 580 582, 1202 }
Icilius , misspelling of <i>Icilius</i> , Dana,	1637
Ieridium , Grube (1863), 1864. ἵκριδιον, diminutive of ἵκρια, cross-benches of a vessel, a cross,	348, 441, 580, 582
Iduna , A. Boeck, 1860. In Scandinavian mythology a nymph who kept the golden apples for the rejuvenescence of the gods. Preoccupied for a bird, in 1840, by Keyserling and Blasius. <i>Liljeborgia</i> , Sp. Bate, 1862, takes its place,	322, 324, 360, 581
Ione , Latreille, 1817. Not an Amphipod genus,	105, 137, 143, 191
Iphigencia , O. Grimm, 1880,	509
Iphigenia , G. M. Thomson, 1881. Ιφιγένεια, daughter of Agamemnon and Clytemnestra. }	545, 1637
Preoccupied among the Mollusca by Schumacher in 1817,	

Iphimedia , Rathke, 1843. In Greek Ἰφιμέδεια. “ <i>Iphimedia</i> , habe ich diese nach einer Geliebten Neptuns benannt,”	204, 229, 258, 270, 328, 395, 581 889
Isaea , Milne-Edwards, 1830. Mythological name (Agassiz),	141, 176, 187, 228, 258, 328, 581
<i>Ischyroccras</i> , misspelling of <i>Ischyrocerus</i> , Kröyer,	228, 284
<i>Ischyrocerus</i> , Kröyer, 1838. “From <i>ἰσχυρός</i> , strong, and <i>κέρας</i> , horn, i.e., furnished with strong horns. I have chosen this name with regard to the strong structure of the antennæ.” (= <i>Podocerus</i> , Leach),	179, 188, 258, 396, 580
Isocyamus , Gervais and van Beneden, 1859. <i>ἴσος</i> , equal, <i>Cyamus</i> , another genus,	316, 363
<i>Isoca</i> , misspelling of <i>Isaea</i> , Milne-Edwards,	184
<i>Isolus</i> , Rafinesque, 1815. Perhaps from <i>ἰσόκωλος</i> , with equal limbs,	88
Iulopis , Bovallius, 1887. <i>ἴνωλος</i> , down, “hody hirsute,”	588
<i>Janassa</i> , A. Boeck, 1870. “ <i>Ιάνασσα</i> , a Nereid,” see Homer, Iliad, xviii. 47. Preoccupied,	205, 312, 396, 402
<i>Jassa</i> , Leach, 1814. Mythological name (Agassiz). (= <i>Podocerus</i> , Leach),	86, 90, 123, 148, 176, 192, 205 312, 580
Kerguelenia , Stebbing, 1888,	1219
Kröyera , Spence Bate, 1857. “This genus is named in honour of the distinguished Danish naturalist,”	293, 294, 307, 328, 395, 516 572
<i>Kröyerea</i> , a misspelling of <i>Kröyera</i> , Spence Bate,	421
<i>Kröyeria</i> and <i>Kroyeria</i> , misspelling of <i>Kröyera</i> , Spence Bate,	294, 348, 561
<i>Kroyera</i> , intended for <i>Kröyera</i> ,	307, 340, 572, 581
<i>Lada</i> , Wrześniowski, 1879. “Lade, in the Slav mythology, represents the goddess of love,”	502
<i>Læmatophilus</i> , misspelling of <i>Læmatophilus</i> , Bruzelius,	566
Læmatophilus , Bruzelius, 1859. “From λᾱτμα and φ(λ)ος,” meaning “dear to the deep sea,”	312, 396, 580, 1197
<i>Lætmophilus</i> , misspelling of <i>Læmatophilus</i> , Bruzelius (Scudder, Nom. Zool., p. 166).	
Lafystius , Kröyer, 1842. “λαφύστιος, gulosus,” glutinous,	199, 294, 295, 576, 601, 898
<i>Lalaria</i> , Nicolet, 1849. (= <i>Aora</i> , Kröyer),	231, 270, 580
<i>Lalasia</i> , misspelling of <i>Lalaria</i> , Nicolet,	295
<i>Lampra</i> , A. Boeck, 1870. λαμπτός, bright. Preoccupied among the Lepidoptera by Hübner in 1816; among the Coleoptera in 1833; used also in Botany. (= <i>Tritexta</i> , Boeck, 1876),	395, 401, 581
Lanceola , Say, 1818. Lanceola, a small lance. “In allusion to the form of the terminal divisions of the caudal appendices,”	102, 123, 142, 232, 426, 557, 580 588, 593, 1269, 1301
Laothoës , A. Boeck, 1870. “Λαοθόης, a son of Heracles,”	395, 401, 573
<i>Laphystius</i> , altered from <i>Lafystius</i> , Kröyer, to correspond with the derivation,	228, 258, 292, 395, 436, 450 459, 581
<i>Larunda</i> , Leach, 1815. Daughter of the river-god Almo. Her tongue was cut out by Jupiter on account of her talkativeness. (= <i>Cyamus</i> , Latreille),	91
<i>Leda</i> , misspelling of <i>Lada</i> , Wrześniowski. (Scudder, Nom. Zool., pp. 169, 371.)	
<i>Lembos</i> , Spence Bate, 1856-7. λέμβος, a small boat with a sharp prow. (= <i>Microdactopus</i> , Costa),	294, 580
<i>Lepidactylis</i> , Say, 1818. λεπτή, a scale, δάκτυλος, finger. (= <i>Haustorius</i> , P. L. S. Müller),	103, 123, 143, 228, 258, 262 263, 310, 522, 581, 582
<i>Lepidactylus</i> , misspelling of <i>Lepidactylis</i> , Say.	
Lepidepecreum , Bate and Westwood, 1868. Prohahly from λεπίς, a scale, and ἐπίκριον (Latin antenna), a sailyard, alluding to the scale-like process on the upper antenna of the type species,	373, 393, 446, 686
Lepleurus , Rafinesque, 1820. λεπίς, a scale, πλευρά, side. “The name means lateral scales,”	111, 123, 124
<i>Leplurus</i> , misspelling of <i>Lepleurus</i> , Rafinesque,	413
<i>Leptocheirus</i> , Zaddach, 1844. “λεπτός, χείρ, which has thin hands,”	209, 226, 336, 395, 580, 582
<i>Leptochirus</i> , misspelling of <i>Leptocheirus</i> , Zaddach,	228, 258, 279, 561
<i>Leptochela</i> , A. Boeck, 1876. λεπτός, thin, χηλή, claw. See Boeck, De Skand. og Arkt. Amph., p. 190. It is a synonym of <i>Euonyx</i> , Norman, 1878,	373, 453
Leptocotis , Streets, 1878. λεπτός, thin, κοτίς, head,	470, 493, 590, 1593
<i>Leptomera</i> , Latreille, 1816. λεπτός, thin, μηρός, thigh. (= <i>Proto</i> , Leach),	95, 119, 123, 126, 135, 138, 171 175, 182, 183, 191, 192, 202, 270 282, 329, 426

¹ Boeck uses the form *Laphystius* in De Skand. og Arkt. Amph., but in the table of errata adopts *Lafystius*.

² On p. 111, line 13, for band read hand.

<i>Leptotheoc</i> , Stimpson, 1854. <i>λεπτός</i> , thin, θέω, I run. (= <i>Mæra</i> , Leach),	277, 581
<i>Lestrigon</i> , misspelling of <i>Lestrigonius</i> , Milne-Edwards,	175, 184
<i>Lestrigonius</i> , misspelling of <i>Lestrigonus</i> .	
<i>Lestrigonus</i> , Milne-Edwards, 1830. Seemingly from Δαστρυγονες, an ancient savage tribe of Italy and Sicily. (= <i>Hyperia</i> , Latreille),	142, 170, 189, 258, 263, 328, 382 426, 456, 469, 473, 580, 1377
<i>Leucothœca</i> , misspelling of <i>Leucothoe</i> , Leach,	170
<i>Leucothœ</i> , Leach, 1813. <i>Leucothoë</i> graisis, Matuta vocabere nostris, Ovid, Fasti., vi. 545,	84, 86, 90, 122, 148, 176, 184 188, 192, 200, 228, 249, 258, 283 296, 328, 349, 394, 581, 771
Liljeborgia , Spence Bate, 1862. "It is named in compliment to Prof. Liljeborg,"	328, 333, 360, 394, 565, 980
<i>Lilljeborgia</i> , A. Boeck, 1870. Altered from <i>Liljeborgia</i> , Spence Bate, apparently to suit the spelling of Professor Lilljeborg's name as it appears in his later, changed from that in his earlier, papers,	394, 458, 459, 561, 570, 581, 582
<i>Limnoria</i> , Leach, 1814. An Isopod genus, which has been used in error for <i>Chelura</i> terebrans,	383, 580
<i>Liparis</i> , Bosc, 1802. This word is in Latin the name of an island, of a river, and of an unknown fish. Preoccupied among fishes in 1738. (= <i>Caprella</i> , Lamarek),	1618
<i>Liriope</i> , Rathke, 1843. "Den für sie gewählten Gattungsnamen führte eine Meernymphe, deren Ovid in seinen Metamorphosen (Buch III. Vers 342) gedenkt." The mother of Narcissus. (Not an Amphipod genus, but a parasitic Isopod.) Preoccupied,	204
<i>Lisianassa</i> , a misspelling of <i>Lysianassa</i> ,	183
<i>Lonchomerus</i> , Spence Bate, 1856-7. <i>λόγχη</i> , lance, <i>μηρός</i> , thigh. "Meros of first gnathopod produced into a long spine." (= <i>Aora</i> , Kröyer),	294, 259, 580
<i>Lonchomeres</i> , a misspelling of <i>Lonchomerus</i> , Spence Bate.	
<i>Lusyta</i> , Nardo, 1847. (= <i>Ericthonius</i> , Milne-Edwards),	220, 390, 1157
Lycæa , Dana, 1852,	{ 259, 269, 431, 492, 590, 1538 1563
<i>Lycæopsis</i> , Claus, 1878-9. <i>Lycæa</i> , another genus, <i>Ὄψις</i> , appearance; "General form like <i>Lycæa</i> ,"	476, 493, 589, 598, 1458
<i>Lycesta</i> , Savigny, 1816. (= <i>Leucothoe</i> , Leach),	93, 120, 123, 581
<i>Lycianassa</i> , misspelling of <i>Lysianassa</i> , Milne-Edwards,	281
<i>Lysianassa</i> , Milne-Edwards, 1830. <i>Λυσιάνασσα</i> , a Nereid. Hesiod, Theogonia, 258. Pre-occupied among Mollusca in 1826. (See <i>Lysianax</i> , 1888),	{ 141, 170, 177, 184, 185, 228, 248 255, 257, 270, 296, 328, 361, 365 384, 393, 580, 681
<i>Lysianassina</i> , subgenus, Costa, 1867. Preoccupied as name of a group,	368, 369
<i>Lysianella</i> , G. O. Sars, 1882. Diminutive from <i>Lysianassa</i> , another genus,	538
<i>Lysianax</i> , 1888. Substitute for <i>Lysianassa</i> , preoccupied,	681
<i>Lysianassa</i> , misprint for <i>Lysianassa</i> ,	176
<i>Macleayia</i> , Haswell, 1880. Probably in compliment to the naturalist, Macleay. The name subsequently changed to <i>Wyvillea</i> ,	514, 581, 583
<i>Macrocephalus</i> , Spence Bate, 1858. <i>μακρός</i> , long, <i>κεφαλή</i> , head. (= <i>Rhabdosoma</i> , Adams and White),	307, 591
<i>Mæra</i> , Leach, 1813. <i>Μαῆρα</i> , a Nereid, mentioned by Homer, Iliad., xviii. 47,	{ 84, 86, 90, 122, 192, 229, 258 263, 299, 386, 395, 569, 581 1007, 1649
<i>Mærza</i> , misspelling of <i>Mæra</i> , Leach,	99
<i>Megalorchestes</i> , variation in the spelling of <i>Megalorchestia</i> ,	246
<i>Megalorchestia</i> , Brandt, 1851. <i>μεγάλη</i> , great, <i>Orchestia</i> , another genus. "Ich bezeichne sie nach Maassgabe der Grösse der ihr zum Grunde liegenden Art als <i>Megalorchestia</i> ." (= <i>Orchesteidea</i> , Nicolet),	246, 262, 295
<i>Megamæra</i> , A. Boeck, alteration of <i>Megamæra</i> , Spence Bate's genus, no doubt in order to make it tally with the spelling of <i>Mæra</i> , Leach, from which it is obviously derived,	581
<i>Megamdera</i> , misspelling of <i>Megamera</i> , Spence Bate,	494
<i>Megamæra</i> , Spence Bate, 1862. <i>μέγας</i> , great, <i>Mæra</i> , another genus. (Doubtfully distinct from <i>Mæra</i> , Leach),	229, 328, 335, 386
<i>Megamphopus</i> , Norman, 1869. "μέγας, great, ἄμφω, both, πούς, a foot." (= <i>Podoecropsis</i> , Boeck),	1108, 1628
<i>Melita</i> , Leach, 1813. <i>Μελίτη</i> , a Nereid. Hesiod, Theogonia, 246,	{ 84, 86, 90, 122, 148, 176, 192 222, 229, 258, 263, 296, 297, 299 328, 378, 395, 502, 569, 581

Melphidippa , A. Boeck, 1870. "Melphidippa, a maid-servant in Plantus," probably referring to Milphidippa, a maid-servant in the Miles gloriosus,	357, 395, 402, 581
Menigrates , A. Boeck, 1870. "Μενιγράτης, name of a Greek,"	321, 398, 580
Metæchus , misspelling of <i>Metæcus</i> , Kröyer.	
Metæcus , Kröyer, 1838. "μέτεικος, inquilinus, an inmate, or one who resides with another." Preoccupied in 1833 among Coleoptera. (See <i>Hyperoche</i> , Bovallius),	{ 179, 189, 258, 263, 268, 558, 580 1398
Metoicus , misspelling of <i>Metæcus</i> , Kröyer,	317
Metopa , A. Boeck, 1870. "Μετόπα, a proper name,"	200, 293, 394, 400, 569, 581, 752
Microchelus , Kröyer, 1846. μικρός, small, χηλή, a claw. (= <i>Iphimedia</i> , Rathke),	205, 216, 229, 258, 581, 582
Microdentopus , misspelling of <i>Microdeutopus</i> , Costa,	334, 369, 1636
Microdeuteropus , altered from <i>Microdeutopus</i> , Costa, to tally with the derivation,	370, 434, 459, 551, 562
Microdeutopus , A. Costa, 1853. "From the Greek words μεκρός, little, δεύτερος, second, and πόδις, foot." It is clear that the words μικρός and δεύτερος were intended,	{ 274, 294, 296, 299, 350, 396 520, 580
Microplax , Lilljeborg, 1865. μικρός, little, πλάξ, a flat surface. Preoccupied among Hemiptera, 1861. (= <i>Liljeborgia</i> , Sp. Bate),	360, 581
Microprotopus , Norman, 1867. μικρός, little, πρώτος, first, πόδις, foot. "Second gnathopods larger than first,"	370, 396, 580
Mimonectes , Bovallius, 1885. "Derivatio, Μίμος: mimic, imitator, and νήκτης: swimmer,"	558, 580, 588, 593
Mæra , misspelling of <i>Mæra</i> , Leach,	176, 328, 335, 1649
Monoculodes , Stimpson, 1853. <i>Monoculus</i> , one-eyed (a hybrid word from μόνος, single, and οὐσία, eye), εἶδος, appearance,	{ 278, 294, 328, 394, 516, 572 581
Montagua , Spence Bate, 1856-7. "This genus is named after Colonel Moutagu, who was a worthy pioneer in this branch of Zoology, and the discoverer of the first species." Pre-occupied. (= <i>Stenothoe</i> , Dana, and <i>Metopa</i> , Boeck),	{ 290, 293, 328, 394, 581
Montaguana , Chilton, 1882. Altered from <i>Montagua</i> , Spence Bate,	551
Mulleria , Leach, in Desmarest, 1825. A synonym of <i>Mæra</i> , Leach. Probably in honour of O. F. Müller,	122
Næara , mentioned by Kiuhau, 1863, as if an Amphipod genus; the species <i>Næara bicuspidata</i> , being perhaps named by some confusion for the Isopod <i>Næsa bidentata</i> . Pre-occupied in 1840,	344
Nænia , Spence Bate, 1862. The Goddess of dirges, in Mythology. Preoccupied in 1829,	336, 396, 580, 1108
Natalius , A. Costa, 1864. "In memory of Giuseppe De Natale, a young Naturalist of Messina,"	346, 561
Naupredia , Latreille, 1829. (= <i>Proto</i> , Leach),	138, 144, ¹ 183, 192, 202, 329
Naupredia , misspelling of <i>Naupredia</i> , Latreille,	191, 426
Necrogammarus , Woodward, 1870. "From νεκρός, dead, and proper name,"	409, 472
Nemertes , Leach, MS., White, 1847. Νημερτῆς, a Nereid, Hesiod, Theogonia, 263. (= <i>Chelura</i> , Philippi),	220, 223, 580
Neobule , Haswell, 1880. The name of a girl, in Horace, Odes, III. 12.5,	511, 533, 564
Neohela , S. I. Smith, 1881. "Neohela, nom. nov., vice <i>Hela</i> , Boeck, præoc.,"	322, 396, 530, 581, 1215
Nicea , Nicolet, 1849. (= <i>Hyale</i> , Rathke),	{ 172, 231, 233, 263, 293, 328 365, 380, 501, 519, 560
Nicippe , Brñzelius, 1859. "Name of a daughter of Pelops,"	315, 394, 581
Niphargus , Schiødte, 1849-1851. νίφαργος, snow-white,	{ 220, 233, 234, 270, 391, 311 328, 350, 378, 395, 413, 494, 510 581, 1656
Noenia , misspelling of <i>Nænia</i> , Spence Bate,	446
Normania , A. Boeck, 1870. "Named after the English Zoologist, Rev. A. M. Norman,"	393, 399, 576, 580, 582, 601
Nototropis , A. Costa, 1853. "From the Greek words νῶτος, back, and τρόπις, keel."	{ 250, 274, 296, 297, 581 (= <i>Atylus</i> , Leach),
Nototropis , misspelling of <i>Nototropis</i> , Costa,	274
Nymphon , Fabricius. νυμφᾶν, a bridal chamber. This genus, wrongly included by Rissó among the Læmodipoda, does not belong to that or any other Amphipod-group,	129
Odius , Lilljeborg, 1865. Altered from <i>Otus</i> , Spence Bate, preoccupied,	333, 360, 395, 581
Œdiceroides , Stebbing, 1888,	461, 547, 843
Œdiceropsis , Lilljeborg, 1865. <i>Œdiceros</i> , another genus, ὄψις, appearance,	361, 395, 461, 581
Œdiceros , Kröyer, 1842. "οἰδέω, tumeo, et κέρας, cornu,"	199, 394, 569, 837
Œdicerus , misspelling of <i>Œdiceros</i> , Kröyer,	228, 255, 258, 288, 315, 516, 581
Onchomene , a misprint for <i>Orchomene</i> .	

¹ On p. 144, line 17, for *Nempredia*, read *Naupredia*.

Onesimoides , Stebbing, 1888,	647
Onesimus , A. Boeck, 1872, corrected spelling of <i>Onisimus</i> ,	215, 393, 509, 510, 568
Onidium , Parkinson, MS., 1768,	1329, 1617
Oniscus , Linnæns, 1735, ὄντος, a little ass, a wood-louse. Not properly an Amphipod genus, } though in the early authors it from time to time gave its name to various Amphipoda,	11,40
Onisimus , A. Boeck, 1870, altered afterwards by Boeck to <i>Onesimus</i> , from "Ὀνήσιμος, a Greek man's name." (= <i>Alibrotus</i> , Milne-Edwards),	393, 398, 568
Opis , Krøyer, 1842. "Opis nomen virginis Hyperborææ, cuius in Melpomene (cap. 33) mentionem facit Herodotus." Preoccupied among Mollusca, 1825. (See <i>Opisa</i> , Boeck),	198, 228, 257, 283, 393, 580, 582
Opisa , A. Boeck, 1876. "Ὀπίσα, a girl in Herodotus." (Instead of <i>Opis</i> , preoccupied),	393, 453
Orattrina , de Natale, 1850. ? from <i>orata</i> , a goldfish, and <i>trina</i> , trilobed (W. Stebbing),	248, 1622
Orattrino , misspelling of <i>Orattrina</i> , de Natale,	1624
Orchestes , misspelling of <i>Orchestia</i> , Leach,	457
Orchestia , Leach, 1813. ὄρχηστρη, a dauber,	3, 84, 90, 122, 126, 148, 170, 176
	184, 185, 191, 194, 226, 228, 235
	244, 248, 254, 257, 262, 265
	283, 291, 395, 296, 313, 328, 380
	384, 393, 477, 515, 554, 602
	1636
Orchestia , Brandt, 1851, a subgenus of <i>Orchestia</i> ,	245
Orchestia , Dana, 1852, a subgenus of <i>Orchestia</i> ,	257, 262
Orchestoidea , Nicolet, 1849. <i>Orchestia</i> , another genus, εἶδος, appearance,	231, 262, 295
Orchomena , misspelling of <i>Orchomene</i> , Boeck. (Scudder, Nom. Zool., p. 222.)	
Orchomene , A. Boeck, 1870. "Ὀρχομένη, a town." The name as found in sundry Greek towns is Ὀρχόμενος,	215, 321, 393, 399, 446, 580, 673
	676
Orchostoidea , misspelling of <i>Orchestoidea</i> , Nicolet. (Scudder, Nom. Zool., p. 222.)	
Orio , Cocco, 1832. "Un nuovo genere di crustacei, che vo appallare dal nome del primo fondatore di Messina <i>Orione</i> ." (In exchange for <i>Charybdis</i> , preoccupied),	145, 150, 152, 240, 248, 492, 562
Orione , the vernacular name of <i>Orio</i> , Cocco,	190, 426
Ornithoramphus , de Natale, 1850. ὄρνις, a bird, ράμφος, a beak,	239, 248, 493
Ornithoramphus , another spelling of <i>Ornithoramphus</i> , de Natale,	369, 561, 562
Orthopalamē , Hoek, 1879. "From ὅρθος, straight, and παλάμη, palm,"	496
Otus , Spence Bate, 1862. "From the close approximation of this genus to the preceding [i.e., <i>Iphimedia</i>], I have chosen for its name that of the son of Iphimedia." Preoccupied among birds, Cuvier, 1799-1800. (See <i>Odius</i> , Lilljeborg),	328, 333, 360, 395, 581
Oxycephalus , Milne-Edwards, 1830. ὀξυκέφαλος, with pointed head,	143, 171, 175, 184, 190, 232
	236, 241, 259, 327, 347, 452, 470
	476, 493, 553, 561, 590, 1576
Palæocrangon , Schauroth, 1854. παλαιός, of a past age, κραγγῶν, another Crustacean genus,	277, 5081
Palæogammarus , Zaddach, 1864. παλαιός, of a past age, <i>Gammarus</i> , another Amphipod genus,	353
Pallasea , Spence Bate, 1862. Named after Pallas the Zoologist. (One of the Diptera was named <i>Pallasia</i> , in 1830, by Robineau-Desvoidy, and an Isopod was named <i>Pallasius</i> , in 1825, by Leach, according to Desmarest),	33, 309, 335, 372, 395, 581
Pallasia , alteration of <i>Pallasea</i> , Spence Bate,	33, 395, 465
Panope , Leach, 1813. Πανόπη, a Nereid, Hesiod, Theogonia, 250. (= <i>Cyamus</i> , Latreille),	85
Pandora , O. Grimm, 1880. Preoccupied,	509
Pantoporeia , O. Grimm, 1880. ? for <i>Pontoporeia</i> ,	509
Panopla , G. M. Thomson, 1880. Πάνοπλος, in full armour; the genus "so named from the coat-of-mail which envelopes the first-discovered form." Trans. New Zealand Inst., xiii. p. 213,	524
Panoploca , G. M. Thomson, 1880. Alternative spelling of <i>Panopla</i> ,	524
Paradryope , Stebbing, 1888,	1151
Paradulichia , A. Boeck, 1870. "παρά, near to, <i>Dulichia</i> ," another genus,	396, 402, 580
Paralyceæa , Claus, 1879. παρά, near to, <i>Lycæa</i> , another genus,	498, 590, 1567
Paramæra , variation from <i>Paramæra</i> , Miers. (Scudder, Nom. Zool., p. 232.)	
Paramæra , Miers, 1875. παρά, near to, <i>Mera</i> , misspelling of another genus,	447, 458, 913, 1654
Paramaphithoe , Bruzelius. 1858. παρά, near to, <i>Amphithoe</i> , another genus,	{ 313, 314, 356, 395, 425, 569, 581
	582

¹ The Carboniferous *Palæoncrangon* mentioned on p. 508 is perhaps distinct from Schauroth's Permian genus, but whether an earlier or later name I have not discovered.

<i>Paramphitoc</i> , misspelling of <i>Paramphithoc</i> , Bruzelins,	546
<i>Paranxnia</i> , Chilton, 1883. <i>πάρα</i> , near to, <i>Nəνία</i> , another genus. (?= <i>Gammaropsis</i> , Lilljeborg),	550, 1092
<i>Paraphronima</i> , Claus, 1879. <i>πάρα</i> , near to, <i>Phronima</i> , another genus,	{ 264, 338, 476, 488, 558, 588 1269, 1335 }
Parapleustes , Buchholz, 1874. <i>πάρα</i> , near to, <i>Pleustes</i> , another genus,	424
Parapronoë , Claus, 1879. <i>πάρα</i> , near to, <i>Pronoe</i> , another genus,	492, 591, 1521
<i>Parascellus</i> , misspelling of <i>Parascellos</i> , Claus. (Scudder, Nom. Zool., p. 248),	1496
<i>Parascelus</i> , Claus, 1879. <i>πάρα</i> , <i>σκέλος</i> , leg,	492, 591, 1496
<i>Parathemisto</i> , A. Boeck, 1870. " <i>πάρα</i> , beside and <i>Θεμιστώ</i> , a Nereid," or rather, <i>παρα</i> ,	{ 393, 397, 473, 1580, 588, 593, 1419 near to, <i>Themisto</i> , another genus, }
<i>Paratyphes</i> , alteratioi of <i>Paratypis</i> , Claus,	591
<i>Paratyphis</i> , Claus, 1879. <i>πάρα</i> , near to, <i>Typhis</i> , another genus,	491, 591
<i>Pardalisca</i> , Krøyer, 1842. " <i>Nomeu</i> auxillæ apud Plautum in Casina,"	{ 199, 228, 258, 394, 581, 991 1476 }
Parelasmopus , Stebbing, 1888,	1029
Pariambus , 1888. (In exchange for <i>Podalirius</i> , Krøyer, preoccupied),	1268
<i>Pediculus</i> , ancient comprehensive genus ; used by Seba in 1734 to include the Whale-louse, afterwards named <i>Cyamus</i> ,	11
Peltocoxa , Catta, 1875. Pelta, a shield, coxa, name given to the true first joint of the leg in Amphipoda,	{ 441, 513, 539, 574, 581 }
Pephredo , Rafinesque, 1815-1817. " The name is mythological,"	88, 100
Pereionotus , Bate and Westwood, 1862. Pereion, Spence Bate's name for the central portion of an Amphipod, <i>vāτos</i> , back. " Pereion distended,"	340, 580, 582
<i>Phedra</i> , Spence Bate, 1858. A girl in the Aulularia of Plautus, also, a daughter of Minos in mythology. Preoccupied,	311, 328, 581
<i>Phasmatocarcinus</i> , Tilesius, 1819. <i>φάσμα</i> , a phantom, <i>καρκίνος</i> , a crab. Not an Amphipod genus,	109, 135, 148, 149
<i>Phersua</i> , misspelling of <i>Pherusa</i> , Leach,	494
<i>Pherusa</i> , Leach, 1814. <i>Φέρουσα</i> , a Nereid, Hesiod, Theogonia, 248,	{ 86, 90, 123, 125, 141, 148, 192 229, 270, 328, 378, 560, 581, 913 }
<i>Philius</i> , mistake for <i>Phlias</i> , Guérin,	426
<i>Phlias</i> , Guérin, 1836. " <i>Phlias</i> , one of the Argonauts,"	{ 165, 176, 184, 186, 228, 257, 296 341, 348, 551, 580 }
<i>Phocus</i> , misspelling of <i>Phoxus</i> , Krøyer,	494
Phorcorrhaphis , 1888, altered from <i>Phorcus</i> , Milne-Edwards, preoccupied,	1451
<i>Phorcus</i> , Milne-Edwards, 1830. A son of Neptune. Preoccupied. (See <i>Phorcorrhaphis</i>),	{ 142, 170, 175, 184, 189, 259, 493 580, 589 }
<i>Photis</i> , Krøyer, 1842. " <i>Nomen ancillæ apud Apulcium in Asino aurco</i> ,"	{ 199, 228, 258, 341, 396, 581, 597 1063 }
Phoxocephalus , 1888, altered from <i>Phoxus</i> , preoccupied,	810
<i>Phoxus</i> , Krøyer, 1842. " <i>Φοξός</i> , capite acuto. Ιλιαδος, B, 219 ; φοξός ἔην κεφαλήν, κ. τ. λ." Preoccupied. (See <i>Phoxocephalus</i>),	{ 198, 228, 258, 328, 394, 568, 581 810 }
Phreatoicus , Chilton, 1882. <i>φρέαρ</i> , <i>φρέατος</i> , a well, <i>οἶκος</i> , a dwelling. (Allied to the Amphipoda, if not an Amphipod),	543, 587
Phronima , Latreille, 1803. <i>φρόνιμος</i> , prudent. " Ce nom grec répond à notre adjectif <i>prudent</i> , et convient sans doute à un animal qui, pour garantir sa faiblesse naturelle, a la sage précaution de s'envelopper d'un corps gélatineux, n'ayant aucune indice extérieure de vitalité et qui ne réveille point ainsi l'appétit carnassier de ses ennemis." Latr., Hist. Nat., tome vi. p. 289,	{ 72, 78, 84, 88, 89, 96, 97, 122 134, 135, 137, 143, 144, 148, 170 175, 184, 190, 191, 248, 259, 272 307, 316, 328, 338, 350, 429 436, 438, 439, 452, 469, 476 487, 553, 562, 566, 589, 597 1269, 1346 }
<i>Phronimatopsis</i> , variation from <i>Phronimopsis</i> , Claus. (Scudder, Nom. Zool., pp. 375, 244.)	
<i>Phronime</i> , misspelling of <i>Phronima</i> , Latreille,	87
<i>Phronimella</i> , Claus, 1871. Diminutive from <i>Phronima</i> , another genus,	{ 339, 405, 476, 487, 542, 589 1269, 1361 }
Phronimopsis , Claus, 1878-9. <i>Phronima</i> , another genus, <i>ψις</i> , appearance,	476, 488, 589, 1373
<i>Phronoma</i> , misspelling of <i>Phronima</i> , Latreille,	290
<i>Phonyma</i> , misspelling of <i>Phronima</i> , Latreille,	81, 91, 95, 107, 477

¹ On p. 473, line 7, for *Parathemists* read *Parathemisto*.

Phrosina , Risso, 1822. ?from Εὐφροσύνη (cheerfulness), one of the Graces, Hesiod, Theogonia, 900. Costa says, "the name <i>Frosine</i> , assigned to this genus by Risso, is derived from the Latin word <i>Phrosine</i> , which means <i>cheerful</i> , according to Voss. The author chose this name with a view to the beautiful violet shot with gold, which adorns the pearly white of this Crustacean." Phrosine does not appear as a Latin word in ordinary lexicons,	117, 127, 128, 137, 175, 190, 248 476, 487, 589
<i>Phrosine</i> , spelling of <i>Phrosina</i> , Risso, in Desmarest, 1825, Hope's Catalogue, &c.,	
<i>Phtisiea</i> , Slabber, 1769,	122, 144, 183, 191, 259, 272, 349 1424
Pisitoe , Rafinesque, 1814,	32
<i>Pisitoë</i> , misspelling of <i>Pisitoe</i> , Rafinesque,	87, 88, 123, 272
Platamon , Stebbing, 1888,	190
Platophium , Dana, 1852. No doubt from πλατύς, broad, in allusion to the dorsal breadth of the peraeon at the centre, the termination <i>ophium</i> pointing to the connection between this genus and <i>Corophium</i> , Latreille,	642
Platycamus , Lütken, 1870. πλατύς, broad, <i>Cyamus</i> , another genus,	257, 261, 265, 500, 521, 566, 580 581, 1184
Platyischnopus , Stebbing, 1888,	282, 397, 402, 419, 1226 830
Platyscelus , Spence Bate, 1861. "πλατύς, broadly dilated; σκέλος, leg,"	327, 337, 470, 476, 490, 1269 1462
Pleonexes , Spence Bate, 1856-7. ?πλεονέκτης, one who is grasping. "Posterior pereiopoda prehensile." (= <i>Sunamphithoe</i> , Spence Bate),	294, 580, 582
Pleustes , Spence Bate, 1858. πλευστικός, fit for sailing,	179, 308, 395, 569, 581, 870
Plexaura , Rafinesque, 1815. ?from πλῆξις, a stroke, ὥρα, tail,	88
Podalirius , Kröyer, 1845. Ποδαλείριος, a son of Aesculapius; a name derived from πόνος, a foot, and λειρός, thin, and therefore very applicable to this genus. Kröyer says "the name refers to the rudimentary condition of the legs of the fifth segment (λειρος, gracilis)." (See <i>Pariambus</i>),	210, 256, 397, 535, 537
Podocerosis , A. Boeck, 1870. "Podoceros, ὄψις, appearance,"	322, 324, 396, 1108
Podoceros , Goës, 1865. A variation in the spelling of <i>Podocerus</i> , Leach, to suit the derivation,	358, 390, 580
Podocerus , Leach, 1814. πόνος, foot, κέρας, horn, antenna,	86, 90, 123, 148, 170, 176, 184 189, 192, 219, 228, 257, 261, 283 296, 298, 307, 312, 328, 375, 396 570, 580, 1129
Podura , Linnæus, 1740. πόνος, a foot, ὥρα, a tail. (Used by Poda, 1761, in describing what is probably an <i>Orecheta</i>),	20
Polyheria , Haswell, 1880. πολυχειρία, a multitude of hands. "Pereiopoda all prehensile." (= <i>Tritæta</i> , Boeck),	451, 513, 514, 581, 583
Pontiporeia , misspelling of <i>Pontoporeia</i> , Kröyer,	258
Pontocrates , A. Boeck, 1870. "πόντος, sea, κρατέω, I rule,"	294, 307, 395, 400, 572, 581
Pontogeneia , A. Boeck, 1870. "ποντογένεια, sprung from the sea,"	395, 401, 581
Pontogenia , misspelling of <i>Pontogeneia</i> , Boeck,	546
Pontopareia , misspelling of <i>Pontoporeia</i> , Kröyer,	301
Pontoporeia , Kröyer, 1842. "Ποντοπόρεια (pontivaga), Nomen Nereidis Apud Hesiodum (Theogon. vers. 256)."	198, 228, 384, 393, 580, 582 1644
Pontoporeja , misspelling of <i>Pontoporeia</i> , Kröyer,	296
Pontoporia , misspelling of <i>Pontoporia</i> , Kröyer,	408
Praniza , Leach, MS. Not distinct from <i>Anceus</i> , which is generally considered an Isopod genus,	192
Primno , Guérin, 1836. "Primno, nymphe, fille de l'Océan," in Greek Πρυμνά, see Hesiod, Theogonia, 350. Rafinesque's genus <i>Primno</i> , among the Oniscia, 1815, was left undescribed,	164, 175, 184, 189, 232, 259, 487 589, 1440
Prinassus , Hansen, 1887. "Πρινασσός, name of a Greek town,"	1644
Priscilla , A. Boeck, 1870. "Πρισκιλλα, a Greek woman's name." It is, however, very clearly not a Greek but a Latin name, diminutive of <i>prisca</i> , old-fashioned. Preoccupied. (See <i>Priscillina</i>),	322, 393, 399, 580, 582, 1644
Priscillina , 1888. (In exchange for <i>Priscilla</i> , Boeck, preoccupied.)	
Probolium , A. Costa, 1857. "From the Greek word προβόλιον, loricula, a little cuirass." (= <i>Stenothoe</i> , Dana),	274, 293, 296, 297, 322, 380, 460 560, 581
Pronoe , Guérin, 1836. "Pronoe, nymphe, fille de Nérée." Hesiod, Theogonia, 261,	165, 175, 184, 190, 232, 236, 241 259, 269, 492, 591, 1507
Prosoponiseus , Kirkby, 1857. "From πρόσωπον, a face or mask, and ὄψις." A synonym of <i>Palaevocrangon</i> , Schaueroth,	300, 472, 521

Protella , Dana, 1852. Diminutive of <i>Proto</i> , another genus,	{ 256, 265, 328, 375, 535, 537 1244
Protellopsis , Stebbing, 1888,	1240
Proto , Leach, 1814. Πρωτώ, a Nereid, Hesiod, Theogonia, 243,	{ 86, 90, 119, 157, 202, 256, 265 270, 328, 396, 535, 537, 1228
<i>Pontogeneia</i> , a misprint for <i>Pontogencia</i> .	
Protomedea , Kröyer, 1842. “Πρωτομέδεια, filia Νερει et Doridis. Hesiod, Theogonia, vers. 249,”	{ 186, 199, 228, 258, 366, 396 561, 580
<i>Protomedia</i> , misspelling of <i>Protomedea</i> , Kröyer, and given by mistake for <i>Proto</i> , Leach,	328, 494
<i>Proton</i> , Desmarest's spelling of <i>Proto</i> , Leach,	95, 123, 126, 171
<i>Protomia</i> , Rafinesque, 1815,	88, 126
Psammylla , Rafinesque, 1817. ψάμμος, sand, ψύλλα, a flea. “The name is abbreviated from Psammiopsylla, which means sand-flea.” Probably a synonym among the Orchestidae,	99
Pseudolycæa , Claus, 1879. ψευδο-, in composition, unreal, simulating, <i>Lycæa</i> , another genus,	493, 590
<i>Pseudophthalmus</i> , altered spelling of <i>Pseudophthalmus</i> , Stimpson, to suit the derivation,	279, 295, 332, 581
<i>Pseudophthalmus</i> , Stimpson, 1854. ψευδῆς, false, ὀφθαλμός, eye. (= <i>Ampelisca</i> , Kröyer),	279
<i>Pterygocera</i> , a new spelling of <i>Pterygocrus</i> adopted by Latreille in 1829,	{ 138, 143, 192, 228, 257, 261, 474 581
<i>Pterygocerus</i> , Latreille, 1825. πτέρυξ, wing, κέρας, horn, antenna. “Ses quatre antennes sont très-garnies de poils barbus ou formant des pinuules aux premiers articles.” (= <i>Haustorius</i> , P. L. S. Müller),	125, 126
<i>Ptilocheirus</i> , Stimpson, 1854. πτίλων, feather, down, χεῖρ, hand. (? = <i>Leptocheirus</i> , Zaddach),	279, 366, 466, 580
<i>Ptilochirus</i> , misspelling of <i>Ptilocheirus</i> , Stimpson,	561
<i>Pulex</i> , ancient comprehensive genus,	3, 4, 9
<i>Pycnogonum</i> , misspelling of <i>Pycnogonium</i> , Brünich,	209
<i>Pycnogonum</i> , Brünich, 1764. πυκνός, frequent, γωνία, angle, “nouum genus, quod e crebris articulationibus <i>Pycnogonum</i> dieo.” A genus not belonging to the Amphipoda except as a synonym of <i>Cyamus</i> , Latreille,	26, fig. 10, 29, 1618
Pycnus , Dana, 1852. “The name of the genus <i>Pycnus</i> is from πυκτης, a boxer, and alludes to the very large and well-formed hands of the species.” (? = <i>Ericthonius</i> , Milne-Edwards),	{ 255, 258, 267, 268, 375, 559 580
<i>Pygmonum</i> , misspelling of <i>Pycnogonum</i> , Brünich,	129
<i>Reptorramphus</i> , error or intended correction for <i>Erectoramphus</i> , de Natale,	1624
<i>Rhabdonectes</i> , ¹ Bovallius, 1887. ράβδος, a rod, νήκτης, a swimmer. (= <i>Rhabdosoma</i> , Adams and White),	591, 1606
<i>Rhabdosoma</i> , Adams and White, 1848. ράβδος, rod, σῶμα, body,	{ 191, 224, 225, 259, 327, 452, 493 553, 591, 598, 1606
Rhachotropis , S. I. Smith, 1883. “Ράχις et τρόπις, nom. nov., vice <i>Tritropis</i> , Boeck, præoc.” ράχις, ridge of the back, τρόπις, keel. (See <i>Amphithonotus</i> and <i>Tritropis</i>),	394, 546, 954
<i>Rhaea</i> , Milne-Edwards 1828, ?from <i>rhaea</i> , wild poppy. A synonym of <i>Apiscuds</i> , Leach, not generally considered an Amphipod genus,	127, 134
<i>Sanuazaria</i> , O. G. Costa and A. Costa, 1840. Apparently named after Sanuazarius, a writer of piscatory elegances; see Johnson, Rambler, July 21, 1750,	183, 249
<i>Scamballa</i> , Leach, MS., White, 1847. ?from <i>scambus</i> , bow-legged. (= <i>Orchestia</i> , Leach),	222, 245
Schizoscelus , Claus, 1879. σχιζω, 1 split, σκέλος, leg; in allusion to the slit in the femoral-plate (first joint) of the fourth peræopods,	491, 591, 1503
<i>Schnellagenia</i> , Claus, 1871. Named after Captain Schnellagen. (= <i>Brachyscelus</i> , Sp. Bate),	337, 406, 492, 1543
<i>Schraderia</i> , Pfeffer, 1888,	1653, 1654
<i>Scinà</i> , Prestandrea, 1833. “Ho voluto dedicarlo al dottissimo abbate Cav. Domenico Scinà, qual celebre conoscitore delle scienze naturali,”	151, 249, 1270
<i>Scopclocheirus</i> , Spence Bate, 1856-7. Seemingly from σκόπελος, a bigh rock, and χεῖρ, hand; but as White, Hist. Brit. Crust., p. 168, says “First pair of jaw-feet ending in a brush,” hence the generic name, from σκοπηλος, a brush, and χεῖρ, the hand, it may be inferred that it is in reality a hybrid from Latin <i>scopula</i> , a little broom, and Greek χεῖρ, hand; σκοπηλος being an imaginary word. (= <i>Callisoma</i> , Costa),	{ 18, 334, 451, 550, 560, 581, 782 1624
Seba , Spence Bate, ² 1862. After Seba, the eminent naturalist,	

¹ The name *Rhabdonectes* was given under the impression that *Rhabdosoma*, Adams and White, was a preoccupied name, but so far as I can discover, the ophidian genus to which Bovallius alludes has a later date and a different spelling, being *Rhabdosoma*, Duméril, 1853.

² Spence Bate does not claim this genus as his own, but A. Costa, to whom he assigns it, has definitely disowned it, see Note on de Natale, 1850 (in Appendix, p. 1624).

<i>Siljeborgia</i> , misprint for <i>Liljeborgia</i> ,	473
Simorhynchotus , 1888. New name for <i>Simorhynchus</i> , preoccupied,	1572
<i>Simorhynchus</i> , Claus, 1871. <i>σιμός</i> , flat-nosed, <i>βύχος</i> , beak. Preoccupied,	406, 493, 590, 597, 1572
<i>Siphonocetes</i> , misspelling of <i>Siphonacetes</i> , Kröyer,	494
<i>Siphonocetes</i> , misspelling of <i>Siphonacetes</i> , Kröyer,	302, 518, 1634
Siphonacetes , Kröyer, 1845. “ <i>σίφων</i> , a tube, <i>οἰκέτης</i> , an inmate,”	212, 229, 256, 307, 396, 580
<i>Siphonacetus</i> , misspelling of <i>Siphonacetes</i> , Kröyer,	396, 430
<i>Siphonocetus</i> , ¹ misspelling of <i>Siphonacetes</i> , Kröyer,	290, 292, 295
<i>Siphonocatus</i> , misspelling of <i>Siphonacetes</i> , Kröyer,	328
Sirenocyamus , J. F. Brandt, 1847. <i>Σειρήν</i> , a siren, and <i>Cyamus</i> , another genus,	15, 218, 227
Socarnes , A. Boeck, 1870. “ <i>Σωκαρνής</i> , name of a Greek,”	177, 225, 398, 397, 568, 580, 690
Socarnoides , Stebbing, 1888,	690
Sophrosyne , Stebbing, 1888,	607, 652
Sperchius , Rafinesque, 1820. “The name was that of an ancient fluvial God of Thessaly,”	110, 123, 143, 190, 426
Spinifer, Holboell, MS., 1842,	198
<i>Squilla</i> , ancient comprehensive genus,	12, 13, 16, 19, 134, 135, 148
Stebbingia , Pfeffer, 1888,	1653, 1654
Stegocephalus , Kröyer, 1842. “ <i>στέγω</i> , <i>tego</i> , et <i>κεφαλή</i> , caput,”	198, 228, 257, 394, 450, 580, 728
Stegoplax , G. O. Sars, 1882. <i>στέγω</i> , I cover, <i>πλάξ</i> , a flat surface. “The enormous development of the 3d and 4th pairs of Epimera is characteristic.” (Perhaps = <i>Peltocoxa</i> , Catta),	441, 513, 539, 574
<i>Stenia</i> , Dana, 1849. Perhaps from <i>στενός</i> , narrow. Preoccupied,	228, 229, 255, 257
Stenopleura , Stebbing, 1888,	949
Stenothoe , Dana, 1852. Probably from <i>στενός</i> , narrow, and the termination <i>-thoë</i> found in some other genera; Dana says “the slender maxillipeds without the inner lamellar processes and the non-palpigerous mandibles, are alone sufficient to mark this genus as distinct from others to which it is related,”	257, 293, 322, 394, 560, 581, 582 748
Sterylus, Rafinesque, 1815,	88
Stimpsonia , Spence Bate, 1862. “The name given to this genus is in compliment to the industrious and intelligent naturalist of the United States’ Exploring Expedition in the North Pacific.” Preoccupied among <i>Vermes</i> , 1848,	328, 334, 520, 580, 582
Streetsia , Stebbing, 1888,	1603
Stygobromus , Cope, 1872. <i>Στρόξ</i> , the river of Hades, <i>βρόμος</i> , roaring. A genus from the Mammoth Cave, Kentucky. A synonym of <i>Crangonyx</i> , according to S. I. Smith, 1875,	406, 413
<i>Stygodromus</i> , misspelling of <i>Stygobromus</i> , Cope. (Scudder, Nom. Zool., p. 306.)	
Sulcator , Spece Bate, 1854. “The name being derived from the furrow which it makes in the wet sand when crawling.” = (<i>Haustorius</i> , P. L. S. Müller),	244, 283, 290, 328, 394, 581 1624
Sunamphitoë , Spence Bate, 1856–7. <i>σύν</i> , with, <i>Αmphitoë</i> , another genus,	263, 294
Sunamphithoë , Spence Bate, 1862, altered spelling of <i>Sunamphitoë</i> , to correspond with <i>Amphithoë</i> , to which it is so closely allied,	328, 376, 396, 1115
Symprenoë , Stebbing, 1888,	1533
<i>Synamphithoë</i> , White, 1857. A change in the spelling of <i>Sunamphitoë</i> , to correspond with the general practice of latinizing Greek words,	305, 580
Synopia , Dana, 1852. From <i>σύν</i> , together, <i>ψυ</i> , eye. “Pigmentum oculorum uniuersum,”	259, 264, 268, 406, 517, 576, 799
Synopioides , Stebbing, 1888,	999
<i>Synurella</i> , Wrzesiowski, 1877. <i>σύν</i> , together, <i>οὐρά</i> , a tail. No proper generic description was given in 1877, and on philological grounds the name was afterwards changed to <i>Goplana</i> by Wrzesiowski,	472
Syrrhoë , Goës, 1865. <i>συρροή</i> , a flowing together, conflux,	357, 386, 394, 581, 788
<i>Talitronus</i> , Dana, 1850. “ <i>Talitro</i> pedes primos antennasque similis.” (= <i>Orchestoides</i> , Nicolet),	235, 254
<i>Talitrorchestia</i> ? J. F. Braudt, 1851. A subgenus of <i>Talitrus</i> . <i>Talitrus</i> and <i>Orchestia</i> , two genera of Amphipods,	244, 245
	{ 67, 72, 78, 79, 84, 88, 90, 96
Talitrus , Latreille and Bosc, 1802. Talitrum, a fillip with the finger, in French chiquenande. “Ils donnent, si on peut employer cette expression, de continnelles chiquenodes au sol sur lequel ils se trouvent,” Bosc,	99, 114, 122, 126, 135, 147, 148 170, 176, 184, 185, 192, 226, 228 235, 244, 248, 254, 262, 280 283, 295, 296, 328, 384, 393

¹ On p. 292, last line, for *Siphonocetu* read *Siphonocetus*.

<i>Talitrus</i> , Dana, 1852. A subgenus of <i>Orchestia</i> ,	257, 262
Talorchestia , Dana, 1852. A subgenus of <i>Orchestia</i> , adopted by Spence Bate, 1862, as an independent genus. <i>Talitrus</i> and <i>Orchestia</i> , two other genera,	257, 262, 265
<i>Talytrus</i> , a misspelling of <i>Talitrus</i> ,	183, 275
<i>Tanais</i> , Milne-Edwards, 1828. Not usually considered an Amphipod genus,	201, 527, 544, 549, 579
<i>Tanyssclus</i> , Claus, 1879. <i>τανν-</i> , in composition, long, outstretched, <i>σκέλος</i> , leg. (= <i>Thyropus</i> , Dana),	492, 591, 1492
Tauria , Dana, 1852. A proper name (Boeck),	258, 263, 268, 558, 580, 588
<i>Temisto</i> , misspelling of <i>Themisto</i> , Guérin,	302
<i>Teraticum</i> , Chilton, 1883. <i>τερατικόν</i> , a strange thing. (= <i>Seba</i>),	451, 550
<i>Tessarops</i> , Norman, 1868. <i>τέσσαρες</i> , four, &ψ, eye. "Eyes four." (= <i>Tiron</i> , Lilljeborg),	386, 581
Tetrathyrs , Claus, 1879. <i>τετράθυρος</i> , with four doors,	491, 591, 1480
<i>Tetromatus</i> , Spence Bate, 1856-7. <i>τετρα-</i> , in composition, four, and <i>υματα</i> , eyes. (= <i>Ampelisca</i> , Kröyer),	290, 293, 295
<i>Tetrommatus</i> , a variation in the spelling of <i>Tetromatus</i> , to correspond with the derivation,	581
<i>Thalitrus</i> , a misspelling of <i>Talitrus</i> , Latreille and Bosc.,	79, 87, 157
Thamneus , Bovallius, 1887,	590, 1558
<i>Thamyris</i> , Spence Bate, 1862. Θάμυρις, the Thracian poet blinded for presuming to compete with the Muses. (= <i>Brachyscelus</i> , Sp. Bate),	328, 337, 476, 492, 558, 590 593, 597, 1543
<i>Thaumalea</i> , Templeton, 1836. θαυμαλέος, wondrous. Preoccupied,	110, 167, 175
<i>Thaumatops</i> , alteration of <i>Thaumops</i> , von Willemoes Suhm, on philological grounds,	444, 575, 588, 593, 1318
<i>Thaumops</i> , von Willemoes Suhm, 1873. θαῦμα, wonder, &ψ, cyc. "Oculis maximis superiorem capitatis partem tegentibus." (= <i>Cystisoma</i> , Guériu),	196, 423, ¹ 437, 439, 575, 580
Themistella , Bovallius, 1887. Diminutive of <i>Themisto</i> , another genus,	589
<i>Themisto</i> , Guérin, 1825. "Thémisto, nymphe, fille de Neptune et de Doris," Hesiod, Theogonia, 261. Preoccupied. (See <i>Euthemisto</i>),	115, 127, 133, 137, 143, 144, 170 175, 184, 190, 259, 437, 487, 580
<i>Thersites</i> , Spence Bate, 1856-7. Θερσίτης, a well-known character in Homer's Iliad,	290, 294, 295, 305, 394, 581
<i>Thessarops</i> , misspelling of <i>Tessarops</i> , Norman,	431
<i>Thiella</i> , Rafinesque, 1815. ? for <i>Thyella</i> , from θύελλα, a whirlwind,	88
Thyropus , Dana, 1852. "The name is from θύρον [θύρα], door, and πούς, foot. Pedes 5ti 6tique articulo 1mo latè lamellati,"	259, 269, 437, 490, 591, 1269 1492, 1496
<i>Tiphis</i> , misspelling of <i>Typhis</i> , Risso,	126, 184
<i>Titanethes</i> , Schiödte, 1851. An Isopod genus referred to by mistake as if belonging to the Amphipoda,	234, 560
Tiron , Lilljeborg, 1865. "Τείρων, proper name,"	361, 386, 394, 581, 788
<i>Trilobites</i> , used by Schlotheim in 1820, to include what some suppose to be a fossil Amphipod,	111
Trischizostoma , Esmark and Boeck, 1860. "τρεῖς, three, σχίζω, 1 split, στόμα, mouth," so named from the trifid tube formed by the upper lip and outer plates of the maxillipeds. (See Note on <i>Guerinia</i> (Hope), A. Costa, 1853),	272, 321, 323, 393, 412, 576 581, 798
Tritæta , Boeck, 1876. "Τριταλα, a proper name,"	334, 395, 451, 454, 573, 583, 941
<i>Trityropis</i> , Boeck, 1870. "τρόπτις, a keel." Preoccupied by Fitzinger, 1843, for a genus of reptiles. Altered to <i>Rhachotropis</i> , S. I. Smith,	394, 400, 424, 570, 954
<i>Triura</i> , Tellkampf, 1844. τρι-, in composition, three, and οὐρά, a tail. Wrongly supposed to be an Amphipod genus,	208
Tryphana , Boeck, 1860. "Τρύφαινα, a Greek woman's name,"	393, 397, 580, 1538
<i>Tryphæna</i> , alteration of <i>Tryphana</i> , Boeck, to tally with the derivation,	590, 593, 1538
Tryphosa , Boeck, 1870. "Τρυφώσα, a Greek woman's name,"	215, 393, 399, 420, 568, 580, 617
Tullbergella , Bovallius, 1887. Named after the naturalist Tullberg,	590
<i>Typhimedia</i> , error for <i>Iphimedia</i> ,	461
<i>Typhis</i> , Risso, 1816. τύφη, tomentum (Agassiz), or ? from <i>Tiphys</i> , helmsman of the ship "Argo." Preoccupied among Mollusca in 1810. (See <i>Platysclus</i>),	96, 97, 123, 127, 128, 138, 143 144, 171, 174, 190, 192, 236, 241 259, 282, 327, 476, 490
<i>Tyro</i> , Milne-Edwards, 1840. A daughter of Salmoneus, mythological. (= <i>Scinæ</i> , Pres-tandrea),	189, 229, 258, 558, 575, 580, 587 1272
<i>Unciata</i> , misspelling of <i>Unciola</i> , Say,	176, 1168
Unciola , Say, 1818. <i>Unciola</i> , a little ounce, a paltry twelfth, Juvenal, Sat. 1.40. It might mean "a little inch," but it only occurs in the passage referred to,	104, 170, 184, 189, 228, 263, 270 283, 296, 307, 370, 396, 522 571, 580, 1168

¹ On p. 423, line 17, for 1879 read 1876.

Uristes , Dana, 1849. Perhaps from <i>ovpī̄çēw</i> , to carry with a fair wind, or from <i>εip̄v̄s</i> , wide,	as Dana says, "the epimerals are very broad." The genus was evidently founded on a misunderstood specimen,	} 228, 229, 255, 257, 263
Urothoe , Dana, 1852. Perhaps from <i>oθpos</i> , a fair wind, but more probably from <i>oθpā</i> , tail,		
as Dana says, "the large and long foliaceous posterior stylets distinguish the species	} 257, 297, 328, 394, 460, 569, 581 readily from related genera,"	} 582, 824
Uruios , Iarzynsky, 1870 (undescribed ?),		
Valettia , Stebbing, 1888,		403
Vertumnus , Leach, MS., White, 1847. Vertumnus, the god of the changing year. Pre-	occupied. (See <i>Epimeria</i> , Costa),	} 223, 242, 243, 356, 395, 581
Vibilia , Milne-Edwards, 1830. Vibilia, the goddess of roads,		
<i>Westwoodea</i> , Spence Bate, 1856. Described as <i>Westwoodia</i> , 1857,		290
<i>Westwoodia</i> , Speuce Bate, 1857. Preoccupied among Hymenoptera and Entomostraca. (See	<i>Westwoodilla</i>),	} 142, 170, 175, 184, 189, 258 431, 476, 580, 588, 593, 1269
Westwoodilla , Spence Bate, 1862. "Westwoodia having been already adopted by Dana	for a genus of Entomostracous Crustacea, I have felt obliged to alter the termination of the name of this genus, which I have designated in honour of one of the most eminent of European entomologists,"	} 293, 328, 333, 516, 581
Weyprechtia , Stuxberg, 1880. Named in honour of Lieutenant Weyprecht,		
<i>Wyvillea</i> , Haswell, 1880. "I have named this genus in honour of Prof. Sir C. Wyville	Thomson." (= <i>Macleayia</i> , Haswell, 1880),	} 523, 581 } 513, 583
Xenocheira , Haswell, 1880. ξέρος, strange, χείρ, hand,		
<i>Xenochira</i> , alteration of <i>Xenocheira</i> , Haswell. (Scudder, Nom. Zool., pp. 353, 336.)		512, 514, 565, 580
Xenoclea , A. Boeck, 1870. "Ξενόκλεια, a Delphic priestess." (See <i>Podocropsis</i>),		396, 402, 580, 1062, 1108
Xenodice , A. Boeck, 1870. "Ξενοδίκη, a daughter of Minos,"		396, 402, 580
Zacoreus , Rafinesque, ¹ 1815. ? from ζάκοπος, a minister,		88
Zaramilla , Stebbing, 1888,		866
<i>Zuphea</i> , ² misspelling of <i>Zuphea</i> , Risso,		127
<i>Zuphea</i> , Risso, 1826. Derivation unknown. An Isopod (?) genus placed by Risso among the Læmodipoda,		129

¹ My friend Mr. William Bradford of New York informs me that Rafinesque-Schmaltz used sometimes the name Rafinesque and sometimes the name Schmaltz to suit his varying circumstances, but that, though he had a right to both names, he never used them in combination.

² In Nardo's Adriatic Crustacea, 1869 (see p. 389), the names of several genera are wrongly spelt; thus, *Lisianassa* for *Lysianassa*, *Amphi-tonotus* for *Amphithonotus*, *Gamarus* for *Gammarus*, *Lemothoe* for *Leucothoe*, *Calomastix* for *Colomastix*, *Amphitae* for *Amphithoe*, *Megamoera* for *Megamoera*, *Gamarella* for *Gammarella*, *Callisoma* for *Callisoma*, *Iphimedia* for *Iphimedia*, *Leucothoe* for *Leucothoe*, *Cyrtophium* for *Cyrtophium*, *Lysita* for *Lusyta*. Some of these names are given in the right as well as in the wrong form, and of *Lysita* Nardo himself supplies the correction. The errors are noticed here as some safeguard against the repetition of them.

INDEX OF SPECIES.

NOTE.—Generic and specific names, when there is good reason to regard them as synonyms, are printed in italics; of the specific names printed in plain letters many are of more or less doubtful validity, the descriptions hitherto given not sufficing for their accurate determination. With the earliest name of a species the name of the author who established it is printed in plain letters, italics being used for the authors of all subsequent names. Dark numerals indicate the page at which a description of a species or remarks upon it will be found.

¹ On p. 314, line 34, for *Gainardi* read *Gaimardii*.² If Boeck be right in stating, De Skand. og Arkt. Amph., p. 57, that Stimpson's *Pseudothalassius limicola* can scarcely be separated from *Ampelisca tenuicornis*, Liljeborg, the specific name *limicola* has the priority.³ This species makes a near approach to *Ampelisca carinata*, Bruzelius; on p. 1061, line 27, for upper antennæ, read lower antennæ.⁴ May not this be the same as *Amphilochus tenuimanus*, Boeck?

¹ On page 49, line 32, for 1834 read 1835, and for *Edwardsii* read *Edwardsi*, with a full stop.² In the Brit. Mus. Catal. Amph. Crust., p. 186, "Amphithoe *Fresnelli*, Audouin," is given as a synonym of "*Melita Fresnelli*," instead of *Gammarus Fresnelli*, Audouin, Milne-Edwards having previously attributed his "*Amphithoe Fresnelli*" to Audouin.³ *Amphitoe Jurinii?* (Kroy.), is given by Bell and Westwood, probably by mistake so far as the authority cited is concerned, see pp. 281 and 1634.⁴ On p. 305, lines 41, 42, omit the words "both before and;" *Cancer Gammarus obtusatus*, Montagu, was transferred to the genus *Melita* by Spence Bate in 1862.

¹ Boeck, De Skand. og Arkt. Amph., p. 510, says that Stimpson referred the species "*A. serratus*, O. Fabr." to *Amphithonctus*, but that is a mistake, see p. 278, and Boeck himself, *op. cit.*, p. 240.

² This is Bruzelius' *Paramphithoe tridentata*, which Boeck in 1870 transferred to *Halirages*.

Anonyx—continued.

------------------------------	---	---	---	-----

¹ The name *Dactylocera Nicetensis*, p. 190, line 16, had not been previously used, but is given by Milne-Edwards in a footnote as though it had been.² This name is given in the Brit. Mus. Catal. Amph. Crust., p. 151, from "Cat. Crust. Mus. Roy. Coll. Surgeons, p. 94," as a synonym of "*Amphithonotus Edwardsii*."³ see *Pherusa fucicola*, Leach.⁴ This species should have been mentioned in the Note on Grube, p. 348.⁵ See Brit. Mus. Catal. Amph. Crust., p. 376. Boeck names the species *Halirages tridentatus*.

Eurymera—						
<i>monticulosa</i> , Pfeffer, 1888,						1653

¹ The suggestion, p. 97, that "*Typhis ovoides*, Risso," should be called *Dithyrus oroides*, as well as the suggestion, p. 500, that *Platyscelus intermedius*, Thomson, should be called *Dithyrus intermedius*, is withdrawn for the reasons mentioned on pp. 1463, 1464.

² Bocck, De Skand. og. Arkt. Amph., p. 56, spells this name *Aegidia*.

² Since *Ephippiphora* is preoccupied, the suggestion made on p. 177 that it will take precedence of Boeck's *Socarnes* must be cancelled, and with it the name "*Ephippiphora vahlii*, Krøyer," falls to the ground.

⁴ Bate and Westwood, Brit. Sess. Crust., vol. ii. p. 528, identify *Acanthonotus owenii*, Sp. Bate, and *Epimera tricristata*, Costa, with *Epimera cornigera* (Fabricius), therefore anticipating Boeck, who independently took the same view in 1870.

¹ Spence Bate in his Synopsis, 1857, gives "*G. Moggridgei* (mīhi) Ann. Nat. Hist. 1851," as a synonym of *Gammarus Sabini*, instead of *A. Moggridgei*.

² On p. 56, line 24, for accidentally read accidentally.

³ On p. 274, line 10, for *Gammarus orchestipes* read *Ceradocus orchestipes*.

⁴ Milne-Edwards gives this species as *Peloponnesicus* in the index to the Hist. Nat. des Crustacés.

---	---	--

¹ For the disentanglement, so far as practicable, of the synonymy of *Hyperia medusarum*, the papers by Bovallius and Hansen in 1887 should be consulted.

² Gosse's species, according to the Brit. Mus. Catal. Amph. Crust., pp. 292, 293, is *Hyperia galba*, Montagu.

¹ The Brit. Mus. Catal. Amph. Crust., p. 229, gives this name to the "Gammarus Kroyeri" of Bell and Westwood, 1855, which Boeck identifies with *Melita dentata*, Kröyer, although the third uropods do not agree with the definition of *Melita*.

² Grube's paper, already noticed p. 388, is in the "Abhandlungen der Schlesischen Gesellschaft für vaterländische Cultur. Abtheilung für Naturwissenschaften und Medicin, 1868–69. Breslau 1869," pp. 91–129, Taf. 2. A list of Crustacea at p. 125 contains under *Megamoera* the entry "*M. subserrulata* Sp. B. ?," probably by a mistake for *Megamoera semiserrata*, Spence Bate.³

³ White in 1847 gives "*Melita obtusata*, Leach" as a synonym of *Amphithoe obtusata*.

<i>simplex</i> , Hansen, 1887,	1644, 1646
Stimpsoni, Sp. Bate, 1862,	314, 333, 542, 546

¹ A synonym of *Autonoe plumosa*, Boeck, according to the Museum Normanianum, 1886.² *Autonoe longipes*, Brüzelius, 1859.³ *Gammarus macronyx*, Liljeborg = *Protomediea fasciata*, Krøyer, 1842.⁴ This is named *Autonoe versicolorata* in the Museum Normanianum, 1886, so that the priority of the genus *Lembos* over *Autonoe* comes in question.⁵ Boeck in 1870, but not in 1876, makes *Microdeutopus websteri*, Sp. Bate, a synonym of *Protomediea fasciata*, Krøyer. It is named "Autonoe *Websteri*" in the Museum Normanianum, 1886, in regard to which the remark made in the preceding note will apply.⁶ On page 334, line 24, for *nubeculatus* read *nubeculus*, and on page 371, line 11, for *nubilatus* read *nubilus*.

¹ The name *Ediceroides conspicua* mentioned on p. 547, lines 7, 8, was never established, see p. 850.² Boeck subsequently referred this species to two distinct genera, as will be seen by comparing his Crust. amph. bor. et arct., pp. 84, 91, with his De Skand. og Arkt. Amph., pp. 267, 288.³ There is nothing to show whether Grimm's genus *Onesimus* is an independent but preoccupied name or a synonym of Boeck's *Onisimus*.

¹ See Brit. Mus. Catal. Amph. Crust., p. 369.² " *Orchestra Bonelliana*, White, Cat. Crust. B. M. 1847," is given as a synonym of "*Allorchestes Pereiri*" in the Brit. Mus. Catal. Amph. Crust., p. 42, 1862, but I cannot find any such name in White's Catalogue.³ This species is given as *Chilensis* in the index to Milne-Edwards' work, and that form has been adopted by Dana and Speuse Bate.⁴ " *Orchestra constructa* (young?), Costa," is given by mistake for *Orchestra constructa*, as a synonym of "*Orchestra Mediterranea*" in the Brit. Mus. Catal. Amph. Crust., p. 24, 1862.

¹ On p. 254, line 41, for *quadrinanus* read *quadrinana*.² Adams and White, in the synonymy of *Rhabdosoma armatum*, give “*Oxycephalus armatus*, M.-Edw., Crust. III. p. 101. pl. 30. f. 10, copied. (Tab. XIII. Fig. 8.),” but their previous statements and the lettering of Tab. XIII. alike show that the words “pl. 30. f. 10, copied. (Tab. XIII. Fig. 8.)” should have been referred to the independent species, *Oxycephalus piscator*, M.-Edw.³ On p. 353, lines 6, 7, for *Palaeocrangon problematicus* read *Palaeocrangon problematica*. The carboniferous *Palaeocrangon* referred to by Claus, see p. 508, is perhaps a distinct genus from Schaueroth's.

-----------------	-----------	--

² On p. 254, line 40, for *rectimanus* read *rectimana*.³ Adams and White, in the synonymy of *Rhabdosoma armatum*, give “*Oxycephalus armatus*, M.-Edw., Crust. III. p. 101. pl. 30. f. 10,copied. (Tab. XIII. Fig. 8.),” but their previous statements and the lettering of Tab. XIII. alike show that the words “pl. 30. f. 10, copied. (Tab. XIII. Fig. 8.)” should have been referred to the independent species, *Oxycephalus piscator*, M.-Edw.⁴ On p. 353, lines 6, 7, for *Palaeocrangon problematicus* read *Palaeocrangon problematica*. The carboniferous *Palaeocrangon* referred to by Claus, see p. 508, is perhaps a distinct genus from Schaueroth's.

¹ Echinimana is a provisional name only.² The species of *Proto* printed in plain letters belong to the genus *Phthisica*, Slabber.³ Spence Bate, Brit. Mus. Catal. Amph. Crust., p. 169, gives this name to "Gammareus fimbriatus, Stimpson, MS." but he says of it, "I do not feel quite satisfied that this species is distinct from *P. pinguis*."⁴ Limiculus, in the index to Stimpson's work.

¹ The figure which Westwood gives of "Stegocephalus (Kroy.) ampulla (Phipps)" has the postero-lateral angle of the third pleon-segment acute and a little upturned, but otherwise it closely agrees with Krøyer's *Stegocephalus inflatus*. Bell gives "Stegocephalus Ampulla, Kroy." in the synonymy by mistake for *Stegocephalus inflatus*. In the definition of *Stegocephalus* (see p. 198) Krøyer says, "Pedes quinti paris pedibus tertii quartique paris structura et directione similes," a peculiarity at which he himself expresses his surprise, *Naturh. Tidsskrift*, ser. 2, Bd. i. p. 528, but Dana and Boeck are no doubt right in regarding the statement as an error.

² On p. 394, line 4, and p. 538, line 42, for *Christianensis* read *Christianiensis*.

³ The statement that this species is the same as *Cancer ampulla*, Phipps, has lately been corrected by Hansen, see pp. 599, 729.

ADDENDA.—Since the earlier part of the Index was printed, E. Chevreux has described *Ampelisca sarsi*, n. sp., and *Egina capillacea*, n. sp. For *Phædra kinahani*, Sp. Bate, in accordance with the suggestion of Boeck, 1876, he adopts the name *Liljeborgia* [*Liljeborgia*] *kinahani*. His paper is entitled, “Nouvelles espèces de Crustacés Amphipodes du sud-ouest de la Bretagne. Association française pour l'avancement des sciences Fusionnée avec l'association scientifique de France, Congrès de Toulouse.—1887. Paris, 1888.” Another paper by the same author is entitled “Contribution à l'étude de la distribution géographique des Amphipodes sur les côtes de France. Extrait du Bulletin de la Société d'études scientifiques de Paris, 11^e année, 1^{er} semestre 1888.” No new species are described, unless it should prove that one which is named “?*Caprella spinosissima*” is in fact novel.

“Les Plages du Croisic, récoltes zoologiques par Adrien Dollfus avec la collaboration de MM. Ed. Chevreux et Ph. Dautzenberg, Paris, 1888,” is another recent addition to the literature of the Amphipoda. No new species are described.

In a note dated Stazione Zoologica, Napoli, November 19, 1888, Dr. Mayer informs me that he has quite recently seen specimens of *Eginella spinosa*, Boeck. From the examination of these he is inclined to keep *Eginella* distinct from Krøyer's *Egina*. Should this eventually be considered necessary, whatever new generic name may be substituted for the preoccupied *Egina* will apply to the species *ochinata*, Boeck, *longicornis*, Krøyer, and *spinossissima*, Mayer, while *aculata*, Dana, *tenella*, Dana, and *tristancensis*, of this Report, will remain indeterminate as regards their generic position (see pp. 1248, 1686).

In re-examining the Challenger collection of Gammarina, I find that in a few instances some duplicate specimens have been omitted from the enumeration given in the text, and that one addition must be made to the series of specimens obtained from below 300 fathoms. For this last the following preliminary description may here suffice:—

Genus *Pardaliscoides*,¹ n. gen. Near to *Pardalisca*. Peduncle of the upper antennæ not very short. Palp of first maxillæ of moderate breadth. Outer plate of the maxillipedes narrow as well as short. The pereopods slender; the third joint in the first and second pairs moderately long, not dilated. Telson shorter than the peduncle of the third uropods, divided nearly to the base, dehiscent.

Pardaliscoides tenellus, n. sp. Rostrum acute. In the upper antennæ the second joint of the peduncle narrower but rather longer than the first, the third joint longer than broad; the secondary flagellum elongate, with eight joints remaining. Lower antennæ having the fourth joint of the peduncle longer than the fifth, and about equal in length to the nine-jointed flagellum. Mandibles, first maxillæ, and gnathopods having a general resemblance to those of *Pardalisca abyssi*, the second maxillæ to those of *Pardalisca marionis*, the pereopods and telson to the figures given by Bruzelius for *Nicippe tumida*. There are three spines in

¹ In the Introduction, p. xxii, it should have been stated that two specimens were obtained of *Elasmopus delaplata*, and two of *Podocerus hooki*. To include these together with *Pardaliscoides tenellus*, the statistics should be that in the 34 specimens 26 genera are represented, of which 11 are new, and 29 species, of which 27 are new. On p. xxiv, line 4, for thirty-one read thirty-two, and line 28, for Prestandres read Prestandrea.

the spine-row of the left, two in that of the right, mandible. The palp of the first maxillæ is apically fringed with nine spine-teeth. The joint of the maxillipeds which carries the outer plate is not largely developed; the third joint of the palp is elongate as well as the second. The finger in the gnathopods carries very inconspicuous spinules. In the first and second pereiopods the fourth joint is considerably longer than the third; the fifth joint in the second pair has a fringe of about a dozen short blunt spinules, which are not seen on the first pair. The uropods of the specimen were damaged. The peduncle in the first pair is long; in the second pair the outer ramus is rather longer than the peduncle but much shorter than the inner ramus; in the third pair the rami are laminar, longer than the peduncle. There appears to be a small dorsal tooth on each of the hinder segments of the pleon. This species seems to stand between *Pardalisca* and *Nicippe*, as *Synopiooides* between *Nicippe* and *Halice*. Length of specimen, without the antennæ, not quite a third of an inch. It was taken at Station 297, November 11, 1875; South Pacific; lat. $37^{\circ} 29' S.$, long. $83^{\circ} 7' W.$; tow-net at the trawl; depth, 1775 fathoms; bottom temperature, $35^{\circ} 5$; surface temperature, 57° .

On p. 1690, to the species of *Anonyx* should be added on Krøyer's authority, *bona speci*, Holbøll, MS., 1842; *flagelliformis*, Holbøll, MS., 1846; *medius*, Holbøll, MS., 1846; *perfoliatus*, Holbøll, MS., 1846. The first three of these Krøyer identifies with Holbøll's *Anonyx Eschrichtii* under the name *Opis typica*; the fourth he unites with his own *Anonyx holbølli* (compare pp. 200, 215). The footnote on p. 1690 must be cancelled, since "An. bona spec." in Krøyer's work was merely a misprint for *An. bona speci*, a species distinct from *Anonyx brevipes*.

GLOSSARY AND GENERAL INDEX.

NOTE.—Dark numerals indicate pages on which definitions or descriptions will be found.

Abdomen (perhaps for adipomen, from *adeps*, fat), sometimes used of the pleon, which Boeck calls the post-abdomen, considering that the last five segments of the peraeon in the Amphipoda are homologous to the abdomen in the Insecta, 105, 184, 189, 553.

Adactyle (*ἀ-*, without, *δάκτυλος*, finger), “Le mot *adactyle* signifie simplement que ces mains n’ont pas de doigts comme celles des crabes” (Latreille, Hist. Nat., tome vi. p. 298), 89, 104.

Addome=abdome, 150, 152.

Adipose body (*adeps*, fat), 300, 481, 503.

Afterdarm, 289.

Afterdrüse, 505.

Agonata, 40, 50, 62, 63, 64.

Alène ; en alène, acuminate, awl-shaped, 139.

Alimentary canal, 154, 482, 489, 504, 574.

Amfipodi anomalii, 297.

Amphipoda (*ἀμφί*, around, *πούς*, a foot, “pieds dirigés en tout sens,” Latreille, Nouveau Dict., tome viii. p. 493, 1817.

Agassiz, in his *Nomenclator zoologicus*, derives the word from *ἀμφί*, utrinque, and *πούς*, pes; but since animals with feet seem universally to have them on both sides (utrinque), that derivation makes the word unmeaning. Bate and Westwood say that it is “derived from the Greek *ἀμφω*, both; *πόδες*, feet,” and that “this name was given by Latreille to the present order of Crustacea on account of the animals contained in it having both swimming and walking legs, and to distinguish it from the order Isopoda, in which the legs are adapted for walking only.” Latreille’s own explanation is, however, the most satisfactory, since it suits the form of the word as well as the facts of the case, for, without taking into account the pieds-nageoires, we find the gnathopods capable of very free movement, the first two pairs of pereopods commonly directed forwards, and the last three pairs directed in various positions upwards, backwards or downwards, and sometimes spread out to some extent sideways).

The Amphipoda are first mentioned in the Nouveau Dict. Hist. Nat., tome i. p. 467, 1816. The description Latreille there gives is as follows:—“Amphipodes, *Amphipoda*, Lat. Ordre de crustacés ayant pour caractères; mandibules portant un palpe; yeux sessiles et immobiles; tête distincte du trone; troisième et dernière paire de mâchoires en forme de lèvre, avec deux palpes ou deux petits pieds réunis à leur base. Leur corps est foiblement

crustacé, le plus souvent comprimé et arqué. La tête est distincte, avec deux yeux et quatre antennes presque toujours sétacées. La bouche est formée d’un labre, de deux mandibules portant un palpe filiforme et saillant ou découvert, d’une languette, de deux paires de mâchoires, avec deux pieds-mâchoires, au dessous, et recouvrant les organes pré cédeus, tantôt dilatés au côté interne, tantôt réunis à leur base; ils représentent une lèvre inférieure avec deux palps. Le trone est divisé en sept anneaux, portant chacun une paire de pieds, dont les quatre premiers dirigés en avant, sont souvent terminés par une serre, avec un seul doigt, ou en griffe. A la base intérieure de chaque pied, en commençant à la seconde paire, est un corps ovale et vésiculeux, qui me paraît être une branchie. La poitrine offre en outre, dans les femelles de petites lames ciliées sur leurs bords, destinées à recouvrir leurs œufs. Le cœur s’étend dans la longueur du trone, comme dans les stomatopodes, et ressemble à un vaisseau dorsal, mais ayant des rameaux. Le trone se termine par une queue de six à sept articles, ayant en dessous cinq paires de pieds-nageoires sous la forme de filets, et divisées en deux branches articulées; ils sont très-mobiles, analogues aux pieds branchiaux des stomatopodes, et servent peut-être aux mêmes fonctions; l’extrémité de cette queue est courbée en dessous, et le dernier anneau est ordinairement terminé par de petits appendices en forme de styles articulés, épineux, et rarement par de petites lames en feuillets. Les amphipodes nagent et sautent avec agilité, et toujours posés sur le côté. Les uns habitent les ruisseaux et les fontaines, les autres les eaux salées. Leur accouplement ressemble à celui des insectes, le mâle étant placé sur le dos de sa femelle; l’union dure quelque temps, et la femelle emporte souvent le mâle, qui est alors sous son ventre. Les œufs sont rassemblés sur la poitrine et recouverts par les petites écailles dont nous avons parlé, ce qui leur forme une sorte de poche; ils s’y développent; les petits restent attachés aux pieds ou à d’autres parties du corps de leur mère, jusqu’à ce qu’ils aient acquis assez de vigueur pour n’avoir plus besoin de ce secours.” There have been numerous subsequent definitions, some of which will be found under the references, 95, 99, 122, 137, 139, 144, 170, 175, 184, 206, 208, 215, 222, 256, 259, 282, 289, 316, 365, 480, 508, 547, 553, 579, 601, 1655.

- Anfipodi, 205.
 Anfipodos, 231.
 Anisopoda, 256, 260, 289, 554.
 Annulosa, a subkingdom in zoology comprising the Arthropoda and Anarthropoda, in which the body is more or less evidently composed of a succession of *annuli* or rings, 91, 478.
 Annulus, a body-ring, segment, or somite, 153, 264.
 Anostézoaires (α -, without, $\delta\sigma\tau\epsilon\omega$, bone, $\zeta\omega\nu$, animal), 94.
 Anostia (α -, without, $\delta\sigma\tau\epsilon\omega$, bone), 88.
 Antennæ (antenna, in Latin, a sailyard), in a Crustacean the appendages of the (theoretical) second and third segments. The two pairs are distinguished by different writers as respectively first and second, 473; upper and lower, 84, 122, 245; anterior and posterior, 487, 536; posterior and anterior, 64, 149; inner and outer, 78, 515; antennules and antennæ, 463, 1215; auditory and olfactory (Spence Bate, Brit. Assoc. Rep. for 1875); Milne-Edwards, 154; Spence Bate, 280, 473; Bruxelins, 313; Fritz Müller, 349; Leydig, 349, 480; Clans, 487, 597.
 Antennæform processes, palps of the mandibles, 102.
 Antennal gland, 505, 510, 553.
 Antennæ, see Antennæ. This diminutive is not well suited to the Amphipoda, seeing that in many species of this group the upper antennæ exceed the lower in size.
 Antennules, applied to parts of the mandibles, maxillæ, and maxillipeds, 57.
 Antens=Antennæ, 99.
 Anterior. By a conventional use, this word is applied to that edge of the leg which, when the limb is extended downwards, is turned towards the head; thus in the gnathopods and first two pairs of pereiopods what would naturally be regarded as the back of the hand is called the anterior or front margin, while the clasping edge is called the posterior or hind margin.
 Antihi (ἀντλέω, I drain, in reference to the *haustellum* or sucking apparatus), 41, 65.
 Aorta (ἀορτή, from ἀείρω, I raise), 388, 372, 476, 489, 505, 526.
 Apiropodes ($\delta\pi\epsilon\iota\pos$, without limit, $\pi\delta\delta\epsilon\varsigma$, feet), 92.
 Apodeme ($\alpha\pi\omega\delta\epsilon\omega$, I bind fast), 463.
 Appendages, appendices, 153, 463, 563; correlation of, 474; renewal of, 474.
 Appendiculata, 478.
 Appendix caudalis, the telson, 178.
 Apta (ἀπτέρος, unwinged), 11, 14, 15, 18, 20, 26, 36, 42, 52, 53, 55, 58, 62, 65, 69, 86.
 Arteries ($\delta\alpha\tau\pi\rlap{\alpha}$, originally supposed to be an air-duct, the derivation suggested for the word being ἀήρ, air, $\tau\eta\rho\epsilon\omega$, I preserve), 338, 476, 487, 505, 526, 527, 549, 598.
 Arthrocephalés ($\delta\pi\theta\omega\nu$, a joint, $\kappa\epsilon\phi\alpha\lambda\eta$, head), 78.
 Arthropoda ($\delta\pi\theta\omega\nu$, a joint, $\pi\omega\nu$, foot). The Encycl. Brit., vol. ii. 1875, explains that the Class is named from the articulations of the limbs, and also says, "Leach, and later (1825) Latreille, proposed *Condylipoda* as the name of the group for which Arthropoda was afterwards devised. Custom has overborne the rule of priority, and the latter is now the more common name."
 Latreille, however, employed the term *Condylipoda* in 1802, and must therefore have preceded Leach, 477, 479, 552.
 Arthrostraca¹ ($\delta\pi\theta\omega\nu$, a joint, $\delta\sigma\tau\pi\alpha\kappa\omega\nu$, shell), proposed by Brümeister in place of the older term Edriophthalma or sessile-eyed. Sars, Hist. Nat. Crust. d'ean d'occe de Norvège, explains that it refers to the regularly segmented body and the considerable development of the dorsal arch of each segment which seems to represent a sort of separate carapace, of which the lateral portions are often very prominent, covering more or less distinctly the base of the corresponding limbs. As the second order of the Malacostraca, in the classification adopted by Sars, it includes the Amphipoda and Isopoda, the first order, the Thoracostraca, embracing the Decapoda, Stomatopoda, and Cymacea, 169, 477, 508, 552, 601, 1655.
 Articulata, "the name given by Cuvier to his third great division of the Animal kingdom. Arthropoda is the designation now generally adopted, which includes the *Crustacea*, *Arachnida*, *Myriapoda*, and *Insecta*, but excludes the *Annelida*, which Cuvier classed with these among the Articulata" (Encycl. Brit., vol. ii. 1875), 101.
 Articulation, used by Bate and Westwood, Brit. Sess. Crust., vol. i. p. 6, to express the connecting hinge, as distinguished from *joint*, used for a portion of a limb.
 Astacoides, Astacoidea, 78, 87.
 Auditory apparatus, 290, 325, 449, 474, 504.
 Bacilli, hyaline, 457.
 Baguettes olfactives, olfactory rods or filaments, 595.
 Basipodite (Milne-Edwards, according to Wrzesiowski, 1881), or basopodite, 290 ($\beta\delta\sigma\iota\varsigma$, a stepping, $\pi\omega\nu$, foot), shortened into basis, 290, basos (Bate and Westwood), or hasus, the second (first free) joint of the Amphipod leg. The equivalents in different authors are—first joint (used in this Report); second joint; hanche, 140, 155; trochanter supérien; femur, 34, 37; thigh; second coxalplate; Häfte, 485; arm, 536; Oherarm; Schenkel, 1607; tibia, 149.
 Bastoncelli, little rods, 1652.
 Bâtonnets hyalins, olfactory filaments, 548; cylindres à bâtonnets, 515.
 Biliary vessels. See Liver.
 Bismarck-brown, strongly recommended for the coloring of living organisms. See Mayer, Dic Caprelliden, pp. 153, 160.
 Blastoderm ($\beta\lambda\alpha\sigma\tau\delta\varsigma$, germen, embryo, $\delta\epsilon\mu\alpha$, skin), 464, 531, 553.
 Blastomere ($\beta\lambda\alpha\sigma\tau\delta\varsigma$, and $\mu\epsilon\pos$, a part), 463.
 Brain, 133, 349, 364, 489, 567, 1646.
 Branchiae ($\beta\rho\acute{a}\gamma\chi\iota\alpha$, in Latin branchiae, the gills of fishes). Latreille, 95; Milne-Edwards, 154, 184, 185; Kröyer, 202; Frey and Leuckart, 219; Nicolet, 232; Dana, 260, 264; Williams, 280; Costa, 296; Vallette, 304; Boeck, 324; Lilljeborg, 361; Grönbech, 366; Hesse, 419; Dezsö, 476; Wrzesiowski, 501, 507; Smith, 522; Claus, 598.
 Branchiæ, number of, in *Phronima*, Milne-Edwards, 185; Giles, 1642.

¹ Page 552, line 36, for *Arthrocostraca* read *Arthrostraca*.

Branchiogastera (*βράγχια*, breathing-organs, *γαστήρ*, abdomen), 72, 73, 74, 79.
 Branchypia, 88.
 Brangasteria (*βράγχια*, *γαστήρ*), 87.
 Bras, 155. See Meropodite.
 Cabeza, 232. See Cephalon.
 Caeca, 304, 438, 489, 504, 519, 574.
 Calceolns (in Latin, a small shoe), a name suggested by Stimpson (in the form *calccola*) for certain appendages of the antennæ, variously explained as olfactory, auditory, or prehensile; Milne-Edwards, 141; Guérin, 148; Kröyer, 177, 200; Valette, 304; Leydig, 349, 481; Marcusen, 369; Bos, 423; Hoek, 496; Dybowsky and Wrzesiński, 504; Blaue, 543, 548; Barrois, 587.
 Capités, 78.
 Capture of specimens, 197, 484, 600, 1655.
 Carcinology (*καρκίνος*, a crab, *λόγος*, discussion), the natural history of Crustaceans, 495.
 Cardiac (*καρδιακός*, belonging to the heart, *καρδία*); from analogy with vertebrates, the anterior part of the stomach in Amphipoda is called cardiac, without reference to the actual position of the heart, 482.
 Cardio-aortic¹ valves; arterial ostia; these connect the heart with the upper and the lower aorta, opening at the systole to admit the passage of the blood, and closing at the diastole to prevent its flowing back from the aortas, 505, 526.
 Cardio-pericardiac openings; venous ostia; the oblique lateral orifices of the heart, which admit the blood into it from the pericardium, when the heart dilates at the diastole; during the systole they are closed. Normally they occur in pairs in the second, third, and fourth pereon-segments; in *Corophium* only in the fourth segment, 505, 527.
 Carpopodite (*καρπός*, wrist, *πόδις*, foot), the fifth (fourth free) joint of the leg, 290. The equivalents in different authors are—fifth joint; fourth joint, 291; wrist; jambe, 93; carpe, 155; geou; Handwurzel, 532; Afterhandwurzel, 532; Fusswurzel, 532; carpns, 290, 291; pseudocarpus, 532; tarsus, 532; metatarsns, 149, 532.
 Caudal stylets. See Uropods.
 Cement glands, 482, 496, 522, 1651.
 Cephalization, 264.
 Cephalon (*κεφαλή*, head), head, tête, Kopf, Kopfsegment, cabeza, caput, cephalothorax, 259; the front portion of an Amphipod, comprising (theoretically) seven coalesced segments, of which the first six are properly cephalic, the seventh being homologous with the first of the three thoracic segments in the Insecta, 264, 289, 463.
 Cephalostegite (*κεφαλή*, head, *στέγω*, I cover), 463.
 Cerebral ganglion. See Brain.
 Chelate (*χηλή*, a claw), cheliferous, 27, 44; cheliform, 29, 54, 88, 179, 588; with a didactyle hand, 97, 143, 1622; Scheere, 597; properly used of a limb in which a movable joint closes almost throughout its whole length against the lateral margin of another joint, but in early writers often equivalent to subchelate.
 Chiasma, a crosswise position, like the strokes of the Greek letter χ, 1646, 1652.

Chitin, Chitine (*χιτών*, a coat). Huxley, The Crayfish, p. 347, in regard to the exoskeleton of the crayfish, says:—"The animal matter consists for the most part of a peculiar substance termed *Chitin*, which enters into the composition of the hard parts not only of the *Arthropoda* in general, but of many other invertebrate animals. Chitin is not dissolved even by hot caustic alkalies, whence the use of solutions of caustic potash and soda in cleansing the skeletons of crayfishes. It is soluble in cold concentrated hydrochloric acid without change, and may be precipitated from its solution by the addition of water. Chitin contains nitrogen, and according to the latest investigations (Ledderhose, 'Ueber Chitin und seine Spaltungsprodukte' Zeitschrift für Physiologische Chemie, II. 1879), its composition is represented by the formula $C_{15}H_{26}N_2O_{10}$." (See also Milne-Edwards, Hist. nat. des Crust., t. i. p. 10, and Darwin, The Lepadidae, p. 30). 134, 279.
 Chorion (*χορίον*, skin, leather), 320.
 Choristopoda ("From *χωριστός*, separate, and *πούς*, foot, alluding to the fact that the pairs of feet belong each to a distinct segment of the body"), 215, 256, 259, 289, 601.
 Chromatophore (*χρωμα*, colour, *φέρω*, I bear), 477, 548.
 Cilia, ciliæ (cilium, in Latin an eyelash), variously applied to delicate hairs and slender hair-like appendages. The term seems inappropriate for the "auditory cilia" of Bate and Westwood, see pp. 290, 504, which, as those authors themselves remark, are quite distinct from the "auditory cilia" of Hensen.
 Circulation of the blood, Zeuker, 148; Milne-Edwards, 153; Templeton, 169; Wiegmann, 182; Goodwin, 195; Frey and Leuckart, 219; Williams, 280; Leydig, 300, 482; Claparède, 343; Dohrn, 364; Sars, 372; Parfitt, 422; Claus, 338, 476, 489, 598; Wrzesiński, 505; Delage, 525; Mayer, 535.
 Classification, Lamarck, 66, 105; Latreille, 71, 79, 81, 95, 99, 125, 136; Duméril, 78; Leach, 83, 85, 89, 91, 107; Rafinesque, 87, 88, 110; Tilesius, 87; Savigny, 92; Blainville, 94; Risso, 96; Desmarest, 122; Zenker, 135, 149; Milne-Edwards, 140, 153, 155, 184; Burmeister, 169; White, 222, 242; Dana, 254, 256, 259, 264; Gosse, 282; Bate and Westwood, 289, 290, 328, 332; Costa, 296; Bruzelius, 312; Gervais and Beneden, 316; Boeck, 321, 393, 410; Lilljeborg, 360; Czerniavski, 375; Buchholz, 423; Schiödte, 449; Stalio, 468; Gegenbaur, 477; Hayek, 479; Claus, 487, 490, 508, 552; Nicholson, 521; Woodward, 547; Kingsley, 554; Carus, 559; Sars, 567; Bovallius, 576; Gerstaecker, 579; Rolleston and Jackson, 1655.
 Clavate (clava, a club), club-shaped, thickening gradually towards the distal end.
 Clypeus (Latin clipeus, or clypeus, a round shield), 102, 103. See Epistome.
 Colouring. Mr. Murray informs me that nearly all the Amphipoda taken in the dredge and trawl from deep water were of a red or rose colour, the eyes being frequently golden coloured. 221, 319, 382, 416, 430, 437, 438, 468, 578, 600, 1627, 1629.

¹ On p. 526, line 30, reference is made to an expression used by Delage, "une valvule cardio-péricardique antérieure," in which the epithet "cardio-aortique" would seem to be the one intended.

Commensal, one that feeds with, not like a parasite at the expense of, another, 392, 579.

Commissures (commissura, a connection, a band), the longitudinal fibres connecting the various ganglia. In *Gammarus neglectus* Sars describes a cerebral ganglion, seven thoracic and four abdominal ganglia, with a pair of separate commissures between each and its successor. The last three are considerably longer than those in front. From all of them nerves are given off as well as from the ganglia. In their structure Sars distinguishes an outer membrane and an inner granular content, composed of numerous ganglionic cells. In the Caprellidae the abdominal commissures are naturally reduced to the vanishing point. 133, 489, 1646.

Complexly chelate or subchelate. "By this term [complexly] I mean, whenever the chelate character depends upon other joints than the propodos" (Brit. Mus. Catal. Amph. Crust., p. 262). For the German equivalents, see p. 597.

Condylipoda, condylipodes, condylopa, condylopes, condylopoda (*κόρδυλος*, knuckle or knob of a joint, *πόντος*, a foot), "pattes noueuses," 72, 125.

Condylopia, 88.

Connective-tissue. "Immediately beneath the epithelial layer follows a tissue, disposed in bands or sheets, which extend to the subjacent parts, invest them, and connect one with another. Hence this is called *connective tissue*" (Huxley, The Crayfish, p. 178). Mayer describes it as a thin layer, not continuous but with lacuuae, under the whole epidermis in the head and body, present also in the antennae and legs, except at their extreme points, throwing out attachments to the liver and stomach and heart, dividing the body into dorsal and ventral compartments, sheathing the ganglionic chain, and by its strong development in the brauchiæ assisting in the purification of the blood, which is thus the longer exposed to the influence of the surrounding water. (Die Caprelliden, p. 130).

Coxopodite (coxa, the hip, *πόντος*, a foot); the equivalents are first joint, side-plate, hanche, Basalghid, Hüftglied, Seitenplatte, erstes Coxalplatte, Coxa, Femur, Epimeron, Epimerum. It is a disputed question whether we have at the base of the Amphipod leg a lateral plate which is an outgrowth of the body-ring, carrying the more or less obsolescent first joint of the leg soldered to it, or whether the side-plate is itself a protective expansion of the first joint. 149, 289, 290, 365.

Crochet, 48, 140. See dactylopodite.

Crustacea (crusta, the hard surface of a body, the rind or shell, "Aquatilium tegumenta plura sunt. Alia . . . integruntur . . . crustis, ut locustæ," Plin. ix, 14), 6, 17, 52, 62, 66, 71, 78, 79, 125, 155, 169, 479, 552, 1655. See also Encycl. Brit., vol. vi. p. 333, 1878 (H. Woodward).

Crustaceology, a hybrid word used by Leach to include the natural history of Crustacea and Arachnidae, 83.

Crustata. The word *Crustata* applied to animals appears first to occur in Pliny, xi, 62, "Et cochlear deutes habent: indicio est etiam a minimis carnem derosa vitis. At in marinis crustata et cartilaginea primores habere, item

echinis quinos esse, unde intelligi potuerit, miror." In Facciolati's Lexicon, the quotation, "in marinis crustata et cartilaginea primores dentes hahent," makes Pliny assert the very thing of which he expresses himself as doubtful. Facciolati gives as an explanation of the word crustata, "h.e. pisces crusta, seu testa obducti." Jonston, De Exanguibus aquaticis, Lib. ii. c. 1, says, "Quae Crustata Plinio, illa Latinis aliis Crustacea, quod molli crusta operta sint, Graecis μαλακότρακα, eandem ob causam dicuntur. Medium inter Testacea et Molusca sortita locum videntur. Nam quatenus foris crusta, etsi fragili et tenui obtieguntur, cum testaceis convenient: quateus molle carnosumque intus continent, mollibus comparantur." 2, 4, 193.

Cryptobranches (κρύπτω, I conceal, *βράγχια*, breathing-organs), 96.

Crystalline cones, Krystalkegel, cristallin, 154, 462, 481, 490, 495, 1638, 1652.

Crystallites, Cristallites, little plates, concentrically striped and radiated, found between the epithelium and cuticle in *Caprella* and some of the Gammaridae. In diluted acetic acid they disappear with a lively evolution of gas. The markings can sometimes be subsequently traced in the cuticle (Hoek, Carcin., p. 98, 1879).

Cnissc. See Meropodite, 93, 140, 155.

Cupule membraneuse, 141, 543. See Calceolns.

Cuticle (cuticula, skin, diminutive of cutis); the outer layer of the integument, lining both the body externally, and internally the alimentary canal, with the exception of the midgut (Bruzelius, Mayer, Spencer), 574. According to Huxley, The Crayfish, pp. 33, 196, the exoskeleton or cuticle is "produced by the cells which underlie it, either by the exudation of a chitinous substance, which subsequently hardens, from them; or, as is more probable, by the chemical metamorphosis of a superficial zone of the bodies of the cells into chitin." It is this exoskeleton, and not the epidermis or true skin which secretes it, that is thrown off in the process of exuviation.

Cylinders, 480, 626. In the descriptive part of this Report the expression filamentary cylinders has been frequently used for the Ricchzapfen or olfactory tubes, as they are generally supposed to be: but the single word filaments has been adopted in the later descriptions, since Leydig has applied the name cylinder to a different kind of appendage.

Cystibranches, Cystibranchia (κύστης, a bladder, *βράγχια*, breathing-organs), 95, 96, 99, 135.

Dactia (δάκνω, I bite), 282.

Dactylopodite (δάκτυλος, a finger or toe, *πόντος*, a foot), seventh (sixth free) joint of the Amphipod leg; the equivalents are—sixth joint, seventh joint, claw, finger, nail, crochet, doigt, griffe, tarse, Klaue, Endklaue, dactylos, dactylus, ungnis, 140, 149, 155, 290, 532.

Dactyloptera (δάκτυλος, finger, πτερόν, a wing), "this name is suggested for the two little wing-like plates on each pair of gnathopoda" (Spence Bate on *Phronima sedentaria*, Brit. Mus. Catal. Amph. Crust., p. 317), 1341.

Darmcanal, 489, 562, 598. See Alimentary Canal and Intestine.

- Deutognathes (*δεύτερος*, second, *γνάθος*, jaw), Milne-Edwards gives this name to the first maxillæ, as following the mandibles which he calls protognathæ.
- Development, Milne-Edwards, 154, 160; Rathke, 171, 182; Leydig, 225, 482; Meissner, 287; Spence Bate, 290, 327; Valette, 320; Fritz Müller, 350; Bessels, 387; Bencden, 391; Bencden and Bessels, 392; Dohrn, 403; Packard, 448; Huxley, 463; W. Thomsou, 472; Uljanin, 525, 531; Faxon, 533; Claus, 539, 553, 598; this Report, 1214, 1602.
- Diastole (*διαστολή*, a drawing asunder, dilatation), 505, 507.
- Didactyle, vaguely used by the older authors for hands that were either chelate or subchelate, but from its contrast to monodactyle, the correct use was probably for the former; 86, 97.
- Dimorphism of males, 349, 408, 554, 562, 1024.
- Dimorphism, sexual, 596, 1649.
- Distribution, Kröyer, 180, 197; Eichwald, 193; Dana, 264; Lindström, 287; Heller, 359; Lilljeborg, 360; Bate, 363; Brady, 375; Edward, 381; v. Martens, 384, 566; Norman, 386, 458, 584; Boeck, 410; Möbius, 421; Smith, 434, 557; Metzger, 445, 446; Miers, 467, 555; Forel, 476; Fries, 494; Joseph, 496; Wrześniowski, 501, 1655; Haswell, 514; Markham, 517; Stuxberg, 523; Mayer, 535; Blanc, 548; Chilton, 551; Schmarda, Forstrand, 577; Gerstaecker, 578; Koelbel, 584; Perrier, 585; Bovallius, 592; Chevreux, 596; Ross, 1620; Örsted, 1621; Whymper, 1648; Barrois, 1649.
- Dolabriform (dolabra, a mattock or pick-axe), 103.
- Domicola (domus, a house, colo, I inhabit), a term applied by Bate and Westwood to a group formed by the two families Corophiidae and Cheluridae, but in fact of more extensive application; 290, 328, 375, 483, 522, 527, 529, 542, 564, 578.
- Drehgelenk (trochlea, turuing-joint), 485. See Ischiopodite.
- Dündarm, 489.
- Ecdysis (*ἐκδύσις*, a getting out; *ἐκδύω*, I strip off). See Exuviation.
- Edrioftalmi, 205.
- Edriophthalmes, 174, 417, 1647.
- Edriophthalma (*ἐδραῖος*, sittting, sessile, *ὁφαλός*, an eye), Leach, 1815; a term evidently based on the word "sessiliocles" introduced by Lamarck in 1801; 89, 122, 157, 166, 169, 242, 246, 281, 282, 289, 295, 304, 601.
- Edriophthalmaria. Gerstfeldt, 1858, adopts this form, giving the reference "Legio *Edriophthalmaria* M. Edw. (Ann. d. sc. nat. 3ème sér., 1852, xviii. 120, 121)." He also observes that Dana's *Edriophthalma* embrace not only the *Choristopoda*, that is the *Edriophthalma* of most other authors, but also the Trilobita, Eumotostraca, and Rotifera, giving a reference to "Unit. Stat. expl. exped. Crust. I, 10."
- Edriophthalmata, 222, 375, 521.
- Edriophthalmes, 136, 155, 184, 316.
- Edriophthalmia, 215, 259, 264, 463, 468, 528, 547, 554.
- Edriottalmi, 389, 390, 468.
- Eleutherognatha (*ἐλεύθερος*, free, *γνάθος*, a jaw), 449.
- Endophragmal arch (*ἐνδόν*, within, *φράγμα*, a fence), 299, 463, 485.
- Endopodite (*ἐνδόν*, within, *ποδός*, a foot), 1655; in the Crustacea the typical appendage attached to each side of a segment

is considered to be composed of a basal piece, the protopodite, bearing a podobranchia, an endopodite and an exopodite, the endopodite, attached to the inner side of the extremity of the protopodite, the exopodite to the outer side. In the seven-jointed limbs of the Amphipoda, the first joint coalescent with the side-plate and the first free joint constitute the protopodite, the remaining five joints being the endopodite. To some of these appendages in the female a marsupial plate is attached, which possibly represents the exopodite. Some of them also in both sexes carry a branchial vesicle. In the upper antenna the protopodite by way of exception exhibits three joints, the so-called primary flagellum being in all probability the endopodite, while the secondary flagellum when present would seem to be the exopodite, although it is found on the inner side of the appendage. The bifurcation of the limbs is readily observable in the appendages of the pleon. See Huxley, The Crayfish, pp. 145, 173. Sec Tige, 153.

Enoplopods, Hesse, 1873 ("De ἐνοπλος, armé; πούς, ποδός, pied"), 417.

Enteron (*ἐντέρον*, a paunch), 477.

Entomeiline, 134.

Entomozaires (*ἐντομα*, insects, *ζῶα*, living creatures), 94.

Enzyme (*ζύμη*, leaven), 489, 525.

Epimera (*ἐπί*, over, *μηρός*, thigh), 185, 202, 289, 452, 485, 597, 598. See Coxopodite.

Epipharynx (*ἐπί*, over, *φάρυγξ*, throat), the palate or upper part of the throat that succeeds the mouth-opening, 450.

Epistome (*ἐπί*, over, *στόμα*, the mouth). In the Amphipoda it is generally placed vertically, sometimes forming a ridge or produced to a sharp point. It sends up a narrow prolongation between the lower and upper antennæ to the rostrum. Below it widens, and forms the clypeus, in which the labrum is attached. Its inner surface gives attachment to the flexor muscles of the mandibles (Boeck). 289.

Epithelium (*ἐπί*, over, *θηλή*, a nipple); "Under the general name of *epithelium*, may be included a form of tissue, which everywhere underlies the exoskeleton (where it corresponds with the epidermis of the higher animals), and the enticular lining of the alimentary canal, extending thence into the hepatic cæca. It is further met with in the generative organs, and in the green gland. Where it forms the subecticular layer of the integument and of the alimentary canal, it is found to consist of a protoplasmic substance, in which close-set nuclei are imbedded. If a number of blood-corpuscles could be supposed to be closely aggregated together into a continuous sheet, they would give rise to such a structure as this; and there can be no doubt that it really is an aggregate of nucleated cells, though the limits between the individual cells are rarely visible in the fresh state. In the liver, however, the cells grow, and become detached from one another in the wider and lower parts of the cæca, and their essential nature is thus obvious" (Huxley, The Crayfish, pp. 177, 178). Bruzelius in describing the inner structure of an Amphipod gives a similar account. In *Amphithoe podoceroides* he notes as a peculiarity that the epithelial liver-cells, which are hexagonal, contain two nuclei

furnished with nucleoli. The hexagonal epithelial cells from various parts are figured by Claus, *Der Org. der Phronimiden*, 1879. In some Amphipoda these cells are very clearly visible in the pellucid skin. 464, 489, 562. *Epizoaires* (*ἐπί*, upon, *ζῷα*, living creatures), 94.

Erioptalmi, 145, 152.

Euryhaline (*εὐρύς*, wide, *ἅλς*, salt), 421.

Eurytherm (*εὐρύς*, wide, *θέρμη*, heat), 421.

Exappendiculate, applied to the upper antennæ when without a secondary flagellum.

Exochnata (*ἐξω*, without, and *γνάθος*, a jaw), 64. Latreille, *Hist. Nat.* t. v. p. 151, says "the Kleistagnatha have the palps broad and short, while the Exochnata have them narrow, elongated, in form of arms or true palps. The former have more resemblance to maxillæ. Fabricius in applying two denominations to like objects, of slightly different form, has been able to establish two Orders, but the distinction is little tenable, not being founded in nature."

Exopodite (*ἐξω*, without, *πόδης*, a foot). See Endopodite.

Exuviation (exuviae, what is stripped from the body, a cast skin), also called Ecdysis, the periodical process of casting the skin, which is essential to growth in the Amphipoda as in other Crustacea, 67, 153, 195, 290, 333, 474. See Cuticle, and compare also Brit. Sess. Crust., vol. i. p. xxv.

Eyes, 139, 154, 201, 260, 270, 327, 372, 383, 386, 423, 449, 461, 471, 474, 475, 480, 481, 486, 490, 495, 509, 553, 559, 597, 1638, 1651.

Facetted, an expression applied to the transparent enticle or cornea over a compound eye, when the cornea is divided, by a slight modification of its substance along the dividing lines, into square or hexagonal spaces. The cornea in the Amphipoda is said as a rule to be externally smooth, not facetted, 154, 260, 471, 474, 480, 481, 516, 597, 1638.

Fangorgane, grasping instruments, 274, 477.

Fauusses pattes, or pates, 95, 139, 186, 189. See Pleopods and Uropods.

Femur (in Latin, the thigh), 34, 49, 149. See Coxopodite and Basipodite.

Ferment-cells. In the epithelium of the liver-tubes in the Gammaridæ Max Weber distinguishes ferment-cells and liver-cells. The former have in their plasma a pellucid secretion in form of a large vesicle. The liver-cells are full of little drops of secretion which are not affected by water, though they are by ether. In the opinion of P. Mayer, from whom these statements are taken, one and the same cell in its passage in the liver-tube from behind forwards probably performs different functions, at one time secreting fat-drops, then differentiating itself to a ferment-cell, after this being dispersed, or, on being pressed further forwards, resuming the production of fat (Die Caprelliden, pp. 150-156). 489.

Fibres musculaires, 1647.

Filament (filum, a thread), a term sometimes applied to the antennary flagellum, sometimes to the so-called olfactory tubes or cylinders.

Flagellum, also called terminal filament, fouet, funiculus, lash, seta, Geissel; in the Amphipoda generally used only of

the more or less whiplike series of joints attached to the peduncle in the upper and lower antennæ. The shorter lash (? the exopodite) often found on the inner side of the upper antennæ is known as accessory seta, 105, secondary or accessory flagellum, secondary appendage, Nebengeissel, flagellum appendiculare. For a more extended use of the word flagellum, see p. 153.

Flohkrebse, 170, 480.

Foot-jaws. See Maxillipeds.

Frontal organ, 477.

Gammarus (*κάμμαρος*, *κάμαρος*, *κάμμυρος*, cammarus, gammarns, a kind of crab, lobster or shrimp, according to Martial turning red when cooked), 5, 12, 40, 53, 1620.

Gancetto, a subchelate hand, 1622.

Ganglion (*γάγγλιον*, a tumour under the skin), a collection of nerve-cells from which nerve-fibres are given off. For the Caprellidae Mayer distinguishes a hind-brain with the ganglionic knots in connection with it, namely, the optic ganglion and the ganglia for the two pairs of antennæ; the suboesophageal ganglion consisting of several coalesced ganglia; the supra-oesophageal ganglion connected with the frontal organ; and a small unpaired ganglion lying medio-dorsally, from which runs an unpaired nerve, probably to the constrictores pharyngis. The ganglion of the first pereon-segment is in most genera in contact with the suboesophageal ganglion, in *Proto* actually coalesced with it. Each pereon-segment, from the second to the sixth, is provided with a ganglion; for the seventh segment and the rudimentary abdomen there is a ganglion-complex, bearing traces of the same arrangement as prevails in the Gammaridæ. In *Gammarus neglectus* G. O. Sars describes fourteen ganglia, of which the three first belong to the head, the following seven to the seven segments of the pereon, and the succeeding four to the pleon, three corresponding to the three first pleon-segments, and the fourth and largest to the three remaining segments, being itself probably composed of three originally distinct ganglia. The first or cerebral ganglion is much larger than the rest. It has an upper and a lower division. The lower, almost on a level with the rest of the gangliouc chain, and situated at the lower corner of the head, ends in four large conical processes which supply nerves to the antennæ. The upper division, placed vertically, much larger than the lower, and of rounded square form, has above two obtusely rounded lobes, separated by a median groove. Each of these shoots forward a fine nerve, which ends in a little ganglionic swelling at the root of the rudimentary rostrum. From the hinder outer part of each lobe runs the optic nerve. On the border of the two divisions of the central ganglion are a pair of little rounded lateral lobes. Two ganglia in close contact, separated from the cerebral ganglion by the esophageal commissures, supply nerves to the mouth-organs. For the Phronimidae Claus states that the suboesophageal ganglion mass is derived from the coalescence of six or seven ganglia, those of the two first pereon-segments being included in the complexus. The five following segments have each a ganglion, but that of the seventh segment lies immediately under its predecessor in the sixth segment instead of its own.

- The three first abdominal segments have each a ganglion. Close upon the last follows the little last ganglion corresponding to three reduced and coalesced ganglia. The ganglion having a constituent from each side of the body is sometimes spoken of as the ganglion-pair or double-ganglion. 132, 219, 260, 304, 364, 438, 471, 489, 567, 597, 1646.
- Garnell, 6, 7.
- Gasteruri (*γαστήρ*, abdomen, *οὐρά*, tail), 83, 85.
- Gattung, 120.
- Genealogy, 134, 406, 423, 455, 479, 482, 526, 537.
- Genera, rejection of, 140, 144, 187, 229, 256, 270, 356, 516, 568, 582.
- Genon (genu, a knee). See Carpopodite.
- Genn. See Ischiopodite.
- Geschlecht, 120.
- Gibbous (Latin gibbosns), protuberant, convex, hump-backed.
- Gimnocefali (*γυμνός*, naked, *κεφαλή*, head), 145.
- Ginglymus (*γίγλυμος*, a joint), a kind of articulation admitting of only two motions, as in a hinge or the elbow-joint. In the legs of the Arthropoda, as a rule only flexion and extension of the joints are possible. Latreille, *Le Règne Animal*, p. 1, 1817, says of them, "Chaque article est tubulaire, et contient, dans son intérieur, les muscles de l'article suivant, qui se meut toujours par gynglyme, c'est-à-dire dans un seul sens."
- Gland (glans, an acorn), "a cell or collection of cells, having the power of secreting or separating some peculiar substance from the blood or animal fluids." Anal-gland, 505; antennary gland, 372, 481, 506, 510, 549; cement-glands, 432, 496, 522, 1651; frontal-gland, 477, 478; hand or leg-glands, 432, 482, 489, 496, 518, 519, 1651; liver-glands, 525; oil-glands, 548; renal-glands, 504, 506, 549, 552; salivary-glands, 489, 538; sexual-glands, ovigerous and spermatic, 535.
- Gliedfüssler. See Arthropoda, 544.
- Gnathaptères (*γνάθος*, jaw, Apta, wingless), 65.
- Gnathopoda (*γνάθος*, jaw, *πούς*, a foot), 289, 332, 362, 394, 487, 516; a term proposed by Milne-Edwards, and in 1856 adopted by Bate and Westwood for the appendages of the first and second segments of the pereon. Gerstaecker objects to the name because in numerous cases he can find no connection between these limbs and the taking up of food, while Claus retains it because in so many cases there is such a connection. The equivalents are—first and second pairs of anterior feet or legs, 81, 82, 84, 90, 100, 141, 179, 186; claws, 101; piedi-mani, 145, 150; Pedes thoracici primi et secundi paris, 211, 217, 284, 286; Manus or hands, 220; first and second pairs of feet, 286, 323, 326, 347, 351, 376, 397; Pedes trunci primi et secundi paris, 360; pattes thoraciques, 383, 417; quatrième et cinquième siagonopodes, 454; Handbeine, 427; first and second pereiopods, 516; second and third pairs of appendages, 563.
- Gnathopoda, a name proposed by H. Woodward for the Entomostraca, "in allusion to the prevailing character in the Entomostraca, in which the head and mouth-organs are also mainly used in locomotion" (Encycl. Brit., art. Crustacea, 1878).
- Gnathopoda, = Arthropoda, 478.
- Gnathopodes, Straus-Durckheim, 134.
- Greifband, subchelate hand, 487, 537, 597.
- Greifzange, chelate hand, 487.
- Gymnobrauches (*γυμνός*, naked, *βράγχια*, breathing-organs), "branchies extérieures, ou inconnues," the character, "branchies cachées ou inconnues," found in Risso's definition in 1816, was probably due to a slip of the pen, 96.
- Haltopoden (*ἅλομα*, I leap, *πούς*, a foot), 1654. See Uropods.
- Hanche, 93, 140, 155. See Basipodite.
- Hand. See Propodite.
- Heart, 184, 219, 280, 304, 338, 350, 364, 372, 383, 422, 471, 476, 480, 489, 505, 526, 549, 598.
- Hedrioftalmos, 1632.
- Hedriophthalmalma, 477.
- Hedriophthalmata, 473.
- Hepato-pancreas (*ἡπαρ*, the liver, *πάγκρεας*, the sweetbread), 525, 1636.
- Heterobranchia (*ἕτερος*, other, *βράγχια*, breathing-organs), 131.
- Heteropa (*ἕτερόποδος*, with uneven feet, or *ἕτερος*, other, *πούς*, foot, with the feet varied), the definition given by Latreille does not well accord with the apparent meaning of the name, 125, 126, 138.
- Histology (*ἱστός*, a web or tissue, *λόγος*, discussion), "the science which treats of the minute structure of the tissues of plants, animals, etc.," 535.
- Homology (*δημολογία*, agreement), conformity in the plan of organisation, correspondence in type of structure; thus the arm of a man is homologous with the foreleg of a horse, the maxillipeds of an Amphipod with its gnathopods, and its gnathopods with the second and third maxillipeds of a crayfish. Analogy, on the other hand, is correspondence not in type but in function, as the legs of an Amphipod and the legs of a horse are alike denominated legs from analogy, because of their application to similar purposes. 280, 289, 462, 473.
- Hüfte, 485. See Basipodite.
- Hüftglied, 365. See Coxopodite.
- Hyperexapi (*ὑπέρ*, over, *ἕξ*, six, *πόδες*, feet), 125.
- Hypodermis, 503, 597, 1652.
- Hypopharynx (*ὑπό*, under, *φάρνηξ*, the throat), the floor of the throat, between the mouth-opening and the oesophagus.
- Hypostome (*ὑπό*, under, *στόμα*, the mouth), the ventral piece of the mouth, in which the two pairs of maxillæ are socketed, and which supplies a fulcrum to the labium. From its analogy to the os sphenoideum of vertebrates Schiödte (Naturh. Tidssk., ser. 3, Bd. iv. 1866) proposes to call it the sphenoid plate.
- Imbricated (imbrex, a tile), said of plates overlapping one another in order like tiles on a roof. In the Amphipoda the segments of the body overlap from before backwards, and when the hinder edges are notably raised the structure is said to be imbricated.
- Incubatory pouch, also called incubatory lamellæ, appendices flabelliformes, marsupial plates, marsupium, ovigerous lamellæ, oostegites, ovarian plates, scales (Schuppen). These plates are developed in the female of the Gammarina within the side-plates of the second, third, fourth, (and occasionally the fifth) segments, between the branchial vesicles and the body. They are generally fringed with long hairs. When needed for use they fold

- in beneath the body forming a pouch in which the fertilised eggs and young attain their development. In the Caprellidae they appear only on the third and fourth segments. Rudiments of them are said to be occasionally found in male Amphipods. 153, 185, 321, 418, 502, 522, 558, 1621.
- Insecta, 62, 65, 92.
- Integument, 290. See Cuticle, Epithelium.
- Internal structure, 290, 315.
- Intestine, that part of the alimentary canal which extends from the pyloric end of the stomach to the anus, 489, 504, 562, 598.
- Intima, 489, 504.
- Ionelles, so called from *Ione*, one of the genera included, 105.
- Ischiopodite (*ἰσχιόν*, the socket in which the thigh-joint, *μηρός*, turns, and *πόδις*, a foot), the third (second free) joint of the leg; the equivalents are—second joint, third joint, knee, trochanter, second trochanter, Drehgelenk, Rollstück, genu, ischium, rotula, trochlea, tarsus, 140, 149, 155, 290, 485.
- Isopoda (*ἴσος*, equal, *πόδις*, a foot), “tous les pieds simples et uniquement propres à la locomotion ou à la préhension” (Latrelle, Le Règne Animal, t. iii. p. 49), 99, 105, 122, 125, 155, 160, 169, 174, 184, 215, 282, 368.
- Jambe, 93, 155. See Carpopodite.
- Kaumagen, 482.
- Kanplatten, 482.
- Kieme, 365, 366. See Branchiae.
- Kleistognatha (*κλείειν*, to shut, *γνάθος*, a jaw), 64.
- Kupferschiefer, marl-slate, in the Permian system; in certain parts of Germany this is charged with ores of copper, hence the German name, 148.
- Labium (in Latin, a lip), a deeply bifid organ, attached centrally to the hypostome and forming the lower side of the mouth-opening; equivalent names are—lower lip, tongue, langue, langnette, Paragnathen, Zunge, metastoma, Paragnatha, labium inferius; 93, 154, 449, 486, 532.
- Labium, applied by Fabricius to three of the mouth organs, 43, 56; la lèvre inférieure of Olivier is equivalent to the maxillipeds, the terminal joints of which are called palpi by Fabricius, 43, and antennules by Olivier, 57; Say uses the expression “labium (pecipalpi)” for these organs, 102, and Savigny the term lèvre auxiliaire, 93.
- Labrum (in Latin, a lip), upper lip, lèvre supérieure, labium superius. “The labrum is divided into two parts, the lower of which moves on the upper by a slight hinge, and assists in perfecting the shutting of the mouth. The free margin is generally clothed with short hairs, often of club-shaped and deformed appearance” (Brit. Sess. Crust., vol. i. p. xiii.), 56, 154, 449, 450.
- Læmodipoda (*λαιμός*, throat, *δίποδος*, two-footed), “gorge à deux pattes.”
- Langue, languette. See Labium.
- Lavalette'sche Kolbenorgane, 427, 429. See Calceolus.
- Leg, joints of, 93, 140, 149, 155, 290, 360, 365, 485, 1654.
- Leydig'sche Cylinder, 427, 429, 480.
- Liver, 184, 300, 304, 364, 487, 504, 598.
- Lumbe. In Gmelin's Linnaeus, t. i. p. 585, Martens' Lumbe (in the form Linmme) is given as a synonym of *Colymbus Troile*, Guillemot or Sea-lion, Foolish Guillemot, 7.
- Magendarm, 482, 489.
- Main, 155. See Propodite.
- Malacostraca (*μαλακός*, soft, *χτενάρια*, a shell), 1, 2, 4, 6, 79, 83, 107, 136, 1655. See Crustata.
- Mandibles, also called jaws, protognathes, Kiefer, Oberkiefer, 43, 56, 62, 71, 92, 107, 116, 117, 154, 170, 184, 449, 450, 597, 1653.
- Mandibulata, 157, 254.
- Marginate; “the term ‘marginate’ refers to a peculiar margin or thin cutting edge that is found on the palm in some species, the form and appearance of which are liable to variation” (Brit. Mus. Catal. Amph. Crust., p. 212).
- Marksbstanz, 489, 567.
- Marsupium, a pouch. See Incubatory pouch.
- Matrix, 504, 597. See Hypodermis.
- Maxilados, 231. See Maxillosa.
- Maxillæ primi et secundi pars, also called first and second maxilla, Mâchoires de la première et de la seconde paire, dentognathes and tritognathes, first and second siagonopoda, Unterkiefer and Unterlippe, innere Maxillen and äussere Maxillen; 57, 64, 92, 154, 217, 454, 532, 600.
- Maxillipeds, also called foot-jaws, maxillary feet, pattes-mâchoires, pieds-mâchoires, feuilles maxillaires extérieures, lèvre inférieure, tetartognathes, third siagonopoda, Unterkiefer, Unterkieferbeine, Kieferfüsse, Maxillarfüsse, Unterlippe, labium (pedipalpi), palpi, pedes maxillares; 57, 62, 64, 92, 144, 154, 185, 217, 226, 231, 256, 323, 360, 454, 488, 532, 552, 1654.
- Maxillosa, Crustacés maxillés, Crustaceos maxilados, 125, 174, 231.
- Medioliform (probably for modioliform, from Latin modiolus, the nave of a wheel), an epithet applied by Say to the second (in his terminology the third) joint of the second gnathopod of *Ceratus tubularis*, 100.
- Meropodite (*μηρός*, thigh-joint, *πόδις*, a foot), fourth (third free) joint of the leg; the equivalents are—third joint, fourth joint, bras, cuisse, Schenkel, Schienbein, Unterarm, metacarpus, tibia, meros; 93, 140, 155, 290, 485, 491.
- Mesenteries (*μεσεντέριον*, an internal membranæ), scptæ, membranes dividing the interior of the body into distinct cavities, of which one is called the dorsal or pericardiac sinus, another the ventral sinus, 489, 507.
- Metacarpus. See Meropodite.
- Metastoma. See Labium.
- Metatarsns, used by Zenker for the fourth, fifth, and sixth (third, fourth, and fifth free) joints of the leg, 149; by Dybowsky for the fifth (fourth free) joint, by Clans and in the form metatarse by Milne-Edwards for the sixth (fifth free) joint, 155, 532.
- Micropylie apparatus (*μικρός*, small, *πύλη*, a gate), 320, 350, 403, 553.
- Millimètre, 0·03937 of an inch.
- Mitosata, 63.
- Moniliform (monile, a necklace), with numerous small joints like the links in a chain, 58.
- Monodactyle (*μονός*, single, *δάκτυλος*, a finger), “hands without fangs,” 69; used rather vaguely by the older authors, but generally implying a subchelate hand, as opposed to a chelate one, which they called didactyle, 19, 27, 45, 89, 100.

Mosaic vision, in which as in mosaic work the view of an object is obtained by the combination of many small pieces, this according to Johannes Müller being the mode of sight resulting from the structure of the compound eyes of the Arthropoda, 139, 483, 490, 495, 1635.

Muscles, 489, 503, 1636, 1647.

Muticus (ante-classical form of *mutilus*, curtailed, docked), a word used by the early writers apparently not in accordance with its meaning; Latreille, Hist. Nat., t. iv. p. 13 (An. X), thus describes the "pattes mutiques" in the Millepieds, "Leurs pattes sont composées d'articles diminuant insensiblement de grandeur, ce qui leur donne une forme conique; l'article qui les termine est d'une matière plus dure, cornée ou écaillueuse, va en pointe plus ou moins arquée, et sert de crochet; mais on observe ici que ce crochet, par la diminution graduelle des articles de la patte, en est une suite, et que ce n'est pas un corps surajouté brusquement, de même que les petits ongles des tarses des autres insectes. On remarque une semblable configuration dans les tetracères et les crustacés, dont les pattes ne sont pas en nageoires." 23, 26, 29, 44, 51, 96, 126.

Myeloid substance (*μυελός*, marrow), 489, 567.

Myogène (*μύος*, muscle), muscle-producing, 1647.

Nackendrüse, 504.

Nackenorgan, 477.

Natatorii pedes, appendices natatorii, natatory feet, i piedi natatori, 102, 116, 150, 154, 198, 286. See Pleopods.

Nektopoden (*νηκτός*, swimming, *πόδις*, foot), 1654. See Pleopods.

Nervous system, 132, 153, 154, 304, 364, 504, 567, 597. See Brain, Commissure, Ganglion.

Neusteri (*νευστήρ*, a swimmer), 37. See Pleopods and Uropods.

Nidifica, nest-makers, 290, 307.

Normalia, 290, 360.

Nuclei of Semper, 490, 495, 597.

(*Ἐσοφάγος*, the swallow or gullet), 154, 304, 321, 489.

Olfactory, cylinders, filaments, organs, setæ, organa cylindrica, papilles olfactoires, Riechhaare, Riechzapfeu, Spürfaden, 154, 304, 324, 349, 448, 457, 481, 510, 515, 548, 552, 597, 1648.

Olfactory denticle or tubercle (so-called), 290, 372, 481.

Oostegites (*ωόν*, an egg, *στέγω*, I protect), 553. See Incubatory pouch.

Ostia, ostioles, of the heart, 489, 549. See Heart.

Otoliths (*οὖς*, *ωτός*, an ear, *λίθος*, a stone), 405, 473, 553, 597.

Ovaries, 320, 471, 490.

Palma. "By *palma* (palm of the hand) we mean the part of the margin of the hand against which the finger closes" (Dana, U.S. Explor. Exped., vol. xiii. p. 855). Sometimes, however, the palm is defined by some process of the hand, which the finger either passes beyond or does not reach; Costa uses the expression "the unguicular palm."

Palpi, a term used by Scopoli for the upper antennæ, 24, 25; applied by Fabricius to various parts of the mouth-organs, 43, Olivier using the word antennules as an equivalent, 57; by Milne-Edwards the name palp was given to that part of the limb which he afterwards called the exopodite, 153, 154; in writings on the Amphipoda

the term is usually and exclusively applied to what is presumably the endopodite of the mandibles, first maxillæ, and maxillipeds; Bate and Westwood, vol. i. p. xiv, observe "The mandibles are no exception to the fact that all appendages are but modified legs. In all Crustacea, we think that it can readily be demonstrated that the mandible consists of the first three joints being closely ankylosed. The small appendage, that generally consists of three freely articulated joints, represents the fourth, fifth, and sixth joints; the seventh, or dactylos, being seldom present. An homological examination of the genera *Nebalia* and *Pontia*, with *Homarus*, together with the homotypical parts in other appendages in the same animals, we think will readily confirm this opinion;" Milne-Edwards had earlier taken the same view, 154; Huxley, The Crayfish, p. 171, says of the mandible, "The endopodite is represented by the three-jointed palp;" Claus, Die Platysciden, p. 9, appears to take a different view, for he says, "Spence Bate und Westwood betrachten merkwürdigweise den Kautheil der Mandibel bei den Amphipoden als aus drei verschmolzenen Gliedern hervorgegangen und führen den Taster auf das 4., 5. und 6. Glied der Extremität zurück, deren Dactylus selten erhalten sei. Es bedarf wohl keiner weiteren Ausführungen, dass diese Ansicht eine willkürliche ist und durch keine Thatsache gestützt wird."

Paragnathen, Paraguatha, Paragnathi (*παρά*, beside, *γνάθος*, a jaw), 477, 488, 553. See Labium.

Parasites, 149, 317, 427, 490, 566, 579, 714, 1137, 1630.

Parasitic Amphipoda, 137, 392, 436, 464, 579, 1630.

Pata-quijadas, maxillipeds, 231.

Pedestria, 24.

Pedipalpi. See Maxillipeds.

Peduncle, in the Amphipoda applied to the basal portion of the antennæ, pleopods, and uropods.

Peræon, pereion ("from *περαίω*, to walk about, pereion, part which supports the walking legs," Spence Bate, Brit. Assoc. Report, 1855, p. 27), normally consisting of seven segments to which the two pairs of gnathopods and five pairs of pereopods are attached; the equivalents are—body, thorax, trunclus (*thorax* and *abdomen*), Mittelleib, Rumpf, Brust.

Peræopoda, pereiopoda, pedes ambulatorii, the five pairs of appendages that follow the gnathopods. The term is occasionally extended to include the gnathopods, and is then equivalent to—pattes thoraciques, Brustfüsse, Thoracalbeine, Fusspaaren.

Pericardiun (*περι*, round, *καρδία*, the heart), 516, 526.

Pericerebral ring, 526.

Periosophageal collar, 526.

Perirenal ring, 526.

Permian, the geological system between the Carboniferous and the Triassic, 300.

Phosphorescentia, 75, 76, 87, 108, 123, 194, 275, 327.

Phylogenie, 537. See Genealogy.

Phytibranchia (*φυτόν*, a plant, *βράγχια*, breathing-organs), 99, 125, 138.

Piedi mascellari, pedes maxillares, palpi maxillares, applied erroneously to the lower antennæ, 145, 152, 239, 346, 347.

- Piezognatha (*πιέζω*, I press, *γνάθος*, a jaw), 450.
 Pinuule pediformes, 58. See Pleopods and Uropods.
 Plaxolia (? from *πλάξις*, anything flat and broad), 87, 88.
 Plaxomia, 110. See Plaxolia.
 Pleo ("from *πλέω*, navel; pleon, part which supports the swimming legs," Spence Bate, Brit. Assoc. Report, 1855, p. 27), all that part of an Amphipod which is behind the peraeon. Equivalents are—abdomen, post-abdomen, 467; Hinterleib, Schwanz, 181; Bovallius restricts the name to the first three segments of the original group, those usually which carry the pleopods, 558.
 Pleopods, abdominal feet, swimming feet, fesses pattes natatoires, Nektopoden, Schwimmbeine, Schwimmfüsse, pedes spurii natatorii, pleopoda; sometimes applied to all the appendages of the pleon, but more usually restricted to the first three pairs, the three following being called uropoda, 182, 350, 372. They have also been called fausses pattes branchiales. 417.
 Polygnates, 79.
 Polygnathes (*πολύς*, many, *γνάθος*, jaw), 65.
 Polygonata (perhaps from *πολύς*, many, and *γνάθος*, jaw), 64.
 Polymeria (*πολύς*, many, *μέρος*, part), 149.
 Procellaria glacialis, the Arctic Petrel, 116, 117.
 Proctodænum, 478.
 Propodite, the sixth (fifth free) joint of the leg. The equivalents are—hand, fifth joint, sixth joint, jambe, main, tarse, metatarsal, Hand, Afterhand, Fuss-stück, manus, pseudomanus, tarsus, metatarsus, metacarpus, propodus, propodus, propus. 93, 104, 140, 155, 290, 532, 536.
 Prothorax, the first of the three segments of the insect thorax, homologous with the segment which bears the maxillipedes in the Amphipoda.
 Protognathes (*πρώτος*, first, *γνάθος*, a jaw). See Mandibles.
 Protopodite, the basal part of an appendage, comprising the coxopodite and basipodite, to the extremity of which the endopodite and exopodite are attached. See under Endopodite and Peduncle.
 Pyloric (*πυλωρός*, a gate-keeper), applied to that end of the stomach which is connected with the intestine, 482.
 Punktsubstanz, 489, 567.
 Rectaldrüsen, 504.
 Retinula, 495.
 Retrally, ? from retro, behind, or a missprint for ventrally, 221.
 Rhabdon (*ῥάβδος*, a rod), 495, 1638, 1652.
 Riechzapfen. See Olfactory Organs.
 Rostrum, rostral spine, Rüssel, the sometimes strongly produced centre of the head's frontal margin, 467, 497.
 Ruderhaare, Ruderborsten, hairs or setæ of motive valve, 477, 1245, 1254.
 Salivary gland, 538.
 Saltatori pedes. See Uropods.
 Schalendrüse, 481.
 Schenkel, 485, 491, 1607. See Basipodite and Meropodite.
 Schienbein. See Meropodite.
 Schienenglieder, 485.
 Schlundmagen (Schlund, throat, Magen, stomach), 489.
 Schwanz. See Pleon.
 Scuds, 435.
 Seestengel, sea-stalk, 32.
 Segment. See Annulus.
 Semper'sche Kerne. See Nuclei of Semper.
 Sensitive capsules, 457, 480.
 Sessiliocles; Lamarck says, "J'ai donné le nom de *crustaces sessiliocles* aux animaux du second ordre, parcequ'ils ont les yeux fixes et sessiles," 66.
 Sessilioclia, 88.
 Seta, sometimes used in Latin, and the earlier English, descriptions for the antennal flagellum, the antennæ with accessory flagellum being called *bisetæ*; the term has been also applied to the rami of the pleopods; but in later usage it is confined to the more or less hair-like processes of the cuticle, which are developed in various forms, and probably with very varied functions, in different parts of the body, 457, 480, 481, 504; Huxley, The Crayfish, pp. 197, 198, explains their nature and origin.
 Sexes and sexual appendages, 284, 350, 364, 406, 408, 417, 457, 542, 548, 597.
 Siagonopodes (*σιαγών*, the jawbone, *πόδις*, a foot), 454. See Maxillæ, Maxillipeds, Gnathopods.
 Sinnesborsten, sensitive setæ, 1254.
 Sinus, abdominal, dorsal, pericardiac, ventral, 489, 506, 507, 526, 527.
 Size of Amphipods, 198, 461, 467, 468, 497, 557.
 Somiologie (*σῶμα*, body, *λόγος*, discussion), 87.
 Somite (*σῶμα*, body), 463, 655. See Annulæ.
 Somobiqnes (*σῶμα*, body, *βίος*, life), 88.
 Spermatogenesis, 520, 563, 1638.
 Stemmatæ, simple eyes, 92, 104, 154, 199, 306, 553, 1652. In *Ampelisca* the form eyes ordinarily observed are externally simple, but internally their structure is complicated; Della Valle speaks of a third pair of rudimentary eyes in some species, which may perhaps be properly described as Stemmatæ.
 Stenothernum (*στενός*, narrow, *θέρμη*, heat), 421.
 Sternum (*στέρνον*, the breast or chest), the ventral portion of a segment or somite.
 Stomodænum, 478.
 Strudelorgane, instruments for exciting a current or eddying of water, 477.
 Stylets, abdominal, caudal, posterior. See Uropods.
 Subchelate, subcheliferous, 80, subcheliform. "By a subchelate hand is meant one in which the finger folds upon the hand, but in which the inferior angle of the palm is not produced into an antagonistic thumb" (Brit. Sess. Crust., vol. i. p. 51). Complexly subchelate. "By this term I mean, whenever the chelate character depends upon other joints than the propodus" (Brit. Mus. Catal. Amph. Crust., p. 262).
 Submoniliform, 101. See Moniliform.
 Subnlate, awl-shaped.
 Sugeskaaler, suckers. See Calceolus.
 Swimming, 167, 168, 274, 527, 578.
 Syncerebrum, 567.
 Synistata (*συνίστημι*, I unite), 40, 62, 63.
 Systole (*συστρολή*, a contracting), 506.
 Tactile bristles, 481, 504.
 Tanaidæ, 201, 527, 544, 549, 554, 587.
 Tanaidea, 576, 579.

- Tarse, 93, 140, 155, 532. See Propodite and Dactylopodite.
- Tarsus, 149, 485, 532. See Ischiopodite, Carpopodite, Propodite, and Dactylopodite.
- Taste, organs and sense of, 481, 504, 510.
- Telson ("the last [segment of the abdomen or pleon] which for convenience we shall designate by the name of Telson (from *τέλσον*, extremity)," Spence Bate, Brit. Assoc. Report, 1855, p. 28), 289, 350; equivalents are—terminal joint, or segment, 102; middle tail-piece; dernier segment abdominal, 165; segment caudal; septième anneau ou segment abdominal, 153; la pièce du milieu, 97; Schwanzanhang, 427; Schwanzplatte; appendix caudalis, 178, 425; abdominis appendicula terminalis, 172. Telson supposed to be wanting in many Amphipods by Milne-Edwards, 153; in "*Amphilochus nilssonii*" and "*Amphithoe tenuicornis*" by Rathke, 173, 204; in *Iridium fuscum* by Grube, 348, 354; in the Orchestidae by Zaddach, 485; in species of *Ichthyomyzocetus* by Hesse, 1631; in "*Phronina bucephala*" by Giles, 1642.
- Tergum, dorsal arch of the segment or somite, 153, 463.
- Τεστερεσκαιδεκάποδα, having fourteen feet, 9.
- Testes, 452, 471, 520.
- Tetartognathes (*τέταρτος*, fourth, *γνάθος*, jaw). See Maxillipeds.
- Tetracères (*τετρά-*, in composition, four, *κέρας*, horn, antenna), 71, 72, 94.
- Tetradecapoda (*τετρά-*, δέκα, ten, *πούς*, foot), 256, 259, 264, 289.
- Tetradecapoden, 384.
- Tétradécapodes, 94, 289, 601.
- Thelastia (*θηλάζω*, I suckle), 282.
- Thoracipoda (*θώραξ*, the middle body, *πούς*, a foot), 547; the first part of the word Malacostraca not being especially appropriate to such hard-shelled Crustacea as Crabs and Lobsters, H. Woodward proposes instead of it the name Thoraeipoda, "in allusion to the prevalent use in the Malacostraca of the thoracic series of appendages as special organs of locomotion." In many Crustacea, however, the thorax proper supplies no organs of locomotion, so that the new name would only present a new difficulty in exchange for the old.
- Thoracostraca (*θώραξ*, and ὄστρακον, shell), 169, 477, 552, 1655.
- Thorax. See Peraon.
- Tibia (in Latin, the shin-bone), 149, 491. See Basipodite and Meropodite.
- Tige, stem, a term used by Milne-Edwards for the combined parts of an appendage which he afterwards distinguished as Protopodite and Endopodite, 153.
- Tracks in sand, 103, 310.
- Tritognathes (*τρίτος*, third, *γνάθος*, jaw). See Maxille.
- Triturating organs, 154, 321, 482.
- Trochalognatha (*τροχαλός*, running, whence *τροχαλία*, a cylinder revolving on its own axis, *γνάθος*, a jaw), 450, 606.
- Trochanter (*τροχαντήρ*, the ball on which the hip-bone turns in its socket). See Basipodite and Ischiopodite.
- Truncus. See Peraon.
- Tubicola, Tubifica, 168, 271, 290, 522, 555, 595.
- Under-riding, 263, 582, 1344.
- Unguis (in Latin, a nail); sometimes used as the equivalent of the dactylopodite, at other times for the apical portion of that joint.
- Unogata, 63.
- Unterlippe, 532. See (second) Maxillæ and Maxillipeds.
- Urinary organs, 304, 372, 504, 511, 519, 552, 574.
- Uropods (*οὐρά*, tail, *πούς*, foot), the appendages of the fourth, fifth, and sixth segments of the pleon. The equivalents are—caudal appendages, caudal stylets, pleopods, fausses pattes, pattes sauteuses, Haltopoden, Springbeine, Springfüsse, Schwanzfüsse, pedes spurii, pedes saltatorii. Dybowsky calls the first two pairs die Springbeine, and each member of the last pair das Steuerbein.
- Uroptera (*οὐρά*, tail, *πτερόν*, a wing), 125.
- Urus (*οὐρά*, tail), a name given by Bovallius to that part of the abdomen which carries the uropods and telson, the name pleon being restricted to the three preceding segments, 576.
- Vasa deferentia, 452.
- Vejiguillas branquiales, branchial vesicles, 232. See Branchiae.
- Vlookreeften, equivalent to the German Flohkrebse, 327.
- Voracity of Amphipods, 197, 271, 355, 1619, 1632.
- Vormagen, 482, 489.
- Zange, pincers, 181, 491. Claus uses Zange of a subchelate hand, 491, and Greifzange of one that is chelate, 487.
- Zechsteindolomite. The name Zechsteiu is given to a group of strata in the Permian system, including dolomites, the Kupferschiefer, &c., 176.
- Zee-Scherminkel, sca-skeleton, or marine spindle-legs, which Slabber latinizes into *Phtisica marina*, presumably taking *Phtisica* from the Greek *φθισικός*, a consumptive person or creature. The general neglect of this generic name, to whatever causes due, does not seem justifiable. In the numerous passages of this Report in which *Proto* has been accepted as valid, I now wish that *Phtisica* should be read in its place, and in like manner I hold that *Phtisica marina*, Slabber, should be substituted for *Proto ventricosa* (O. F. Müller). 32.
- Zostolia (perhaps from *ζῷον*, an animal, and ὄστρακον, bone), 88.
